Use this parameter if the **-dataStore** parameter is specified. Do not use this parameter if the **-cluster** parameter is specified.

-datasourceJndiName *jndiname*
The JNDI name of the data source that the messaging engine uses to access the relational database management system (RDBMS) for the data store. Use this parameter if the **-dataStore** parameter is specified.

-authAlias *authalias*
The name of the authentication alias that the messaging engine uses to connect to the database in its data store. Use this parameter if the **-dataStore** parameter is specified.

-createTables *datasource*
Create the database tables for the specified data source automatically. If this option is not specified, the database administrator must create the tables. Use this parameter if the **-dataStore** parameter is specified.

-schemaName *schemaname*
The name of the database schema that contains the tables for the data store, if you do not want to use the default schema name. For details about the default schema, see "Creating users and schemas in the database" on page 1959. Use this parameter if the **-dataStore** parameter is specified.

-initialHeapSize *size*
The initial Java virtual machine (JVM) heap size, in megabytes, of the server or of each server in a cluster. There is no default value. If this parameter is not specified, no change is made. If this parameter is specified, the supplied value must be greater than or equal to zero and less than or equal to 2048. If the parameter is supplied without a value, an error message is generated.

-maxHeapSize *size*
The maximum JVM heap size, in megabytes, of the server or of each server in a cluster. There is no default value. If this parameter is not specified, no change is made. If this parameter is specified, the supplied value must be greater than or equal to zero and less than or equal to 2048. If the parameter is supplied without a value, an error message is generated.

Examples

Add a server1 on node1 as a member of bus1 with a default file store.

```
AdminTask.addSIBusMember('[-bus bus1 -node node1 -server server1 ]')
```

Add server1 as a member of bus1, and use a file store to save messages.

```
AdminTask.addSIBusMember('[-bus bus1 -node node1 -server server1 -fileStore ]')
```

Add server1 as a member of bus1, and use a file store to save messages, with options.

```
AdminTask.addSIBusMember('[-bus bus1 -node node1 -server server1 -fileStore
-logSize 100 -logDirectory C:\filestore1 ]')
```

Add server1 as a member of bus1, and use a data store to save messages.

```
AdminTask.addSIBusMember('[-bus bus1 -node node1 -server server1 -dataStore ]')
```

Add server1 as a member of bus1, and use a data store to save messages, with options.

```
AdminTask.addSIBusMember('[-bus bus1 -node node1 -server server1 -dataStore
-createDefaultDatasource true -datasourceJndiName myjndi]')
```

Change the initial JVM heap size to 256 and the maximum JVM heap size to 512.

```
AdminTask.addSIBusMember('[-bus bus1 -node node1 -server server1
-initialHeapSize 256 -maxHeapSize 512]')
```

listSIBusMembers command

Use the listSIBusMembers command to list the members of a service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command lists the names of all members in a service integration bus. The list includes all WebSphere MQ servers that are bus members.

Target object

A service integration bus.

Required parameters

-bus *busname*

The name by which the service integration bus is known. You can use the listSIBuses command to list the names of existing buses.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.listSIBusMembers('[-bus Bus1 ]')

[cells/9994GKCCell/buses/Bus1|sib-bus.xml#SIBusMember_1092155259869]
[cells/9994GKCCell/buses/Bus1|sib-bus.xml#SIBusMember_1092159844593]
[cells/9994GKCCell/buses/Bus1|sib-bus.xml#SIBusMember_1092160253751]
```

---

removeSIBusMember command

Use the removeSIBusMember command to remove a member from a service integration bus by using the wsadmin tool. A bus member can be an application server or a WebSphere MQ server.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The removeSIBusMember command removes a bus member from the named bus. It cleans up artifacts that are associated with the removed membership, for example, associated WebSphere MQ server bus member artifacts, mediation execution points, or core group policies for messaging engines that are associated with the bus member. To remove a bus member by using this command, specify one of the following resources:

- The server and the node on which that server runs
- The WebSphere MQ server

This command does not delete messages from the associated WebSphere MQ queues, and it does not delete the queues.

Target object

A service integration bus.

Required parameters

-bus *bus_name*
The name by which the service integration bus is known. You can use the listSIBuses command to list the names of existing buses.

Conditional parameters

-node *node_name*
-server *server_name*
To remove an application server from a bus, specify both the name of the node on which the server runs and the name of the server.

If you specify these parameters, do not specify the **-wmqServer** parameter.

-wmqServer *mqservername*
To remove a WebSphere MQ server from a bus, specify the name of the WebSphere MQ server. This is the name that was specified in the **-name** parameter when the WebSphere MQ server was created.

If you specify this parameter, do not specify the **-node** or **-server** parameters.

Optional parameters

None.

Example

Remove server1 from bus1.

```
AdminTask.removeSIBusMember('[-bus bus1 -node node1 -server server1 ]')
```

showSIBusMember command

Use the showSIBusMember command to show the properties of a service integration bus member.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('SIBAdminCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command lists the details of a specified member of a service integration bus. You can also use this command to list the details of a WebSphere MQ server bus member.

Target object

A bus member.

Required parameters

-bus *busname*
The name by which the service integration bus is known. You can use the listSIBuses command to list the names of existing buses.

-wmqServer
The name of the WebSphere MQ server bus member.

Conditional parameters

-node *nodename* **-server** *servername*
To list details of an application server as a bus member, specify both the name of the node on which the server runs and the name of the server.

-cluster *cluster*
To list details of a server cluster, specify the name of the cluster.

Use this option only in WebSphere Application Server environments that support server clusters.

Optional parameters

None.

Example

```
AdminTask.showSIBusMember(['-bus bus1 -node node1 -server server1'])
'{node=node1, server=server1}'
```

listAllSIBBootstrapMembers command

Use the listAllSIBBootstrapMembers command to list all the bootstrap members that can bootstrap into a selected bus.

You can use this command to list all the bootstrap members for a specified bus, or you can use the administrative console, see “Listing the bootstrap members for a bus” on page 1895.

This command requires the name of the bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The listAllSIBBootstrapMembers command lists all the servers and clusters that can bootstrap into a selected bus.

Target object

Bootstrap members for a selected bus.

Required parameters

-bus
The name of the bus for which you want to list all the bootstrap members. The data type is string. There is no default value.

Conditional parameters

None

Optional parameters

None

Example

The following example lists all the bootstrap members of `bus1`:

```
AdminTask.listAllSIBBootstrapMembers('[-bus bus1]')
```

listSIBNominatedBootstrapMembers command

Use the listSIBNominatedBootstrapMembers command to list all the nominated bootstrap members for a specified bus.

You can use this command to list all the nominated bootstrap members for a specified bus, or you can use the administrative console, see “Listing the bootstrap members for a bus” on page 1895.

This command requires the name of the bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The listSIBNominatedBootstrapMembers command lists all the nominated bootstrap members for a specified bus.

Target object

Nominated bootstrap members.

Required parameters

-bus
The name of the bus for which you want to list all nominated bootstrap members. The data type is string. There is no default value.

Conditional parameters

None

Optional parameters

None

Example

The following example lists the nominated bootstrap members for `bus1`:

```
AdminTask.listSIBBootstrapMembers('[-bus bus1]')
```

addSIBBootstrapMember command

Use the addSIBBootstrapMember command to add a nominated bootstrap member to a specified bus.

You can use this command to add a nominated bootstrap member to a specified bus, or you can use the administrative console: “Nominating bootstrap members for a bus” on page 1896.

This command requires the name of a bus, and a node and server name, or a cluster name.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The addSIBBootstrapMember command adds a nominated bootstrap member to the specified bus.

Target object

A nominated bootstrap member.

Required parameters

-bus
The name of the bus to which the nominated bootstrap member is added.

Conditional parameters

None

Optional parameters

-node
The name of the node on which the server you want to add exists. The data type is string. You must specify either the **node** or the **cluster** parameter. If you specify the **node** parameter, you must also specify the **server** parameter.

-server
The name of the server that you want to add as a nominated bootstrap member. The data type is string. You must only use this parameter with the **node** parameter, not with the **cluster** parameter.

-cluster
The name of the cluster that you want to add as a nominated bootstrap member. The data type is string. You must specify either the **cluster** or the **node** parameter. You cannot use the **cluster** parameter with the **node** or the **server** parameter.

Example

The following example adds `server1` on `node1` as a nominated bootstrap member of `bus1`:

```
AdminTask.addSIBBootstrapMember('[-bus bus1 -node node1 -server server 1]')
```

removeSIBBootstrapMember command

Use the removeSIBBootstrapMember command to remove a nominated bootstrap member from a selected bus.

You can use this command to remove a nominated bootstrap member from a selected bus, or you can use the administrative console: “Deleting nominated bootstrap members from a bus” on page 1896.

This command requires the name of a bus, and either the node and server name, or the cluster name, of an existing bootstrap member.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The removeSIBBootstrapMember command removes a nominated bootstrap member from a selected bus.

Target object

The nominated bootstrap member is removed from the selected bus.

Required parameters

-bus
The name of the bus from which you want to remove the nominated bootstrap member. The data type is string.

Conditional parameters

None

Optional parameters

-node
The name of the node where the server you want to remove exists. The data type is string. You must specify either the **node** or the **cluster** parameter. If you specify the **node** parameter, you must also specify the **server** parameter.

-server
The name of the server that you want to remove. The data type is string. You must only use this parameter with the **node** parameter, not with the **cluster** parameter.

-cluster
The name of the cluster that you want to remove. The data type is string. You must specify either the **cluster** or the **node** parameter. You cannot use the **cluster** parameter with the **node** or the **server** parameter.

Examples

The following example removes a nominated bootstrap member `cluster1` from `bus1`:

```
AdminTask.removeSIBBootstrapMember('[-bus bus1 -cluster cluster1]')
```

SIBAdminCommands: Foreign bus administrative commands for the AdminTask object

You can use these administrative commands to manage foreign buses. A foreign bus represents a service integration bus with which another service integration bus can exchange messages.

These commands provide an alternative to using the administrative console or using the more complex syntax of wsadmin and Jython.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('SIBAdminCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

createSIBForeignBus command

Use the createSIBForeignBus command to create a new service integration foreign bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('SIBAdminCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command creates a new foreign bus for a specified service integration bus. A foreign bus represents a bus with which another bus can exchange messages.

Target object

A specified service integration bus.

Required parameters

-bus *busname*
The name of the service integration bus for which you want to create the foreign bus. You can use the listSIBuses command to list the names of existing buses.

-name *busname*
The name by which you want the foreign bus to be known.

Notes:

- When you create a foreign bus that represents another service integration bus, the name of the foreign bus must match the name of the other service integration bus.
- When you intend to link two buses directly, you must assign them unique names.
- You must not change the name of a foreign bus name after it has been configured.

-routingType Direct | Indirect
Create a foreign bus with the physical link (also known as the *routing type*) specified:

Direct A *service integration bus link* from a messaging engine in the local bus to a messaging engine in the foreign bus.

Indirect
An *indirect link*, that is, a link that is made through one or more intermediate foreign buses.

Conditional parameters

None.

Optional parameters

-description *text*
An optional description for the bus, for administrative purposes.

-type MQ | SIBus
Create a foreign bus with the type specified:

MQ Create a foreign bus to link the service integration bus to a WebSphere MQ network.

SIBus Create a foreign bus to link the service integration bus to another service integration bus.

-sendAllowed True | False
(Default: True) Whether producers can send messages to the foreign bus.

False Producers cannot send messages to the foreign bus.

True Producers can send messages to the foreign bus.

-inboundUserid *userID*
The inbound user ID is used to authorize inbound messages sent from a foreign bus to destinations in a secure service integration bus. If the bus is not secure, the inbound user ID property has no affect on messages. You might want to specify an inbound user ID for use in the following scenarios:

- The foreign bus and the secure service integration bus are in different security domains, and the foreign bus user IDs are not recognized by the secure bus.
- You want local control over access to the secure bus by inbound messages.

Note that if the receiving service integration bus is secure but the foreign bus is not secure, and an inbound user ID is not set, an inbound message from the foreign bus is only authorized to destinations that allow unauthenticated users access.

-outboundUserid *userID*
The outbound user ID replaces the user ID that identifies the source of a message in all messages

being sent to the foreign bus. This user ID is also used by the foreign bus to authorize the message to its destination if both buses are secure buses and the foreign bus has not overridden the user ID with its own inbound user ID.

-nextHopBus *bus_name*
(If **-routingType** is Indirect) The name of the next service integration bus in the sequence of connected buses. An intermediate bus can be a WebSphere MQ system rather than a service integration bus.

-topicSpaceMappings *local topicSpace_name : remote topicSpace_name*
A topic space mapping allows subscribers on the local topic space to receive messages published in the foreign topic space. For publications to flow from the local topic space into the foreign bus, an equivalent topic space mapping is required by the foreign bus. Topic space names for the local bus are mapped to topic space names defined on the foreign bus. It is common for these two names to match. Note that mapping two topic spaces implies that the topics within them are the same. You can specify multiple pairs of topic spaces.

Example

```
AdminTask.createSIBForeignBus('[-bus bus1 -name foreignbus1 -routingType Direct
-type SIBus]')
'foreignbus1(cells/cell01/buses/bus1|sib-bus.xml#SIBForeignBus_1213023645293)'
```

deleteSIBForeignBus command

Use the deleteSIBForeignBus command to delete a foreign bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('SIBAdminCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command deletes a foreign bus. The command does not affect the service integration bus for which the foreign bus was created.

CAUTION:
This command deletes the foreign bus and its additional property configuration. Although there is no confirmation prompt before deleting the bus, the bus is not deleted from the master configuration until you save your changes.

Target object

A foreign bus.

Required parameters

-bus *busname*
The name of the service integration bus for which you want to delete a foreign bus. You can use the listSIBuses command to list the names of existing buses.

-name *busname*
The name of the foreign bus that you want to delete. You can use the listSIBForeignBuses command to list the names of existing buses.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.deleteSIBForeignBus('[-bus bus1 -name foreignbus1]')
```

listSIBForeignBuses command

Use the listSIBForeignBuses command to list all foreign buses for a specified service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('SIBAdminCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command lists the names of all foreign buses for a specified service integration bus. A foreign bus represents a bus in another cell (or within the same cell) or a WebSphere MQ network, with which a service integration bus can exchange messages.

Target object

A bus.

Required parameters

-bus *busname*
The name of the service integration bus for which you want to list foreign buses.

Conditional parameters

None.

Optional parameters

-routingType Direct | Indirect
List the foreign buses with the physical link (also known as the *routing type*) specified:

Direct A *service integration bus link* from a messaging engine in the local bus to a messaging engine in the foreign bus.

Indirect
An *indirect link*, that is, a link that is made through one or more intermediate foreign buses.

-type MQ | SIBus
List the foreign buses with the type specified:

MQ List the foreign buses that link the service integration bus to a WebSphere MQ network.

SIBus List the foreign buses that link the service integration bus to another service integration bus.

Example

```
AdminTask.listSIBForeignBuses('[-bus Bus1]')
```

modifySIBForeignBus command

Use the modifySIBForeignBus command to modify the properties of a foreign bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('SIBAdminCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command modifies the properties of a foreign bus. A foreign bus represents a bus in another cell (or within the same cell) or a WebSphere MQ network, with which a service integration bus can exchange messages.

Target object

A foreign bus.

Required parameters

-bus *busname*
The name of the service integration bus for which you want to modify a foreign bus. You can use the listSIBuses command to list the names of existing buses.

-name *busname*
The name of the foreign bus that you want to modify. You can use the listSIBForeignBuses command to list the names of existing buses.

Conditional parameters

None.

Optional parameters

-description *text*
An optional description for the bus, for administrative purposes.

-sendAllowed False | False
(Default: True) Whether producers can send messages to the foreign bus.

False Producers cannot send messages to the foreign bus.

True Producers can send messages to the foreign bus.

-inboundUserid *userID*
The inbound user ID is used to authorize individual messages arriving from the foreign bus to destinations in the service integration bus. If this is not a secure bus, this property has no affect on messages. You might want to specify an inbound user ID:

- if the foreign bus is in a different security domain from this bus and user IDs from the foreign bus are not recognized in this bus
- to locally-control access of inbound messages to this bus.

If this is a secure bus and the foreign bus is not secure, and no inbound user ID is set, any inbound messages from the foreign bus are only authorized to destinations that allow unauthenticated users access.

-outboundUserid *userID*
The outbound user ID replaces the user ID that identifies the source of a message in all messages being sent to the foreign bus. This user ID is also used by the foreign bus to authorize the message to its destination if both buses are secure buses and the foreign bus has not overridden the user ID with its own inbound user ID.

-nextHopBus *bus_name*
(If -**routingType** is Indirect) The name of the next service integration bus in the sequence of connected buses. An intermediate bus can be a WebSphere MQ system rather than a service integration bus.

-topicSpaceMappings *local topicSpace_name : remote topicSpace_name*
A topic space mapping allows subscribers on the local topic space to receive messages published in the foreign topic space. For publications to flow from the local topic space into the foreign bus, an equivalent topic space mapping is required by the foreign bus. Topic space names for the local bus are mapped to topic space names defined on the foreign bus. It is common for these two names to match. Note that mapping two topic spaces implies that the topics within them are the same. You can specify multiple pairs of topic spaces.

Example

The example below specifies the following additional optional properties for an existing foreign bus called *foreignbus1*:

- An inbound user identity called *iuserid* to authorize messages sent from *foreignbus1* to the local bus, when security is enabled on *foreignbus1*, and the local bus.
- An outbound user identity called *ouserid* to authorize messages sent from the local bus to *foreignbus1*, when security is enabled on *foreignbus1*, and the local bus.

- A topic space mapping between *Topic.Space1* on the local bus and *Topic.Space2* on *foreignbus1*. The mapping allows subscribers on *Topic.Space1* on the local bus to receive messages published in *Topic.Space2* on *foreignbus1*.

```
AdminTask.modifySIBForeignBus('[-bus bus1 -name foreignbus1 -inboundUserid iuserid
-outboundUserid ouserid -topicSpaceMappings [[Topic.Space1 Topic.Space2]]]')
'foreignbus1(cells/cell01/buses/bus1|sib-bus.xml#SIBForeignBus_1213023645293)'
```

showSIBForeignBus command

Use the showSIBForeignBus command to show the properties of a foreign bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command lists details about the properties of a foreign bus. A foreign bus represents a bus in another cell (or within the same cell) or a WebSphere MQ network, with which a service integration bus can exchange messages.

Target object

A foreign bus.

Required parameters

-bus *busname*
The name of the service integration bus for which you want to show a foreign bus. You can use the listSIBuses command to list the names of existing buses.

-name *busname*
The name of the foreign bus that you want to show. You can use the listSIBForeignBuses command to list the names of existing buses.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.showSIBForeignBus('[-bus bus1 -name foreignbus1]')
'Foreign Bus Name = foreignbus1
Foreign Bus Uuid = 17B07B718182CDF6A73E75D2
Foreign Bus Description = A new foreign bus
Foreign Bus Send Allowed = true
mqRfh2 Allowed = false'
```

SIBAdminCommands: WebSphere MQ link administrative commands for the AdminTask object

You can use these administrative commands to manage WebSphere MQ links. A WebSphere MQ link connects a messaging engine as a queue manager to WebSphere MQ, thereby providing a bridge between a service integration bus and a WebSphere MQ network.

These commands provide an alternative to using the administrative console or using the more complex syntax of wsadmin and Jython.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('SIBAdminCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

createSIBMQLink command

Use the createSIBMQLink command to create a new WebSphere MQ link for a specified service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('SIBAdminCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The createSIBMQLink command creates a new WebSphere MQ link for a specified service integration bus. The WebSphere MQ link connects a messaging engine as a queue manager to WebSphere MQ, thereby providing a bridge between a service integration bus and a WebSphere MQ network.

Target object

A bus.

Required parameters

-bus
The name of the service integration bus for which you want to create the WebSphere MQ link. You can use the listSIBuses command to list the names of existing buses.

-messagingEngine
The name of the messaging engine for which you want to create the WebSphere MQ link. The WebSphere MQ link connects a messaging engine as a queue manager to WebSphere MQ, thereby providing a bridge between a service integration bus and a WebSphere MQ network.

-name
The name by which you want the WebSphere MQ link to be known.

-foreignBusName
The name of the foreign bus that defines the WebSphere MQ network for the WebSphere MQ link. You can use the listSIBForeignBuses command to list the names of existing foreign buses.

-queueManagerName
The name of the virtual queue manager associated with the messaging engine, and by which the messaging engine is known to a remote WebSphere MQ network.

The queue manager name must conform to the WebSphere MQ naming conventions; for example, the name must be a maximum of 48 characters.

-senderChannelTransportChain OutboundBasicMQLink | OutboundSecureMQLink
The name of the sender channel that sends messages to the gateway queue manager. The sender channel communicates with a WebSphere MQ receiver channel on the gateway queue manager, and converts service integration bus messages to MQ format messages.

Conditional parameters

None.

Optional parameters

WebSphere MQ link configuration parameters:

-description
An optional description for the bus, for administrative purposes.

-exceptionDestination
The destination for an inbound message when the WebSphere MQ link cannot deliver the message to its target bus destination, or to the exception destination that is configured for that target destination, or when the target destination does not exist.

System
The WebSphere MQ link uses the default exception destination. All messages that cannot be delivered to the bus destination are rerouted automatically to the system default exception destination for the messaging engine that this link is assigned to: _SYSTEM.Exception.Destination*messaging_engine_name*.

None The WebSphere MQ link has no exception destination. Undeliverable messages are not rerouted to an exception destination and can block the processing of other messages waiting for delivery through the link to the same bus. This option can be used to preserve message ordering.

Specify
The WebSphere MQ link uses the exception destination specified here. If this is not possible, it uses the system exception destination.

-batchSize
The maximum number of messages that can be sent through a channel before taking a checkpoint.

The batch size does not affect the way the sender and receiver channels for this link transfer messages. Messages are always transferred individually, but are committed or backed out as a batch.

For more information about choosing the batch size, see the description of the batch size (**BATCHSZ**) property in the *Intercommunication* section of the WebSphere MQ information center.

Default 50
Range 1 through 9999

-maxMsgSize
The maximum message length, in bytes, that can be transmitted on any channel for the WebSphere MQ link. This is compared with the value for the corresponding partner WebSphere MQ channel and the actual maximum used is the lower of the two values.

For information about how to choose an appropriate number, see the description of the Maximum message length (**MAXMSGL**) property in the *Intercommunication* section of the WebSphere MQ information center.

Default 4194304 bytes (4MB)
Range 0 through 104857600

Specify 0 to use the largest value that the target queue manager will honor.

-heartBeat
The negotiated time, in seconds, between heartbeat flows passed from the WebSphere MQ link sender channel to the WebSphere MQ receiver channel when there are no messages on the transmission point being served by the WebSphere MQ link sender channel.

Heartbeats give the receiving channel the opportunity to quiesce the channel connection.

For more information about choosing the value for this property, see the *Intercommunication* section of the WebSphere MQ information center.

Default 300 seconds
Range 0 through 999999

-sequenceWrap
The value at which message sequence numbers wrap to start again at 1. For example, if you specify a value of 1000, when the message sequence number reaches 1001 it will restart at 1.

For more information about choosing the value for this property, see the description of the Sequence Number wrap (**SEQWRAP**) property in the *Intercommunication* section of the WebSphere MQ information center.

Default 999999999
Range 1 through 999999999

-nonPersistentMessageSpeed Fast | Normal
The class of service for nonpersistent messages on channels of this WebSphere MQ link.

Default Fast

Range

Fast Nonpersistent messages can be lost if there is a transmission failure or if the channel stops when the messages are in transit.

Normal
Nonpersistent messages are not lost if there is a transmission failure or if the channel stops when the messages are in transit.

-adoptable True | False
A property of the WebSphere MQ link, which shows whether a running instance of a WebSphere MQ link receiver channel (associated with this WebSphere MQ link) should be adopted. In the event of a communications failure, a running instance of a WebSphere MQ link receiver channel might be left waiting for messages. When communication is reestablished, and the partner WebSphere MQ sender channel next attempts to establish a session with the WebSphere MQ link receiver channel, the request will fail as there is already a running instance of the WebSphere MQ link receiver channel that believes it is in session with the partner WebSphere MQ sender channel. You can overcome this problem by selecting this option, which causes the already running instance of the WebSphere MQ link receiver channel to be stopped and a new instance to be started.

If you set this option to True, the WebSphere MQ sender channels might reestablish a connection to this WebSphere MQ link in the event that a communications failure has occurred and the link has not yet detected the failure condition.

Default True

-initialState Started | Stopped
The state of the WebSphere MQ link, which shows whether the link is started or stopped when the hosting messaging engine is first started. Until it is started, the WebSphere MQ link is unavailable.

Default Started

Range

Stopped
When the associated messaging engine is started, the WebSphere MQ link is in a stopped state and cannot communicate with the WebSphere MQ network.

Started
When the associated messaging engine is started, the WebSphere MQ link is started automatically and is enabled for communication with the WebSphere MQ network.

WebSphere MQ link sender channel parameters:

-senderChannelName
The sender channel that sends messages to the gateway queue manager. The sender channel communicates with a WebSphere MQ receiver channel on the gateway queue manager, and converts service integration bus messages to MQ format messages.

This name must be the same as the name of the receiver channel on WebSphere MQ.

For more information about choosing channel names, see the description of the channel name (**CHANNEL**) property in the *Intercommunication* section of the WebSphere MQ information center.

-hostName
The host name or TCP/IP address for the gateway queue manager that is used to connect into the WebSphere MQ network.

Type the host name or IP address of the host on which the gateway queue manager runs.

If this field is blank, the gateway queue manager is assumed to be running on the same host as the messaging engine on which the WebSphere MQ link is defined.

-port
The TCP/IP port number on which the gateway queue manager is listening for the WebSphere MQ link.

Default	1414
Range	0 through 65535

-connameList
The connection name list for the gateway queue manager which is used to connect to the WebSphere MQ network. The connections are tried in the order in which they are specified in the connection name list until a connection is successfully established. If no connection is successful, the channel starts retry processing.

The connection names must be given as a comma separated list in the following format:

```
Dnsname1(portnumber1) , Dnsname2(portnumber2)
```

Type the DNS name or the IP address of the host on which the gateway queue manager is running. Type the port number in the range 0 through 65535.

If you do not specify the connection name list parameter, the gateway queue manager is assumed to be running on the same host as the messaging engine on which the WebSphere MQ link is defined.

If you do specify the connection name list parameter, you must have already specified a value for the sender channel name parameter, otherwise the value that you specify for the connection name list parameter is ignored.

If you specify the host name and port parameter as well as the connection name list parameter, then at runtime the connection name list takes precedence and host name and port values are ignored.

-discInterval
The time in seconds for which the sender channel waits for new messages to arrive on the transmission queue after sending a batch of messages. The channel disconnects after this interval, and must be restarted manually or by triggering.

The default value is a reasonable interval. Change this value only if you understand the implications for performance, and you need a different value for the requirements of the traffic flowing down your channels.

Performance is affected by the value specified for the disconnect interval. A very low value (a few seconds) can cause an unacceptable amount of processing in constantly starting up the channel. A very large value (more than an hour) might mean that system resources are unnecessarily held up.

If you want your channels to be active only when there are messages for them to transmit, you should set the disconnect interval to a fairly low value. Note that the default setting is quite high and so is not recommended for channels where this level of control is required. Because it is difficult to interrupt the receiving channel, the most economical option is to have the channel automatically disconnect and reconnect as the workload demands. For most channels, the appropriate setting of the disconnect interval can be established heuristically.

Default	900 seconds
Range	0 through 999999 A value of 0 (zero) means never disconnect; the channel waits indefinitely for messages.

-shortRetryCount
The maximum number of times that the sender channel tries to restart after a communication or partner failure. If the connection name list is provided, during each retry the connections are tried in the order in which they are specified in the connection list until a connection is successfully established. If the count of remaining retries reaches zero, and the channel has not restarted, then the long retry mechanism is invoked.

For more information about using retry mechanisms with WebSphere MQ, see the *Intercommunication* section of the WebSphere MQ information center.

Default 10
Range 0 through 999999999

-shortRetryInterval
The number of seconds between attempts by the sender channel to restart after a communication or partner failure.

For more information about using retry mechanisms with WebSphere MQ, see the *Intercommunication* section of the WebSphere MQ information center.

Default 60 seconds
Range 0 through 999999

-longRetryCount
The maximum number of times that the sender channel tries to restart after the short retry mechanism did not recover from a communication or partner failure. If the connection name list is provided, during each retry the connections are tried in the order in which they are specified in the connection list until a connection is successfully established. If the count of remaining retries reaches zero, and the channel has not restarted, then an error is logged and the channel is stopped.

For more information about using retry mechanisms with WebSphere MQ, see the *Intercommunication* section of the WebSphere MQ information center.

Default 999999999
Range 0 through 999999999

-longRetryInterval
The number of seconds between attempts by the sender channel to restart after the short retry mechanism did not recover from a communication or partner failure.

For more information about using retry mechanisms with WebSphere MQ, see the *Intercommunication* section of the WebSphere MQ information center.

Default 1200 seconds
Range 0 through 999999

-senderChannelInitialState Started | Stopped
The state of the WebSphere MQ link, which shows whether the sender channel is started or stopped when the associated WebSphere MQ link is first started. Until it is started, the channel is unavailable.

Default Started

Range

Stopped
When the associated messaging engine is started, the WebSphere MQ link is in a stopped state and cannot communicate with the WebSphere MQ network.

Started
When the associated messaging engine is started, the WebSphere MQ link is started automatically and is enabled for communication with the WebSphere MQ network.

WebSphere MQ link receiver channel parameters:

-receiverChannelName
The name of the receiver channel for the WebSphere MQ link, used to receive messages from WebSphere MQ onto the bus.

This name must be the same as the name of the sender channel on WebSphere MQ.

-inboundNonPersistentReliability Best effort | Express | Reliable
The acceptable reliability of message delivery for nonpersistent message flows from WebSphere MQ through this WebSphere MQ link, from Best effort to Reliable, in order of increasing reliability.

This reliability delivery option is assigned to all WebSphere MQ nonpersistent messages flowing over this receiver channel.

Default
Reliable

Range

Best effort
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable
Messages are discarded when a messaging engine stops or fails.

-inboundPersistentReliability Reliable | Assured
The acceptable reliability of message delivery for inbound persistent message flows from WebSphere MQ through this WebSphere MQ link, from Reliable to Assured, in order of increasing reliability.

Default
Assured

Range

Reliable
Messages might be discarded when a messaging engine fails.

Assured
Messages are not discarded.

-receiverChannelInitialState Started | Stopped

The state of the WebSphere MQ link, which shows whether the receiver channel is started or stopped when the associated WebSphere MQ link is first started. Until it is started, the channel is unavailable.

Default Started

Range

Stopped
When the associated messaging engine is started, the WebSphere MQ link is in a stopped state and cannot communicate with the WebSphere MQ network.

Started
When the associated messaging engine is started, the WebSphere MQ link is started automatically and is enabled for communication with the WebSphere MQ network.

-preferLocal TRUE | FALSE

This option indicates that the link prefers to send incoming messages to the queue point of the target destination that is located on the same messaging engine as the link, if available. The link must be owned by a messaging engine running on a WebSphere Application Server Version 7.0 or later server.

This option is supported only when used by a JMS application that is running with a WebSphere Application Server Version 7.0 or later server or client, and that is connected to a messaging engine running on WebSphere Application Server Version 7.0 or later server. Use on previous versions of WebSphere Application Server will result in an exception to the application.

Default TRUE

Range

TRUE Send each incoming message to the queue point of the target destination that is located on the same messaging engine as the link, if available.

FALSE Send incoming messages to any queue points of the target destinations.

Examples

```
AdminTask.createSIBMQLink('[-bus bus1 -messagingEngine cluster1.000-bus1
-name myMQLink2 -foreignBusName MQNetwork2 -queueManagerName MQMgrIPL
-senderChannelTransportChain OutboundBasicMQLink]')
'myMQLink2(cells/cell01/nodes/node01/servers/server1|sib-engines.xml#
SIBMQLink_1132607756126)'
```

Create a SIBMQLink that uses queue points on the same messaging engine as the target destination, whenever possible.

```
AdminTask.createSIBMQLink('[-bus bus1 -messagingEngine cluster1.000-bus1
-name MyMQLink -foreignBusName -MQQMgr1 -queueManagerName bus1
-senderChannelTransportChain OutboundBasicMQLink  -preferLocal TRUE]')
```

deleteSIBMQLink command

Use the deleteSIBMQLink command to delete a WebSphere MQ link from a service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('SIBAdminCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The deleteSIBMQLink command deletes a WebSphere MQ link from a bus.

CAUTION:
This command deletes the WebSphere MQ link and its additional property configuration. Although there is no confirmation prompt before deleting the WebSphere MQ link, the link is not deleted from the master configuration until you save your changes.

Target object

A bus.

Required parameters

-bus
The name of the service integration bus for which you want to delete a WebSphere MQ link. You can use the listSIBuses command to list the names of existing buses.

-messagingEngine
The name of the messaging engine to which the WebSphere MQ link was assigned when it was created. You can use the listSIBEngines command to list the names of existing messaging engines.

-mqLink
The name of the WebSphere MQ link that you want to delete.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.deleteSIBMQLink('[-bus bus1 -messagingEngine cluster1.000-bus1
-mqLink myMQLink2]')
```

listSIBMQLinks command

Use the listSIBMQLinks command to list all WebSphere MQ links for a specified service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Purpose

The listSIBMQLinks command lists the names of all WebSphere MQ links for a specified service integration bus. A WebSphere MQ link connects a messaging engine as a queue manager to WebSphere MQ, thereby providing a bridge between a service integration bus and a WebSphere MQ network.

Target object

A specified service integration bus.

Required parameters

-bus
The name of the service integration bus for which you want to list WebSphere MQ links.

Conditional parameters

None.

Optional parameters

-node
The name of the node for which you want to list WebSphere MQ links. This option restricts the list of WebSphere MQ links to those links assigned to the node.

-server
The name of the server for which you want to list WebSphere MQ links. This option restricts the list of WebSphere MQ links to those links assigned to the server.

-cluster
The name of the server cluster for which you want to list WebSphere MQ links. This option restricts the list of WebSphere MQ links to those links assigned to the server cluster.

-messagingEngine
The name of the messaging engine for which you want to list WebSphere MQ links. This option restricts the list of WebSphere MQ links to those links assigned to the messaging engine.

Example

```
AdminTask.listSIBMQLinks('[-bus bus1 -foreignBus foreignbus1 ]')
'foreignbus1(cells/cell01/nodes/node01/servers/server1|sib-engines.xml#
SIBMQLink_1213002780841)'
```

modifySIBMQLink command

Use the modifySIBMQLink command to modify the properties of a WebSphere MQ link.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The modifySIBMQLink command modifies the properties of a WebSphere MQ link.

Target object

A WebSphere MQ link.

Required parameters

-bus
The name of the service integration bus for which you created the WebSphere MQ link. You can use the listSIBuses command to list the names of existing buses.

-messagingEngine
The name of the messaging engine for which you created the WebSphere MQ link. You can use the listSIBEngines command to list the names of existing messaging engines.

-name
The name of the WebSphere MQ link.

Conditional parameters

None.

Optional parameters

WebSphere MQ link configuration parameters:

-queueManagerName
The name of the virtual queue manager associated with the messaging engine, and by which the messaging engine is known to a remote WebSphere MQ network.

The queue manager name must conform to the WebSphere MQ naming conventions; for example, the name must be a maximum of 48 characters.

-description
An optional description for the bus, for administrative purposes.

-exceptionDestination
The destination for an inbound message when the WebSphere MQ link cannot deliver the message to its target bus destination, or to the exception destination that is configured for that target destination, or when the target destination does not exist.

System
The WebSphere MQ link uses the default exception destination. All messages that cannot be delivered to the bus destination are rerouted automatically to the system default exception

destination for the messaging engine that this link is assigned to: _SYSTEM.Exception.Destination*messaging_engine_name*.

None The WebSphere MQ link has no exception destination. Undeliverable messages are not rerouted to an exception destination and can block the processing of other messages waiting for delivery through the link to the same bus. This option can be used to preserve message ordering.

Specify
The WebSphere MQ link uses the exception destination specified here. If this is not possible, it uses the system exception destination.

-batchSize
The maximum number of messages that can be sent through a channel before taking a checkpoint.

The batch size does not affect the way the sender and receiver channels for this link transfer messages. Messages are always transferred individually, but are committed or backed out as a batch.

For more information about choosing the batch size, see the description of the batch size (**BATCHSZ**) property in the *Intercommunication* section of the WebSphere MQ information center.

Default	50
Range	1 through 9999

-maxMsgSize
The maximum message length, in bytes, that can be transmitted on any channel for the WebSphere MQ link. This is compared with the value for the corresponding partner WebSphere MQ channel and the actual maximum used is the lower of the two values.

For information about how to choose an appropriate number, see the description of the Maximum message length (**MAXMSGL**) property in the *Intercommunication* section of the WebSphere MQ information center.

Default	4194304 bytes (4MB)
Range	0 through 104857600 Specify 0 to use the largest value that the target queue manager will honor.

-heartBeat
The negotiated time, in seconds, between heartbeat flows passed from the WebSphere MQ link sender channel to the WebSphere MQ receiver channel when there are no messages on the transmission point being served by the WebSphere MQ link sender channel.

Heartbeats give the receiving channel the opportunity to quiesce the channel connection.

For more information about choosing the value for this property, see the *Intercommunication* section of the WebSphere MQ information center.

Default	300 seconds
Range	0 through 999999

-sequenceWrap
The value at which message sequence numbers wrap to start again at 1. For example, if you specify a value of 1000, when the message sequence number reaches 1001 it will restart at 1.

For more information about choosing the value for this property, see the description of the Sequence Number wrap (**SEQWRAP**) property in the *Intercommunication* section of the WebSphere MQ information center.

Default	999999999

Range 100 through 999999999

-nonPersistentMessageSpeed Fast | Normal
The class of service for nonpersistent messages on channels of this WebSphere MQ link.

Default Fast
Range

Fast Nonpersistent messages can be lost if there is a transmission failure or if the channel stops when the messages are in transit.

Normal
Nonpersistent messages are not lost if there is a transmission failure or if the channel stops when the messages are in transit.

-adoptable True | False
A property of the WebSphere MQ link, which shows whether a running instance of a WebSphere MQ link receiver channel (associated with this WebSphere MQ link) should be adopted. In the event of a communications failure, a running instance of a WebSphere MQ link receiver channel might be left waiting for messages. When communication is reestablished, and the partner WebSphere MQ sender channel next attempts to establish a session with the WebSphere MQ link receiver channel, the request will fail as there is already a running instance of the WebSphere MQ link receiver channel that believes it is in session with the partner WebSphere MQ sender channel. You can overcome this problem by selecting this option, which causes the already running instance of the WebSphere MQ link receiver channel to be stopped and a new instance to be started.

If you set this option to True, the WebSphere MQ sender channels might reestablish a connection to this WebSphere MQ link in the event that a communications failure has occurred and the link has not yet detected the failure condition.

Default True

-initialState Started | Stopped
The state of the WebSphere MQ link, which shows whether the link is started or stopped when the hosting messaging engine is first started. Until it is started, the WebSphere MQ link is unavailable.

Default Started
Range

Stopped
When the associated messaging engine is started, the WebSphere MQ link is in a stopped state and cannot communicate with the WebSphere MQ network.

Started
When the associated messaging engine is started, the WebSphere MQ link is started automatically and is enabled for communication with the WebSphere MQ network.

WebSphere MQ link sender channel parameters:

-senderChannelName
The sender channel that sends messages to the gateway queue manager. The sender channel communicates with a WebSphere MQ receiver channel on the gateway queue manager, and converts service integration bus messages to MQ format messages.

This name must be the same as the name of the receiver channel on WebSphere MQ.

For more information about choosing channel names, see the description of the channel name (**CHANNEL**) property in the *Intercommunication* section of the WebSphere MQ information center.

-hostName
The host name or TCP/IP address for the gateway queue manager that is used to connect into the WebSphere MQ network.

Type the host name or IP address of the host on which the gateway queue manager runs.

If this field is blank, the gateway queue manager is assumed to be running on the same host as the messaging engine on which the WebSphere MQ link is defined.

-port
The TCP/IP port number on which the gateway queue manager is listening for the WebSphere MQ link.

Default	1414
Range	0 through 65535

-connameList
The connection name list for the gateway queue manager which is used to connect to the WebSphere MQ network. The connections are tried in the order in which they are specified in the connection name list until a connection is successfully established. If no connection is successful, the channel starts retry processing.

The connection names must be given as a comma separated list in the following format:

```
Dnsname1(portnumber1) , Dnsname2(portnumber2)
```

Type the DNS name or the IP address of the host on which the gateway queue manager is running. Type the port number in the range 0 through 65535.

If you do not specify the connection name list parameter, the gateway queue manager is assumed to be running on the same host as the messaging engine on which the WebSphere MQ link is defined.

If you do specify the connection list parameter, you must have already specified a value for the sender channel name parameter, otherwise the value that you specify for the connection name list parameter is ignored.

If you specify the host name and port parameter as well as the connection name list parameter, then at runtime the connection name list takes precedence and host name and port values are ignored.

-discInterval
The time in seconds for which the sender channel waits for new messages to arrive on the transmission queue after sending a batch of messages. The channel disconnects after this interval, and must be restarted manually or by triggering.

The default value is a reasonable interval. Change this value only if you understand the implications for performance, and you need a different value for the requirements of the traffic flowing down your channels.

Performance is affected by the value specified for the disconnect interval. A very low value (a few seconds) can cause an unacceptable amount of processing in constantly starting up the channel. A very large value (more than an hour) might mean that system resources are unnecessarily held up.

If you want your channels to be active only when there are messages for them to transmit, you should set the disconnect interval to a fairly low value. Note that the default setting is quite high and so is not recommended for channels where this level of control is required. Because it is difficult to interrupt the receiving channel, the most economical option is to have the channel automatically disconnect and reconnect as the workload demands. For most channels, the appropriate setting of the disconnect interval can be established heuristically.

Default	900 seconds

Range 0 through 999999

A value of 0 (zero) means never disconnect; the channel waits indefinitely for messages.

-shortRetryCount

The maximum number of times that the sender channel tries to restart after a communication or partner failure. If the connection name list is provided, during each retry the connections are tried in the order in which they are specified in the connection list until a connection is successfully established. If the count of remaining retries reaches zero, and the channel has not restarted, then the long retry mechanism is invoked.

Default 10
Range 0 through 999999999

-shortRetryInterval

The number of seconds between attempts by the sender channel to restart after a communication or partner failure.

For more information about using retry mechanisms with WebSphere MQ, see the *Intercommunication* section of the WebSphere MQ information center.

Default 60 seconds
Range 0 through 999999

-longRetryCount

The maximum number of times that the sender channel tries to restart after the short retry mechanism did not recover from a communication or partner failure. If the connection name list is provided, during each retry the connections are tried in the order in which they are specified in the connection list until a connection is successfully established. If the count of remaining retries reaches zero, and the channel has not restarted, then an error is logged and the channel is stopped.

For more information about using retry mechanisms with WebSphere MQ, see the *Intercommunication* section of the WebSphere MQ information center.

Default 999999999
Range 0 through 999999999

-longRetryInterval

The number of seconds between attempts by the sender channel to restart after the short retry mechanism did not recover from a communication or partner failure.

For more information about using retry mechanisms with WebSphere MQ, see the *Intercommunication* section of the WebSphere MQ information center.

Default 1200 seconds
Range 0 through 999999

-senderChannelInitialState Started | Stopped

The state of the WebSphere MQ link, which shows whether the sender channel is started or stopped when the associated WebSphere MQ link is first started. Until it is started, the channel is unavailable.

Default Started

Range

Stopped
When the associated messaging engine is started, the WebSphere MQ link is in a stopped state and cannot communicate with the WebSphere MQ network.

Started
When the associated messaging engine is started, the WebSphere MQ link is started automatically and is enabled for communication with the WebSphere MQ network.

WebSphere MQ link receiver channel parameters:

-receiverChannelName
The name of the receiver channel for the WebSphere MQ link, used to receive messages from WebSphere MQ onto the bus.

This name must be the same as the name of the sender channel on WebSphere MQ.

-inboundNonPersistentReliability Best effort | Express | Reliable
The acceptable reliability of message delivery for nonpersistent message flows from WebSphere MQ through this WebSphere MQ link, from Best effort to Reliable, in order of increasing reliability.

This reliability delivery option is assigned to all WebSphere MQ nonpersistent messages flowing over this receiver channel.

Default
Reliable

Range

Best effort
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable
Messages are discarded when a messaging engine stops or fails.

-inboundPersistentReliability Reliable | Assured
The acceptable reliability of message delivery for inbound persistent message flows from WebSphere MQ through this WebSphere MQ link, from Reliable to Assured, in order of increasing reliability.

Default
Assured

Range

Reliable
Messages might be discarded when a messaging engine fails.

Assured
Messages are not discarded.

-receiverChannelInitialState Started | Stopped

The state of the WebSphere MQ link, which shows whether the receiver channel is started or stopped when the associated WebSphere MQ link is first started. Until it is started, the channel is unavailable.

Default
Started

Range

Stopped
When the associated messaging engine is started, the WebSphere MQ link is in a stopped state and cannot communicate with the WebSphere MQ network.

Started
When the associated messaging engine is started, the WebSphere MQ link is started automatically and is enabled for communication with the WebSphere MQ network.

-preferLocal TRUE | FALSE

This option indicates that the link prefers to send incoming messages to the queue point of the target destination that is located on the same messaging engine as the link, if available. The link must be owned by a messaging engine running on a WebSphere Application Server Version 7.0 or later server.

This option is supported only when used by a JMS application that is running with a WebSphere Application ServerVersion 7.0 or later server or client, and that is connected to a messaging engine running on WebSphere Application ServerVersion 7.0 or later server. Use on previous versions of WebSphere Application Server will result in an exception to the application.

Default
TRUE

Range

TRUE Send each incoming message to the queue point of the target destination that is located on the same messaging engine as the link, if available.

FALSE Send incoming messages to any queue points of the target destinations.

Examples

Show the properties of a WebSphere MQ link, modify the link to change the batch size, then show the properties of the link again.

```
wsadmin>AdminTask.showSIBMQLink('[-bus myBus -messagingEngine myHostNode01.server1-myBus
-mqLink myMQLink]')
'{nonPersistentMessageSpeed=FAST, qmName=myBus, adoptable=false, sequenceWrap=999999999,
 name=myMQLink, targetUuid=738AE126B908E5451A3D4691, initialState=STARTED,
 senderChannel=null, brokerProfile=[], receiverChannel=null, preferLocalQueuePoints=true,
 batchSize=50, uuid=6B89C4F08AB072C5, heartBeat=300, description=null, maxMsgSize=4194304,
 exceptionDestination=_SYSTEM.Exception.Destination.myHostNode01.server1-myBus}'
wsadmin>
wsadmin>AdminTask.modifySIBMQLink('[-bus myBus -messagingEngine myHostNode01.server1-myBus
-name myMQLink -batchSize 100]')
'myMQLink(cells/cell01/nodes/node01/servers/server1|sib-engines.xml#SIBMQLink_1132608724468)'

wsadmin>AdminTask.showSIBMQLink('[-bus myBus -messagingEngine myHostNode01.server1-myBus
-mqLink myMQLink]')
'{nonPersistentMessageSpeed=FAST, qmName=myBus, adoptable=false, sequenceWrap=999999999,
 name=myMQLink, targetUuid=738AE126B908E5451A3D4691, initialState=STARTED,
 senderChannel=null, brokerProfile=[], receiverChannel=null, preferLocalQueuePoints=true,
 batchSize=100, uuid=6B89C4F08AB072C5, heartBeat=300, description=null, maxMsgSize=4194304,
 exceptionDestination=_SYSTEM.Exception.Destination.myHostNode01.server1-myBus}'
wsadmin>
```

Modify a WebSphere MQ link so that the link has no preference for which queue points to use.

```
wsadmin>AdminTask.modifySIBMQLink('[-bus Bus1 -messagingEngine
node1.node1server1-Bus1 -name MQLink -queueManagerName QM2 -preferLocal FALSE]')
wsadmin>
```

showSIBMQLink command

Use the showSIBMQLink command to show the properties of a WebSphere MQ link.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('SIBAdminCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

Purpose

The showSIBMQLink command lists details about the properties of a WebSphere MQ link.

Target object

A WebSphere MQ link.

Required parameters

-bus
The name of the service integration bus for which you created the WebSphere MQ link. You can use the listSIBuses command to list the names of existing buses.

-messagingEngine
The name of the messaging engine for which you created the WebSphere MQ link. You can use the listSIBEngines command to list the names of existing messaging engines.

-name
The name of the WebSphere MQ link.

Conditional parameters

None.

Optional parameters

javaFormat
The output from the command is a format suitable for Java program clients.

Example

```
wsadmin>AdminTask.showSIBMQLink('[-bus myBus -messagingEngine myHostNode01.server1-myBus
-mqLink myMQLink]')
'{nonPersistentMessageSpeed=FAST, qmName=myBus, adoptable=false, sequenceWrap=999999999,
name=myMQLink, targetUuid=738AE126B908E5451A3D4691, initialState=STARTED,
senderChannel=null, brokerProfile=[], receiverChannel=null, preferLocalQueuePoints=true,
batchSize=50, uuid=6B89C4F08AB072C5, heartBeat=300, description=null, maxMsgSize=4194304,
exceptionDestination=_SYSTEM.Exception.Destination.myHostNode01.server1-myBus}'
wsadmin>
```

SIBAdminCommands: Bus link administrative commands for the AdminTask object

You can use these administrative commands to manage service integration bus links. A service integration bus link defines a link between a messaging engine in one service integration bus and a messaging engine in a foreign service integration bus.

These commands provide an alternative to using the administrative console or using the more complex syntax of wsadmin and Jython.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

createSIBLink command

Use the createSIBLink command to create a new service integration bus link.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The createSIBLink command creates a new bus link for a specified bus. A bus link defines a link between a messaging engine in one bus and a messaging engine in a foreign bus.

Target object

None.

Required parameters

-bus
The name of the service integration bus for which you want to create the service integration bus link. You can use the listSIBuses command to list the names of existing buses.

-messagingEngine
The name of the messaging engine for which you want to create the service integration bus link. The service integration bus link connects a messaging engine to another messaging engine in a different service integration bus, thereby providing a bridge between two service integration buses.

-name
The name by which you want the service integration bus link to be known.

-foreignBusName
The name of the foreign bus that defines the remote service integration bus for the service integration bus link. You can use the listSIBForeignBuses command to list the names of existing foreign buses.

-bootstrapEndpoints
The comma-separated list of endpoints used to connect to a bootstrap server.

This property is set in the same way as the **Provider endpoint** property in the JMS connection factory settings. For more information, see the steps relating to setting bootstrap endpoints in “Configuring a connection to a non-default bootstrap server” on page 531.

The port for the bootstrap endpoint is the port defined on the SIB endpoint address that is configured on the target application server on the foreign bus.

-remoteMessagingEngineName
The messaging engine on the foreign bus to which this link connects.

Conditional parameters

None.

Optional parameters

-description
An optional description for the bus, for administrative purposes.

-protocolName
The type of transport chain used for communication with the foreign bus.

The transport chain name must be the name of the transport chain as defined on the server on which the target messaging engine is hosted.

-authAlias
The name of the authentication alias, used to authenticate access to the foreign bus.

You must have predefined a J2C authentication alias.

-exceptionDestination
The destination for an inbound message when the service integration bus link cannot deliver the message to its target bus destination, or to the exception destination that is configured for that target destination, or when the target destination does not exist.

System
The service integration bus link uses the default exception destination. All messages that cannot be delivered to the bus destination are rerouted automatically to the system default

exception destination for the messaging engine that this link is assigned to: _SYSTEM.Exception.Destination.*messaging_engine_name*.

None The service integration bus link has no exception destination. Undeliverable messages are not rerouted to an exception destination and can block the processing of other messages waiting for delivery to the same destination. This option can be used to preserve message ordering.

Specify
The service integration bus link uses the exception destination specified here. If this is not possible, it uses the system exception destination.

-initialState Started | Stopped
The state of the gateway link, which shows whether the link is started automatically when the messaging engine is started.

Default Started

Range

Stopped
When the associated messaging engine is started, the gateway link is in a stopped state and cannot process any new requests for connections.

Started
When the associated messaging engine is started, the gateway link is in a started state and can process any new requests for connections.

-preferLocal TRUE | FALSE
Indicates that the link prefers to send incoming messages to the queue point of the target destination that is located on the same messaging engine as the link, if available. The link must be owned by a messaging engine running on a WebSphere Application Server Version 7.0 or later server.

This option is supported only when used by a JMS application that is running with a WebSphere Application ServerVersion 7.0 or later server or client, and that is connected to a messaging engine running on WebSphere Application ServerVersion 7.0 or later server. Use on previous versions of WebSphere Application Server will result in an exception to the application.

Default TRUE

Range

TRUE Send each incoming message to the queue point of the target destination that is located on the same messaging engine as the link, if available.

FALSE Send incoming messages to any queue points of the target destinations.

Examples

```
AdminTask.createSIBLink('[-bus bus1 -messagingEngine node01.server1-myBus
-name mySIBLink -foreignBusName bus2 -bootstrapEndpoints host1:1111:chain1
-remoteMessagingEngineName node02.server2-bus2]')
```

Create a service integration bus link that uses a queue point on the same messaging engine as the link, whenever possible.

```
AdminTask.createSIBLink('[-bus bus1 -messagingEngine node01.server1-bus1
-name mySIBLink -foreignBusName bus2 -bootstrapEndpoints host1:1111:chain1
-remoteMessagingEngineName node02.server2-bus2 -preferLocal TRUE]')
```

deleteSIBLink command

Use the deleteSIBLink command to delete a service integration bus link from a bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The deleteSIBLink command deletes a bus link from a bus.

CAUTION:
This command deletes the service integration bus link and its additional property configuration. Although there is no confirmation prompt before deleting the service integration bus link, the link is not deleted from the master configuration until you save your changes.

Target object

A bus.

Required parameters

-bus
The name of the service integration bus for which you want to delete a service integration bus link. You can use the listSIBuses command to list the names of existing buses.

-messagingEngine
The name of the messaging engine to which the service integration bus link was assigned when created. You can use the listSIBEngines command to list the names of existing messaging engines.

-sibLink
The name of the service integration bus link that you want to delete.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.deleteSIBLink('[-bus bus1 -messagingEngine node01.server1-bus1 -sibLink mySIBLink]')
```

listSIBLinks command

Use the listSIBLinks command to list all service integration bus links for a given bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('SIBAdminCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

Purpose

The listSIBLinks command lists the names of all service integration bus links for a specified service integration bus. A service integration bus link defines a link between a messaging engine in one service integration bus and a messaging engine in a foreign service integration bus.

Target object

A bus.

Required parameters

-bus
The name of the service integration bus for which you want to list service integration bus links.

Conditional parameters

None.

Optional parameters

-node
The name of the node for which you want to list service integration bus links. This option restricts the list of service integration bus links to those links assigned to the node.

-server
The name of the server for which you want to list service integration bus links. This option restricts the list of service integration bus links to those links assigned to the server.

-messagingEngine
The name of the messaging engine for which you want to list service integration bus links. This option restricts the list of service integration bus links to those links assigned to the messaging engine.

Example

```
AdminTask.listSIBLinks('[-bus bus1 -foreignBus bus2]')
'mySIBLink(cells/cell01/nodes/node01/servers/server1|sib-engines.xml#
SIBLink_1212163147845)'
wsadmin>
```

modifySIBLink command

Use the modifySIBLink command to modify the properties of a service integration bus link.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The modifySIBLink command modifies the properties of a service integration bus link.

Target object

None.

Required parameters

-bus
The name of the service integration bus for which you want to modify the service integration bus link. You can use the listSIBuses command to list the names of existing buses.

-messagingEngine
The name of the messaging engine for which you want to modify the service integration bus link. The service integration bus link connects a messaging engine to another messaging engine in a different service integration bus, thereby providing a bridge between two service integration buses.

-name
The name by which you want the service integration bus link to be known.

-foreignBusName
The name of the foreign bus that defines the remote service integration bus for the service integration bus link. You can use the listSIBForeignBuses command to list the names of existing foreign buses.

Conditional parameters

None.

Optional parameters

-bootstrapEndpoints
The comma-separated list of endpoints used to connect to a bootstrap server. This property is set in

the same way as the **Provider endpoint** property in the JMS connection factory settings. For more information, see the steps relating to setting bootstrap endpoints in “Configuring a connection to a non-default bootstrap server” on page 531.

The port for the bootstrap endpoint is the port defined on the SIB endpoint address that is configured on the target application server on the foreign bus.

-remoteMessagingEngineName
The messaging engine on the foreign bus to which this link connects.

-description
An optional description for the bus, for administrative purposes.

-protocolName
The type of transport chain used for communication with the foreign bus.

The transport chain name must be the name of the transport chain as defined on the server on which the target messaging engine is hosted.

-authAlias
The name of the authentication alias, used to authenticate access to the foreign bus.

You must have predefined a J2C authentication alias.

-exceptionDestination
The destination for an inbound message when the service integration bus link cannot deliver the message to its target destination, or to the exception destination that is configured for that target destination, or when the target destination does not exist.

System
The service integration bus link uses the default exception destination. All messages that cannot be delivered to the bus destination are rerouted automatically to the system default exception destination for the messaging engine that this link is assigned to: _SYSTEM.Exception.Destination.*messaging_engine_name*.

None The service integration bus link has no exception destination. Undeliverable messages are not rerouted to an exception destination and can block the processing of other messages waiting for delivery to the same destination. This option can be used to preserve message ordering.

Specify
The service integration bus link uses the exception destination specified here. If this is not possible, it uses the system exception destination.

-initialState Started | Stopped
The state of the gateway link, which shows whether the link is started automatically when the messaging engine is started.

Default
Started

Range

Stopped
When the associated messaging engine is started, the gateway link is in a stopped state and cannot process any new requests for connections.

Started
When the associated messaging engine is started, the gateway link is in a started state and can process any new requests for connections.

-preferLocal TRUE | FALSE
Indicates whether the link prefers to send incoming messages to the queue point of the target destination that is located on the same messaging engine as the link, if available. The link must be owned by a messaging engine running on a WebSphere Application Server Version 7.0 or later server.

This option is supported only when used by a JMS application that is running with a WebSphere Application ServerVersion 7.0 or later server or client, and that is connected to a messaging engine running on WebSphere Application ServerVersion 7.0 or later server. Use on previous versions of WebSphere Application Server will result in an exception to the application.

Default TRUE

Range

TRUE Send each incoming message to the queue point of the target destination that is located on the same messaging engine as the link, if available.

FALSE Send incoming messages to any queue points of the target destinations.

Examples

```
wsadmin>AdminTask.showSIBLink('[-bus bus1 -messagingEngine node01.server1-bus1  -sibLink
mySIBLink]')
'{bootstrapEndpoints=host1:1111:chain1, protocolName=null, authAlias=null,
preferLocalQueuePoints=true, name=mySIBLink, uuid=34647E59163B253D,
remoteMessagingEngineName=node02.server2-bus2, description=null,
targetUuid=BAD49BA75CD36D740E366978, initialState=STARTED,
exceptionDestination=$DEFAULT_EXCEPTION_DESTINATION}'

wsadmin>AdminTask.modifySIBLink('[-bus bus1 -messagingEngine node01.server1-bus1
-name MySIBLink -foreignBusName -bus2
-bootstrapEndpoints anotherhost:2222:BootstrapBasicMessaging]')

wsadmin>AdminTask.showSIBLink('[-bus bus1 -messagingEngine node01.server1-bus1  -sibLink
mySIBLink]')
'{bootstrapEndpoints=anotherhost:2222:BootstrapBasicMessaging, protocolName=null,
authAlias=null, preferLocalQueuePoints=true, name=mySIBLink, uuid=34647E59163B253D,
remoteMessagingEngineName=node02.server2-bus2, description=null,
targetUuid=BAD49BA75CD36D740E366978, initialState=STARTED,
exceptionDestination=$DEFAULT_EXCEPTION_DESTINATION}'
```

Modify a service integration bus link so that there is no preference for which queue points to use.

```
AdminTask.modifySIBLink('[-bus bus1 -messagingEngine cluster1.000-bus1 -name MyLink
-foreignBusName -FB1 bootstrapEndpoints host1:1111:chain1 -remoteMessagingEngineName
-cluster2.000-FB1 -preferLocal FALSE]')
```

showSIBLink command

Use the showSIBLink command to show the properties of a service integration bus link.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  `print AdminTask.help('SIBAdminCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:

  `print AdminTask.help('`*command_name*`')`

Purpose

The showSIBLink command lists details about the properties of a service integration bus link.

Target object

A bus link.

Required parameters

-bus
The name of the service integration bus for which you created the service integration bus link. You can use the listSIBuses command to list the names of existing buses.

-messagingEngine
The name of the messaging engine for which you created the service integration bus link. You can use the listSIBEngines command to list the names of existing messaging engines.

-sibLink
The name of the service integration bus link.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.showSIBLink('[-bus bus1 -messagingEngine node01.server1-bus1
-sibLink mySIBLink]')
'{bootstrapEndpoints=host1:1111:chain1, protocolName=null, authAlias=null,
preferLocalQueuePoints=true, name=aSIBLink, uuid=34647E59163B253D,
remoteMessagingEngineName=wasinstallNode01.server1-MQServerBus, description=null,
targetUuid=BAD49BA75CD36D740E366978, initialState=STARTED,
exceptionDestination=_SYSTEM.Exception.Destination.node01.server1-bus1}'
```

SIBAdminCommands: Messaging engine administrative commands for the AdminTask object

You can use these administrative commands to manage messaging engines.

These commands provide an alternative to using the administrative console or using the more complex syntax of wsadmin and Jython.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('SIBAdminCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

listSIBEngines command

Use the listSIBEngines command to list the messaging engines for a service integration bus member.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command lists all the messaging engines on a bus member.

Target object

A bus member.

Required parameters

-bus *busname*
The name of the service integration bus on which the bus member is configured. You can use the listSIBuses command to list the names of existing buses.

Conditional parameters

-node *nodename* **-server** *servername*
To list the messaging engines for an application server as a bus member, specify both the name of the node on which the server runs and the name of the server.

-cluster *cluster*
To list the messaging engines for a server cluster as a bus member, specify the name of the cluster.

This option should be used only in WebSphere Application Server environments that support server clusters.

Optional parameters

None.

Example

```
AdminTask.listSIBEngines('[-bus bus1 ]')
'node01.server1-bus1(cells/cell01/nodes/node01/servers/server1|sib-engines.xml#
SIBMessagingEngine_1212163145962)\r\n
node02.server2-bus2(cells/cell01/nodes/node02/servers/server2|sib-engines.xml#
SIBMessagingEngine_1212163146273)'
```

modifySIBEngine command

Use the modifySIBEngine command to modify the properties of a messaging engine for a service integration bus member.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command modifies the properties of a messaging engine.

Target object

A messaging engine.

Required parameters

-bus *busname*
The name of the service integration bus on which the bus member is configured. You can use the listSIBuses command to list the names of existing buses.

Conditional parameters

-node *nodename* **-server** *servername*
To change properties of a messaging engine for an application server as a bus member, specify both the name of the node on which the server runs and the name of the server.

-cluster *cluster*
To change properties of a messaging engine for a server cluster as a bus member, specify the name of the cluster.

This option should be used only in WebSphere Application Server environments that support server clusters.

-engine *enginename*
If the bus member has only one messaging engine, you do not need to specify the engine name. If the bus member has several messaging engines, you must specify the name of the engine for which you want to change properties.

Optional parameters

-description *text*
An optional description for the messaging engine, for administrative purposes.

-initialState STARTED | STOPPED
The initial state determines whether the messaging engine is started automatically when the server is started.

Stopped
When the associated application server is started, the messaging engine is stopped and is not available to process messages.

Started
When the associated application server is started, the messaging engine is started and is available to process messages.

-highMessageThreshold *number*
The maximum total number of messages that the messaging engine can place on its message points.

When the messaging engine is created, the high message threshold of the bus is used to set the default value for this property. When a message point is created on this messaging engine, the value of this property is used to set the default high message threshold for the message point.

Example

```
wsadmin>AdminTask.showSIBEngine('[-bus bus1 -node node01 -server server1
-engine node01.server1-bus1 ]')
'{initialState=STARTED, targetGroups=[], name=node01.server1-bus1,
highMessageThreshold=50000, messageStoreType=FILESTORE, uuid=56F8FE11AB84188D,
busName=bus1, busUuid=6DF19B02BC879BD1}'

wsadmin>AdminTask.modifySIBEngine('[-bus bus1 -node node01 -server server1
-engine node01.server1-bus1 -initialState STOPPED ]')

wsadmin>AdminTask.showSIBEngine('[-bus bus1 -node node01 -server server1
-engine node01.server1-bus1 ]')
'{initialState=STOPPED, targetGroups=[], name=node01.server1-bus1,
highMessageThreshold=50000, messageStoreType=FILESTORE, uuid=56F8FE11AB84188D,
busName=bus1, busUuid=6DF19B02BC879BD1}'
```

showSIBEngine command

Use the showSIBEngine command to list properties of a messaging engine for a service integration bus member.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('SIBAdminCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

Purpose

This command lists details about properties of a messaging engine.

Target object

A bus member.

Required parameters

-bus *busname*
The name of the service integration bus on which the bus member is configured. You can use the listSIBuses command to list the names of existing buses.

Conditional parameters

-node *nodename* **-server** *servername*
To list properties of a messaging engine for an application server as a bus member, specify both the name of the node on which the server runs and the name of the server.

-cluster *cluster*
To list properties of a messaging engine for a server cluster as a bus member, specify the name of the cluster.

This option should be used only in WebSphere Application Server environments that support server clusters.

-engine *enginename*
If the bus member has only one messaging engine, you do not need to specify the engine name. If the bus member has several messaging engines, you must specify the name of the engine for which you want to display details.

Optional parameters

None.

Example

```
AdminTask.showSIBEngine('[-bus bus1 -node node01 -server server1
-engine node01.server1-bus1 ]')
'{initialState=STARTED, targetGroups=[], name=node01.server1-bus1,
highMessageThreshold=50000, messageStoreType=FILESTORE, uuid=56F8FE11AB84188D,
busName=bus1, busUuid=6DF19B02BC879BD1}'
```

deleteSIBEngine command

Use the deleteSIBEngine command to delete a messaging engine from a service integration bus member.

You should be wary of deleting and recreating messaging engines on bus members for which WS-Notification-administered subscribers have been configured, because in some cases this can leave the remote web service subscription active (and passing notification messages to the local server) even though there is no longer any record of it. For more information, see the WS-Notification troubleshooting tip Problems can occur when deleting administered subscribers and messaging engines.

If you promote a server bus member to a cluster that is not a member of the bus, do not delete then recreate the messaging engine. Use the migrateServerMEtoCluster command instead.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command deletes a messaging engine from a bus member. Any associated configurations of the messaging engine, such as core group policies or destinations, are also deleted. If the messaging engine uses a data store for the message store, objects in the data stores remain so that you can still access them. If you recreate the same messaging engine, you must remove any old data store tables before you start the new messaging engine.

This command also cleans up any mediation execution points that are on the messaging engine as the result of mediating a destination to a WebSphere MQ server bus member. The command unmediates the destination to which the mediation execution point corresponds.

Target object

A messaging engine.

Required parameters

-bus *bus_name*
The name of the service integration bus on which the bus member is configured. You can use the listSIBuses command to list the names of existing buses.

Conditional parameters

-node *node_name*
-server *server_name*
To delete a messaging engine from an application server that is a bus member, specify both the name of the node on which the server runs and the name of the server.

-engine *engine_name*
If the bus member has only one messaging engine, you do not need to specify the engine name. If the bus member has several messaging engines, you must specify the name of the engine that you want to delete.

Optional parameters

None.

Example

Delete the messaging engine from server1 on node1 that is a member of a bus1.

```
AdminTask.deleteSIBEngine ('[-bus bus1 -node node1 -server server1]')
```

SIBAdminCommands: Destination administrative commands for the AdminTask object

You can use these administrative commands to manage bus destinations.

These commands provide an alternative to using the administrative console or using the more complex syntax of wsadmin and JACL.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

createSIBDestination command

Use the createSIBDestination command to create a new bus destination for a service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The createSIBDestination command creates a new bus destination for a service integration bus. With this command, a messaging destination can also be localized to a WebSphere MQ server bus member.

Target object

A service integration bus.

Required parameters

-bus
The name of the service integration bus on which to create the bus destination. To list the names of existing buses, use the listSIBuses command.

-name
The identifier by which this destination is known for administrative purposes.

-type
Indicates the type of bus destination that you want to create:

Alias An alias destination, that provides a level of abstraction between applications and the underlying target bus destinations that hold messages. Applications interact with the alias destination, so the target bus destination can be changed without changing the application.

Foreign
A foreign destination, which identifies a destination on another bus, and enables applications on one bus to access the destination on another bus directly.

Port Represents a particular message and transport binding for an outbound service that communicates with an externally-hosted target web service.

Queue
A queue, for point-to-point messaging.

TopicSpace
A topic space, for publish/subscribe messaging.

WebService
Represents an externally-hosted target web service.

Conditional parameters

None.

Optional parameters

-cluster
To assign the bus destination to a cluster bus member, specify the name of the cluster. Do not specify the **-node**, **-server** or **-wmqServer** parameters.

-node
To assign the bus destination to a server bus member, specify both the name of the node on which the server runs and the name of the server. Do not specify the **-cluster** or **-wmqServer** parameters.

-server
To assign the bus destination to a server bus member, specify both the name of the node on which the server runs and the name of the server. Do not specify the **-cluster** or **-wmqServer** parameters.

-wmqServer
To assign the bus destination to a WebSphere MQ queue, specify both the name of the WebSphere MQ server bus member where the destination is assigned (this parameter), and the name of the WebSphere MQ queue used to store messages sent to the destination (the **-wmqQueueName** parameter). Set the**-wmqServer** parameter to the name you gave when you created the WebSphere MQ server. Set the **-wmqQueueName** parameter to the name allocated to the WebSphere MQ queue by WebSphere MQ administration. Do not specify the **-cluster**, **-node** or **-server** parameters.

-aliasBus
If you are creating an alias destination, specify the source bus name of the alias mapping.

-targetBus
If you are creating an alias destination, specify the name of the bus to which the alias destination is mapped.

-targetName
If you are creating an alias destination, specify the name of the destination to which the alias destination is mapped.

-foreignBus
If you are creating a foreign destination, specify the name of the foreign bus.

-description
Specify a description for the bus destination, for administrative purposes.

-reliability
Specify the default reliability level to assign to a message produced to this destination when an explicit reliability has not been set by the producer application. Service integration supports five reliability levels (also known as delivery options or qualities of service):

BEST_EFFORT_NONPERSISTENT
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

EXPRESS_NONPERSISTENT
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

RELIABLE_NONPERSISTENT
Messages are discarded when a messaging engine stops or fails.

RELIABLE_PERSISTENT
Messages might be discarded when a messaging engine fails.

ASSURED_PERSISTENT
Messages are not discarded.

Note: Higher levels of reliability have higher impacts on performance.

For more information about service integration reliability levels, see Message reliability levels - JMS delivery mode and service integration quality of service.

-maxReliability
Specify the maximum reliability level that is accepted for values specified by producer applications. Service integration supports five reliability levels (also known as delivery options or qualities of service):

BEST_EFFORT_NONPERSISTENT

EXPRESS_NONPERSISTENT

RELIABLE_NONPERSISTENT

RELIABLE_PERSISTENT

ASSURED_PERSISTENT

For more information about service integration reliability levels, see Message reliability levels - JMS delivery mode and service integration quality of service.

-nonPersistentReliability

Specify the service integration quality of service to use with nonpersistent WebSphere MQ messages that are received by service integration from a WebSphere MQ network. The messages in a WebSphere MQ network have their own quality of service level. This is either persistent or non-persistent. When these messages are received by a service integration application, they are assigned a service integration quality of service level that depends on their WebSphere MQ quality of service level.

For nonpersistent WebSphere MQ messages received, the default service integration quality of service is RELIABLE_NONPERSISTENT. If you choose to override this default, you will probably choose one of the other nonpersistent service integration qualities of service BEST_EFFORT_NONPERSISTENT or EXPRESS_NONPERSISTENT. However, you can choose any of the five possible service integration qualities of service:

BEST_EFFORT_NONPERSISTENT

EXPRESS_NONPERSISTENT

RELIABLE_NONPERSISTENT

RELIABLE_PERSISTENT

ASSURED_PERSISTENT

For more information, see ../ae/rjc0014_.dita.

-persistentReliability

Specify the service integration quality of service to use with persistent WebSphere MQ messages that are received by service integration from a WebSphere MQ network. The messages in a WebSphere MQ network have their own quality of service level. This is either persistent or non-persistent. When these messages are received by a service integration application, they are assigned a service integration quality of service level that depends on their WebSphere MQ quality of service level.

For persistent WebSphere MQ messages received, the default service integration quality of service is ASSURED_PERSISTENT. If you choose to override this default, you will probably choose the other persistent service integration quality of service RELIABLE_PERSISTENT. However, you can choose any of the five possible service integration qualities of service:

BEST_EFFORT_NONPERSISTENT

EXPRESS_NONPERSISTENT

RELIABLE_NONPERSISTENT

RELIABLE_PERSISTENT

ASSURED_PERSISTENT

For more information, see ../ae/rjc0014_.dita.

-overrideOfQOSByProducerAllowed TRUE | FALSE

Controls the quality of service for message flows between producers and the destination. Select this option to use the quality of service specified by producers instead of the quality defined for the destination.

-defaultPriority *number*

The default priority assigned to messages sent to this destination when a priority has not been set by the producer.

-maxFailedDeliveries *number*

The maximum number of failed attempts to process a message. After this number of failed attempts, the message is forwarded from the intended destination to its exception destination. Specify a value in the range 0 through 2147483647. A value of 0 (zero) means that if a message cannot be delivered on the first attempt, it is either forwarded to the exception destination or discarded, as defined by the **-exceptionDestination** parameter.

-exceptionDestination *value*

Use these properties to define what happens to any messages that cannot be delivered to this destination.

By default, all messages that cannot be delivered to this destination are rerouted to the system default exception destination for the messaging engine to which this destination is assigned (_SYSTEM.Exception.Destination.*messaging_engine_name*). Use this parameter to override the default value. You can set a specific exception destination for this destination, or you can specify that undeliverable messages are not rerouted to an exception destination by entering an empty string (""), in which case the maximum failed deliveries count has no effect.

Note: An undeliverable message can block the processing of other messages waiting for delivery to the same destination.

You can use this option and specify no exception destination to preserve message ordering.

-sendAllowed TRUE | FALSE
Clear this option (setting it to FALSE) to stop producers from being able to send messages to this destination.

- For a queue point of a non-mediated destination, or a mediation point of a mediated destination, if you clear this option then new messages (from attached producers or forwarded from another destination) are redirected to any available message point. If no message points are available, then messages that have already been accepted onto the bus, and new messages from attached producers, are preserved by the bus until a message point becomes available. The only exception to this is the case of a destination with only one message point (queue point or mediation point depending on whether the destination is mediated or non-mediated), where the producer is attached to the same messaging engine. In this case, an exception message is generated on each send call. The exception message indicates that the only extant localization has been disabled for send. The producer remains open as usual, and any more send calls succeed if the **Send allowed** property of the localization is reselected (reset to TRUE).
- For a queue point of a mediated destination, if you clear this option then messages from mediation instances are redirected to any available message point. If no message points are available, then the messages are preserved by the bus until a message point becomes available. For any mediation instance (that is, on any server that has a mediation point), if the same server hosts a queue point, and that queue point is the only queue point for the destination, then the mediation changes to the “stopped on error” state.

-receiveAllowed TRUE | FALSE
Clear this option (setting it to false) to prevent consumers from being able to receive messages from this destination. For the message point, if you clear this option then any open consumers change state and an exception is generated if the consumer requests a message. Messages can continue to be sent, and accumulate on the message point.

-receiveExclusive TRUE | FALSE
Select this option (setting it to TRUE) to allow only one consumer to attach to a destination. If you select this option, only a single consumer can be attached to each queue point of a queue destination at any one time. Subsequent consumers attempting to attach to a queue point with a consumer already attached are rejected.

-maintainStrictMessageOrder TRUE | FALSE
Select this option (setting it to TRUE) to maintain the order in which a producer sends messages to the destination.

At run time, this property has priority over other configuration property values. For information about the configuration properties that are overridden at run time, see Strict message ordering for bus destinations.

-topicAccessCheckRequired
Include this option if authorization checks are required for access to topics.

-replyDestination
The name of a destination to be appended to any non-empty reverse routing path of messages sent to this destination. This property is intended for use with mediations on reply messages. For more information about the use of this property, see “Configuring a destination reverse routing path” on page 1989.

-replyDestinationBus
The name of the bus on which the reply destination is configured. This property is intended for use with mediations on reply messages. For more information about the use of this property, see “Configuring a destination reverse routing path” on page 1989.

-delegateAuthorizationCheckToTarget
Indicates whether the authorization check is performed on the alias or the target destination. Include this option if you want the authorization check to be performed on the target destination.

-wmqQueueName
To assign the bus destination to a WebSphere MQ queue, specify both the name of the WebSphere MQ server bus member where the destination is assigned (the **-wmqServer** parameter), and the name of the WebSphere MQ queue used to store messages sent to the destination (this parameter). Set the**-wmqServer** parameter to the name you gave when you created the WebSphere MQ server. Set the **-wmqQueueName** parameter to the name allocated to the WebSphere MQ queue by WebSphere MQ administration. Do not specify the **-cluster**, **-node** or **-server** parameters.

-useRFH2 or -mqRfh2Allowed TRUE | FALSE
Determines whether messages sent to the destination have an MQRFH2 header.

When service integration converts a message from the service integration format to WebSphere MQ format, by default it includes an MQRHF2 header in the WebSphere MQ message. This header contains message attributes, such as JMS message attributes, which are not WebSphere MQ message attributes and therefore do not appear in the WebSphere MQ message descriptor (MQMD). Some WebSphere MQ applications cannot process messages that include an MQRFH2 header. If messages sent to this destination will be processed by WebSphere MQ applications that cannot tolerate an MQRFH2, clear this option (setting it to FALSE).

If you are assigning a queue-type destination to a WebSphere MQ server bus member, use the **-useRFH2** parameter. If you are creating an alias destination or a foreign destination, use the **-mqRfh2Allowed** parameter.

-auditAllowed TRUE | FALSE
Clear this option (setting it to FALSE) to prevent the bus from auditing topic level authorization checks when the bus and application server have auditing enabled. The default value is TRUE. You must have Audit Administrator privileges to use this parameter. The parameter is ignored if it is used in the creation of other types of destination.

-defaultForwardRoutingPath
The value to which a message forward routing path is set if the message contains no forward routing path. This identifies a sequential list of intermediary bus destinations that messages must pass through to reach a target bus destination. The format of the field is a list of bus destinations specified as *bus_name*:*destination_name*.

-queuePoints
A list of the queue points used by users of the alias destination. If no queue points are supplied, all queue points can be used. The target destination must be a queue destination in the same bus as the alias destination definition. The target destination must also be a queue destination with multiple queue points.

A queue point is specified in the following form: *destination_name@messaging_engine_name*

-mediationPoints
A list of the mediation points used by users of the alias destination. If no mediation points are supplied, all mediation points can be used. The target destination must be a mediated queue destination in the same bus as the alias destination definition. The target destination must also be a queue destination with multiple mediation points.

A mediation point is specified in the following form: *destination_name@messaging_engine_name*

Example

- Using Jython:

```
wsadmin>AdminTask.createSIBDestination('[-bus bus1 -name myqueue -type QUEUE
-node node1 -server server1]')
'(cells/9994GKCCell01/buses/bus1|sib-destinations.xml#SIBQueue_1098215169998)'
```

- Using Jacl:

```
wsadmin>$AdminTask createSIBDestination {-bus bus1 -name myqueue -type QUEUE
-node node1 -server server1}
(cells/9994GKCCell01/buses/bus1|sib-destinations.xml#SIBQueue_1098215169998)
```

Example: Create a destination alias for "MyDestination1" called "MyAlias1" that can use two queue points:

- Using Jython:

```
wsadmin>AdminTask.createSIBDestination('[-bus bus1 -type ALIAS
-name MyAlias1 -aliasBus bus1 -targetName MyDestination1
-reliability INHERIT -maxReliability INHERIT
-overrideOfQOSByProducerAllowed INHERIT -sendAllowed INHERIT
-receiveAllowed INHERIT
-queuePoints [[-identifier MyDestination1@cluster1.001-bus1]
[-identifier MyDestination1@cluster1.002-bus1]]]')
```

- Using Jacl:

```
wsadmin>$AdminTask createSIBDestination {-bus bus1 -type ALIAS
-name MyAlias1 -aliasBus bus1 -targetName MyDestination1
-reliability INHERIT -maxReliability INHERIT
-overrideOfQOSByProducerAllowed INHERIT -sendAllowed INHERIT
-receiveAllowed INHERIT
-queuePoints {{"MyDestination1@cluster1.001-bus1"}
{"MyDestination1@cluster1.002-bus1"}}}
```

createSIBDestinations command

Use the createSIBDestinations command to create new bus destinations for a service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The createSIBDestinations command creates multiple new bus destinations for a service integration bus, all with the same properties. If the destinations created are alias destinations, they all target the same destination. With this command, the new bus destinations can also be localized to a WebSphere MQ server bus member.

Target object

A service integration bus.

Required parameters

-bus

The name of the service integration bus on which to create the bus destinations. To list the names of existing buses, use the listSIBuses command.

-nameList
The list of identifiers by which these destinations are known for administrative purposes.

-type
Indicates the type of bus destination that you want to create:

Alias An alias destination, that provides a level of abstraction between applications and the underlying target bus destinations that hold messages. Applications interact with the alias destination, so the target bus destination can be changed without changing the application.

Foreign
A foreign destination, which identifies a destination on another bus, and enables applications on one bus to access the destination on another bus directly.

Port Represents a particular message and transport binding for an outbound service that communicates with an externally-hosted target web service.

Queue
A queue, for point-to-point messaging.

TopicSpace
A topic space, for publish/subscribe messaging.

WebService
Represents an externally-hosted target web service.

Conditional parameters

None.

Optional parameters

-cluster
To assign the bus destinations to a cluster bus member, specify the name of the cluster. Do not specify the **-node**, **-server** or **-wmqServer** parameters.

-node
To assign the bus destinations to a server bus member, specify both the name of the node on which the server runs and the name of the server. Do not specify the **-cluster** or **-wmqServer** parameters.

-server
To assign the bus destinations to a server bus member, specify both the name of the node on which the server runs and the name of the server. Do not specify the **-cluster** or **-wmqServer** parameters.

-wmqServer
To assign the bus destinations to a WebSphere MQ queue, specify both the name of the WebSphere MQ server bus member where the destination is assigned (this parameter), and the name of the WebSphere MQ queue used to store messages sent to the destinations (the **-wmqQueueName** parameter). Set the**-wmqServer** parameter to the name you gave when you created the WebSphere MQ server. Set the **-wmqQueueName** parameter to the name allocated to the WebSphere MQ queue by WebSphere MQ administration. Do not specify the **-cluster**, **-node** or **-server** parameters.

-aliasBus
If you are creating alias destinations, specify the source bus name of the alias mapping.

-targetBus
If you are creating alias destinations, specify the name of the bus to which the alias destinations are mapped.

-targetName
If you are creating alias destinations, specify the name of the destination to which the alias destinations are mapped.

-foreignBus
If you are creating foreign destinations specify the name of the foreign bus.

-description
Specify a description for the bus destinations for administrative purposes.

-reliability
Specify the default reliability level to assign to messages produced to these destinations when an explicit reliability has not been set by the producer application. Service integration supports five reliability levels (also known as delivery options or qualities of service):

BEST_EFFORT_NONPERSISTENT
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

EXPRESS_NONPERSISTENT
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

RELIABLE_NONPERSISTENT
Messages are discarded when a messaging engine stops or fails.

RELIABLE_PERSISTENT
Messages might be discarded when a messaging engine fails.

ASSURED_PERSISTENT
Messages are not discarded.

Note: Higher levels of reliability have higher impacts on performance.

For more information about service integration reliability levels, see Message reliability levels - JMS delivery mode and service integration quality of service.

-maxReliability
Specify the maximum reliability level that is accepted for values specified by producer applications. Service integration supports five reliability levels (also known as delivery options or qualities of service):

BEST_EFFORT_NONPERSISTENT

EXPRESS_NONPERSISTENT

RELIABLE_NONPERSISTENT

RELIABLE_PERSISTENT

ASSURED_PERSISTENT

For more information about service integration reliability levels, see Message reliability levels - JMS delivery mode and service integration quality of service.

-nonPersistentReliability

Specify the service integration quality of service to use with nonpersistent WebSphere MQ messages that are received by service integration from a WebSphere MQ network. The messages in a WebSphere MQ network have their own quality of service level. This is either persistent or non-persistent. When these messages are received by a service integration application, they are assigned a service integration quality of service level that depends on their WebSphere MQ quality of service level.

For nonpersistent WebSphere MQ messages received, the default service integration quality of service is RELIABLE_NONPERSISTENT. If you choose to override this default, you will probably choose one

of the other nonpersistent service integration qualities of service BEST_EFFORT_NONPERSISTENT or EXPRESS_NONPERSISTENT. However, you can choose any of the five possible service integration qualities of service:

BEST_EFFORT_NONPERSISTENT

EXPRESS_NONPERSISTENT

RELIABLE_NONPERSISTENT

RELIABLE_PERSISTENT

ASSURED_PERSISTENT

For more information, see ../ae/rjc0014_.dita.

-persistentReliability

Specify the service integration quality of service to use with persistent WebSphere MQ messages that are received by service integration from a WebSphere MQ network. The messages in a WebSphere MQ network have their own quality of service level. This is either persistent or non-persistent. When these messages are received by a service integration application, they are assigned a service integration quality of service level that depends on their WebSphere MQ quality of service level.

For persistent WebSphere MQ messages received, the default service integration quality of service is ASSURED_PERSISTENT. If you choose to override this default, you will probably choose the other persistent service integration quality of service RELIABLE_PERSISTENT. However, you can choose any of the five possible service integration qualities of service:

BEST_EFFORT_NONPERSISTENT

EXPRESS_NONPERSISTENT

RELIABLE_NONPERSISTENT

RELIABLE_PERSISTENT

ASSURED_PERSISTENT

For more information, see ../ae/rjc0014_.dita.

-overrideOfQOSByProducerAllowed TRUE | FALSE

Controls the quality of service for message flows between producers and the destination. Select this option to use the quality of service specified by producers instead of the quality defined for the destination.

-defaultPriority *number*

The default priority assigned to messages sent to this destination when a priority has not been set by the producer.

-maxFailedDeliveries *number*

The maximum number of failed attempts to process a message. After this number of failed attempts, the message is forwarded from the intended destination to its exception destination. Specify a value in the range 0 through 2147483647. A value of 0 (zero) means that if a message cannot be delivered on the first attempt, it is either forwarded to the exception destination or discarded, as defined by the **-exceptionDestination** parameter.

-exceptionDestination *value*

Use these properties to define what happens to any messages that cannot be delivered to this destination.

By default, all messages that cannot be delivered to this destination are rerouted to the system default exception destination for the messaging engine to which this destination is assigned (_SYSTEM.Exception.Destination.*messaging_engine_name*). Use this parameter to override the default value. You can set a specific exception destination for this destination, or you can specify that

undeliverable messages are not rerouted to an exception destination by entering an empty string (""), in which case the maximum failed deliveries count has no effect.

Note: An undeliverable message can block the processing of other messages waiting for delivery to the same destination.

You can use this option and specify no exception destination to preserve message ordering.

-sendAllowed TRUE | FALSE
Clear this option (setting it to FALSE) to stop producers from being able to send messages to these destinations.

- For a queue point of a non-mediated destination, or a mediation point of a mediated destination, if you clear this option then new messages (from attached producers or forwarded from another destination) are redirected to any available message point. If no message points are available, then messages that have already been accepted onto the bus, and new messages from attached producers, are preserved by the bus until a message point becomes available. The only exception to this is the case of a destination with only one message point (queue point or mediation point depending on whether the destination is mediated or non-mediated), where the producer is attached to the same messaging engine. In this case, an exception message is generated on each send call. The exception message indicates that the only extant localization has been disabled for send. The producer remains open as usual, and any more send calls succeed if the **Send allowed** property of the localization is reselected (reset to TRUE).
- For a queue point of a mediated destination, if you clear this option then messages from mediation instances are redirected to any available message point. If no message points are available, then the messages are preserved by the bus until a message point becomes available. For any mediation instance (that is, on any server that has a mediation point), if the same server hosts a queue point, and that queue point is the only queue point for the destination, then the mediation changes to the “stopped on error” state.

-receiveAllowed TRUE | FALSE
Clear this option (setting it to false) to prevent consumers from being able to receive messages from this destination. For the message point, if you clear this option then any open consumers change state and an exception is generated if the consumer requests a message. Messages can continue to be sent, and accumulate on the message point.

-receiveExclusive TRUE | FALSE
Select this option (setting it to true) to allow only one consumer to attach to a destination. If you select this option, only a single consumer can be attached to each queue point of a queue destination at any one time. Subsequent consumers attempting to attach to a queue point with a consumer already attached are rejected.

-maintainStrictMessageOrder TRUE | FALSE
Select this option (setting it to TRUE) to maintain the order in which a producer sends messages to a destination.

At run time, this property has priority over other configuration property values. For information about the configuration properties that are overridden at run time, see Strict message ordering for bus destinations.

-topicAccessCheckRequired
Include this option if authorization checks are required for access to topics.

-replyDestination
The name of a destination to be appended to any non-empty reverse routing path of messages sent to this destination. This property is intended for use with mediations on reply messages. For more information about the use of this property, see “Configuring a destination reverse routing path” on page 1989.

-replyDestinationBus
The name of the bus on which the reply destination is configured. This property is intended for use

with mediations on reply messages. For more information about the use of this property, see “Configuring a destination reverse routing path” on page 1989.

-delegateAuthorizationCheckToTarget
Indicates whether the authorization check is performed on the alias or the target destination. Include this option if you want the authorization check to be performed on the target destination.

-wmqQueueName
To assign these bus destinations to a WebSphere MQ queue, specify both the name of the WebSphere MQ server bus member where the destinations are assigned (the **-wmqServer** parameter), and the name of the WebSphere MQ queue used to store messages sent to these destinations (this parameter). Set the**-wmqServer** parameter to the name you gave when you created the WebSphere MQ server. Set the **-wmqQueueName** parameter to the name allocated to the WebSphere MQ queue by WebSphere MQ administration. Do not specify the **-cluster**, **-node** or **-server** parameters.

-useRFH2 or -mqRfh2Allowed TRUE | FALSE
Determines whether messages sent to these destinations have an MQRFH2 header.

When service integration converts a message from the service integration format to WebSphere MQ format, by default it includes an MQRHF2 header in the WebSphere MQ message. This header contains message attributes, such as JMS message attributes, which are not WebSphere MQ message attributes and therefore do not appear in the WebSphere MQ message descriptor (MQMD). Some WebSphere MQ applications cannot process messages that include an MQRFH2 header. If messages sent to this destination will be processed by WebSphere MQ applications that cannot tolerate an MQRFH2, clear this option (setting it to FALSE).

If you are assigning queue-type destinations to a WebSphere MQ server bus member, use the **-useRFH2** parameter. If you are creating alias destinations or foreign destinations, use the **-mqRfh2Allowed** parameter.

-auditAllowed TRUE | FALSE
Clear this option (setting it to FALSE) to prevent the bus from auditing topic level authorization checks when the bus and application server have auditing enabled. The default value is TRUE. You must have Audit Administrator privileges to use this parameter. The parameter is ignored if it is used in the creation of other types of destination.

-defaultForwardRoutingPath
The value to which a message forward routing path is set if the message contains no forward routing path. This identifies a sequential list of intermediary bus destinations that messages must pass through to reach a target bus destination. The format of the field is a list of bus destinations specified as *bus_name*:*destination_name*.

-queuePoints
A list of the queue points used by users of the alias destination. If no queue points are supplied, all queue points can be used. The target destination must be a queue destination in the same bus as the alias destination definition. The target destination must also be a queue destination with multiple queue points.

A queue point is specified in the form *destination_name*@*messaging_engine_name*.

-mediationPoints
A list of the mediation points used by users of the alias destination. If no mediation points are supplied, all mediation points can be used. The target destination must be a mediated queue destination in the same bus as the alias destination definition. The target destination must also be a queue destination with multiple mediation points.

A mediation point is specified in the form *destination_name*@*messaging_engine_name*.

Example

- Using Jython:

```
wsadmin>AdminTask.createSIBDestinations('[-bus bus1 -type QUEUE
-cluster cluster1 -nameList [[-identifier myqueue1][-identifier myqueue2]]]')
'(cells/9994GKCCell01/buses/bus1|sib-destinations.xml#SIBQueue_1098215169998)'
```

- Using Jacl:

```
wsadmin>$AdminTask createSIBDestinations {-bus bus1 -type QUEUE
-cluster cluster1 -nameList {{myqueue1} {myqueue2}}}
(cells/9994GKCCell01/buses/bus1|sib-destinations.xml#SIBQueue_1098215169998)
```

Example: Create aliases for "MyDestination1" called "MyAlias1" and "MyAlias2". These alias destinations give access to a single queue point of the target destination:

- Using Jython:

```
wsadmin>cluster=AdminConfig.list("ServerCluster").splitlines()[0]
wsadmin>AdminTask.createSIBDestinations('[-bus bus1 -type ALIAS
-nameList [[-identifier MyAlias1][-identifier MyAlias2]] -aliasBus bus1
-targetName MyDestination1 -reliability INHERIT -maxReliability INHERIT
-overrideOfQOSByProducerAllowed INHERIT -sendAllowed INHERIT
-receiveAllowed INHERIT -queuePoints [[-identifier MyDestination1@cluster1.001-bus1]
[-identifier MyDestination1@cluster1.002-bus1]]]')
```

- Using Jacl:

```
wsadmin>set cluster [ lindex [ $AdminConfig list ServerCluster ] 1 ]
wsadmin>$AdminTask createSIBDestinations {-bus bus1 -type ALIAS
-nameList {{MyAlias1} {MyAlias2}} -aliasBus bus1
-targetName MyDestination1 -reliability INHERIT -maxReliability INHERIT
-overrideOfQOSByProducerAllowed INHERIT -sendAllowed INHERIT
-receiveAllowed INHERIT -queuePoints {{"MyDestination1@cluster1.001-bus1"}
{"MyDestination1@cluster1.002-bus1}}}
```

deleteSIBDestination command

Use the deleteSIBDestination command to delete a bus destination.

This command deletes the named destination on the named bus, and deletes all related message points.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The deleteSIBDestination command deletes the named destination on the named bus, and deletes all related message points. This command also finds and cleans up all destinations that are assigned to WebSphere MQ server bus members, and all destinations that are mediated to a WebSphere MQ queue.

This command does not delete messages from WebSphere MQ queues, and it does not delete the queues.

Target object

A bus destination.

Required parameters

-bus
The name of the service integration bus on which the bus destination is configured. You can use the listSIBuses command to list the names of existing buses.

-name
The identifier by which this destination is known for administrative purposes.

-aliasBus
If the destination to be deleted is an alias destination and was created with the **aliasBus** parameter, then the same value must be used to delete the destination.

-foreignBus
If the destination to be deleted is a foreign destination, then the foreign destination parameter must be supplied.

Conditional parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminTask.deleteSIBDestination("-bus abus -name myqueue")

wsadmin>AdminConfig.save()
```

- Using Jacl:

```
wsadmin>$AdminTask deleteSIBDestination {-bus abus -name myqueue}

wsadmin>$AdminConfig save
```

deleteSIBDestinations command

Use the deleteSIBDestinations command to delete bus destinations.

This command deletes the named destinations on the named bus, and deletes all related message points.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when it is used with WebSphere Application Server Version 6.1.0 (Fix Pack 15) or later. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The deleteSIBDestinations command deletes the named destinations on the named bus, and deletes all related message points. This command also finds and cleans up all destinations that are assigned to WebSphere MQ server bus members, and all destinations that are mediated to a WebSphere MQ queue. This command does not delete messages from WebSphere MQ queues, and it does not delete the queues.

Target object

Bus destinations.

Required parameters

-bus
The name of the service integration bus on which the bus destination is configured. You can use the listSIBuses command to list the names of existing buses.

-nameList
The identifiers by which these destinations are known for administrative purposes.

-aliasBus
If the destination to be deleted is an alias destination and was created with the **aliasBus** parameter, then the same value must be used to delete the destination.

-foreignBus
If the destination to be deleted is a foreign destination, then the foreign destination parameter must be supplied.

Conditional parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminTask.deleteSIBDestinations(["-bus" , "abus" , "-nameList" , [["myqueue1"] ,["myqueue2"]]])

wsadmin>$AdminConfig save
```

- Using Jacl:

```
wsadmin>$AdminTask deleteSIBDestinations {-bus myBus -nameList {{myqueue1} {myqueue2}} }

wsadmin>$AdminConfig save
```

listSIBDestinations command

Use the listSIBDestinations command to list the bus destinations for a service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command lists all the bus destinations on a bus.

Target object

A bus.

Required parameters

-bus *busname*
The name of the service integration bus on which the bus destinations are configured. You can use the listSIBuses command to list the names of existing buses.

Conditional parameters

None.

Optional parameters

-type Queue | TopicSpace | WebService | Port
To list destinations of the specified type.

Example

- Using Jython:

```
wsadmin>AdminTask.listSIBDestinations("-bus abus")
'(cells/9994GKCCell01/buses/abus|sib-destinations.xml#SIBTopicSpace_1098181446388)
(cells/9994GKCCell01/buses/abus|sib-destinations.xml#SIBQueue_1098181503600)
(cells/9994GKCCell01/buses/abus|sib-destinations.xml#SIBQueue_1098184221748)'

AdminTask.listSIBDestinations("-bus abus -type TopicSpace")
'(cells/9994GKCCell01/buses/abus|sib-destinations.xml#SIBTopicSpace_1098181446388)'
```

- Using Jacl:

```
wsadmin>$AdminTask listSIBDestinations {-bus abus}
(cells/9994GKCCell01/buses/abus|sib-destinations.xml#SIBTopicSpace_1098181446388)
(cells/9994GKCCell01/buses/abus|sib-destinations.xml#SIBQueue_1098181503600)
(cells/9994GKCCell01/buses/abus|sib-destinations.xml#SIBQueue_1098184221748)

wsadmin>$AdminTask listSIBDestinations {-bus abus -type TopicSpace}
(cells/9994GKCCell01/buses/abus|sib-destinations.xml#SIBTopicSpace_1098181446388)
```

mediateSIBDestination command

Use the mediateSIBDestination command to mediate a bus destination for a service integration bus.

Mediating a destination associates a mediation with a selected bus destination. At run time, the mediation applies some message processing to the messages handled by the bus destination. Note that you can only mediate a destination with a single mediation at a time. You can mediate more than one destination with the same mediation.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command mediates a bus destination for a service integration bus. There are parameters that you can use to create a mediation queue point on a WebSphere MQ server, and create the corresponding mediation execution point on a cluster or a server.

You should only use the **node**, **server**, and **cluster** parameters in WebSphere Application Server environments that support server clusters.

Note: If you are mediating a destination where the mediation point is a queue on a WebSphere MQ server (using the **wmqServer** parameter), you must specify where the mediation code runs. If the mediation code runs in a service integration bus member, you must specify a mediation execution point by using the **node**, **server**, and **cluster** parameters. If the mediation code runs externally, you must omit the **node**, **server**, and **cluster** parameters.

- If you are not using a mediation point that is a queue on a WebSphere MQ server, use the **node**, **server**, and **cluster** parameters to specify where the mediation point is located. This is also where the mediation runs. If you omit these parameters, the mediation point defaults to the bus member to which the destination being mediated is assigned.
- If you are using a mediation point that is a queue on a WebSphere MQ server, use the **wqmServer** and **wmqQueueName** parameters to specify the mediation point.
  - If you omit the **node**, **server**, and **cluster** parameters, the service integration bus assumes that the mediation process is performed by an external WebSphere MQ application.
  - If you want to assign the mediation point to a WebSphere MQ server bus member, use the **wmqServer** and **wmqQueueName** parameters to specify a WebSphere MQ queue. In this situation, because you have omitted the **node**, **server**, and **cluster** parameters, an external WebSphere MQ application can run the mediation. The **node**, **server**, and **cluster** parameters are used for nominating the bus member where the mediation code runs.

Target object

None.

Required parameters

-bus *bus_name* **-destinationName** *destination_name*
The destination to be mediated.

-mediationName *mediation_name*
The name of the mediation to be applied to the bus destination. This mediation must exist before this command can be used.

Conditional parameters

-wmqServer *mq_server_name* **-wmqQueueName** *mq_queue_name*
[Queue or web service destination] To assign the mediation point to a WebSphere MQ queue, specify both the name of the WebSphere MQ server bus member where the mediation point is to be assigned, and the name of the WebSphere MQ queue to be used to store messages ready for mediation. *mq_server_name* is the name of the WebSphere MQ server as specified in the **-name** parameter when creating the WebSphere MQ server. *mq_queue_name* is the name allocated to the WebSphere MQ queue by WebSphere MQ administration.

-node *node_name* **-server** *server_name*
[Not topic space] To mediate the bus destination to a server bus member, specify both the name of the node on which the server runs and the name of the server.

-cluster *cluster_name*
[Not topic space] To mediate the bus destination to a cluster bus member, specify the name of the cluster.

This option should be used only in WebSphere Application Server environments that support server clusters.

Optional parameters

-nonPersistentReliability

Specify the service integration quality of service to use with nonpersistent WebSphere MQ messages that are received by service integration from a WebSphere MQ network. The messages in a WebSphere MQ network have their own quality of service level. This is either persistent or non-persistent. When these messages are received by a service integration application, they are assigned a service integration quality of service level that depends on their WebSphere MQ quality of service level.

For nonpersistent WebSphere MQ messages received, the default service integration quality of service is RELIABLE_NONPERSISTENT. If you choose to override this default, you will probably choose one of the other nonpersistent service integration qualities of service BEST_EFFORT_NONPERSISTENT or EXPRESS_NONPERSISTENT. However, you can choose any of the five possible service integration qualities of service:

BEST_EFFORT_NONPERSISTENT
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

EXPRESS_NONPERSISTENT
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

RELIABLE_NONPERSISTENT
Messages are discarded when a messaging engine stops or fails.

RELIABLE_PERSISTENT
Messages might be discarded when a messaging engine fails.

ASSURED_PERSISTENT
Messages are not discarded.

Note: Higher levels of reliability have higher impacts on performance.

For more information, see ../ae/rjc0014_.dita.

-persistentReliability

Specify the service integration quality of service to use with persistent WebSphere MQ messages that are received by service integration from a WebSphere MQ network. The messages in a WebSphere MQ network have their own quality of service level. This is either persistent or non-persistent. When these messages are received by a service integration application, they are assigned a service integration quality of service level that depends on their WebSphere MQ quality of service level.

For persistent WebSphere MQ messages received, the default service integration quality of service is ASSURED_PERSISTENT. If you choose to override this default, you will probably choose the other persistent service integration quality of service RELIABLE_PERSISTENT. However, you can choose any of the five possible service integration qualities of service:

BEST_EFFORT_NONPERSISTENT

EXPRESS_NONPERSISTENT

RELIABLE_NONPERSISTENT

RELIABLE_PERSISTENT

ASSURED_PERSISTENT

For more information, see ../ae/rjc0014_.dita.

-useRFH2
Determines whether service integration technologies includes an RFH2 header in messages it places on the mediation point. Possible values are:

TRUE

FALSE

The default value is TRUE.

-maintainStrictMessageOrder
Maintain strict message order. Possible values are:

Selected
Maintains the order in which a producer sends messages to the destination.

At run time, this property has priority over other configuration property values. For information on the configuration properties that are overridden at run time, see Strict message ordering for bus destinations.

Cleared
Message order is not preserved for this destination.

Example

- Using Jython:

```
wsadmin>AdminTask.mediateSIBDestination("-bus abus -destinationName myqueue
 -mediationName filterMed -cluster cluster1")
```

- Using Jacl:

```
wsadmin>$AdminTask mediateSIBDestination {-bus abus -destinationName myqueue
 -mediationName filterMed -cluster cluster1}
```

modifySIBDestination command

Use the modifySIBDestination command to change properties of a bus destination for a service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The modifySIBDestination changes properties of a bus destination for a service integration bus.

Target object

A bus destination.

Required parameters

-bus
The name of the service integration bus on which the bus destination is configured. You can use the listSIBuses command to list the names of existing buses.

-name
The identifier by which this destination is known for administrative purposes.

Conditional parameters

None.

Optional parameters

-description
Specify a description for the bus destination, for administrative purposes.

-reliability
Specify the default reliability level to assign to a message produced to this destination when an explicit reliability has not been set by the producer application. Service integration supports five reliability levels (also known as delivery options or qualities of service):

BEST_EFFORT_NONPERSISTENT
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

EXPRESS_NONPERSISTENT
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

RELIABLE_NONPERSISTENT
Messages are discarded when a messaging engine stops or fails.

RELIABLE_PERSISTENT
Messages might be discarded when a messaging engine fails.

ASSURED_PERSISTENT
Messages are not discarded.

Note: Higher levels of reliability have higher impacts on performance.

For more information about service integration reliability levels, see Message reliability levels - JMS delivery mode and service integration quality of service.

-overrideOfQOSByProducerAllowed TRUE | FALSE
Controls the quality of service for message flows between producers and the destination. Select this option to use the quality of service specified by producers instead of the quality defined for the destination.

-defaultPriority *number*
The default priority assigned to messages sent to this destination when a priority has not been set by the producer.

-maxFailedDeliveries *number*
The maximum number of failed attempts to process a message. After this number of failed attempts, the message is forwarded from the intended destination to its exception destination. Specify a value in the range 0 through 2147483647. A value of 0 (zero) means that if a message cannot be delivered on the first attempt, it is either forwarded to the exception destination or discarded, as defined by the **-exceptionDestination** parameter.

-exceptionDestination *value*
Use these properties to define what happens to any messages that cannot be delivered to this destination.

By default, all messages that cannot be delivered to this destination are rerouted to the system default exception destination for the messaging engine to which this destination is assigned (_SYSTEM.Exception.Destination.*messaging_engine_name*). Use this parameter to override the default value. You can set a specific exception destination for this destination, or you can specify that undeliverable messages are not rerouted to an exception destination by entering an empty string (""), in which case the maximum failed deliveries count has no effect.

Note: An undeliverable message can block the processing of other messages waiting for delivery to the same destination.

You can use this option and specify no exception destination to preserve message ordering.

-sendAllowed TRUE | FALSE
Clear this option (setting it to FALSE) to stop producers from being able to send messages to this destination.

- For a queue point of a non-mediated destination, or a mediation point of a mediated destination, if you clear this option then new messages (from attached producers or forwarded from another destination) are redirected to any available message point. If no message points are available, then messages that have already been accepted onto the bus, and new messages from attached

producers, are preserved by the bus until a message point becomes available. The only exception to this is the case of a destination with only one message point (queue point or mediation point depending on whether the destination is mediated or non-mediated), where the producer is attached to the same messaging engine. In this case, an exception message is generated on each send call. The exception message indicates that the only extant localization has been disabled for send. The producer remains open as usual, and any more send calls succeed if the **Send allowed** property of the localization is reselected (reset to TRUE).

- For a queue point of a mediated destination, if you clear this option then messages from mediation instances are redirected to any available message point. If no message points are available, then the messages are preserved by the bus until a message point becomes available. For any mediation instance (that is, on any server that has a mediation point), if the same server hosts a queue point, and that queue point is the only queue point for the destination, then the mediation changes to the “stopped on error” state.

-receiveAllowed TRUE | FALSE
Clear this option (setting it to false) to prevent consumers from being able to receive messages from this destination. For the message point, if you clear this option then any open consumers change state and an exception is generated if the consumer requests a message. Messages can continue to be sent, and accumulate on the message point.

-receiveExclusive TRUE | FALSE
Select this option (setting it to true) to allow only one consumer to attach to a destination. If you select this option, only a single consumer can be attached to each queue point of a queue destination at any one time. Subsequent consumers attempting to attach to a queue point with a consumer already attached are rejected.

-maintainStrictMessageOrder TRUE | FALSE
Select this option (setting it to TRUE) to maintain the order in which a producer sends messages to the destination.

At run time, this property has priority over other configuration property values. For information about the configuration properties that are overridden at run time, see Strict message ordering for bus destinations.

-topicAccessCheckRequired
Include this option if authorization checks are required for access to topics.

-replyDestination
The name of a destination to be appended to any non-empty reverse routing path of messages sent to this destination. This property is intended for use with mediations on reply messages. For more information about the use of this property, see “Configuring a destination reverse routing path” on page 1989.

-replyDestinationBus
The name of the bus on which the reply destination is configured. This property is intended for use with mediations on reply messages. For more information about the use of this property, see “Configuring a destination reverse routing path” on page 1989.

-delegateAuthorizationCheckToTarget
Indicates whether the authorization check is performed on the alias or the target destination. Include this option if you want the authorization check to be performed on the target destination.

-auditAllowed TRUE | FALSE
Clear this option (setting it to FALSE) to prevent the bus from auditing topic level authorization checks when the bus and application server have auditing enabled. The default value is TRUE. You must have Audit Administrator privileges to use this parameter. The parameter is ignored if it is used in the creation of other types of destination.

-defaultForwardRoutingPath
The value to which a message forward routing path is set if the message contains no forward routing

path. This identifies a sequential list of intermediary bus destinations that messages must pass through to reach a target bus destination. The format of the field is a list of bus destinations specified as *bus_name*:*destination_name*.

-queuePoints
A list of the queue points used by users of the alias destination. If no queue points are supplied, all queue points can be used. The target destination must be a queue destination in the same bus as the alias destination definition. The target destination must also be a queue destination with multiple queue points.

A queue point is specified in the following form: *destination_name@ messaging_engine_name*

-useAllQueuePoints TRUE | FALSE
If you set this option to TRUE all available queue points are used whereas, if you set this option to FALSE, only those queue points in the list specified by the **-queuePoints** option are used.

-mediationPoints
A list of the mediation points used by users of the alias destination. If no mediation points are supplied, all mediation points can be used. The target destination must be a mediated queue destination in the same bus as the alias destination definition. The target destination must also be a queue destination with multiple mediation points.

A mediation point is specified in the following form: *destination_name@ messaging_engine_name*

-useAllMediationPoints TRUE | FALSE
If you set this option to TRUE all available queue points are used whereas, if you set this option to FALSE, only those queue points in the list specified by the **-mediationPoints** option are used.

Example

- Using Jython:

```
wsadmin>AdminTask.showSIBDestination(["-bus", "abus", "-name", "myqueue"])
'{receiveExclusive=false, defaultForwardRoutingPath=[], defaultPriority=0,
exceptionDestination=_SYSTEM.Exception.Destination.node01.aserver-abus,
uuid=97CC75AC71E5932CAB3417AC,  overrideOfQOSByProducerAllowed=true,
sendAllowed=true, maxFailedDeliveries=5,
maxReliability=ASSURED_PERSISTENT, reliability=ASSURED_PERSISTENT,
receiveAllowed=true, identifier=myqueue}'

wsadmin>AdminTask.modifySIBDestination(["-bus", "abus", "-name", "myqueue",
 "-receiveAllowed", "FALSE"])

wsadmin>AdminTask.showSIBDestination(["-bus", "abus", "-name", "myqueue"])
'{receiveExclusive=false, defaultForwardRoutingPath=[], defaultPriority=0,
exceptionDestination=_SYSTEM.Exception.Destination.node01.aserver-abus,
uuid=97CC75AC71E5932CAB3417AC, overrideOfQOSByProducerAllowed=true,
sendAllowed=true, maxFailedDeliveries=5,
maxReliability=ASSURED_PERSISTENT, reliability=ASSURED_PERSISTENT,
receiveAllowed=false, identifier=myqueue}'
```

- Using Jacl:

```
wsadmin>$AdminTask showSIBDestination {-bus abus -name myqueue}
{receiveExclusive=false, defaultForwardRoutingPath=[], defaultPriority=0,
exceptionDestination=_SYSTEM.Exception.Destination.node01.aserver-abus,
uuid=97CC75AC71E5932CAB3417AC, overrideOfQOSByProducerAllowed=true,
sendAllowed=true, maxFailedDeliveries=5,
maxReliability=ASSURED_PERSISTENT, reliability=ASSURED_PERSISTENT,
receiveAllowed=true, identifier=myqueue}

wsadmin>$AdminTask modifySIBDestination {-bus abus -name myqueue
-receiveAllowed FALSE}
(cells/9994GKCCell01/buses/abus|sib-destinations.xml#SIBQueue_1098215169998)

wsadmin>$AdminTask showSIBDestination {-bus abus -name myqueue}
{receiveExclusive=false, defaultForwardRoutingPath=[], defaultPriority=0,
```

```
exceptionDestination=_SYSTEM.Exception.Destination.node01.aserver-abus,
uuid=97CC75AC71E5932CAB3417AC, overrideOfQOSByProducerAllowed=true,
sendAllowed=true, maxFailedDeliveries=5,
maxReliability=ASSURED_PERSISTENT, reliability=ASSURED_PERSISTENT,
receiveAllowed=false, identifier=myqueue}
```

Example: Modify a destination alias "MyAlias2" to use a subset of the available queue points and mediation points:

- Using Jython:

```
cluster=AdminConfig.list("ServerCluster").splitlines()[0]
Qp1=AdminConfig.list("SIBQueueLocalizationPoint" , cluster).splitlines()[0]
Mp1=AdminConfig.list("SIBMediationLocalizationPoint").splitlines()[0]
AdminTask.modifySIBDestination(["-bus" , "bus1" , "-name" , "MyAlias2",
 "-queuePoints", [[Qp1]], "-mediationPoints" , [[Mp1]]])
```

- Using Jacl:

```
set cluster [ lindex [ $AdminConfig list ServerCluster ] 1 ]
set Qp1 [ lindex [ $AdminConfig list SIBQueueLocalizationPoint $cluster ] 0 ]
set Mp1 [ lindex [ $AdminConfig list SIBMediationLocalizationPoint ] 0 ]
$AdminTask modifySIBDestination {-bus bus1 -name MyAlias2
 -queuePoints [[$Qp1]]-mediationPoints [[$Mp1]]}
```

Example: Modify a destination alias to remove any limitation on the queue points used:

- Using Jython:

```
AdminTask.modifySIBDestination(["-bus" , "bus1" , "-name" , "MyAlias2",
 "-queuePoints", [[]]])
```

- Using Jacl:

```
$AdminTask modifySIBDestination {-bus bus1 -name MyAlias2
-useAllQueuePoints=true -useAllMediationPoints=true}
```

showSIBDestination command

Use the showSIBDestination command to list the property values for a bus destination.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command lists details about properties of a bus destination.

Target object

A bus destination.

Required parameters

-bus *busname*
The name of the service integration bus on which the bus destination is configured. You can use the listSIBuses command to list the names of existing buses.

-name *destname*
The identifier by which this destination is known for administrative purposes.

Conditional parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminTask.showSIBDestination("-bus abus -name myqueue")
'{receiveExclusive=false, defaultForwardRoutingPath=[], defaultPriority=0,
 exceptionDestination=_SYSTEM.Exception.Destination.node01.server1-abus,
 uuid=97CC75AC71E5932CAB3417AC, overrideOfQOSByProducerAllowed=true,
 sendAllowed=true, maxFailedDeliveries=5,
 maxReliability=ASSURED_PERSISTENT, reliability=ASSURED_PERSISTENT,
 receiveAllowed=true, identifier=myqueue}'
```

- Using Jacl:

```
wsadmin>$AdminTask showSIBDestination {-bus abus -name myqueue}
{receiveExclusive=false, defaultForwardRoutingPath=[], defaultPriority=0,
 exceptionDestination=_SYSTEM.Exception.Destination.node01.server1-abus,
 uuid=97CC75AC71E5932CAB3417AC, overrideOfQOSByProducerAllowed=true,
 sendAllowed=true, maxFailedDeliveries=5,
 maxReliability=ASSURED_PERSISTENT, reliability=ASSURED_PERSISTENT,
 receiveAllowed=true, identifier=myqueue}
```

unmediateSIBDestination command

Use the unmediateSIBDestination command to remove a mediation from a service integration bus destination.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command removes a mediation from a bus destination for a service integration bus. The mediation is left on the bus, in case it is needed to mediate other bus destinations.

If you unmediate a destination that is assigned to a WebSphere MQ server bus member, or a destination that has a mediation point on a WebSphere MQ server bus member, the mediation process stops, and messages already queued on the mediation point are not mediated.

Target object

None.

Required parameters

-bus *busname*
The name of the service integration bus on which the bus destination is to be created. You can use the listSIBuses command to list the names of existing buses.

-destinationName *destname*
The identifier by which this destination is known for administrative purposes.

Conditional parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminTask.listSIBMediations(["-bus", "abus"])
'(cells/9994GKCCell01/buses/abus|sib-mediations.xml#
SIBDestinationMediation_1098217858584)'

wsadmin>AdminTask.unmediateSIBDestination(["-bus", "abus", "-destinationName", "myqueue"])
```

- Using Jacl:

```
wsadmin>$AdminTask listSIBMediations {-bus abus}
(cells/9994GKCCell01/buses/abus|sib-mediations.xml#SIBDestinationMediation_1098217858584)

wsadmin>$AdminTask unmediateSIBDestination {-bus abus -destinationName myqueue}
```

SIBAdminCommands: Mediation administrative commands for the AdminTask object

You can use these administrative commands to manage mediations.

These commands provide an alternative to using the administrative console or using the more complex syntax of wsadmin and JACL.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('SIBAdminCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

createSIBMediation command

Use the createSIBMediation command to create a new mediation.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('SIBAdminCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command creates a new mediation.

Target object

None.

Required parameters

-bus *busname*
The name of the service integration bus on which the mediation is to be created. You can use the listSIBuses command to list the names of existing buses.

-mediationName *mediation_name*
The name by which this mediation is known for administrative purposes.

-handlerListName
The name of the handler list that was defined when the mediation was deployed.

Conditional parameters

None.

Optional parameters

-description *text*
An optional description for the mediation, for administrative purposes.

-globalTransaction TRUE | FALSE
Whether or not a global transaction is started for each message processed.

FALSE
A local transaction is started for each message processed. You only have to select this option for mediations that access other resource managers such as databases, or interact with enterprise beans that require a global transaction.

TRUE A global transaction is started for each message processed.

-allowConcurrentMediation TRUE | FALSE
Select this option (setting it to true) to apply the mediation to multiple messages concurrently. Message ordering is not preserved. The default option is false.

TRUE Apply the mediation to multiple messages concurrently, and preserve message ordering.

FALSE
Apply the mediation to a single message at a time. This setting is required to ensure that message ordering is preserved.

-selector *text*
Controls which messages are sent to the mediation. If a message matches the rule defined by the selector text string, then the mediation is applied to the message.

If the message does not match the rule defined by the selector text string, then the message is not mediated. If a message contains both Selector and Discriminator, it must match both rules for the message to be mediated. If either the Selector or the Discriminator rule does not match, the message is not mediated.

-discriminator *text*
Discriminator

Compare this property with the selector property. The rule specified by the selector examines the header and properties of the message, whereas the discriminator examines the topic of the message. If a message contains both selector and discriminator, it must match both rules for the message to be mediated. If either the selector or the discriminator rule does not match, the message is not mediated.

Example

- Using Jython:

```
wsadmin>AdminTask.createSIBMediation("-bus abus -mediationName switchMed
 -handlerListName switchHandler")
'(cells/9994GKCCell01/buses/abus|sib-mediations.xml#SIBDestinationMediation_1098219493014)'
```

- Using Jacl:

```
wsadmin>$AdminTask createSIBMediation {-bus abus -mediationName switchMed
 -handlerListName switchHandler}
(cells/9994GKCCell01/buses/abus|sib-mediations.xml#SIBDestinationMediation_1098219493014)
```

deleteSIBMediation command

Use the deleteSIBMediation command to delete a mediation.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command deletes a mediation. If the mediation point relates to a WebSphere MQ queue, the contents of the mediation point are not deleted.

Target object

None.

Required parameters

-bus *busname*
The name of the service integration bus on which the mediation is to be created. You can use the listSIBuses command to list the names of existing buses.

-mediationName *mediation_name*
The name by which this mediation is known for administrative purposes.

Conditional parameters

None.

Optional parameters

None.

Example

- Using Jython:

  ```
  wsadmin>AdminTask.deleteSIBMediation(["-bus", "abus", "-mediationName", "switchMed"])
  ```

- Using Jacl:

  ```
  wsadmin>$AdminTask deleteSIBMediation {-bus abus -mediationName switchMed}
  ```

listSIBMediations command

Use the listSIBMediations command to list mediations on a service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('SIBAdminCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

Purpose

This command lists all mediations on a service integration bus.

Target object

A service integration bus

Required parameters

-bus *busname*
The name of the service integration bus on which the mediations are configured. You can use the listSIBuses command to list the names of existing buses.

Conditional parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminTask.listSIBMediations("-bus abus")
(cells/9994GKCCell01/buses/abus|sib-mediations.xml#SIBDestinationMediation_1098217858584)
(cells/9994GKCCell01/buses/abus|sib-mediations.xml#SIBDestinationMediation_1098220051588)
```

- Using Jacl:

```
wsadmin>$AdminTask listSIBMediations {-bus abus}
(cells/9994GKCCell01/buses/abus|sib-mediations.xml#SIBDestinationMediation_1098217858584)
(cells/9994GKCCell01/buses/abus|sib-mediations.xml#SIBDestinationMediation_1098220051588)
```

modifySIBMediation command

Use the modifySIBMediation command to change the properties of a mediation.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('SIBAdminCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command changes properties of a mediation.

Target object

A mediation.

Required parameters

-bus *busname*
The name of the service integration bus on which the mediation is to be created. You can use the listSIBuses command to list the names of existing buses.

-mediationName *mediation_name*
The name by which this mediation is known for administrative purposes.

Conditional parameters

None.

Optional parameters

-description *text*
An optional description for the mediation, for administrative purposes.

-handlerListName
The name of the handler list that was defined when the mediation was deployed.

-globalTransaction TRUE | FALSE
Whether or not a global transaction is started for each message processed.

FALSE
A local transaction is started for each message processed. You only have to select this option for mediations that access other resource managers such as databases, or interact with enterprise beans that require a global transaction.

TRUE A global transaction is started for each message processed.

-allowConcurrentMediation TRUE | FALSE
Select this option (setting it to true) to apply the mediation to multiple messages concurrently. Message ordering is not preserved. The default option is false.

TRUE Apply the mediation to multiple messages concurrently, and preserve message ordering.

FALSE
Apply the mediation to a single message at a time. This setting is required to ensure that message ordering is preserved.

-selector *text*
Controls which messages are sent to the mediation. If a message matches the rule defined by the selector text string, then the mediation is applied to the message.

If the message does not match the rule defined by the selector text string, then the message is not mediated. If a message contains both Selector and Discriminator, it must match both rules for the message to be mediated. If either the Selector or the Discriminator rule does not match, the message is not mediated.

-discriminator *text*

Discriminator

Compare this property with the selector property. The rule specified by the selector examines the header and properties of the message, whereas the discriminator examines the topic of the message. If a message contains both selector and discriminator, it must match both rules for the message to be mediated. If either the selector or the discriminator rule does not match, the message is not mediated.

Example

- Using Jython:

```
wsadmin>AdminTask.showSIBMediation("-bus abus -mediationName switchMed")
{uuid 39588C4821BB046E}
{selector {}}
{contextInfo {}}
{discriminator {}}
{allowConcurrentMediation false}
{globalTransaction false}
{mediationName switchMed}
{handlerListName switchHandler}
{description {}}

wsadmin>AdminTask.modifySIBMediation(["-bus", "abus",
 "-mediationName", "switchMed",
 "-selector", ["JMSXDeliveryCount > 1000"]] )

wsadmin>AdminTask.showSIBMediation("-bus abus
-mediationName switchMed")
{uuid 39588C4821BB046E}
{selector {JMSXDeliveryCount > 1000}}
{contextInfo {}}
{discriminator {}}
{allowConcurrentMediation false}
{globalTransaction false}
{mediationName switchMed}
{handlerListName switchHandler}
{description {}}
```

- Using Jacl:

```
wsadmin>$AdminTask showSIBMediation {-bus abus -mediationName switchMed}
{uuid 39588C4821BB046E}
{selector {}}
{contextInfo {}}
{discriminator {}}
{allowConcurrentMediation false}
{globalTransaction false}
{mediationName switchMed}
{handlerListName switchHandler}
{description {}}

wsadmin>$AdminTask modifySIBMediation {-bus abus -mediationName switchMed
 -selector {JMSXDeliveryCount > 1000}}

wsadmin>$AdminTask showSIBMediation {-bus abus -mediationName switchMed}
{uuid 39588C4821BB046E}
{selector {JMSXDeliveryCount > 1000}}
{contextInfo {}}
{discriminator {}}
{allowConcurrentMediation false}
{globalTransaction false}
{mediationName switchMed}
{handlerListName switchHandler}
{description {}}
```

showSIBMediation command

Use the showSIBMediation command to list the property values for a mediation.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command changes properties of a mediation.

Target object

A mediation.

Required parameters

-bus *busname*
The name of the service integration bus on which the mediation is to be created. You can use the listSIBuses command to list the names of existing buses.

-mediationName *mediation_name*
The name by which this mediation is known for administrative purposes.

Conditional parameters

None.

Optional parameters

None.

Example

- Using Jython:

  ```
  wsadmin>AdminTask.showSIBMediation("-bus abus -mediationName switchMed")
  {uuid 39588C4821BB046E}
  {selector {JMSXDeliveryCount > 1000}}
  {contextInfo {}}
  {discriminator {}}
  {allowConcurrentMediation false}
  {globalTransaction false}
  {mediationName switchMed}
  {handlerListName switchHandler}
  {description {}}
  ```

- Using Jacl:

  ```
  wsadmin>$AdminTask showSIBMediation {-bus abus -mediationName switchMed}
  {uuid 39588C4821BB046E}
  {selector {JMSXDeliveryCount > 1000}}
  ```

```
{contextInfo {}}
{discriminator {}}
{allowConcurrentMediation false}
{globalTransaction false}
{mediationName switchMed}
{handlerListName switchHandler}
{description {}}
```

SIBAdminCommands: WebSphere MQ server administrative commands for the AdminTask object

Use command scripts to create, modify, list, show and delete WebSphere MQ servers and server bus members. These commands do not support the automatic resource discovery feature provided by the administrative console.

Decide which method to use to configure these resources. You can configure WebSphere MQ server resources by using the wsadmin tool as described in this topic, or by using the administrative console as described in “Using a WebSphere MQ server to integrate WebSphere MQ queues into a bus” on page 573.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Note: To add a WebSphere MQ server as a bus member, use the addSIBusMember command.

createSIBWMQServer command

Use the createSIBWMQServer command to create a new WebSphere MQ server at cell scope.

You can create a new WebSphere MQ server by using the wsadmin tool as described in this topic, or by using the administrative console as described in “Creating a WebSphere MQ server definition” on page 574.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

A WebSphere MQ server represents a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. This command creates a new WebSphere MQ server at cell scope, and uses the supplied values to populate its parameters.

Note: When creating a WebSphere MQ server, it is important to understand the significance of the **-name** and **-serverName** parameters. For example, if WebSphere Application Server administration created a WebSphere MQ server object with the name “My European area server” that represented a WebSphere MQ queue manager with the **serverName** QM1. WebSphere Application Server administration could then create a second WebSphere MQ server object with the name “My UK country server”, that also represented the same WebSphere MQ queue manager with the **serverName** QM1.

Target object

A WebSphere Application Server cell.

Required parameters

-name
The name of the WebSphere MQ server. This value is for administrative purposes only and can be decided by the administrator. The name is only meaningful inside WebSphere Application Server administration, and must be unique at cell level. There is no default value. This parameter cannot be modified.

-serverName
The name of the queue manager or queue-sharing group. This value is the name by which the queue manager or queue-sharing group is identified, and is allocated by WebSphere MQ administration to that WebSphere MQ object. The WebSphere Application Server administrator must always use the name allocated by WebSphere MQ administration.

-host
The host to which a connection is established for communicating with a queue manager or queue-sharing group. This value is the host name or the IP address of the queue manager or queue-sharing group, that this WebSphere MQ server represents. The value is a string and must be one of the following:

- symbolic host name
- IPv4 address
- IPv6 address

-transportChain
The channel framework outbound transport chain to use when establishing a connection with WebSphere MQ. If you do not specify this option, a default value of OutboundBasicWMQClient is assumed.

Conditional parameters

None

Optional parameters

The optional host, port, channel, and authentication alias attributes together specify the connection access path to this WebSphere MQ server, for messaging applications running in service integration. For more information, see WebSphere MQ server: Connection and authentication.

-port
The TCP/IP port number on which the queue manager or queue-sharing group that this WebSphere MQ server represents listens. The default value is 1414.

-channel
The WebSphere MQ client channel name to use when connecting to the queue manager or queue-sharing group that this WebSphere MQ server represents. This value is the name allocated by WebSphere MQ administration to the WebSphere MQ object, and must always be used by WebSphere Application Server administration. The default value is SYSTEM.DEF.SVRCONN.

-description
A short description of the WebSphere MQ server. This value is used for administrative purposes only.

-securityAuthAlias
The authentication alias to use when connecting to a queue manager or queue-sharing group. This parameter should not be confused with the discovery authentication alias.

-trustUserIds
Determines whether user IDs received in messages from WebSphere MQ are passed on with the messages by the service integration bus. The application user ID is always set from the **jsAppUserId** RFH2 value. If this is not present (either because the key/value pair is not present in the RFH2 header, or because the message does not have a RFH2 header), this field is not set. If you set this value to FALSE, the user ID is overwritten with the WebSphere MQ server name. This parameter has two possible values:

TRUE User IDs are propagated into messages.

FALSE
User IDs are not propagated into messages.

The default is TRUE.

-allowDiscovery
Determines whether automated discovery of WebSphere MQ resources is performed. This parameter has two possible values:

TRUE Automated discovery is used.

FALSE
Automated discovery is not used.

The default is TRUE.

-discoveryAuthAlias
The authentication alias to use when establishing a resource discovery connection to the queue manager or queue-sharing group. This value should not be confused with the security authentication alias.

-replyToQueue
The reply-to queue to use for resource discovery. This value is the name allocated by WebSphere MQ administration to the WebSphere MQ object, and must be the name of a model queue for a temporary dynamic queue. The WebSphere Application Server administrator must always use the name allocated by WebSphere MQ administration. The default is SYSTEM.DEFAULT.MODEL.QUEUE.

-type
Determines whether the WebSphere MQ server object is either a queue manager or a queue-sharing group, as determined by WebSphere Application Server administration. This parameter had two possible values:

MQ_QUEUE_MANAGER
The WebSphere MQ server represents a queue manager. If you select this value, the resource discovery process retrieves queue names that belong to queue managers.

MQ_QUEUE_SHARING_GROUP
The WebSphere MQ server represents a queue-sharing group. If you select this value, the resource discovery process retrieves queue names that belong to queue-sharing groups.

-bindingsMode
Determines whether bindings transport mode connections are used when connecting to a queue manager or queue-sharing group. Bindings mode connection is available if the application server and the queue manager are on the same node. It is only possible to connect to a single queue manager in bindings mode, even if multiple queue managers exist on the same node. This parameter has two possible values:

TRUE Bindings mode is used if available. If you select this option and bindings mode is not available, the connections mechanism defaults to client transport mode.

FALSE
Client mode is always used.

Example

- Using Jython:

```
wsadmin>AdminTask.createSIBWMQServer(["-name", "Finance dept QM",
 "-serverName", "FDQM", "-type", "MQ_QUEUE_MANAGER", "-bindingsMode", "true",
 "-host", "findep01.ibm.com", "-port", 1414,
 "-transportChain", "OutboundSecureWMQClient"])
```

- Using Jacl:

```
wsadmin>$AdminTask createSIBWMQServer {-name "Finance dept QM"
-serverName FDQM -type MQ_QUEUE_MANAGER -bindingsMode true
-host findep01.ibm.com -port 1414
-transportChain OutboundSecureWMQClient}
```

modifySIBWMQServer command

Use the modifySIBWMQServer command to modify a WebSphere MQ server.

You can modify a WebSphere MQ server by using the wsadmin tool as described in this topic, or by using the administrative console as described in “Modifying a WebSphere MQ server definition” on page 575.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

A WebSphere MQ server represents a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. This command modifies a WebSphere MQ server. It is not possible to modify the name or type attributes by using this command.

Note: When modifying a WebSphere MQ server, it is important to understand the significance of the **name** and **serverName** attributes. For example, if a WebSphere Application Server administrator creates a WebSphere MQ server called “My European Area Server” that represents a WebSphere MQ queue manager with the **serverName** QM1, it would then be possible for the administrator to create a second WebSphere MQ server called “My UK Country Server”, which also represents the same queue manager.

Target object

A selected WebSphere MQ server.

Required parameters

-name
The name of the WebSphere MQ server. The name is specified when creating the WebSphere MQ server definition.

Conditional parameters

None

Optional parameters

-serverName
Name of the queue manager or queue-sharing group. This is the name by which the queue manager or queue-sharing group is identified. The value is allocated by WebSphere MQ administration to that WebSphere MQ resource. The administrator always uses the name that is allocated by WebSphere MQ administration.

-host
New value for the **host** attribute. This value is the name or the IP address of the host to which a connection is established when communicating with a queue manager or queue-sharing group that this WebSphere MQ server represents. The value is a string and must be one of the following:

- Symbolic host name
- IPv4 address
- IPv6 address

-bindingsMode
New value for the **bindingsMode** attribute. This value determines whether bindings transport mode connections are used when connecting to a queue manager or queue-sharing group. Bindings mode connection is possible if the application server and the queue manager are on the same node, but connection is only allowed to a single queue manager, even if multiple queue managers exist on the same node. This parameter has two possible values:

TRUE Bindings mode is used if available. If you select this option and bindings mode is not available, the connections mechanism defaults to client transport mode.

FALSE
Client mode is always used.

The default is TRUE.

-port
New value for the WebSphere MQ **port** attribute. This value is the TCP/IP port number on which the queue manager or queue-sharing group that this WebSphere MQ server represents listens. The default value is 1414.

-channel
New value for the WebSphere MQ **channel** attribute. This value is the WebSphere MQ client channel name to use when connecting to the queue manager or queue sharing group that this WebSphere MQ server represents. This name is allocated by WebSphere MQ administration to the WebSphere MQ object, and must always be used by the WebSphere Application Server administrator. The default value is SYSTEM.DEF.SVRCONN.

-description
New value for the **description** attribute. This value is a short description of the WebSphere MQ server, and is used for administrative purposes only.

-securityAuthAlias
New value for the **securityAuthorizationAlias** attribute. This value is the authentication alias to use when connecting to a queue manager or queue-sharing group. This parameter is not the same as the discovery authentication alias.

-transportChain
New value for the **transportChain** attribute. This value is the outbound transport chain to use when establishing a connection with WebSphere MQ. The default value is OutboundBasicWMQClient.

-trustUserIds
New value for the **trustUserIds** attribute. Determines whether user IDs received in messages from WebSphere MQ are propagated into the message or not (that is, whether user IDs received as part of message data are used in the service integration bus). The application user ID is always set from the **jsAppUserId** RFH2 value. If this is not present (either because the key/value pair is not present in the RFH2 header, or because the message does not have a RFH2 header), this field is not set. If you set this value to FALSE, the user ID is overwritten with the WebSphere MQ server name. This parameter has two possible values:

TRUE User IDs are propagated into messages.

FALSE
User IDs are not propagated into messages.

The default is TRUE.

-allowDiscovery
New value for the **allowDiscovery** attribute. This value determines whether automated discovery of WebSphere MQ resources is performed. This parameter has two possible values:

TRUE Automatic resource discovery is enabled.

FALSE
Automatic resource discovery is disabled.

The default is TRUE.

-discoveryAuthAlias
New value for the **discoveryAuthAlias** attribute. This value is the authentication alias to use when establishing a resource discovery connection to a queue manager or queue-sharing group, and is not the same as the security authentication alias parameter.

-replyToQueue
New value for the **replyToQueue** attribute. This value is the reply-to queue to use for resource discovery, is the name allocated by WebSphere MQ administration to the WebSphere MQ object, and must be the name of a model queue for a temporary dynamic queue. WebSphere Application Server administration must always use the name that is agreed with WebSphere MQ administration. The default is SYSTEM.DEFAULT.MODEL.QUEUE.

Example

- Using Jython:

```
wsadmin>AdminTask.modifySIBWMQServer(["-name", "Finance dept QM",
 "-allowDiscovery", "false"] )
```

- Using Jacl:

```
wsadmin>$AdminTask modifySIBWMQServer {-name "Finance dept QM"
 -allowDiscovery false}
```

listSIBWMQServers command

Use the listSIBWMQServers command to list the WebSphere MQ servers known to a cell.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Purpose

A WebSphere MQ server represents a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. This command lists the WebSphere MQ servers known to the cell.

Target object

The current cell.

Required parameters

None

Conditional parameters

None

Optional parameters

None

Example

- Using Jython:

```
wsadmin>AdminTask.listSIBWMQServers()
```

- Using Jacl:

```
wsadmin>$AdminTask listSIBWMQServers
```

showSIBWMQServer command

Use the showSIBWMQServer command to show details of a WebSphere MQ server.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

A WebSphere MQ server represents a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. This command shows the details of a WebSphere MQ server.

Target object

A selected WebSphere MQ server.

Required parameters

-name
The name of the WebSphere MQ server. This value is the name that you specified in the **-name** parameter when creating the WebSphere MQ server.

Conditional parameters

None

Optional parameters

None

Example

- Using Jython:

```
AdminTask.showSIBWMQServer(["-name", "Finance dept QM"])
```

- Using Jacl:

```
$AdminTask showSIBWMQServer {-name "Finance dept QM"}
```

deleteSIBWMQServer command

Use the deleteSIBWMQServer command to delete a specified WebSphere MQ server and remove the associated WebSphere MQ server bus members, assigned queue points and mediation points.

You can delete a WebSphere MQ server by using the wsadmin tool as described in this topic, or by using the administrative console as described in “Deleting a WebSphere MQ server definition” on page 576.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

A WebSphere MQ server represents a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. This command deletes a specified WebSphere MQ server and removes any associated WebSphere MQ server bus members, assigned queue points and mediation points. This operation does not remove the corresponding WebSphere MQ queue manager or queue-sharing group, and it does not remove messages from any queues that are assigned to corresponding WebSphere MQ server bus members. The bus members for a given WebSphere MQ server are those created when the server is added to a bus.

Target object

A selected WebSphere MQ server.

Required parameters

-name
The name of the WebSphere MQ server to delete. This value is specified for the **-name** parameter (not the **-serverName** parameter), when the WebSphere MQ server is created, and is the name of the WebSphere Application Server administrative object, not the name of the WebSphere MQ object. If you issue the delete command, it is the WebSphere Application Server administrative object that is deleted, not the WebSphere MQ resource.

Conditional parameters

None

Optional parameters

None

Example

- Using Jython:

```
AdminTask.deleteSIBWMQServer(["-name", "Finance dept QM"])
```

- Using Jacl:

```
$AdminTask deleteSIBWMQServer {-name "Finance dept QM"}
```

modifySIBWMQServerBusMember command

Use the modifySIBWMQServerBusMember command to modify the attributes of a WebSphere MQ server bus member.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

A WebSphere MQ server bus member is used for assigning queue points and mediation points to WebSphere MQ queues. This command modifies the attributes of a WebSphere MQ server bus member.

Target object

A selected WebSphere MQ server bus member.

Required parameters

-name
The administrative name of the WebSphere MQ server bus member. This value is the name specified in the **-name** parameter when creating the WebSphere MQ server definition.

-bus
The name of the service integration bus of which the WebSphere MQ server is a member.

Conditional parameters

None

Optional parameters

-virtualQueueManagerName
When sending messages to WebSphere MQ, the WebSphere MQ gateway queue manager sees the bus as a remote queue manager. The virtual queue manager name is the name that is passed to WebSphere MQ as the name of this remote queue manager.

The default value is the name of the Service Integration bus. If this bus name is not a valid name for a WebSphere MQ queue manager, or if another WebSphere MQ queue manager already has the same name, replace the default value with a unique, valid name for a WebSphere MQ queue manager.

- It must contain between 1 and 48 characters.
- It must conform to the WebSphere MQ queue naming rules (see the *Rules for naming WebSphere MQ objects* topic in the WebSphere MQ information center).

-host
The new value for the overridden **host** attribute. This value is the name or the IP address of the host to which a connection is established for communicating with a queue manager or queue-sharing group that this WebSphere MQ server represents. The value is a string and must be one of the following:

- Symbolic host name
- IPv4 address
- IPv6 address

-port
The new value for the overridden **port** attribute. This value is the TCP/IP port number on which the queue manager or queue-sharing group that this WebSphere MQ server represents listens. The default value is 1414.

-channel
The new value for the overridden channel attribute. This value is the WebSphere MQ client channel name to use when connecting to the queue manager or queue-sharing group that this WebSphere MQ server represents. The default value is SYSTEM.DEF.SVRCONN.

-securityAuthAlias
The new value for the overridden **securityAuthAlias** attribute. This value is the authentication alias to use when connecting to a queue manager or queue-sharing group. This parameter is not the same as the discovery authentication alias.

-transportChain
The new value for the overridden **transportChain** attribute. This value is the outbound transport chain to use when establishing a connection with WebSphere MQ. The default value is OutboundBasicWMQClient.

-trustUserIds TRUE | FALSE
The new value for the overridden **trustUserIds** attribute. This value determines whether user identifiers that are received in messages from WebSphere MQ are propagated into the message (that is, whether user identifiers that are received as part of message data are used in the service integration bus). The application user identifier is always set from the **jsAppUserId** RFH2 value. If this is not present (either because the key/value pair is not present in the RFH2 header, or because the message does not have a RFH2 header), this field is not set. If you set this value to FALSE, the user identifier is overwritten with the WebSphere MQ server name. This parameter has two possible values:

TRUE User identifiers are propagated into messages.

FALSE
User identifiers are not propagated into messages.

The default is TRUE.

Example

- Using Jython:

```
wsadmin>AdminTask.modifySIBWMQServerBusMember(["-name", "Finance dept QM-Bus1",
"-bus", "Bus1", "-trustUserIds", "false"])
```

- Using Jacl:

```
wsadmin>$AdminTask modifySIBWMQServerBusMember {-name "Finance dept QM-Bus1"
 -bus Bus1 -trustUserIds false}
```

listSIBWMQServerBusMembers command

Use the listSIBWMQServerBusMembers command to list the WebSphere MQ server bus members known to the bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('SIBAdminCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

Purpose

A WebSphere MQ server represents a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. This command lists the WebSphere MQ server bus members known to the bus.

Target object

The current cell.

Required parameters

-bus
The name of the service integration bus of which the WebSphere MQ server is a member.

Conditional parameters

None

Optional parameters

None

Example

- Using Jython:
  ```
  AdminTask.listSIBWMQServerBusMembers(["-bus", "Bus1"])
  ```
- Using Jacl:
  ```
  $AdminTask listSIBWMQServerBusMembers {-bus Bus1}
  ```

showSIBWMQServerBusMember command

Use the showSIBWMQServerBusMember command to show a list of attributes for a WebSphere MQ server bus member.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Purpose

A WebSphere MQ server represents a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. This command shows details of a WebSphere MQ server bus member as a set of key/value pairs. The command shows details for those attributes that have a value.

Target object

A selected WebSphere MQ server.

Required parameters

-name
The name of the WebSphere MQ server bus member. This value is the name specified in the -name parameter when creating the WebSphere MQ server definition.

-bus
The name of the bus for which the WebSphere MQ server is a member.

Conditional parameters

None

Optional parameters

None

Example

- Using Jython:

  ```
  wsadmin>AdminTask.showSIBWMQServerBusMember(["-name", "Finance Dept. QM-Bus1",
   "-bus", "Bus1"])
  ```

- Using Jacl:

  ```
  wsadmin>$AdminTask showSIBWMQServerBusMember {-name "Finance Dept. QM-Bus1"
   -bus Bus1}
  ```

SIBAdminBusSecurityCommands command group for the AdminTask object

You can use these administrative commands to manage service integration bus security.

These commands provide an alternative to using the administrative console or using the more complex syntax of wsadmin and JACL.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

populateUniqueNames command

Use the populateUniqueNames command to add missing unique names to the authorization policy for a service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The populateUniqueNames command queries the user repository for missing unique names, and adds the missing unique names to the authorization policy for a selected service integration bus.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

Conditional parameters

None.

Optional parameters

-force TRUE | FALSE
Whether to update all unique names, or only those that are missing in the authorization policy. This parameter has two possible values:

TRUE All unique names are updated.

FALSE
Missing unique names only are updated.

The default is FALSE.

Example

The following example queries the user repository for `Bus1` for unique names, and updates all the unique names in the authorization policy.

```
AdminTask.populateUniqueNames('[-bus Bus1 -force TRUE]')
```

listGroupsInBusConnectorRole command

Use the listGroupsInBusConnectorRole command to list all the groups in the connector role for a local bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the listGroupsInBusConnectorRole command to list the groups in the bus connector role for a local bus.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

Conditional parameters

None.

Optional parameters

-showUniqueNames TRUE | FALSE
Whether to display unique names. This parameter has two possible values:

TRUE Unique names are displayed.

FALSE
Security names are displayed.

The default is FALSE.

Example

The following example lists all the groups in the bus connector role for a bus called `Bus1`.

```
AdminTask.listGroupsInBusConnectorRole ('[-bus Bus1]')
```

addGroupToBusConnectorRole command

Use the addGroupToBusConnectorRole command to add a group to the connector role for a local bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the addGroupToBusConnectorRole command to add a group to the bus connector role for a local bus. This command grants the group permission to connect to local destinations.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-group *groupName*
The name of a group you want to add to the bus connector role for the local bus. You can type a specific group name, or use one of the following specialized group names:

Server
This group contains application servers.

AllAuthenticated
This group contains authenticated users only.

Everyone
This group contains all users. Each user is anonymous.

Conditional parameters

None.

Optional parameters

-uniqueName *uniqueName*
Specify the name that uniquely defines the group in the user registry. If an LDAP user registry is in use, the unique name is the distinguished name (DN) for the group. You can specify values for both **-uniqueName** and **-group**, but you must ensure that they identify the same group. The command does not check that the values match.

Examples

The following example adds a group with the group name `Group1`, and the unique name `Group1` to the bus connector role for a bus called `Bus1`.

```
AdminTask.addGroupToBusConnectorRole ('[-bus Bus1  -group Group1 -uniqueName SalesGroup]')
```

The following example adds the `Server` group to the bus connector role for a bus called `Bus1`.

```
AdminTask.addGroupToBusConnectorRole ('[-bus Bus1  -group Server]')
```

The following example adds the `AllAuthenticated` group to the bus connector role for a bus called `Bus1`.

```
AdminTask.addGroupToBusConnectorRole ('[-bus Bus1  -group AllAuthenticated]')
```

The following example adds the `Everyone` group to the bus connector role for a bus called `Bus1`.

```
AdminTask.addGroupToBusConnectorRole ('[-bus Bus1  -group Everyone]')
```

removeGroupFromBusConnectorRole command

Use the removeGroupFromBusConnectorRole command to remove a group from the connector role for a local bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the removeGroupFromBusConnectorRole command to remove a group from the bus connector role for a local bus. Removing a group from this role prevents the group from accessing local destinations, or sending messages to destinations on foreign buses.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-group *groupName* | *uniqueName*
The name of a group you want to remove from the bus connector role for the local bus. You can type one of the following names:

- A security group name, or one of the following specialized group names:

  Server
  This group contains application servers.

  AllAuthenticated
  This group contains authenticated users only.

  Everyone
  This group contains all users. Each user is anonymous.

- A unique group name.

Conditional parameters

None.

Optional parameters

None.

Examples

The following example removes a group called `Group1` from the bus connector role for a bus called `Bus1`.

```
AdminTask.removeGroupFromBusConnectorRole ('[-bus Bus1  -group Group1]')
```

The following example removes the `Server` group from the bus connector role for a bus called `Bus1`.

```
AdminTask.removeGroupFromBusConnectorRole ('[-bus Bus1  -group Server]')
```

listUsersInBusConnectorRole command

Use the listUsersInBusConnectorRole command to list users in the connector role for a local bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the listUsersInBusConnectorRole command to list all the users in the bus connector role for a selected local bus.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

Conditional parameters

None.

Optional parameters

-showUniqueNames TRUE | FALSE
Whether to display unique names. This parameter has two possible values:

TRUE Unique names are displayed.

FALSE
Security names are displayed.

The default is FALSE.

Example

The following example lists users in the bus connector role for a bus called `Bus1`.

```
AdminTask.listUsersInBusConnectorRole ('[-bus Bus1]')
```

addUserToBusConnectorRole command

Use the addUserToBusConnectorRole command to add a user to the connector role for a local bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the addUserToBusConnectorRole command to add a user to the bus connector role for a local bus. This command grants the user permission to connect to local destinations.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-user *userName*
The name of a user you want to add to the bus connector role for the local bus.

Conditional parameters

None.

Optional parameters

-uniqueName *uniqueName*
Specify the name that uniquely defines the user in the user registry. If an LDAP user registry is in use,

the unique name is the distinguished name (DN) for the user. You can specify values for both **-uniqueName** and **-user**, but you must ensure that they identify the same user. The command does not check that the values match.

Examples

The following example adds a user called `User1` to the bus connector role for a bus called `Bus1`.

```
AdminTask.adduserToBusConnectorRole ('[-bus Bus1  -user User1]')
```

removeUserFromBusConnectorRole command

Use the removeUserFromBusConnectorRole command to remove a user from the connector role for a local bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the removeUserFromBusConnectorRole command to remove a user from the bus connector role for a local bus. Removing a user from this role prevents the user from accessing local destinations, or sending messages to destinations on foreign buses.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-user *userName* **or** *uniqueName*
The name of a user you want to remove from the bus connector role for the local bus. You can type one of the following names:

- A security user name.
- A unique user name.

Conditional parameters

None.

Optional parameters

None.

Examples

The following example removes a user called `User1` from the bus connector role for a bus called `Bus1`.

```
AdminTask.removeUserFromBusConnectorRole ('[-bus Bus1  -user User1]')
```

The following example removes the `Server` user from the bus connector role for a bus called `Bus1`.

```
AdminTask.removeUserFromBusConnectorRole ('[-bus Bus1  -user Server]')
```

listGroupsInDefaultRole command

Use the listGroupsInDefaultRole command to list the groups in the default roles for a local bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the listGroupsInDefaultRole command to list the groups in the default roles for a selected local bus.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-role *roleType*
The role type for which you want to list groups.

Sender
This role type is authorized to send messages to destinations on the local bus.

Receiver
This role type is authorized to receive messages from destinations on the local bus.

Browser
This role type is authorized to browse messages on destinations on the local bus.

Creator
This role type is authorized to create messages on destinations on the local bus.

Conditional parameters

None.

Optional parameters

-showUniqueNames TRUE | FALSE
Whether to display unique names. This parameter has two possible values:

TRUE Unique names are displayed.

FALSE
Security names are displayed.

The default is FALSE.

Examples

The following example lists the groups in the `Sender` role for a bus called `Bus1`.

```
AdminTask.listGroupsInDefaultRole ('[-bus Bus1 -role Sender]')
```

addGroupToDefaultRole command

Use the addGroupToDefaultRole command to add a group to the default roles for a local bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the addGroupToDefaultRole command to grant a group default access to all local bus destinations for the specified roles. Adding a group to the default role does not grant access to local destinations where the inheritance of default access is disallowed. To grant access to a local destination where inheritance is disallowed, you must add the group to a destination role. For more information, see "addGroupToDestinationRole command" on page 2398.

You can use this command to define the access control policy for a messaging resource that does not yet exist. This approach ensures that the messaging resource is secure from the moment it is created.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-role *roleType*
The role type to which you want to assign the group. You can assign a group to the following role types:

Sender
This role type is authorized to send messages to destinations on the local bus.

Receiver
This role type is authorized to receive messages from destinations on the local bus.

Browser
This role type is authorized to browse messages on destinations on the local bus.

Creator
This role type is authorized to create messages on destinations on the local bus.

-group *groupName*
The name of a group you want to add to default roles for the local bus. You can type a specific group name, or use one of the following specialized group names:

Server
This group contains application servers.

AllAuthenticated
This group contains authenticated users only.

Everyone
This group contains all users. Each user is anonymous.

Conditional parameters

None.

Optional parameters

-uniqueName *uniqueName*
Specify the name that uniquely defines the group in the user registry. If an LDAP user registry is in use, the unique name is the distinguished name (DN) for the group. You can specify values for both **-uniqueName** and **-group**, but you must ensure that they identify the same group. The command does not check that the values match.

Examples

The following example adds a group with the group name `Group1`, and the unique name `SalesGroup`, to the sender role type for a bus called `Bus1`.

```
AdminTask.addGroupToDefaultRole ('[-bus Bus1 -role Sender -group Group1 uniqueName SalesGroup]')
```

The following example adds the `AllAuthenticated` group to the browser role for a bus called `Bus1`.

```
AdminTask.addGroupToDefaultRole ('[-bus Bus1 -role Browser -group AllAuthenticated]')
```

removeGroupfromDefaultRole command

Use the removeGroupFromDefaultRole command to remove a group from the default roles for a local bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the removeGroupFromDefaultRole command to remove a group from the default roles for a local bus. Removing a group from the default roles prevents access to the local bus in the default roles.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-role *roleType*
The role type from which you want to remove the group.

Sender
This role type is authorized to send messages to destinations on the local bus.

Receiver
This role type is authorized to receive messages from destinations on the local bus.

Browser
This role type is authorized to browse messages on destinations on the local bus.

Creator
This role type is authorized to create messages on destinations on the local bus.

-group *groupName* **or** *uniqueName*
The name of a group you want to remove from the default roles for the local bus. You can type one of the following names:

- A security group name, or one of the following specialized group names:

  Server
  This group contains application servers.

  AllAuthenticated
  This group contains authenticated users only.

  Everyone
  This group contains all users. Each user is anonymous.
- A unique group name.

Conditional parameters

None.

Optional parameters

None.

Examples

The following example removes a group called `Group1` from the default `Sender` role type for a bus called `Bus1`.

```
AdminTask.removeGroupFromDefaultRole ('[-bus Bus1 -role Sender -group Group1]')
```

The following example removes the `AllAuthenticated` group from the default browser role for a bus called `Bus1`.

```
AdminTask.removeGroupFromDefaultRole ('[-bus Bus1 -role Browser -group AllAuthenticated]')
```

listUsersInDefaultRole command

Use the listUsersInDefaultRole command to list users in the default roles for a local bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the listUsersInDefaultRole command to list all the users in the default roles for a selected local bus.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-role *roleType*
The role type for which you want to list users. You can specify the following role types:

Sender
This role type is authorized to send messages to destinations on the local bus.

Receiver
This role type is authorized to receive messages from destinations on the local bus.

Browser
This role type is authorized to browse messages on destinations on the local bus.

Creator
This role type is authorized to create messages on destinations on the local bus.

Conditional parameters

None.

Optional parameters

-showUniqueNames TRUE | FALSE
Whether to display unique names. This parameter has two possible values:

TRUE Unique names are displayed.

FALSE
Security names are displayed.

The default value is FALSE.

Example

The following example lists users in the `Sender` role type for a bus called `Bus1`.

```
AdminTask.listUsersInDefaultRole ('[-bus Bus1 -role Sender]')
```

addUserToDefaultRole command

Use the addUserToDefaultRole command to add a user to the default roles for a local bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the addUserToDefaultRole command to grant a user default access to all local bus destinations for the specified roles. Adding a user to the default role does not grant access to local destinations where the inheritance of default access is disallowed. To grant access to a local destination where inheritance is disallowed, you must add the user to a destination role. For more information, see “addUserToDestinationRole command” on page 2403.

You can use this command to define the access control policy for a messaging resource that does not yet exist. This approach ensures that the messaging resource is secure from the moment it is created.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-role *roleType*
The role type to which you want to assign the user. You can assign a user to the following role types:

Sender
This role type is authorized to send messages to destinations on the local bus.

Receiver
This role type is authorized to receive messages from destinations on the local bus.

Browser
This role type is authorized to browse messages on destinations on the local bus.

Creator
This role type is authorized to create messages on destinations on the local bus.

-user *userName*
The name of a user you want to add to the bus connector role for the local bus.

Conditional parameters

None.

Optional parameters

-uniqueName *uniqueName*
Specify the name that uniquely defines the user in the user registry. If an LDAP user registry is in use, the unique name is the distinguished name (DN) for the user. You can specify values for both **-uniqueName** and **-user**, but you must ensure that they identify the same user. The command does not check that the values match.

Examples

The following example adds a user called `User1` to the sender role type for a bus called `Bus1`.

```
AdminTask.addUserToDefaultRole ('[-bus Bus1 -role Sender -user User1]')
```

removeUserfromDefaultRole command

Use the removeGroupFromDefaultRole command from remove a user from the default roles for a local bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the removeUserFromDefaultRole command to remove user from default roles for a local bus. Removing a user from the default roles prevents access to the local bus in the default roles.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-role *roleType*
The role type you want to remove the user from. You can remove a user from the following role types:

Sender
This role type is authorized to send messages to destinations on the local bus.

Receiver
This role type is authorized to receive messages from destinations on the local bus.

Browser
This role type is authorized to browse messages on destinations on the local bus.

Creator
This role type is authorized to create messages on destinations on the local bus.

-user *userName* **or** *uniqueName*
The name of a user you want to remove from the default roles for the local bus. You can type one of the following names:

- A security user name.
- A unique user name.

Conditional parameters

None.

Optional parameters

None.

Examples

The following example removes a user called `User1` from the `Sender` role type for a bus called `Bus1`.

```
AdminTask removeUserFromDefaultRole ('[-bus Bus1 -role Sender -User User1]')
```

listGroupsInTopicRole command

Use the listGroupsInTopicRole command to list the groups in topic roles for a topic space on a local bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the listGroupsInTopicRole command to list the groups in topic roles for a selected topic in the topic hierarchy for a selected local bus.

You can use this command to define the access control policy for a topic that does not yet exist.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-topicSpace *topicSpaceName*
The name of the topic space.

-topic *topicName*
The name of the topic.

-role *roleType*
You can specify the Sender or Receiver roles for a topic.

Conditional parameters

None.

Optional parameters

-showUniqueNames TRUE | FALSE
Whether to display unique names. This parameter has two possible values:

TRUE Unique names are displayed.

FALSE
Security names are displayed.

The default value is FALSE.

Examples

The following example lists the groups in the `Sender` role for a topic called `football`, in the topic space called `Sport`, on a local bus called `Bus1`.

```
listGroupsInTopicRole { -bus Bus1 -topicSpace Sport -topic football -role Sender}
```

addGroupToTopicRole command

Use the addGroupToTopicRole command to add a group to a topic role within a specified topic space.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the addGroupToTopicRole command to add a group to the sender or receiver roles for a topic anywhere in the topic hierarchy for a local bus. The roles that you specify for the topic are additional to any roles that the topic inherits from its parent in the topic hierarchy.

You can use this command to define the access control policy for a topic that does not yet exist. By defining the access control policy first, you ensure that the topic is secure from the moment it is created.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-topicSpace *topicSpaceName*
The name of the topic space.

-topic *topicName*
The name of the topic.

-role *roleName*
You can specify the Sender or Receiver roles for a topic.

-group *groupName*
The name of the group that you want to add to the sender or receiver roles for a topic. You can specify a group name, or one of the following specialized group names:

Server
This group contains application servers.

AllAuthenticated
This group contains authenticated users only.

Everyone
This group contains all users. Each user is anonymous.

Conditional parameters

None.

Optional parameters

-uniqueName *uniqueName*
Specify the name that uniquely defines the group in the user registry. If an LDAP user registry is in use, the unique name is the distinguished name (DN) for the group. You can specify values for both **-uniqueName** and **-group**, but you must ensure that they identify the same group. The command does not check that the values match.

Examples

The following example adds a group with the group name `Group1`, and the unique name `SalesGroup`, to the `Sender` role for a topic called `football`, in the topic space called `Sport`, on a local bus called `Bus1`.

```
AdminTask.addGroupToTopicRole ('[-bus Bus1 -topicSpace Sport
 -topic football -role Sender -group Group1 -uniqueName SalesGroup]')
```

removeGroupFromTopicRole command

Use the removeGroupFromTopicRole command to remove a group from a topic role within a specified topic space.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('SIBAdminBusSecurityCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the removeGroupFromTopicRole command to remove a group from the sender or receiver roles for a topic anywhere in the topic hierarchy for a local bus. Removing a group from topic roles prevents the group from accessing the topic space in the topic roles.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-topicSpace *topicSpaceName*
The name of the topic space.

-topic *topicName*
The name of the topic.

-role *roleName*
You can specify the Sender or Receiver roles for a topic.

-group *groupName* **or** *uniqueName*
The name of a group you want to remove from the topic roles for the local bus. You can type one of the following names:

- A security group name, or one of the following specialized group names:

  Server
  This group contains application servers.

  AllAuthenticated
  This group contains authenticated users only.

  Everyone
  This group contains all users. Each user is anonymous.
- A unique group name.

Conditional parameters

None.

Optional parameters

None.

Examples

The following example removes a group called `Group1`, from the `Sender` role for a topic called `football`, in the topic space called `Sport`, on a local bus called `Bus1`.

```
removeGroupFromTopicRole { -bus Bus1 -topicSpace Sport -topic football -role Sender -group Group1}
```

listUsersInTopicRole command

Use the listUsersInTopicRole command to list users in the topic roles within a specified topic space.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the listUsersInTopicRole command to list users in the topic roles for a selected topic in the topic hierarchy for a selected local bus.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-topicSpace *topicSpaceName*
The name of the topic space.

-topic *topicName*
The name of the topic.

-role *roleType*
You can specify the Sender or Receiver roles for a topic.

Conditional parameters

None.

Optional parameters

-showUniqueNames TRUE | FALSE
Whether to display unique names. This parameter has two possible values:

TRUE Unique names are displayed.

FALSE
Security names are displayed.

The default is FALSE.

Example

The following example lists the users in the `Sender` role for a topic called `football`, in the topic space called `Sport`, on a local bus called `Bus1`.

```
AdminTask.listUsersInTopicRole ('[-bus Bus1 -topicSpace Sport -topic football -role Sender]')
```

addUserToTopicRole command

Use the addUserToTopicRole command to add a user to a topic role within a specified topic space.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the addUserToTopicRole command to add a user to the sender or receiver roles for a topic anywhere in the topic hierarchy for a local bus. The roles that you specify for the topic are additional to any roles that the topic inherits from its parent in the topic hierarchy.

You can use this command to define the access control policy for a topic that does not yet exist. By defining the access control policy first, you ensure that the topic is secure from the moment it is created.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-topicSpace *topicSpaceName*
The name of the topic space.

-topic *topicName*
The name of the topic.

-role *roleName*
You can specify the Sender or Receiver roles for a topic.

-user *userName*
The name of the user that you want to add to the Sender or Receiver roles for a topic.

Conditional parameters

None.

Optional parameters

-uniqueName *uniqueName*
Specify the name that uniquely defines the user in the user registry. If an LDAP user registry is in use, the unique name is the distinguished name (DN) for the user. You can specify values for both **-uniqueName** and **-user**, but you must ensure that they identify the same user. The command does not check that the values match.

Examples

The following example adds a user called `User1`, to the `Sender` role for a topic called `football`, in the topic space called `Sport`, on a local bus called `Bus1`.

```
Admintask.addUserToTopicRole ('[-bus Bus1 -topicSpace Sport -topic football -role Sender -user User1]')
```

removeUserFromTopicRole command

Use the removeUserFromTopicRole command to remove a user from a topic role within a specified topic space.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the removeUserFromTopicRole command to remove a user from the sender or receiver roles for a topic anywhere in the topic hierarchy for a local bus. Removing a user from topic roles prevents the user from accessing the topic space in the topic roles.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-topicSpace *topicSpaceName*
The name of the topic space.

-topic *topicName*
The name of the topic.

-role *roleType*
You can specify the Sender or Receiver roles for a topic.

-user *userName* **or** *uniqueName*
The name of a user you want to remove from the topic roles for the local bus. You can type one of the following names:

- A security user name.
- A unique user name.

Conditional parameters

None.

Optional parameters

None.

Examples

The following example removes a user called `User1`, from the `Sender` role for a topic called `footbal`l, in the topic space called `Sport`, on a local bus called `Bus1`.

```
AdminTask.removeUserFromTopicRole ('[-bus Bus1 -topicSpace Sport
 -topic football -role Sender -user User1]')
```

listGroupsInTopicSpaceRootRole command

Use the listGroupInTopicSpaceRootRole command to list all the groups in topic space roles on the topic space root for a local bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('SIBAdminBusSecurityCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the listGroupsInTopicRootSpaceRole command to list groups in topic space root roles for a selected topic space on a selected local bus.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-topicSpace *topicSpaceName*
The name of the topic space.

-role *roleType*
You can specify the Sender or Receiver roles for a topic.

Conditional parameters

None.

Optional parameters

-showUniqueNames TRUE | FALSE
Whether to display unique names. This parameter has two possible values:

TRUE Unique names are displayed.

FALSE
Security names are displayed.

The default is FALSE.

Examples

The following example lists groups in the `Sender` role for the topic space root, for a topic space called `Sport`, on a local bus called `Bus1`.

```
AdminTask.listGroupsInTopicSpaceRootRole ('[-bus Bus1 -topicSpace Sport -role Sender]')
```

addGroupToTopicSpaceRootRole command

Use the addGroupToTopicSpaceRootRole command to add a group to topic space roles on the topic space root.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the addGroupToTopicRootSpaceRole command to grant a group permission to access the topic space root in the sender and receiver roles. This is in addition to any access permissions granted to the topics in the topic space.

You can use this command to define the access control policy for a topic that does not yet exist. By defining the access control policy first, you ensure that the topic is secure from the moment it is created.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-topicSpace *topicSpaceName*
The name of the topic space.

-role *roleName*
You can specify the Sender or Receiver roles for a topic.

-group *groupName*
The name of the group that you want to add to the Sender or Receiver roles for the topic space root. You can specify a group name, or one of the following specialized group names:

Server
This group contains application servers.

AllAuthenticated
This group contains authenticated users only.

Everyone
This group contains all users. Each user is anonymous.

Conditional parameters

None.

Optional parameters

-uniqueName *uniqueName*
Specify the name that uniquely defines the group in the user registry. If an LDAP user registry is in use, the unique name is the distinguished name (DN) for the group. You can specify values for both **-uniqueName** and **-group**, but you must ensure that they identify the same group. The command does not check that the values match.

Examples

The following example adds a group called `Group1`, and the unique name `SalesGroup` to the `Sender` role for the topic space root, for a topic space called `Sport`, on a local bus called `Bus1`.

```
AdminTask.addGroupToTopicSpaceRootRole ('[-bus Bus1 -topicSpace Sport
 -role Sender -group Group1 uniqueName SalesGroup]')
```

removeGroupFromTopicSpaceRootRole command

Use the removeGroupFromTopicSpaceRootRole command to remove a group from access roles on the topic space root.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the removeGroupFromTopicSpaceRootRole command to remove a group from the Sender and Receiver roles for the topic space root.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-topicSpace *topicSpaceName*
The name of the topic space.

-role *roleName*
You can specify the Sender or Receiver roles for a topic.

-group *groupName* **or** *uniqueName*
The name of a group you want to remove from the topic space root roles for the local bus. You can type one of the following names:

- A security group name, or one of the following specialized group names:

  Server
  This group contains application servers.

  AllAuthenticated
  This group contains authenticated users only.

  Everyone
  This group contains all users. Each user is anonymous.

- A unique group name.

Conditional parameters

None.

Optional parameters

None.

Examples

The following example removes a group called `Group1` from the `Sender` role for the topic space root, for a topic space called `Sport`, on a local bus called `Bus1`.

```
AdminTask.removeGroupFromTopicSpaceRootRole ('[-bus Bus1 -topicSpace Sport -role Sender -group Group1]')
```

listUsersInTopicSpaceRootRole command

Use the listUsersInTopicSpaceRootRole command to list the users in the sender and receiver roles on the topic space root.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the listUsersInTopicSpaceRootRole command to list users in the topic space root roles for a selected local bus.

Target object

None.

Required parameters

-bus *busName*

The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-topicSpace *topicSpaceName*
The name of the topic space.

-role *roleType*
You can specify the Sender or Receiver roles for the topic space root.

Conditional parameters

None.

Optional parameters

-showUniqueNames TRUE | FALSE
Whether to display unique names. This parameter has two possible values:

TRUE Unique names are displayed.

FALSE
Security names are displayed.

The default value is FALSE.

Example

The following example lists users in the `Sender` role for the topic space root, for a topic space called `Sport`, on a local bus called `Bus1`.

```
Admin.TasklistUsersInTopicSpaceRootRole { -bus Bus1 -topicSpace Sport -role Sender}
```

addUserToTopicSpaceRootRole command

Use the addUserToTopicSpaceRootRole command to add a user to the sender and receiver roles on the topic space root.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('SIBAdminBusSecurityCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the addUserToTopicSpaceRootRole command to grant a user permission to access the topic space root in the sender and receiver roles. This is in addition to any access permissions granted to the topics in the topic space.

You can use this command to define the access control policy for a topic that does not yet exist. By defining the access control policy first, you ensure that the topic is secure from the moment it is created.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-topicSpace *topicSpaceName*
The name of the topic space.

-role *roleName*
You can specify the Sender or Receiver roles for the topic space root.

-user *userName*
The name of the user that you want to add to the Sender or Receiver roles for the topic space root.

Conditional parameters

None.

Optional parameters

-uniqueName *uniqueName*
Specify the name that uniquely defines the user in the user registry. If an LDAP user registry is in use, the unique name is the distinguished name (DN) for the user. You can specify values for both **-uniqueName** and **-user**, but you must ensure that they identify the same user. The command does not check that the values match.

Examples

The following example adds a user called `User1`, to the `Sender` role for the topic space root, for a topic space called `Sport`, on a local bus called `Bus1`.

```
AdminTask.addUserToTopicSpaceRootRole  ('[-bus Bus1 -topicSpace Sport -role Sender -user User1]')
```

removeUserFromTopicSpaceRootRole command

Use the removeUserFromTopicSpaceRootRole command to remove a user from access roles on the topic space root.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the removeUserFromTopicSpaceRootRole command to remove a user from the Sender and Receiver roles for the topic space root.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-topicSpace *topicSpaceName*
The name of the topic space.

-role *roleType*
You can specify the Sender or Receiver roles for a topic.

-user *userName* **or** *uniqueName*
The name of a user you want to remove from the topic space root roles for the local bus.

Conditional parameters

None.

Optional parameters

None.

Examples

The following example removes a user called `User1` from the `Sender` role for the topic space root, for a topic space called `Sport`, on a local bus called `Bus1`.

```
AdminTask.removeUserFromTopicSpaceRootRole ('[-bus Bus1 -topicSpace Sport -role Sender -user User1]')
```

listGroupsInDestinationRole command

Use the listGroupsInDestinationRole command to list the groups in the destination roles for a local bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the listGroupsInDestinationRole command to list all the groups in destination roles for a selected local bus. The roles you can specify depend on the type of destination.

Target object

None.

Required parameters

-type *destinationType*

You can specify one of the following destination types:

- Queue
- Port
- TopicSpace
- ForeignDestination
- Alias

The allowed roles for a destination depend on the type of the destination as defined in “Administering destination roles” on page 1991.

If you are specifying a *destinationType* that is either foreignDestination or alias, the foreign bus name that you specify must be the name of the foreign bus hosting the destination.

If you specify a *destinationType* of queue or topic, the foreign bus name is ignored. The authorization is granted against the destination in the local bus.

-bus *busName*

The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-role *roleType*

You can specify one of the following role types, depending on the **-type** you have specified.

Sender

This role type is authorized to send messages to destinations on the local bus.

Receiver

This role type is authorized to receive messages from destinations on the local bus.

Browser

This role type is authorized to browse messages on destinations on the local bus.

Conditional parameters

None.

Optional parameters

-showUniqueNames TRUE | FALSE
Whether to display unique names. This parameter has two possible values:

TRUE Unique names are displayed.

FALSE
Security names are displayed.

The default value is FALSE.

Examples

The following example lists groups in the `Sender` role for a queue type destination called `Queue1`, on a local bus called `Bus1`.

```
AdminTask.listGroupsInDestinationRole ('[-type queue -bus Bus1 -destination Queue1 -role Sender]')
```

The following example lists groups in the `Receiver` role for a queue type destination called `Queue2`, on a local bus called `Bus1`.

```
AdminTask.listGroupsInDestinationRole ('[-type queue -bus BusName -destination Queue2 -role Receiver]')
```

---

addGroupToDestinationRole command

Use the addGroupToDestinationRole command to add a group to the destination roles for a local or foreign bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('SIBAdminBusSecurityCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the addGroupToDestinationRole command to grant a group access to local bus destinations for the specified roles. The roles you can specify depend on the type of destination.

Target object

None.

Required parameters

-type *destinationType*
You can specify one of the following destination types:

- Queue
- Port
- TopicSpace
- ForeignDestination
- Alias

The allowed roles for a destination depend on the type of the destination as defined in “Administering destination roles” on page 1991.

If you are specifying a *destinationType* that is either foreignDestination or alias, the foreign bus name that you specify must be the name of the foreign bus hosting the destination.

If you specify a *destinationType* of queue or topic, the foreign bus name is ignored. The authorization is granted against the destination in the local bus.

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-role *roleType*
You can specify one of the following role types, depending on the **-type** you have specified.

Sender
This role type applies to alias, foreignDestination, port, queue, and topicSpace destination types.

Receiver
This role type applies to alias, port, queue, and topicSpace destination types.

Browser
This role type applies to alias, port, and queue destination types.

-group *groupName*
The name of the group that you want to add to the destination role type for the local bus. You can specify a group name, or one of the following specialized group names:

Server
This group contains application servers.

AllAuthenticated
This group contains authenticated users only.

Everyone
This group contains all users. Each user is anonymous.

Conditional parameters

None.

Optional parameters

-foreignBus *foreignBusName*
Specify the name of the foreign bus. If you are adding a group to a destination on a foreign destination or an alias, you must specify the name of the foreign bus that hosts the foreign destination or the alias.

-uniqueName *uniqueName*
This parameter is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions. Specify the name that uniquely defines the group in the user registry. If an LDAP user registry is in use, the unique name is the distinguished name (DN) for the group. You can specify values for both **-uniqueName** and **-group**, but you must ensure that they identify the same group. The command does not check that the values match.

Examples

The following example adds a group with the group name `Group1`, and the unique name `SalesGroup` to the sender role on a queue type destination called `Queue1`, on a local bus called `Bus1`.

```
AdminTask.addGroupToDestinationRole ('[-type queue -bus Bus1
 -destination Queue1 -role Sender -group Group1 -uniqueName SalesGroup]')
```

The following example adds a group called `Group2` to the receiver role on a queue type destination called `Queue2`, on a local bus called `Bus1`.

```
AdminTask.addGroupToDestinationRole ('[-type queue -bus Bus1
 -destination Queue2 -role Receiver -group Group2]')
```

removeGroupFromDestinationRole command

Use the removeGroupFromDestinationRole command to remove a group from the destination roles for a local or foreign bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  `print AdminTask.help('SIBAdminBusSecurityCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:

  `print AdminTask.help('`*command_name*`')`

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the removeGroupFromDestinationRole command remove a group from destination roles for a selected local bus. By removing a group from destination roles, you prevent the group from accessing the local bus.

Target object

None.

Required parameters

-type *destinationType*

You can specify one of the following destination types:

- Queue
- Port
- TopicSpace
- ForeignDestination
- Alias

The allowed roles for a destination depend on the type of the destination as defined in “Administering destination roles” on page 1991.

If you are specifying a *destinationType* that is either foreignDestination or alias, the foreign bus name that you specify must be the name of the foreign bus hosting the destination.

If you specify a *destinationType* of queue or topic, the foreign bus name is ignored. The authorization is granted against the destination in the local bus.

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-role *roleType*
You can specify one of the following role types, depending on the *destinationType* you have specified.

Sender
This role type is authorized to send messages to destinations on the local bus.

Receiver
This role type is authorized to receive messages from destinations on the local bus.

Browser
This role type is authorized to browse messages on destinations on the local bus.

-group *groupName* **or** *uniqueName*
The name of a group you want to remove from the destination roles for the local bus. You can type one of the following names:

- A security group name, or one of the following specialized group names:

  Server
  This group contains application servers.

  AllAuthenticated
  This group contains authenticated users only.

  Everyone
  This group contains all users. Each user is anonymous.
- A unique group name.

Conditional parameters

None.

Optional parameters

-foreignBus *foreignBusName*
Specify the name of the foreign bus. If you are removing a group from a destination role on a foreign destination or an alias, you must specify the name of the foreign bus that hosts the foreign destination or the alias.

Examples

The following example removes a group called `Group1` from the `Sender` role for a queue type destination called `Queue1`, on a local bus called `Bus1`.

```
removeGroupFromDestinationRole { -type queue -bus Bus1
 -destination Queue1 -role Sender -group Group1}
```

The following example removes a group called `Group2` from the `Receiver` role for a queue type destination called `Queue2`, on a local bus called `Bus1`.

```
removeGroupFromDestinationRole { -type queue -bus Bus1
 -destination Queue2 -role Receiver -group Group2}
```

listUsersInDestinationRole command

Use the listUsersInDestinationRole command to list users in the destination roles for a local bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the listUsersInDestinationRole command list the users in destination roles for a selected local bus. The roles you can specify depend on the type of destination.

Target object

None.

Required parameters

-type *destinationType*

You can specify one of the following destination types:

- Queue
- Port
- TopicSpace
- ForeignDestination
- Alias

The allowed roles for a destination depend on the type of the destination as defined in “Administering destination roles” on page 1991.

If you are specifying a *destinationType* that is either foreignDestination or alias, the foreign bus name that you specify must be the name of the foreign bus hosting the destination.

If you specify a *destinationType* of queue or topic, the foreign bus name is ignored. The authorization is granted against the destination in the local bus.

-bus *busName*

The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-role *roleType*

You can specify one of the following role types, depending on the **-type** you have specified.

Sender
This role type applies to alias, foreignDestination, port, queue, and topicSpace destination types.

Receiver
This role type applies to alias, port, queue, and topicSpace destination types.

Browser
This role type applies to alias, port, and queue destination types.

Conditional parameters

None.

Optional parameters

-foreignBus *foreignBusName*
Specify the name of the foreign bus if you have specified a ForeignDestination or Alias destination type.

-showUniqueNames TRUE | FALSE
Whether to display unique names. This parameter has two possible values:

TRUE Unique names are displayed.

FALSE
Security names are displayed.

The default is FALSE.

Example

The following example lists users in the `Sender` role on a queue type destination called `Queue1`, on a local bus called `Bus1`.

```
AdminTask.listUsersInDestinationRole ('[-type queue -bus Bus1 -destination Queue1 -role Sender]')
```

addUserToDestinationRole command

Use the addUserToDestinationRole command to add a user to the destination roles for a local or foreign bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the addUserToDestinationRole command grant a user access to local bus destinations for the specified roles. The roles you can specify depend on the type of destination.

Target object

None.

Required parameters

-type *destinationType*
You can specify one of the following destination types:

- Queue
- Port
- TopicSpace
- ForeignDestination
- Alias

The allowed roles for a destination depend on the type of the destination as defined in “Administering destination roles” on page 1991.

If you are specifying a *destinationType* that is either foreignDestination or alias, the foreign bus name that you specify must be the name of the foreign bus hosting the destination.

If you specify a *destinationType* of queue or topic, the foreign bus name is ignored. The authorization is granted against the destination in the local bus.

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-role *roleType*
You can specify one of the following role types, depending on the **-type** you have specified.

Sender
This role type is authorized to send messages to destinations on the local bus.

Receiver
This role type is authorized to receive messages from destinations on the local bus.

Browser
This role type is authorized to browse messages on destinations on the local bus.

-user *userName*
The name of the user that you want to add to the destination role type for the local bus.

Conditional parameters

None.

Optional parameters

-foreignBus *foreignBusName*
Specify the name of the foreign bus. If you are adding a user to a destination on a foreign destination or an alias, you must specify the name of the foreign bus that hosts the foreign destination or the alias.

-uniqueName *uniqueName*
This parameter is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions. Specify the name that uniquely defines the user in the user registry. If an LDAP user registry is in use, the unique name is the distinguished name

(DN) for the user. You can specify values for both **-uniqueName** and **-user**, but you must ensure that they identify the same user. The command does not check that the values match.

Examples

The following example adds a user called `User1` to the sender role on a queue type destination called `Queue1`, on a local bus called `Bus1`.

```
Admintask.addUserToDestinationRole ('[-type queue -bus Bus1
 -destination Queue1 -role Sender -user User1]')
```

The following example adds a user called `User2` to the receiver role on a queue type destination called `Queue2`, on a local bus called `Bus1`.

```
Admintask.addUserToDestinationRole ('[-type queue -bus Bus1
 -destination Queue2 -role Receiver -user User2]')
```

removeUserFromDestinationRole command

Use the removeUserFromDestinationRole command to remove a user from the destination roles for a local or foreign bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the removeUserFromDestinationRole command to remove a user from destination roles for a selected local bus. By removing a user from destination roles, you prevent the user from accessing the local bus.

Target object

None.

Required parameters

-type *destinationType*
You can specify one of the following destination types:

- Queue
- Port
- TopicSpace
- ForeignDestination

- Alias

The allowed roles for a destination depend on the type of the destination as defined in “Administering destination roles” on page 1991.

If you are specifying a *destinationType* that is either foreignDestination or alias, the foreign bus name that you specify must be the name of the foreign bus hosting the destination.

If you specify a *destinationType* of queue or topic, the foreign bus name is ignored. The authorization is granted against the destination in the local bus.

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-role *roleType*
You can specify one of the following role types, depending on the **-type** you have specified.

Sender
This role type is authorized to send messages to destinations on the local bus.

Receiver
This role type is authorized to receive messages from destinations on the local bus.

Browser
This role type is authorized to browse messages on destinations on the local bus.

-user *userName* **or** *uniqueName*
The name of a user you want to remove from the destination roles for the local bus. You can type one of the following names:

- A security user name.
- A unique user name.

Conditional parameters

None.

Optional parameters

-foreignBus *foreignBusName*
Specify the name of the foreign bus. If you are removing a user from a destination role on a foreign destination or an alias, you must specify the name of the foreign bus that hosts the foreign destination or the alias.

Examples

The following example removes a user called `User1` from the `Sender` role for a queue type destination called `Queue1`, on a local bus called `Bus1`.

```
AdminTask.removeUserFromDestinationRole ('[-type queue -bus Bus1
 -destination Queue1 -role Sender -user User1]')
```

The following example removes a user called `User2` from the `Receiver` role for a queue type destination called `Queue2`, on a local bus called `Bus1`.

```
AdminTask.removeUserFromDestinationRole ('[-type queue -bus Bus1
 -destination Queue2 -role Receiver -user User2]')
```

listGroupsInForeignBusRole command

Use the listGroupsInForeignBusRole command to list the groups in the sender role for a foreign bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the listGroupsInForeignBusRole command to list the groups that can send messages from a local bus to a foreign bus.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-foreignBus *foreignBusName*
The name of the foreign bus.

-role Sender
You can only specify the Sender role for a foreign bus.

Conditional parameters

None.

Optional parameters

-showUniqueNames TRUE | FALSE
Whether to display unique names. This parameter has two possible values:

TRUE Unique names are displayed.

FALSE
Security names are displayed.

The default value is FALSE.

Examples

The following example lists the groups in the `Sender` role for a foreign bus called `ForeignBus1`. The local bus is called `Bus1`.

```
AdminTask.listGroupsInForeignBusRole ('[-bus Bus1 -foreignBus ForeignBus1 -role Sender]')
```

addGroupToForeignBusRole command

Use the addGroupToForeignBusRole command to grant a group permission to access a foreign bus from a local bus, in the sender role.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the addGroupToForeignBusRole command to grant a group permission to send messages from a local bus to a foreign bus.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-foreignBus *foreignBusName*
The name of the foreign bus.

-role *Sender*
You can only specify the Sender role for a foreign bus.

-group *groupName*
The name of the group that you want to add to the sender role for the foreign bus. You can specify a group name, or one of the following specialized group names:

Server
This group contains application servers.

All Authenticated
This group contains authenticated users only.

Everyone
This group contains all users. Each user is anonymous.

Conditional parameters

None.

Optional parameters

-uniqueName *uniqueName*
Specify the name that uniquely defines the group in the user registry. If an LDAP user registry is in use, the unique name is the distinguished name (DN) for the group. You can specify values for both **-uniqueName** and **-group**, but you must ensure that they identify the same group. The command does not check that the values match.

Examples

The following example adds a group with the group name `Group1`, and the unique name `SalesGroup` to the sender role for a foreign bus called `ForeignBus1`. The local bus is called `Bus1`.

```
AdminTask.addGroupToForeignBusRole ('[-bus Bus1 -ForeignBus ForeignBus1
 -role Sender -group Group1 -uniqueName SalesGroup]')
```

removeGroupFromForeignBusRole command

Use the removeGroupFromForeignBusRole command to remove a group from the sender role for a foreign bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('SIBAdminBusSecurityCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the removeGroupFromForeignBusRole command to remove a group from the sender role for a foreign bus. This prevents the group from sending messages from a local bus to a foreign bus.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-foreignBus *foreignBusName*
The name of the foreign bus.

-role Sender
You can only specify the Sender role for a foreign bus.

-group *groupName* **or** *uniqueName*
The name of a group you want to remove from the sender role for a foreign bus. You can type one of the following names:

- A security group name, or one of the following specialized group names:

  Server
  This group contains application servers.

  AllAuthenticated
  This group contains authenticated users only.

  Everyone
  This group contains all users. Each user is anonymous.
- A unique group name.

Conditional parameters

None.

Optional parameters

None.

Examples

The following example removes a group called `Group1` from the `Sender` role for a foreign bus called `ForeignBus1`. The local bus is called `Bus1`.

```
AdminTask.removeGroupFromForeignBusRole ('[-bus Bus1 -ForeignBus ForeignBus1 -role Sender -group Group1]')
```

listUsersInForeignBusRole command

Use the listUsersInForeignBusRole command to list users that can send messages from a local bus to a foreign bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the listUsersInForeignBusRole command to list all the users that can send messages from a selected local bus to a selected foreign bus.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-foreignBus *foreignBusName*
The name of the foreign bus.

-role Sender
You can specify the Sender role only for a foreign bus.

Conditional parameters

None.

Optional parameters

-showUniqueNames TRUE | FALSE
Whether to display unique names. This parameter has two possible values:

TRUE Unique names are displayed.

FALSE
Security names are displayed.

The default value is FALSE.

Example

The following example lists users in the `Sender` role for a foreign bus called `ForeignBus1`. The local bus is called `Bus1`.

```
AdminTask.listUsersInForeignBusRole ('[-bus Bus1 -foreignBus ForeignBus1 -role Sender],)
```

addUserToForeignBusRole command

Use the addUserToForeignBusRole command to grant a user permission to access a foreign bus from a local bus, in the sender role.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the addUserToForeignBusRole command grant a user permission to send messages from a local bus to a foreign bus.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-foreignBus *foreignBusName*
The name of the foreign bus.

-role Sender
You can specify the Sender role only for a foreign bus.

-user *userName*
The name of the user that you want to add to the Sender role for the foreign bus.

Conditional parameters

None.

Optional parameters

-uniqueName *uniqueName*
Specify the name that uniquely defines the user in the user registry. If an LDAP user registry is in use, the unique name is the distinguished name (DN) for the user. You can specify values for both **-uniqueName** and **-user**, but you must ensure that they identify the same user. The command does not check that the values match.

Examples

The following example adds a user called `User1` to the `Sender` role for a foreign bus called `ForeignBus1`. The local bus is called `Bus1`.

```
AdminTask.addUserToForeignBusRole ('[-bus Bus1 -foreignBus ForeignBus1 -role Sender -user User1]')
```

removeUserFromForeignBusRole command

Use the removeUserFromForeignBusRole command to remove a user from the sender role for a foreign bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the removeUserFromForeignBusRole command to remove a user from the sender role for a foreign bus. This prevents the user from sending messages from a local bus to a foreign bus.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-foreignBus *foreignBusName*
The name of the foreign bus.

-role Sender
You can only specify the Sender role for a foreign bus.

-user *userName* **or** *uniqueName*
The name of a user you want to remove from the sender role for a foreign bus. You can type one of the following names:

- A security user name
- A unique user name.

Conditional parameters

None.

Optional parameters

None.

Examples

The following example removes a user called `User1` from the `Sender` role for a foreign bus called `ForeignBus1`. The local bus is called `Bus1`.

```
AdminTask.removeUserFromForeignBusRole ('[-bus Bus1 -ForeignBus ForeignBus1 -role Sender -user User1]')
```

removeGroupFromAllRoles command

Use the removeGroupFromAllRoles command to remove a group from all access roles for a local bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the removeGroupFromAllRoles command to remove a group from all access roles for a local bus. This prevents the group from accessing the local bus.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-group *groupName*
The name of the group that you want to remove from all roles for the bus. You can specify a group name, or one of the following specialized group names:

Server
This group contains application servers.

AllAuthenticated
This group contains authenticated users only.

Everyone
This group contains all users. Each user is anonymous.

Conditional parameters

None.

Optional parameters

None.

Examples

The following example removes a group called `Group1` from all roles for a local bus called `Bus1`.

```
removeGroupFromAllRoles { -bus Bus1 -group Group1}
```

removeUserFromAllRoles command

Use the removeUserFromAllRoles command to remove a user from all access roles for a local bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

Use the removeUserFromAllRoles command to remove a user from all access roles for a local bus. This prevents the user from accessing the local bus.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-user *userName* **or** *uniqueName*
The name of a user you want to remove from the bus connector role for the local bus. You can type one of the following names:

- A security group name.
- A unique group name.

Conditional parameters

None.

Optional parameters

None.

Examples

The following example removes a user called `User1` from all roles for a local bus called `Bus1`.

```
AdminTask.removeUserFromAllRoles ('[-bus Bus1 -user User1]')
```

Determining destination defaults inheritance by using the wsadmin tool

By default, the inheritance of default permissions by destinations is allowed for all local destinations. Use this command to determine whether the inheritance of default permissions is enabled or disabled for a local destination.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Command

To determine whether a specified destination inherits default destination user roles, use the following command:

- Using Jython:

  ```
  AdminTask.isInheritDefaultsForDestination("-type destinationType -bus busName
   -destination destinationName")
  ```

- Using Jacl:

  ```
  $AdminTask isInheritDefaultsForDestination {-type destinationType -bus busName
   -destination destinationName}
  ```

This command will return either `True` or `False`.

Defining destination defaults inheritance by using the wsadmin tool

By default, the inheritance of default permissions by destinations is allowed for all local destinations. Use this command to override inheritance for an individual destination, or to restore default inheritance in cases where you have previously overridden it.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Command

Note: When a user or group tries to access a destination for which you have overridden default inheritance, the default permissions are not checked. Only the permissions that you specify for the destination itself are checked.

To override or restore the inheritance of default permissions for a destination, use the following command:

- Using Jython:

  ```
  AdminTask.setInheritDefaultsForDestination("-type destinationType -bus busName
   -destination destinationName -inherit <true|false>")
  ```

- Using Jacl:

  ```
  $AdminTask setInheritDefaultsForDestination {-type destinationType -bus busName
   -destination destinationName -inherit <true|false>}
  ```

The *destinationType* must be a local destination type: *foreignDestination* is not allowed.

Set **-inherit** to false to override defaults inheritance, or to true to restore defaults inheritance.

Defining topic role inheritance by using the wsadmin tool

Use these commands to define the inheritance of topic roles by child topics within a topic hierarchy.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Commands

Defining Sender role inheritance

To set or disable Sender role inheritance for a topic within the specified topic space, use the following command:

- Using Jython:

  ```
  AdminTask.setInheritSenderForTopic("-bus busName
   -topicSpace topicSpaceName
   -topic topicName -inherit <true|false>")
  ```
- Using Jacl:

  ```
  $AdminTask setInheritSenderForTopic {-bus busName
   -topicSpace topicSpaceName
   -topic topicName -inherit <true|false>}
  ```

Defining Receiver role inheritance

To set or disable Receiver role inheritance for a topic within the specified topic space, use the following command:

- Using Jython:

  ```
  AdminTask.setInheritReceiverForTopic("-bus busName
   -topicSpace topicSpaceName -topic topicName
   -inherit <true|false>")
  ```
- Using Jacl:

  ```
  $AdminTask setInheritReceiverForTopic {-bus busName
   -topicSpace topicSpaceName
   -topic topicName -inherit <true|false>}
  ```

Determining topic role inheritance by using the wsadmin tool

Use these commands to list whether the child topics within a topic hierarchy currently have inheritance set or disabled.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Commands

Determining Inherit Receiver for Topic

To determine whether a role is inheritance Receiver for a topic within the specified topic space, use the following command:

- Using Jython:

```
AdminTask.isInheritReceiverForTopic("-bus busName -type typeName
 -destination destinationName")
```

- Using Jacl:

```
$AdminTask isInheritReceiverForTopic {-bus busName -type typeName
 -destination destinationName}
```

Determining Inherit Sender for Topic

To determine whether a role is inheritance Sender for a topic within the specified topic space, use the following command:

- Using Jython:

```
AdminTask.isInheritSenderForTopic("-bus busName -type typeName
 -destination destinationName")
```

- Using Jacl:

```
$AdminTask isInheritSenderForTopic {-bus busName -type typeName
 -destination destinationName}
```

Listing security roles for service integration by using the wsadmin tool

When you are administering messaging security, use these commands to list the security roles that are associated with service integration bus destinations, foreign buses, topics within a topic space, users and groups.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Commands

Listing all destinations with roles

To list all destinations that have roles defined for them, use the following command:

- Using Jython:

```
AdminTask.listAllDestinationsWithRoles("-bus busname
 -type destinationType")
```

- Using Jacl:

```
$AdminTask listAllDestinationsWithRoles {-bus busname
 -type destinationType}
```

Listing all foreign buses with roles

To list all foreign buses that have roles defined for them, use the following command:

- Using Jython:

```
AdminTask.listAllForeignBusesWithRoles("-bus busname")
```

- Using Jacl:

```
$AdminTask listAllForeignBusesWithRoles {-bus busname}
```

Listing all topics within a topic space with roles

To list all topics within a topic space that have roles defined for them, use the following command:

- Using Jython:

```
AdminTask.listAllTopicsWithRoles("-bus busname
 -topicSpace topicSpaceName")
```

- Using Jacl:

```
$AdminTask listAllTopicsWithRoles {-bus busname
 -topicSpace topicSpaceName}
```

Listing user roles

To list all the roles that a user belongs to, use the following command in wsadmin:

- Using Jython:

```
AdminTask.listAllRolesForUser("-bus busname -user userName")
```

- Using Jacl:

```
$AdminTask listAllRolesForUser {-bus busname -user userName}
```

Listing group roles

To list all the roles that a group belongs to, use the following command in wsadmin:

- Using Jython:

```
AdminTask.listAllRolesForGroup("-bus busname -group groupName")
```

- Using Jacl:

```
$AdminTask listAllRolesForGroup {-bus busname -group groupName}
```

Removing users and groups by using the wsadmin tool

Use these commands to remove a user or group. Removing a user or group withdraws the authorization permissions for all roles to which they have previously been added.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBAdminBusSecurityCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Commands

Removing a user

To remove a user from all the roles that they belong to, use the following command:

- Using Jython:

  ```
  AdminTask.removeUserFromAllRoles("-bus busname -user userName")
  ```

- Using Jacl:

  ```
  $AdminTask removeUserFromAllRoles {-bus busname -user userName}
  ```

Removing a group

To remove a group from all the roles that it belongs to, use the following command:

- Using Jython:

  ```
  AdminTask.removeGroupFromAllRoles("-bus busname -group groupName")
  ```

- Using Jacl:

  ```
  $AdminTask removeGroupFromAllRoles {-bus busname -group groupName}
  ```

After using these commands, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Removing authorization data by using the wsadmin tool

Use these commands to remove authorization data for the default roles, or for a destination or a foreign bus.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminBusSecurityCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Commands

Removing authorization data for the defaults

To remove all users and groups from every role (sender, receiver and so on) in the defaults, use the following command:

- Using Jython:

```
AdminTask.removeDefaultRoles("-bus busname")
```

- Using Jacl:

```
$AdminTask removeDefaultRoles {-bus busname}
```

Removing all authorization data for a destination

To delete all authorization data for a destination, use the following command:

- Using Jython:

```
AdminTask.removeDestinationRoles("-type destinationType -bus busname
 -foreignBus foreignBusName -destination destinationName")
```

- Using Jacl:

```
AdminTask.removeDestinationRoles("-type destinationType -bus busname
 -foreignBus foreignBusName -destination destinationName")
```

Notes:

- This command deletes all authorization data for the specified destination. If the destination is a topic space, the command removes all authorization data for the virtual root and for the topics within the topic space, as well as for the topic space itself.
- You can use this command if you are deleting the destination and want to remove all associated authorization permissions, or if you want to block all access to a destination by removing all authorization permissions for it. In this second case a user might still be able to access the destination if they have been granted default authorization permissions. If you have specified default authorization permissions and you want to block all access to the destination, you must stop the destination inheriting the default permissions by using the command `setInheritDefaultsForDestinations` (see “Defining destination defaults inheritance by using the wsadmin tool” on page 2417). You should use the `removeDestinationRoles` command first, followed by the `setInheritDefaultsForDestinations` command.

Removing all authorization data for a foreign bus

To delete all authorization data for the specified foreign bus, use the following command:

- Using Jython:

```
AdminTask.removeForeignBusRoles("-bus busname
 -foreignBus foreignBusName")
```

- Using Jacl:

```
$AdminTask removeForeignBusRoles {-bus busname
 -foreignBus foreignBusName}
```

After using these commands, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

listSIBPermittedChain command

Use the listSIBPermittedChain command to list the permitted transport chains for a service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('SIBAdminBusSecurityCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The listSIBPermittedChain command lists the permitted transport chains for a selected service integration bus.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

Conditional parameters

None.

Optional parameters

None.

Example

The following example lists the permitted transport chains for a bus called `Bus1`.

```
AdminTask.listSIBPermittedChain('[-bus Bus1]')
```

addSIBPermittedChain command

Use the addSIBPermittedChain command to add a new transport mechanism to the list of permitted transports for a service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('SIBAdminBusSecurityCommands')`

- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The addSIBPermittedChain command add a new transport chain to the list of permitted transports for a selected service integration bus.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-chain *chainName*
The name of the transport chain you want to add to the list of permitted transports.

Conditional parameters

None.

Optional parameters

None.

Example

The following example adds the transport chain `MyTransportChain` to a bus called `Bus1`.

```
AdminTask.addSIBPermittedChain('[-bus Bus1 -chain MyTransportChain]')
```

removeSIBPermittedChain command

Use the removeSIBPermittedChain command to remove a selected transport chain from the list of permitted transport chains for a selected service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

This command is valid only when used with WebSphere Application Server Version 7.0 or later application servers. Do not use it with earlier versions.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus security commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('SIBAdminBusSecurityCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The removeSIBPermittedChain command removes a selected transport chains from the list of permitted transport chains for a selected service integration bus.

Target object

None.

Required parameters

-bus *busName*
The name of the local bus. You can use the listSIBuses command to list the names of existing buses.

-chain *chainName*
The name of the transport chain you want to remove from the list of permitted transports.

Conditional parameters

None.

Optional parameters

None.

Example

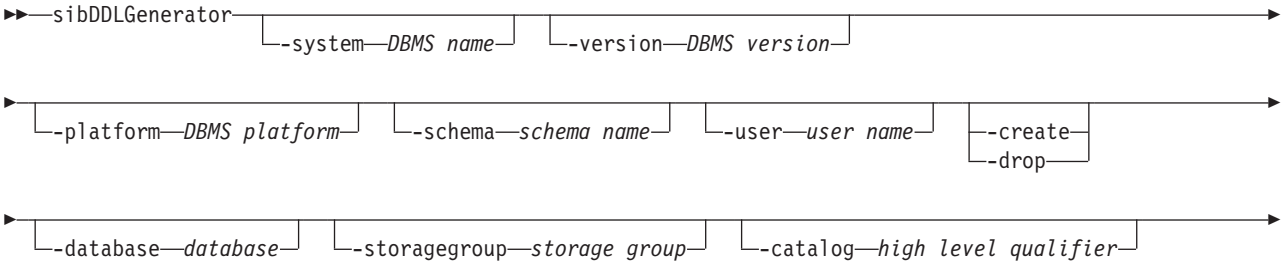
The following example removes the transport chain called `MyTransportChain` from the list of permitted transport chains for a bus called `Bus1`.

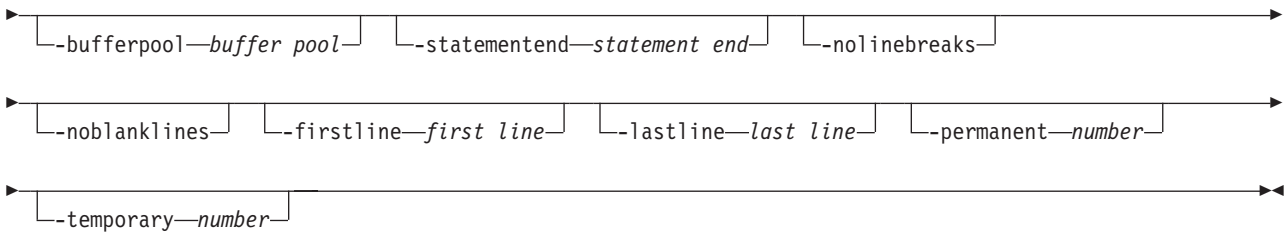
```
AdminTask.removeSIBPermittedChain('[-bus Bus1 -chain MyTransportChain]')
```

sibDDLGenerator command

A messaging engine needs data definition language (DDL) statements to create the DBMS (Database Management System) resources. These DBMS resources are generated by the sibDDLGenerator command.

Syntax





Purpose

A messaging engine needs DBMS resources, such as database tables, which it can create when starting. If your installation has a policy that only a database administrator has the authority to create database tables, use the sibDDLGenerator command to enable your database administrator to create the DBMS resources that the messaging engine needs. The sibDDLGenerator command generates the DDL statements that your database administrator can save, and later process, to create the DBMS resources that are listed in “Data store tables” on page 1967.

The command also generates DDL statements that grant the appropriate authorities to allow a messaging engine use these tables.

To access the IBM i command line, use the STRQSH command to start a Qshell session. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Note: The sibDDLGenerator command is able to generate the DDL statements for creating or dropping all of the data store tables. It is less well suited for adding more item tables to an existing data store. However, it is possible to reissue the DDL statements to create existing tables without harming the data store.

Optional parameters

Tip: The sibDDLGenerator command is case-sensitive. For example, the parameter value Oracle is not the same as the parameter value oracle.

Some parameters apply to a specific DBMS only, as indicated in the parameter list; for example:
-database [Applies only to DB2 for z/OS]

-system
Identifies the type of DBMS on which the administrator will process the DDL statements. Valid values are:

- db2
- oracle
- sqlserver
- sybase
- informix
- derby
- cloudscape

If you do not supply a **-system** parameter, the default value is derby.

-version
The version number of the DBMS identified by the **-system** parameter. The following table shows the default value that is used if you do not supply a **-version** parameter.

If you receive a CWSIS1595E or CWSIS1503E error when you run the tool, consult the notes after the table to determine whether an alternative **-version** parameter value can be used for your database version.

Table 225. Values for the **-version** *parameter. The first column of the table lists the -system parameter values. The second column of the table lists the -platform parameter values. The third column of the table lists the default values of the -version parameters. The fourth column of the table lists the other accepted values of the -version parameters.*

-system parameter value	-platform parameter value	Default value for the -version parameter	Other accepted -version parameter values
db2	zos	7.1	8.1, 9.1 (see Note 1)
db2	unix, windows	8.1	9.1 (see Note 1)
db2	iseries	5.2 (see Note 2)	5.3 (see Note 2)
oracle		8i	9i, 10g, 11g (see Note 3)
sqlserver		2000	2005
sybase		12.0	12.5, 15.0
informix		9.3	7.3, 9.4, 10.0, 11.0 (see Note 4)
derby		10.1	

Notes:

1. The DDL generated for DB2 for UNIX or Windows by using **-version** parameter values 8.1, and 9.1 is identical. The DDL generated for DB2 for z/OS by using **-version** parameter values 7.1, 8.1, and 9.1 is identical.
2. For IBM i, the DB2 database is part of the operating system, so the version number given is for the OS/400 version.
3. The DDL generated for Oracle by using **-version** parameter values 9i, 10g, and 11g is identical.
4. The DDL generated for Informix by using **-version** parameter values 9.4, 10.0, and 11.0 is identical.

-platform
The operating system platform on which the DBMS runs. Valid values are:

- iseries
- unix
- windows
- zos

-schema
The name of the schema that contains all the objects used by the messaging engine. If you do not supply a **-schema** parameter, the default value is IBMWSSIB.

-user
The name of the user ID that is used to interact with the DBMS. If you do not supply a **-user** parameter, the default value is IBMUSER.

-create | -drop
Indicates whether the DDL statements create the DBMS resources or delete them. If you do not supply either parameter, the default value is **-create**.

-database [Applies only to DB2 for z/OS]
The name of the database that is allocated for the messaging engine tables. If you do not supply a **-database** parameter, the default value is SIBDB.

-storagegroup [Applies only to DB2 for z/OS]
The name of the storage group that is allocated for the messaging engine tables.

- If you supply both the **-storagegroup** and the **-catalog** parameters, the sibDDLGenerator command includes both values in the CREATE STOGROUP statement.
- If you supply only a **-storagegroup** parameter, the sibDDLGenerator command uses the storage group name in other statements but does not create a CREATE STOGROUP statement.
- If you supply only a **-catalog** parameter, the sibDDLGenerator command displays the usage statement and then terminates.
- If you omit both parameters, the sibDDLGenerator command uses the default value SIBSG for the storage group name in other statements but does not create a CREATE STOGROUP statement.

-catalog [Applies only to DB2 for z/OS]
The name of the high level qualifier for the storage group that is allocated for the messaging engine tables. For information about defaults, refer to the **-storagegroup** parameter.

-bufferpool [Applies only to DB2 for z/OS]
The name of the buffer pool that is allocated for the messaging engine tables. If you do not supply a **-bufferpool** parameter, the default value is BP1.

-statementend
Appends *statement_end* to each DDL statement. For example, you can use ; to append a semicolon to each DDL statement. By default, the sibDDLGenerator command appends nothing to each statement.

Tip: On UNIX platforms, escape the semicolon to prevent the shell from interpreting it.

-nolinebreaks
Places each statement on a single line, with no line breaks. By default, the sibDDLGenerator command breaks statements across lines to improve readability.

-noblanklines
Omits blank lines between each statement. By default, the sibDDLGenerator command inserts a blank line between each statement to improve readability.

-firstline
Generates *first_line* as the first line of output. For example, you can use *first_line* to identify the target database. By default, the sibDDLGenerator command does not generate a first line.

-lastline
Generates *last_line* as the last line of output. For example, you can use *last_line* to invoke a command that executes the commands in the script. By default, the sibDDLGenerator command does not generate a last line.

Tip: The optional parameters that control the format of the DDL statements, for example **-statementend**, enable you to generate output that is suitable for particular scripting tools, for example the DB2 CLP. By default, the sibDDLGenerator command generates blank lines between each DDL statement but does not append a semicolon at the end of each DDL statement.

The following two optional parameters are used for spreading the data store across multiple tables:

-permanent
The number of permanent tables, with

- Default value: 1
- Minimum value: 1
- Maximum value: see **Note**

-temporary
The number of temporary tables, with

- Default value: 1
- Minimum value: 1
- Maximum value: see **Note**

Note: The maximum number of SIB*nnn* tables that can be used by a messaging engine is 32. This includes all stream, permanent and temporary tables.

Examples

- **sibDDLGenerator -system** *db2* **-version** *8.1* **-platform** *zos*

  Generates DDL statements for DB2 8.1, running on z/OS, with a default schema, user ID, database, storage group, and buffer pool.
- **sibDDLGenerator -system** *db2* **-version** *8.1* **-platform** *windows* **-statementend** *;*

  Generates DDL statements for DB2 8.1, running on Windows, with a default schema, user ID, and database. You can input the statements directly to the DB2 CLP, which requires that each statement is terminated with a semicolon.
- **sibDDLGenerator -system** *oracle* **-version** *8i* **-schema** *SIB* **-user** *fred*

  Generates DDL statements for Oracle 8i.
- **sibDDLGenerator -system** *oracle* **-schema** *SIB* **-user** *fred*

  A concise version of the preceding example.

Access role assignments for bus security resources

Icons are used in the administrative console to represent users and groups that have access roles for service integration bus resources.

Security access roles

In the administrative console, access role icons are used to represent whether a user or a group is in a particular access role. You can click an icon to add or remove selected users and groups to a particular access role for a selected resource.

An access role icon has three states:

- Access role type set.
- Access role type not set.
- Access role type inherited from group.

The following table describes how the access role icons represent these states, and how to change between them:

Table 226. Interacting with access role icons

Access role icon	Access role assignment state	User action
	Role type not set.	Click to change to role type set  .
	Role type set.	Click to change to role type not set. The icon changes to role type not set  if the user or group does not inherit access roles, or to role type inherited  if the role type does inherit access roles.
	Role type inherited from group.	Click to change to role type set  .

Table 226. Interacting with access role icons (continued)

Access role icon	Access role assignment state	User action
	Role type not set for a group. The group to which a user belongs does not have a role type.	Read only.
	Role type set for a group. The group to which a user belongs has a role type.	Read only.
	Role type not applicable.	Read only.

Message properties support for mediations

The SIMessage metadata properties enable the main data types, and are supported by JMS Message Selectors.

Syntax

The selector syntax is the same as for JMS Message Selectors. For more information, refer to the JMS specification.

Supported types

Support is provided for the following data types:

- Boolean
- Byte and byte[]
- Integer
- Long
- Float
- Double
- String

The data types listed above are supported by JMS Message Selectors with the exception of byte[].

Properties

For more information about each property, refer to “JMS_IBM properties and equivalent SI_system properties” on page 2432.

SIMessage metadata properties

The SIMessage metadata properties contain message metadata that you can use in mediation configuration selectors. You can work with these properties by using the SIMessage interface.

You can access and modify the SIMessage metadata properties using individual SIMessage get and set methods. You cannot set or access these properties by using the methods `getMessageProperty()`, `setMessageProperty()`, or `deleteMessageProperty()`.

The method `clearMessageProperty()` does not clear these properties.

Property name	Data type	Comments
SI_NextDestination	String	Name of the first destination in the Forward Routing Path.

Property name	Data type	Comments
SI_Reliability	String	Value of `getReliability.toString()`.
SI_Priority	Integer	
SI_TimeToLive	Long	
SI_Discriminator	String	
SI_ReplyPriority	Integer	
SI_ReplyReliability	String	Value of `getReliability.toString()`.
SI_ReplyTimeToLive	Long	
SI_ReplyDiscriminator	String	
SI_RedeliveredCount	Integer	
SI_MessageID	String	
SI_CorrelationID	String	
SI_Userid	String	
SI_Format	String	

JMS headers

Support is provided by the SIMessage interface and the mediation configuration selector for JMS headers properties. JMS headers properties match in the SIMessage interface in the same way as they do for the JMS API, but you can only modify properties that map to SIMessage metadata.

The method `getMessageProperty()` method supports all of these properties.

The methods `setMessageProperty()` and `deleteMessageProperty()` only support JMSType.

The method `clearMessageProperties()` only clears JMSType.

Property name	Can be matched?	Can be modified?	Data type	Comments
JMSDestination	No	Indirectly	Byte array	`getMessageProperty()` returns opaque byte array.
JMSDeliveryMode	Yes	Yes, by using `setReliability`.	String	String value, as for JMS.
JMSMessageID	Yes	Yes, by using `setMessageID`.	String	Equivalent to SI_MessageID.
JMSTimestamp	Yes	No	Long	
JMSExpiration	Yes	Indirectly, by using `setTimeToLive` or `setRemainingTimeToLive`.	Long	
JMSRedelivered	Yes	No	Boolean	
JMSPriority	Yes	Yes, by using `setPriority`.	Integer	Equivalent to SI_Priority.
JMSReplyTo	No	Indirectly	Byte array	`getMessageProperty()` returns opaque byte array.
JMSCorrelationID	Yes	Yes, by using `setCorrelationId`.	String	Equivalent to SI_CorrelationID.
JMSType	Yes	Yes, by using `setMessageProperty()`.	String	

JMSX properties

Support is provided by the SIMessage interface and the mediation configuration selector for JMSX properties. You can use the SIMessage interface to match and access supported JMSX properties defined in the JMS API. You can only use the SIMessage interface to set properties that are not defined as set by the JMS provider.

The methods `getMessageProperty()`, `setMessageProperty()` and `deleteMessageProperty()` provide access and, where supported, modification.

The method `clearMessageProperties()` does not clear properties that cannot be set.

Property name	Can be matched?	Can be modified?	Data type	Comments
JMSXUserID	Yes	Yes	String	
JMSXAppID	Yes	Yes	String	
JMSXProducerTXID	No	No		Not supported
JMSXConsumerTXID	No	No		Not supported
JMSXRcvTimestamp	No	No		Not supported
JMSXDeliveryCount	Yes	No	Integer	
JMSXState	No	No		Not supported
JMSXGroupID	Yes	Yes	String	
JMSXGroupSeq	Yes	Yes	Integer	

JMS_IBM properties and equivalent SI_system properties

Support is provided by the SIMessage interface and the mediation configuration selector for JMS_IBM properties and the equivalent SI_system properties. You can access JMS_IBM_ properties through the JMS API. Many of the values held by JMS_IBM_ properties apply to an SIMessage and have SI_ synonyms. You can access all these properties through the SIMessage interface, and can match and set many of them. You cannot set exception properties because they are controlled by the messaging engine.

You can match SI_ExceptionReason, JMS_IBM_ExceptionReason and JMS_IBM_ExceptionTimestamp. The method `clearMessageProperties()` does not clear properties that cannot be set.

Where the data types are different, the equivalent values are modified before being returned to the JMS API caller. For example with JMS_IBM_Report_XXX, the JMS_IBM_Report... and JMS_IBM_Feedback values are modified before being returned to the JMS API caller. The values used by service integration and WebSphere Application Server are different, however they are modified before being returned by the JMS API caller, so that they can then be passed to WebSphere MQ.

For information about the mapping of message fields and properties between WebSphere MQ and JMS see Mapping the message header fields and properties to and from WebSphere MQ format.

In the following table, the SIMessage API data type column indicates the data type of the property if accessed by a mediation handler, or when specifying the selectors for a mediation handler. The JMS API data type column indicates the data type of the property if accessed by a JMS application, either when specifying selectors or when using the get and set property methods:

Table 227. JMS_IBM properties and SIMessage properties. The first column of the table provides the JMS_IBM property names. The second column provides the equivalent SIMessage property names if available. The third column indicates if the properties can be matched. The fourth column indicates the state of setMessageProperty. The fifth column contains the data type of the SIMessage API property if accessed by a mediation handler or when specifying the selectors for the mediation handler. The sixth column contains the data type of the JMS API property if accessed by a JMS application.

JMS_IBM property name	Equivalent SIMessage property	Can be matched?	setMessageProperty	SIMessage API data type	JMS API data type
JMS_IBM_Format		Yes	Yes	String	String
JMS_IBM_MsgType		Yes	Yes	Integer	Integer
JMS_IBM_Feedback	SI_ReportFeedback	Yes	Yes	Integer	Integer
JMS_IBM_PutApplType		Yes	Yes	Integer	Integer
JMS_IBM_Report_Exception	SI_ReportException	Yes	Yes	Byte	Integer
JMS_IBM_Report_Expiration	SI_ReportExpiry	Yes	Yes	Byte	Integer
JMS_IBM_Report_COA	SI_ReportCOA	Yes	Yes	Byte	Integer
JMS_IBM_Report_COD	SI_ReportCOD	Yes	Yes	Byte	Integer
JMS_IBM_Report_PAN	SI_ReportPAN	Yes	Yes	Boolean	Integer
JMS_IBM_Report_NAN	SI_ReportNAN	Yes	Yes	Boolean	Integer
JMS_IBM_Report_Pass_Msg_ID	SI_ReportPassMsgID	Yes	Yes	Boolean	Integer
JMS_IBM_Report_Pass_Correl_ID	SI_ReportPassCorrelID	Yes	Yes	Boolean	Integer
JMS_IBM_Report_Discard_Msg	SI_ReportDiscardMsg	Yes	Yes	Boolean	Integer
JMS_IBM_Last_Msg_In_Group		Yes	Yes	Boolean	Boolean
JMS_IBM_PutDate		Yes	Yes	String	String
JMS_IBM_PutTime		Yes	Yes	String	String
JMS_IBM_Encoding		Yes	Yes	Integer	Integer
JMS_IBM_Character_Set		Yes	Yes	String	String
JMS_IBM_ExceptionMessage		No	No	String	String
JMS_IBM_ExceptionTimestamp	SI_ExceptionTimestamp	Yes	No	Long	Long
JMS_IBM_ExceptionReason	SI_ExceptionReason	Yes	No	Integer	Integer
JMS_IBM_ ExceptionProblemDestination	SI_Exception ProblemDestination	Yes	No	String	String
N/A	SI_ExceptionInserts	No	No	List of strings	n/a
JMS_IBM_System_MessageID	SI_SystemMessageID	Yes	No	String	String

Using the JMS_IBM Feedback property

The JMS_IBM_Feedback property identifies the type of report a message contains.

Property	Type	Values
JMS_IBM_Feedback	Integer	• REPORT_EXPIRY=3 • REPORT_EXCEPTION=4 • REPORT_COA=5 • REPORT_COD=6

If a report message is generated as a result of a message expiry, the value of the JMS_IBM_Feedback property is 3.

User properties

Support for user properties is provided by the SIMessage interface and the mediation configuration selector. The JMS API supports user properties of primitive wrapper or string types. The property name can be any valid Java identifier providing it does not have the prefix JMS. The SIMessage API also supports user properties of primitive wrapper or string types, and additionally supports byte[] and serializable types. Arbitrary serializable objects are stored as byte arrays, and are selected on as byte arrays only (using equals only).

User properties supported by the SIMessage API must have the prefix `user`. You can set and access these properties using `getMessageProperty`, `setMessageProperty` and `deleteMessageProperty`.

Interaction with JMS

Alternatively, you can set and access user properties by using `xxxUserProperty` methods. In this case, the prefix `user` must be omitted. The property name, excluding the prefix `user`, exists in the same namespace as the JMS user properties.

For example, a JMS application calls a property as follows:

```
setStringProperty("color", "green");
```

A mediation can access the property by making one of the following calls:

- `getMessageProperty("user.color");`
- `getUserProperty("color");`

Note: Mediation message selectors must contain the `user` prefix.
JMS property methods only affect user properties that have types supported by the JMS API:

- `clearProperties()` clears only those properties supported by JMS.
- `propertyExists()` returns true only when the property type is supported by JMS.
- `getPropertyNames()` includes only those properties with types supported by JMS.
- `setObjectProperty("xxxx", null);` clears a property only if it is supported by JMS.

Note that `setxxxxProperty("xxxx", value)` overrides a user property of any type when the value is non-null.

Error handling in mediations

The actions taken in the event of an error occurring during mediation processing are summarized in the following table:

Table 228. Actions and errors in mediation processing. The first column of the table lists the errors that occur during the mediation processing. The second column describes the actions to be taken when the errors occur.

Error	Action taken
Unchecked runtime exception	• The message is sent to the exception destination. • Any transaction is rolled back.
Checked message context exception	• The message is sent to the exception destination. • Any transaction is committed.
Enterprise JavaBeans (EJB) exception	• Message is eligible for re-mediation.
An error occurs in the process of calling a mediation.	• The mediation is not called. • The message is eligible for re-mediation.

Table 228. Actions and errors in mediation processing (continued). The first column of the table lists the errors that occur during the mediation processing. The second column describes the actions to be taken when the errors occur.

Error	Action taken
The mediation returns true, and the message is not well formed.	• The original pre-mediated message is sent to the exception destination. • Any transaction is committed.

WebSphere MQ naming restrictions

The naming restrictions for WebSphere MQ queues, queue managers, and queue-sharing groups are more restrictive than those that apply to equivalent objects in WebSphere Application Server. Use this information to help you administer the WebSphere Application Server objects, so that the names of these objects can be passed successfully to and from WebSphere MQ.

Rules for naming WebSphere MQ objects

- A WebSphere MQ object cannot have the same name as any other object of the same type.
- Names in WebSphere MQ are case sensitive.
- In WebSphere MQ, the names of queues can have up to 48 characters. The names of queue managers can have also have up to 48 characters, except in the case of WebSphere MQ for z/OS, where both queue manager and queue sharing group names are limited to four non-blank characters.
- The character set to use for naming all WebSphere MQ objects is as follows:
  - Uppercase A-Z
  - Lowercase a-z (but there are restrictions on the use of lowercase letters for z/OS console support)
  - Numerics 0-9
  - Period (.)
  - Forward slash (/).
  - Underscore (_)
  - Percent sign (%).
- Leading or embedded blanks are not allowed.
- Any structure to the names (for example, the use of the period or underscore) is not significant to the queue manager.

For further details, see the WebSphere MQ information center.

Mediation thread pool properties

The table below describes the default thread pool properties for the mediationsThreadPool object for a messaging engine.

Property name	Description	Data type	Comment
minimumSize	Specifies the minimum number of threads to allow in the pool.	integer	Default value is 1.
maximumSize	Specifies the maximum number of threads to allow in the pool.	integer	Default value is 5.
isGrowable	Can the pool grow beyond the maximumSize	boolean	true or false. Default is false.

Property name	Description	Data type	Comment
inactivityTimeout	Specifies the number of milliseconds of inactivity that should elapse before a thread is reclaimed. A value of 0 indicates not to wait and a negative value (less than 0) means to wait forever.	integer, units milliseconds.	Default value: 3500

Chapter 25. Administering Session Initiation Protocol (SIP) applications

This page provides a starting point for finding information about SIP applications, which are Java programs that use at least one Session Initiation Protocol (SIP) servlet written to the JSR 116 specification.

SIP is used to establish, modify, and terminate multimedia IP sessions including IP telephony, presence, and instant messaging.

Deploying SIP applications

Use the administrative console to customize your Session Initiation Protocol (SIP) application installation

About this task

When you deploy a Session Initiation Protocol (SIP) application, you can perform various tasks such as installing, starting, stopping, upgrading, and uninstalling the application.

SIP applications are installed as Java Platform, Enterprise Edition (Java EE) applications. You can deploy a SIP application from a graphical interface or from a command line.

Deploying SIP applications through the console

You can deploy a Session Initiation Protocol (SIP) application through the administrative console.

Before you begin

SIP applications are deployed as Java 2 Platform Enterprise Edition (J2EE) applications. In order to process requests, a virtual host must be defined when deploying the SIP application. If there is no virtual host defined for the configured SIP container listen port, the installed application will be inaccessible.

Procedure

1. Open the administrative console.

   In a browser, go to URL `http://`*`hostname`*`:9090/admin`, where *hostname* is the name of the host computer. Enter the appropriate login information, and click **OK**.
2. In the left frame click **Applications** > **Install New Application**.
3. Browse and select a SAR file. Specify the context root, beginning with a slash (/), in the **Context Root** field. For example, if your application is named ThisApplication, type `/ThisApplication`.
4. Click **Next** (under the **Context Root** field not beside the WebSphere Status title). If the SAR file has been assembled correctly, the screen will still have the title “Preparing for the application installation”, but the content will change. If an error message appears, check the contents of the SAR file; in particular, verify the `web.xml` file contents, and try to reload the SAR file.
5. Click **Next**. If you see a screen indicating “Application Security Warnings”, click **Continue**.
6. The **Install New Application** screen should appear with “Step 1: Select application options” highlighted. Select the options you need and click **Next**.
7. “Step 2: Map modules to servers” should appear highlighted now. You can choose the cluster or server where you want to install the application's modules.
   - If you are installing the application in a stand-alone system, click **Next**.
   - If you are installing the application in a clustered system, select **WebSphere:cell=*cellname*,cluster=*cluster_name*** in the **Clusters and Servers** field, select the check box beside the web module that you want to install, and click **Apply** and **Next**.

8. Now “Step 3: Map virtual hosts for web modules” should appear highlighted. To the right of the application name there should be a drop-down labeled **Virtual Host**.
   - If you are installing the application in a stand-alone system, set the value of the drop-down to **default_host**, and click **Next**.
   - If you are installing the application in a clustered system, set the value of the drop-down to the name of the virtual host that was chosen during setup, and click **Next**.

   Remember: You must define a virtual host for your configured SIP container listen port or else you will not be able to access the application.
9. You should now see “Step 4: Summary” highlighted. In the right panel you will see a **Summary of installation options** table that details your selected options and their values. If you need to change an option, click **Previous** to return to the section where you can make your change. Click **Finish** to install the application with your settings. The screen should display, `Application` *appname*`_sar installed successfully`, where *appname* is the name of the application.
10. Click the **Save to Master Configuration** link. A Save to Master Configuration window appears.
11. In the Save to Master Configuration window, click **Save**. The application has now been saved in the current configuration.
12. To confirm that the installation succeeded, in the left frame click **Applications** > **Enterprise Applications**. The newly installed application should appear in the list of installed applications as *appname*_sar.
13. To start the application so that it can service SIP requests, check the box beside *appname*_sar, and click **Start**. You might also want to look at the logs for a successful startup message.

Results

The application can service SIP requests now.

Deploying SIP applications through scripting

You can deploy a Session Initiation Protocol (SIP) application not only from the administrative console but also from a command line.

About this task

Note: To deploy a SIP application, the application must exist with an enterprise archive (EAR) file, a Session Initiation Protocol (SIP) module (SAR file), or a web application archive (WAR) file.

Use the wsadmin scripting tool to deploy applications from a command line.

Procedure

- Launch a scripting client.

  For more information, see AdminApp object for scripted administration.
- List applications.

  For more information, see Listing applications using the wsadmin scripting tool.
- Install stand-alone archive files.

  For more information about installation, see Installing enterprise applications using wsadmin scripting and Installation options for the AdminApp object.
- Edit application configurations.

  For more information, see Editing application configurations using the wsadmin scripting tool.
- Uninstall applications.

  For more information, see Uninstalling enterprise applications using the wsadmin scripting tool.

Administering SIP applications

Configuring the SIP container

Configure the Session Initiation Protocol (SIP) container to adjust message response times or set a custom property.

About this task

Use the administrative console to configure SIP container settings. Complete the following steps to find and configure the SIP container settings.

Procedure

1. Start WebSphere Application Server.
2. From the administrative console, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
3. From **Container Settings**, expand **SIP Container Settings**, and click **SIP Container**. Select the container settings that you want to change.
   - From **General Properties**, you can configure session, message, and response time maximums. See *Session Initiation Protocol container settings* and *SIP container custom properties*.
   - From **Additional Properties**, you can define custom properties, manage transport chains or inbound channel settings, or configure the session manager.
4. After configuring the SIP container, click **Apply** to save the changes.
5. Restart WebSphere Application Server.

Results

Changes to the SIP container settings take effect after you restart WebSphere Application Server.

gotcha: As the number of SIP containers grow in a deployment, the larger the heap settings need to be on the SIP proxy server. For example, a deployment of 20 containers requires a minimum heap size of 60 MB, so a -Xmo60m parameter should be added to the Generic JVM arguments field on the Java virtual machine panel of the admin console. However, a deployment of 70 containers requires a larger value such as 200 MB (-Xmo200m). See the information center topic *Java virtual machine settings* for more information about Generic JVM arguments.

Enabling Session Initiation Protocol (SIP) flow token security

The Session Initiation Protocol (SIP) container supports client-initiated connection reuse. SIP flow token security enables you to establish communication between a server and SIP clients in situations where the SIP clients can create a connection to the server, but are not prepared to accept connections from the server.

About this task

Managing client-initiated connections in the SIP container involves generating flow tokens, as described in the SIP standard RFC 5626. When the SIP container delivers a flow token to the network, it encodes the token in a way that prevents anyone from modifying this token. When the container receives a flow token that it previously generated, it decodes the flow token and verifies its integrity.

WebSphere Application Server SIP flow token security implements the outbound SIP protocol extension, as defined in RFC 5626, with the following exceptions:

- Only TCP and TLS stream transports are supported.
- UDP flows are not reused.

- TCP keepalives are supported, but STUN keepalives are not.
- Support of this protocol extension is provided for SIP applications that act as a proxy/registrar, as described in RFC 5626, but not as a user agent, as described in this RFC.

Encoding and decoding the flow token requires a pre-defined key. The SIP container obtains this security key from your SIP container settings. Complete the following steps to configure the SIP container to support flow token security.

Procedure

1. Create a key set, if one does not already exist.

   If you already have a key set configured, you can use that key set as the key set for SIP flow token security.

   If you need to create a new key set, the scope of the key set must be at the cell level. See the topic *Creating a key set configuration* for a description of how to create a new key set.
2. Add the com.ibm.ws.sip.key.set custom property to the SIP container settings.
   a. In the administrative console, expand **Servers > Server Types > WebSphere application servers > *server_name*** to open the configuration tab for the server.
   b. From **Container settings**, expand **SIP Container settings**, and click **SIP container**.
   c. From **Additional properties**, select **Custom Properties** > **New**.
   d. On the settings page, specify `com.ibm.ws.sip.key.set` in the **Name** field, and the name of the key set to use for flow token security in the **Value** field.
   e. Click **Apply** or **OK**.
   f. Click **Save** on the console task bar to save your configuration changes.
   g. Restart the server.

Results

SIP flow token security is enabled for the SIP container.

SIP container custom properties

You can add any of the following custom properties to the configuration settings for a Session Initiation Protocol (SIP) container.

To specify custom properties for a specific SIP container, navigate to the custom properties page, and then specify a value for the custom property.

Important: The custom properties are supported as the primary method of configuration. Therefore, if a custom property is set and then you set the corresponding setting in the administrative console, the custom property value is used.

1. In the administrative console, expand **Servers > Server Types > WebSphere application servers > *server_name*** to open the configuration tab for the server.
2. From **Container settings**, expand **SIP Container settings**, and click **SIP container**.
3. From **Additional properties**, select **Custom Properties** > **New**.
4. On the settings page, type the custom property to configure in the **Name** field, and then type the value of the custom property in the **Value** field.
5. Click **Apply** or **OK**.
6. Click **Save** on the console task bar to save your configuration changes.
7. Restart the server.

The following list of SIP container custom properties is provided with the product. These properties are not shown on the settings page for the container.

You can define the following SIP container custom properties that are provided with the product. These properties are not shown on the settings page for the container.

- “auth.int.enable” on page 2442
- “com.ibm.sip.sm.lnm.size” on page 2442

- “SIP_RFC3263_nameserver” on page 2452
- “thread.message.queue.max.size” on page 2453
- “weight.overload.watermark” on page 2453

auth.int.enable:

Specifies the **auth-int** quality of protection (QOP) for digest authentication. Digest authentication defines two types of QOP: **auth** and **auth-int**. By default, **auth** is used. When this custom property is set to True, the highest level of protection is used, which is the **auth-int** QOP.

Data type	String
Default	False

com.ibm.sip.sm.lnm.size:

Specifies the number of logical names in the application server. Each SIP object that can be replicated, such as a SIP session, is associated with a logical name. All objects with the same logical name are replicated to the same back-up container. The proxy can route messages to the correct container using the logical name found in the message. The value must be greater than 1.

Data type	String
Default	10

com.ibm.webspehere.sip.security.digest.ldap.cachecleanperiod:

Specifies the clean Lightweight Directory Access Protocol (LDAP) cache period in minutes.

Data type	String
Default	120

com.ibm.websphere.sip.security.tai.usercachecleanperiod:

Specifies the clean security subject cache period in minutes.

Data type	String
Default	15

com.ibm.ws.sip.key.set:

Specifies the key to use for SIP flow token security. When a value is specified for this property, SIP flow token security is automatically enabled.

Data type	String
Default	There is no default value

com.ibm.ws.sip.tai.DisableSIPBasicAuth:

Specifies whether to allow basic authentication for SIP.

Data type String
Default False

DigestPasswordServerClass:

Specifies types of user registries that are supported, except LDAP. To configure DigestTAI without the LDAP user registry, complete the following steps.

1. Create a class that implements this interface: com.ibm.ws.sip.security.digest.DigestPasswordServer
2. Add the following property to the SIP container custom property:

   Default LdapPasswordServer
3. Ensure that all users declared by the impl class are declared in the user registry configured for the product security.

Data type String
Default impl

enable.system.headers.modify:

Specifies whether the application has access to headers that are otherwise restricted.

Data type String
Default False

end.of.service.replication: Specifies whether changes are buffered until the thread for a siplet is about to end. If the value is set to `true`, then each change is buffered until the thread for the siplet is about to end.

Data type Boolean
Default true

immediate.replication: Specifies whether each change is immediately sent to the Data Replication Service. When this property is set to `true`, when replication is issued from a non-SIP container thread, the replication is immediately performed on the calling thread. When this property is set to `false`, the changes are buffered, and replication does not occur until all changes are made.

Setting this property to true might have a negative impact on performance.

Data type Boolean
Default false

javax.servlet.sip.ar.dar.configuration:

Specifies the location of the default application router (DAR) properties file. The properties file defines the order in which the application router sends SIP requests to applications as described in Appendix C of the JSR 289 specification.

Data type String
Default Null

javax.servlet.sip.ar.spi.SipApplicationRouterProvider:

Specifies the custom application router implementation fully qualified class name as described in section 15.4.2 of the JSR 289 specification. The custom application router implementation class defines the order in which the application router sends SIP requests to applications.

Data type	String
Default	Null

javax.sip.bind.retries:

Specifies the amount of time, in milliseconds, between attempts to start the SIP channel if the SIP port is busy with another process during server startup.

Data type	String
Default	60

javax.sip.bind.retry.delay:

Specifies the delay, in milliseconds, between attempts to start the SIP channel if the SIP port is busy with another process during server startup.

Data type	String
Default	5000

javax.sip.detect.pre.escaped.params:

Specifies whether to prevent the container from re-escaping Uniform Resource Identifier (URI) parameters that were pre-escaped by the application.

Enabling this property provides the application with more control over escaping URI parameters, when calling the **javax.servlet.sip.SipFactory.createURI()** and the **javax.servlet.sip.SipURI.setParameter()** parameters.

By default, the container only escapes characters that it must encode according to the RFC 3261 25.1 specification. In some cases, however, escaping additional characters might be required. Due to a limitation in the JSR 116 (5.2.1) specification, the application cannot perform its own escaping. Because of this limitation, attempts by the application to encode URI parameters causes the container to re-encode the percent sign. If the value of this property is set to true, the container cannot re-encode the percent sign.

Setting the value to true is not in compliance with the JSR 116 (5.2.1) specification, but provides the application with greater control over URI parameter escaping. APAR PK37192 describes the problem and the workaround.

Data type	String
Default	False

javax.sip.force.connection.reuse:

Specifies whether to force reuse of inbound connections for outbound requests. This custom property is only relevant for stream transports, such as Transmission Control Protocol (TCP) and Transport Layer Security (TLS). Disabling this property causes the container to create a separate connection for outbound requests, even if an existing connection is already established to the same peer address. The connection is automatically reused if the top Via header in the inbound request contains an alias parameter. (http://www.ietf.org/internet-drafts/draft-ietf-sip-connect-reuse-07.txt)

Data type	String
Default	False

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.hide.message.body:

Specifies to hide message content in logs. Set the value of this property to `true` to remove the message body text from SIP messages printed in the log files. This property only affects the representation of the messages in log files.

Data type	String
Default	False

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.hide.message.headers:

Specifies to hide the specified message header field names in log files. The value of this property is a comma-separated list of header field names that you want removed from SIP messages printed in the log files. This property only affects the representation of the messages in log files.

Data type	String
Default	None

javax.sip.hide.request.uri:

Specifies to hide request URIs in log files. Set the value of this property to `true` to remove request URIs from SIP messages printed in the log files. This property only affects the representation of the messages in log files.

Data type	Boolean
Default	False

javax.sip.OUTBOUND_PROXY:

Specifies the fixed address for routing all outbound SIP messages. The format is *address:port/transport*, such as `1.2.3.4:5065/tcp`.

Note: Do not use this property if the container is fronted by an application server SIP proxy.

Data type	String
Default	null

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.PATH_MTU:

Specifies the maximum transmission unit, in bytes, for outbound User Datagram Protocol (UDP) requests. The SIP stack measures the size of a request before sending it out on the UDP channel. If the request is larger than the value specified for **PATH_MTU-200** (1300 bytes by default), then the transport is switched from UDP to TCP before transmission. Increase this value to send larger requests over the UDP channel; however, messages might be truncated or dropped. See the RFC 3261-18.1.1 specification for details.

Data type	String
Default	1500

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.stat.report.interval:

Specifies the amount of time, in milliseconds, for reporting dispatch and timer statistics to a system.out file. A value of zero indicates no report.

Data type	String
Default	0

javax.sip.trace.msg.in:

Specifies whether to print incoming messages to a system.out file.

Data type	String
Default	False

javax.sip.trace.msg.out:

Specifies whether to print outbound messages to a system.out file.

Data type	String
Default	False

javax.sip.transaction.invite.auto100:

Specifies whether to automatically reply to invite requests with a `100 Trying` response. Disabling this property might increase the number of invite retransmissions.

Data type	String
Default	True

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.transaction.timer.a:

Specifies, for UDP only, the amount of time, in milliseconds, before retransmitting invite requests for timer A for the RFC 3261 specification. This property is relevant for the invite client transaction.

Data type	String
Default	javax.sip.transaction.timer.t1

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.transaction.timer.b:

Specifies the amount of time, in milliseconds, for the invite client transaction timeout timer (timer B) for the RFC 3261 specification.

Data type	String
Default	64*javax.sip.transaction.timer.t1

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.transaction.timer.cancel:

Specifies the amount of timer, in milliseconds, for the timer to keep the cancelled client transaction in the proceeding state before completing the cancelled transaction for the RFC 3261 9.1 specification. This property is relevant for the invite client transaction.

Data type	String
Default	64*javax.sip.transaction.timer.t1

javax.sip.transaction.timer.d:

Specifies the wait time, in milliseconds, before retransmission of the invite response for timer D for the RFC 3261 specification. This property is relevant for the invite client transaction.

Data type	String
Default	32000

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.transaction.timer.e:

Specifies, for UDP only, the amount of time, in milliseconds, before the retransmission of the initial non-invite request for timer E for the RFC 3261 specification. This property is relevant for the non-invite client transaction.

Data type	String
Default	javax.sip.transaction.timer.t1

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.transaction.timer.f:

Specifies the amount of time, in milliseconds, for the non-invite transaction timeout timer (timer F) for the RFC 3261 specification. This property is relevant for the non-invite client transaction.

Data type	String
Default	64*javax.sip.transaction.timer.t1

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.transaction.timer.g:

Specifies the amount of time, in milliseconds, before retransmission of an initial invite response for timer G for the RFC 3261 specification. This property is relevant for the invite server transaction.

Data type	String
Default	javax.sip.transaction.timer.t1

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.transaction.timer.h:

Specifies the amount of time, in milliseconds, to wait for an acknowledgement (ACK) receipt for timer H for the RFC 3261 specification. This property is relevant for the invite server transaction.

Data type	String
Default	64*javax.sip.transaction.timer.t1

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.transaction.timer.i:

Specifies the amount of time in milliseconds to wait for an ACK retransmission for timer I for the RFC 3261 specification. This property is relevant for the invite server transaction.

Data type	String
Default	javax.sip.transaction.timer.t4

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.transaction.timer.invite.server:

Specifies the amount of time, in milliseconds, for the timer to keep the invite server transaction in the complete state. This timer is not defined in the RFC specification.

To avoid creating a new server transaction when a client retransmits an invite request, keep the completed server transaction for a period of time before removing invite retransmissions. This timer is started when the transaction changes to the terminated state. When the timer completes, the transaction is removed.

Data type	String
Default	32000

javax.sip.transaction.timer.j:

Specifies the amount of time in milliseconds to wait for non-invite request retransmission for timer J for the RFC 3261 specification. This property is relevant for the non-invite server transaction.

Data type	String
Default	64*javax.sip.transaction.timer.t1

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.transaction.timer.k:

Specifies the amount of time, in milliseconds, to wait for non-INVITE response retransmissions for timer K for the RFC 3261 specification. This property is relevant for the non-invite client transaction.

Data type	String
Default	javax.sip.transaction.timer.t4

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.transaction.timer.non.invite.server:

Specifies the amount of time, in milliseconds, for an Application Programming Interface (API) timer for the application to respond to a non-invite request. This property is relevant for non-invite server transactions.

This timer is not defined in the RFC specification. This property is needed to stop the transaction if the application does not generate a final response to the request. The timer starts when the request arrives in the stack and stops when a response is generated by the application. If no response is generated before the timer stops, then the transaction completes.

Data type	String
Default	34000

javax.sip.transaction.timer.t1:

Specifies the amount of time, in milliseconds, for a network round trip delay for timer T1 for the RFC 3261 specification. The value is used as a base for calculating some timers and is relevant for all types of transactions, such as client, server, invite, and non-invite transactions.

Data type	String
Default	500

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.transaction.timer.t2:

Specifies the maximum time in milliseconds before retransmitting non-invite requests and invite responses for timer T2 for the RFC 3261 specification.

Data type	String
Default	4000

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.transaction.timer.t4:

Specifies the maximum amount of time, in milliseconds, for a message to remain in the network. This value is used as a base for calculating other timers for timer T4 for the RFC 3261 specification.

Data type	String
Default	5000

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

on.outgoing.message.replication: Specifies whether changes are buffered until a siplet issues a request.send() or response.send() call. If the value is set to `true`, then each change is buffered until a siplet issues a request.send() or response.send() call.

Data type	Boolean
Default	false

pws_atr_name:

Specifies the LDAP attribute name that stores the user password.

Data type	String
Default	userpassword

replicate.with.confirmed.dialog.only:

Specifies whether to replicate the application session, even when no dialogs are confirmed. If the value is set to `false`, then the application session is replicated immediately after the session is created. Otherwise, the application session is only replicated when an associated dialog is confirmed.

Data type	String
Default	False

sip.container.heartbeat.enabled:

Specifies whether or not SIP network outage detection is enabled for the SIP container. SIP network outage detection allows the SIP proxy to send keepalive messages to the SIP container if the value of this property is set to `true`.

If the value is set to `false` for the SIP container, then this property has no effect on the SIP proxy. However, if the value is set to `true` for the SIP container, the value should also be set to `true` for the SIP proxy to ensure that keepalive messages are answered at the SIP container and not presented to the application.

Data type	String
Default	true

sip.jsr289.parse.address:

Specifies to use the SIP Servlet Specification 1.1, JSR 289 required format for createRequest() and createAddress() methods.

Note: The JSR 289 API requires that for any SIP URI that contains address parameters, you must enclose the SIP URI in angle brackets. The default behavior of the sip.jsr289.parse.address property is compliant with JSR 289 and correctly parses the address parameter as if it belongs to the SIP address. For example, when the property is set to `false`, the SIP address, `sip:fred@acme.com;param1=1`, is converted to `<sip:fred@acme.com;param1=1>`. When the property is set to `true`, the SIP address `sip:fred@acme.com;param1=1`, is converted to `<sip:fred@acme.com;>param1=1`.

Data type	String
Default	True

SIP_RFC3263_nameserver:

Specifies whether to allow a SIP URI to be resolved through Domain Name System (DNS) into the IP address, port, and transport protocol of the next hop.

The value of the property is a string containing one or two address and port tuples, where two tuples are separated by a space. The following examples specify a one address and port tuple or a two address and port tuple.

dottedDecimalAddress@.port

hostname.domain@port

IPV6address@port

The following example values represent a single tuple.

- 1.2.3.4@53
- example.com@53
- a:b:c::d@53

The following example values represent two tuples separated by a space.

- 1.2.3.4@53 example.com@53
- a:b:c::d@53 9.32.211.14@53

Data type	String
Default	null

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

thread.message.queue.max.size:

Specifies the maximum number of events allowed in the container threads queue. When this number is exceeded, the proxy server is notified that the container is overloaded and requests for new sessions are not accepted. Instead, the container returns an error message that indicates that the container is temporarily unavailable.

This value represents the total number of messages for all queues and reflects the state of the CPU. When the CPU approaches 100%, the maximum value for this custom property is reached quickly. Configure your system to limit the queue size and prevent the queue from reaching this threshold.

Data type	String
Default	1000

weight.overload.watermark:

Specifies the threshold value for the internal weight calculated by the container. When the container calculates the internal weight to be higher than the value specified, an overloaded container becomes available for service again.

This custom property represents a percentage of the maximum internal weight, such as 30 percent when the default value is set. When the high-water mark, or maximum threshold, is exceeded, the container waits until the weight drops below the maximum weight. This value cannot exceed `10`.

Data type	String
Default	3

Using DNS procedures to locate SIP servers

The Session Initiation Protocol (SIP) can use Domain Name Server (DNS) procedures for a client to resolve a SIP Uniform Resource Identifier (URI).

About this task

WebSphere Application Server provides support for the RFC 3263 standard. This allows a SIP URI to be resolved through DNS into the IP address, port, and transport protocol of the next hop to contact.

Note: SIP does not support use of DNS procedures for a server to send a response to a back-up client if the primary client fails.

Complete these steps to configure WebSphere Application Server to support the RFC 3263 standard.

Procedure

1. Start WebSphere Application Server.
2. From the administrative console, expand **Servers**, and click **Application servers** > ***serverName***.
3. Under **General Properties**, check the **Enable locating SIP servers using DNS NAPTR records** checkbox, then fill in the **Primary DNS server name** and **Secondary DNS server name** fields.
4. Click **Apply** to save your changes.
5. Restart WebSphere Application Server.

What to do next

You must configure your DNS server in order for RFC 3263 support to work for the SIP container. The following example is a BIND db file for configuring RFC 3263 support on a DNS server.

SIP container settings

Use this page to configure the SIP container settings for Session Initiation Protocol (SIP).

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **SIP container settings** > **SIP container**.

Maximum application sessions:

Specifies the maximum number of SIP application sessions that the container manages. When the maximum is reached, no new SIP conversations are started. When the maximum is exceeded in a clustered environment, the server does not forward new dialogs until the number of application sessions no longer exceeds the maximum.

Application sessions are typically created by new incoming calls, but can also be created by other events. The application session count does not impact failover, but applies only to new sessions that are created as a result of incoming calls.

When application sessions are transferred from one application server to another due to failover, the active application server inherits the sessions created on the failed server. In addition, the servlet might create a new application session in the SIP container by calling SipFactory.createApplicationSession().

New application sessions created for events other than starting SIP conversations are not controlled by this setting. But all new application sessions are included when computing the maximum number of application sessions allowed. Thus, all active application sessions, including those not related to starting SIP conversations, can cause the maximum to be exceeded.

Data type	Integer
Default	120000 (recommended)
Range	1 <= n <= java.lang.Integer.MAX_VALUE

Maximum messages per averaging period:

Specifies the maximum amount of SIP messages processed per averaging period. The averaging period is the period of time during which the average number of messages received by the container is calculated.

This average is used to determine the load for the container and to determine if the number of messages is approaching the maximum. When the maximum is exceeded, the stand-alone server or the proxy server continues to handle all in-dialog messages. Other non-dialog requests are rejected. When a container is in an overloaded state, the proxy server returns a 503 error.

Data type	Integer
Default	5000 (recommended)
Range	1 <= n <= java.lang.Integer.MAX_VALUE

Maximum dispatch queue size:

Specifies the size of the internal dispatch queue. When the maximum queue size threshold is reached, the container queue becomes overloaded and begins to drop requests for new sessions. In this case, the container does not report its overloaded state to the proxy server.

Configure your system to limit the queue size to prevent the queue from reaching this threshold. If the internal queue reaches the overloaded state, incoming UDP packets are dropped until the queue is no longer in an overloaded state. Limiting the queue size enables better recovery if the CPU is used by other processes or threads and prevents the container from reaching out-of-memory conditions. When the value is set to `0`, the queue size is unlimited.

Data type	Integer
Default	3200 (recommended)
Range	0 <= n <= java.lang.Integer.MAX_VALUE

Maximum response time:

Specifies the maximum response time, in milliseconds, for an application. When the amount of time is exceeded, the container notifies the clustering framework that it is unavailable. You can disable this feature in the administrative console by deselecting the check box and specifying a value of `0`.

Use the maximum SIP response time setting cautiously because the calculated response time does not match the behavior of all applications. For requests, such as INVITE requests, where the responses are generated as a result of a user interaction, the calculated response time is extensive. However, the extensive response time is not caused by a delay in the SIP container. Therefore, you should not calculate the response time as a load factor. The recommended applications for effective calculation of response time are applications that respond immediately without a user interaction. The subscribe and register applications are relevant examples.

Data type	Integer
Default	0
Range	1 <= n <= java.lang.Integer.MAX_VALUE

Averaging period in milliseconds:

Specifies the amount of time, in milliseconds, to use for calculating the maximum messages per averaging period. This setting is the sliding window during which the SIP container counts the number of messages sent to the container.

Data type	Integer
Default	1000 (recommended)
Range	1000 <= n <= java.lang.Integer.MAX_VALUE

Statistic update rate:

Specifies control over the interval for which the container calculates averages and publishes statistics to Performance Monitoring Infrastructure.

Data type	Integer
Default	10000 (recommended)
Range	1000 <= n <= java.lang.Integer.MAX_VALUE

Locating SIP servers using DNS:

Specifies whether to enable locating SIP servers using DNS (Directory Name Service).

A SIP Uniform Resource Identifier (URI) can be resolved through DNS into the Internet Protocol (IP) address, port, and transport protocol of the next hop.

The value for the **Primary DNS server name** or **Secondary DNS server name** fields is a string containing one address and port tuple. The following examples specify an address and port tuple.

Note: The container contacts the primary DNS server first; however, if the primary DNS server is unavailable, then the container contacts the secondary DNS server. If the secondary DNS server remains responsive, the container does not attempt to contact the primary DNS server.

dottedDecimalAddress@.port

hostname.domain@port

IPV6address@port

Data type	Boolean
Default	False

`Primary DNS server name`

Specifies an IP address and port tuple for the primary DNS server. If this server is not available, then the container sends a response to the secondary DNS server.

Data type String
Default empty string.

Secondary DNS server name
Specifies an IP address and port tuple for the secondary DNS server.

Data type String
Default empty string.

Thread pool:

Specifies the thread pool to use for the SIP container.

If you do not choose a thread pool, the SIP container creates a new thread pool with maximum size of 15.

SIP stack settings

Use this page to configure values for the Session Initiation Protocol (SIP) stack settings that are different from those specified in RFC 3261. The default values are the same as those specified for RFC 3261.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **SIP container settings** > **SIP container** > **SIP stack**.

Automatically reply to INVITE with "100 Trying" response:

Specifies whether to automatically reply to INVITE requests with a 100 Trying response. Disabling this setting might increase the number of INVITE retransmissions.

Data type Boolean
Default True

Hide message body:

Specifies whether to hide message content in log files. Set the value to `True` to remove the message body text from SIP messages printed in the log files. This setting only affects the representation of the messages in log files.

Data type Boolean
Default False

Enable outbound connection timeout:

Specifies whether to enable the outbound connection timeout.

Data type Boolean
Default False

Outbound connection timeout:

Specifies the amount of time, in milliseconds, for creating outbound connections. This setting is relevant only for stream transports, such as Transmission Control Protocol (TCP) and Transport Layer Security (TLS). The default value of `0` provides an infinite amount of time.

Data type Integer

Default 0

Maximum transmission unit:

Specifies the maximum transmission unit, in bytes, for outbound User Datagram Protocol (UDP) requests. The SIP stack measures the size of a request before sending it out on the UDP channel. If the request is higher than the value specified for PATH_MTU-200, 1300 bytes by default, then the transport is switched from UDP to TCP before transmission.

Increase this value to send larger requests over the UDP channel; however, messages might be truncated or discarded. See the RFC 3261-18.1.1 specification for details.

Data type Integer
Default 1500

Outbound proxy:

Specifies the fixed address for routing all outbound SIP messages. The format is address:port/transport, such as 1.2.3.4:5065/tcp.

Best Practice: Do not use this setting if the container is fronted by an application server SIP proxy.

Data type String
Default empty string

SIP timers settings

Use this page to set values for the Session Initiation Protocol (SIP) timers that are different from those specified in RFC 3261. SIP timers provide a mechanism for session expiration.The default values are the same as those specified for RFC 3261.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **SIP container settings** > **SIP container** > **SIP stack** > **SIP timers**.

The following SIP timers can be configured from the administrative console.

T1:

Specifies the amount of time, in milliseconds, for a network round trip delay for timer T1 for the RFC 3261 specification. The value is used as a base for calculating some timers and is relevant for all types of transactions, such as client, server, invite, and non-invite transactions.

Data type Integer
Default 500

A Specifies, for UDP only, the amount of time, in milliseconds, before retransmitting invite requests for timer A for the RFC 3261 specification. This setting is relevant for the invite client transaction.

Data type Integer
Default T1

B Specifies the amount of time, in milliseconds, for the invite client transaction timeout timer (timer B) for the RFC 3261 specification.

Data type Integer

Default T1*64

E Specifies, for UDP only, the amount of time, in milliseconds, before the retransmission of the initial non-invite request for timer E for the RFC 3261 specification. This setting is relevant for the non-invite client transaction.

Data type Integer
Default T1

F Specifies the amount of time, in milliseconds, for the non-invite transaction timeout timer (timer F) for the RFC 3261 specification. This setting is relevant for the non-invite client transaction.

Data type Integer
Default T1*64

G Specifies the amount of time, in milliseconds, before retransmission of an initial invite response for timer G for the RFC 3261 specification. This setting is relevant for the invite server transaction.

Data type Integer
Default T1

H Specifies the amount of time, in milliseconds, to wait for an acknowledgement (ACK) receipt for timer H for the RFC 3261 specification. This setting is relevant for the invite server transaction.

Data type Integer
Default T1*64

J Specifies the amount of time, in milliseconds, to wait for non-invite request retransmission for timer J for the RFC 3261 specification. This setting is relevant for the non-invite server transaction.

Data type Integer
Default T1*64

T2:

Specifies the maximum amount of time, in milliseconds, before retransmitting non-invite requests and invite responses for timer T2 for the RFC 3261 specification.

Data type Integer
Default 4000

T4:

Specifies the maximum amount of time, in milliseconds, for a message to remain in the network. This value is used as a base for calculating other timers for timer T4 for the RFC 3261 specification.

Data type Integer
Default 5000

I Specifies the amount of time, in milliseconds, to wait for an ACK retransmission for timer I for the RFC 3261 specification. This setting is relevant for the invite server transaction.

Data type Integer
Default T4

K Specifies the amount of time, in milliseconds, to wait for non-INVITE response retransmissions for timer K for the RFC 3261 specification. This setting is relevant for the non-invite client transaction.

Data type	Integer
Default	T4

D:

Specifies the amount of time to wait, in milliseconds, before retransmission of the invite response for timer D for the RFC 3261 specification. This setting is relevant for the invite client transaction.

Data type	Integer
Default	32000

Configuring SIP timers

You can configure SIP timers to set values for the Session Initiation Protocol (SIP) timers that are different from default values specified in RFC 3261. SIP timers provide a mechanism for session expiration. The default values are the same as those specified for RFC 3261.

Before you begin

About this task

You can set values for the SIP timers from the administrative console.

Note: If you have already used the custom properties to specify a value for a SIP timer, the custom property value is the primary value. Therefore, the SIP timer value specified from the administrative console is not used.

Procedure

1. From the administrative console, click **Servers** > ***server_name*** > **SIP container** > **SIP stack** > **SIP timers**.
2. Specify a value for a timer by clicking the Use Custom Value check box beside the timer.
3. Specify a value for the timer in the Value column.
4. Click **OK**.
5. Restart the application server.

Results

The container uses the times specified in the administrative console and not the RFC defaults.

SIP timer summary:

Request for Comments (RFC) 3261, “SIP: Session Initiation Protocol,” specifies various timers that SIP uses.

Table 229 on page 2461 summarizes for each SIP timer the default value, the section of RFC 3261 that describes the timer, and the meaning of the timer.

Table 229. Summary of SIP timers.

This table lists a summary of SIP timers.

Timer	Default value	Section	Meaning
T1	500 ms	17.1.1.1	Round-trip time (RTT) estimate
T2	4 sec.	17.1.2.2	Maximum retransmission interval for non-INVITE requests and INVITE responses
T4	5 sec.	17.1.2.2	Maximum duration that a message can remain in the network
Timer A	initially T1	17.1.1.2	INVITE request retransmission interval, for UDP only
Timer B	64*T1	17.1.1.2	INVITE transaction timeout timer
Timer D	> 32 sec. for UDP	17.1.1.2	Wait time for response retransmissions
	0 sec. for TCP and SCTP		
Timer E	initially T1	17.1.2.2	Non-INVITE request retransmission interval, UDP only
Timer F	64*T1	17.1.2.2	Non-INVITE transaction timeout timer
Timer G	initially T1	17.2.1	INVITE response retransmission interval
Timer H	64*T1	17.2.1	Wait time for ACK receipt
Timer I	T4 for UDP	17.2.1	Wait time for ACK retransmissions
	0 sec. for TCP and SCTP		
Timer J	64*T1 for UDP	17.2.2	Wait time for retransmissions of non-INVITE requests
	0 sec. for TCP and SCTP		
Timer K	T4 for UDP	17.1.2.2	Wait time for response retransmissions
	0 sec. for TCP and SCTP		

Performing controlled failover of SIP applications

You can take an active application out of the loop via a controlled failover.

Before you begin

SipContainerMBean is used to initiate a server quiesce through wsadmin (command line interface). This MBean is used to set the container's weight to 0, which prevents new messages from being routed to it.

WebSphere Application Server PMI is used to monitor the server's active sessions. The remaining active sessions can be watched by enabling a counter on the server being quiesced. The server can be shut down once the number of active sessions reaches an acceptable level. A script can be written to monitor active sessions and shut down the server when an acceptable threshold is achieved.

About this task

Quiescing a single server

1. On an ND machine, start the wsadmin utility:
   a. Go to `<nd_installation_path>/bin`
   b. Run the command: ./setupCmdLine.sh
   c. Run the command: ./wsadmin.sh
   d. Verify that received: wsadmin>

2. Run the command: set scBean [$AdminControl queryNames type=SipContainerMBean,process=<server name>,*]
3. Run the command: $AdminControl invoke $scBean quiesce true

From the admin console, command line or scripts

Use the following commands to stop application servers from the admin console, command line or scripts:

- **Stop:** Quiesces the application server. The sessions will failover to another server. It is important to manually quiesce the server on shutdown.
- **Immediate Stop:** Stops the server, but bypasses the normal server quiesce process that supports in-flight requests to complete before shutting down the entire server process. This shutdown mode is faster than the normal server stop processing, but some application clients can receive exceptions.
- **Terminate:** Deletes the application server process. Use this if immediate stop fails to stop the server.

Configuring SIP application routers

Use the Session Initiation Protocol (SIP) application router to select the order in which SIP applications are triggered. When configuring a SIP application router, you can either use the default application router or create a custom application router.

About this task

The SIP container provides an application router component called the Default Application Router (DAR). The DAR component uses a configuration text file, similar to a Java properties file, that defines the order in which the application router sends SIP requests to applications.

Restriction: WebSphere Application Server has a default way of sorting the order of SIP applications invocation using the Startup behavior settings. The sorting order is based on the application weight. This weighting policy only applies if you do not specify a DAR configuration file, or if a custom application router has not been associated with the server or cluster.

You can either use the DAR or a custom application router to perform application routing, as described in the procedure.

Use the following procedure to select the best method to implement the SIP application router for your configuration.

Procedure

- Use the DAR component with a DAR configuration file.
  1. In the administrative console, click **Environment** > **SIP application routers**. The table displays a list of available application routers, including the DAR component.
  2. Click the **DefaultSIPApplicationRouter** link.
  3. View the list of server and cluster targets that are associated with the application router in the **Targets** table.
  4. Targets may or may not be available. To change the target of an application router, go back to the SIP application routers panel, click on a router name, and check to see if a target is listed. If a target is listed, select a target and then click the **Move to Application Router** button. The drop-down menu lets you select another application router.
  5. For the **DefaultSIPApplicationRouter**, click a target link name to set the application routing configuration for the target.
  6. Click **Advanced application routing rules (DAR configuration)** to use a DAR configuration file, and click **Apply**.
  7. Click **Configure routing rules** to view or edit the routing rules.

8. If you have an existing DAR configuration file, you can click the **Import...** button to upload the new DAR configuration file. The **File Import** window is displayed, which allows you to browse to the file and upload it; then click the **Import** button.
9. Use the **New**, **Delete**, **Move up**, and **Move down** buttons on the **DAR Configuration File** page to create and modify routing rules.
10. Click **Save** directly to the master configuration and then restart server or cluster to pick up the changes.

- Use the DAR component with manual application ordering.
  1. In the administrative console, click **Environment** > **SIP application routers**. The table displays a list of available application routers, including the DAR component.
  2. Click the **DefaultSIPApplicationRouter** link.
  3. View the list of server and cluster targets that are associated with the application router in the Targets table.
  4. Targets may or may not be available. To change the target of an application router, go back to the SIP application routers panel, click on a router name, and check to see if a target is listed. If a target is listed, select a target and then click the **Move to Application Router** button. The drop-down menu lets you select another application router.
  5. For the **DefaultSIPApplicationRouter**, click a target link name to set the application routing configuration for the target.
  6. Click **Basic application startup order** to use the application order from the target; then click **Apply**.
  7. Click **Configure application startup order** to view the application startup order weights for the applications on this target.
  8. Enter a numerical value in the **Startup order weight** column for the application. The startup order weight determines the order in which the SIP application router sends SIP requests to applications. These values also determine the startup order of applications after a server restart. Applications with lower startup values start first.

     Restriction: If there are two or more SIP applications bundled inside one enterprise archive (EAR) application file, the bundled SIP applications will have the same weight. If more complex routing rules are needed, a different application router method must be used.
  9. Click **Update**.
  10. Click **Save** directly to the master configuration and then restart server or cluster to pick up the changes.

  Attention: The CEA samples package includes a wsadmin (Jython) script library that you can use to simplify the development and testing of scripts that automate configuration changes. For further information, see the wsadmin (Jython) scripting procedures for CEA information.
- Use a custom application router.
  1. In the administrative console, click **Environment** > **SIP application routers**. The table displays a list of available application routers, including the DAR component.
  2. Select a custom SIP application router from the list, or click **New** to create a new one. The Configuration tab shows the name of the application router and the provider name of the application router. The provider name of the application router must be set to the custom application router implementation fully qualified class name.
  3. Place the Java archive (JAR) file in the server class path. For example, place the JAR file in the *java_home*/lib/ext directory, and ensure this directory is included in the class path for the server.

     gotcha: Do not add this path to the **Servers** > **Server Types** > **Websphere application servers** > ***server_name*** > **Sip Container** > **Java and Process Management** > **Process Definition** > **Java Virtual Machine** > **Classpath** entry, because this can cause conflicts.

4. Enter or edit the information in the required fields as needed. The required fields are identified with an asterisk (*).
5. Click **Apply** and then click **Save** directly to the master configuration.
6. To change the target of an application router, click on a router name, and check to see if a target is listed. If a target is listed, select a target and then click the **Move to Application Router** button. The drop-down menu lets you select another application router.
7. Click **Save** directly to the master configuration and then restart server or cluster to pick up the changes.

Attention: The CEA samples package includes a wsadmin (Jython) script library that you can use to simplify the development and testing of scripts that automate configuration changes. For further information, see the wsadmin (Jython) scripting procedures for CEA information.

- Use custom properties to configure the SIP application router. You can use the following custom properties to configure a DAR or a custom application router. These custom properties override the administrative console settings.
  1. In the administrative console, click **Servers > Server Types > WebSphere application servers > *server_name***.
  2. Under **Container Settings**, expand **SIP Container Settings** and click **SIP container**.
  3. Under **Additional Properties**, click **Custom properties**, then click **New**.
  4. For the DAR, use the **javax.servlet.sip.ar.dar.configuration** custom property. This property specifies the location of the DAR properties file that defines the order in which the application router sends SIP requests to applications as described in Appendix C of the JSR 289 specification.
  5. For the custom application router, use the **javax.servlet.sip.ar.spi.SipApplicationRouterProvider** custom property. This property specifies the custom application router implementation fully qualified class name as described in section 15.4.2 of the JSR 289 specification. The custom application router implementation class defines the order in which the application router sends SIP requests to applications.
  6. Click **Save** directly to the master configuration and then restart server or cluster to pick up the changes.

Results

You have successfully configured a SIP application router.

SIP application router collection

Use this page to create and delete SIP application routers. The Session Initiation Protocol (SIP) application router allows you to select the order in which SIP applications are run at an initial SIP request.

To view this administrative console page, click **Environment > SIP application routers**. The table displays a list of available application routers, including the default application router (DAR).

New:

Click **New** to create a new SIP application router.

On the Configuation tab, specify the following required fields. Click **Apply** to save the entry or **Reset** to clear.

- **SIP application router name** – Specify a logical name for the application router.
- **SIP application router provider name** – Specifies the provider name of the application router. This is defined in the custom application router jar file, which must be in the application server's classpath.

Delete:

To delete a listed application router, select it, then click **Delete**. The DefaultSIPApplicationRouter cannot be deleted.

SIP Application Router Name:

Specifies the SIP application router name that you entered on the Configuration tab or the Default SIP Application Router.

SIP application router settings

Use this page to configure SIP application router container settings. The Session Initiation Protocol (SIP) application router allows you to select the order in which SIP applications are triggered. You can use the default application router (DAR) or specify a custom application router adhering to the SIP Servlet specification.

To view this administrative console page, click **Environment > SIP application routers**, then click *SIP_application_router_name* from the list displayed.

SIP application router name:

Enter a logical name representing the application router. If you selected the default application router, this field cannot be edited.

SIP application router provider name:

Specifies the provider name of the application router. This is defined in the custom application router jar file, which must be in the application server's classpath. This field is not visible when you edit the DAR.

Targets:

Specifies a list of server and cluster targets that are associated with an application router. By default, all servers and clusters defined in the system are listed as targets of the DAR. Each target can only be associated with one application router. For the DAR, you can also set the order in which the applications are run on each target.

Move to Application Router:

Specifies the **Move to Application Router** button, which allows you to change the targets of an application router. Each application router can have a set of targets to choose from. Click this button to move the selected target to another application router.

Target:

Specifies the target associated with an application router. Click the target name to view more information about the target server, such as whether to use a DAR configuration file or to specify the application order.

Full name:

Specifies the full name of the target. This can be helpful to distinguish each target. For example, if you have multiple targets named "server1" on different nodes, you can tell them apart by looking at the **node=** part of the Full Name.

Application routing order settings:

Use this page to specify whether the Default SIP Application Router (DAR) must rely on the basic application startup order or advanced application routing rules (DAR configuration).

To view this administrative console page, click **Environment > SIP application routers > DefaultSIPApplicationRouter > *target***.

Basic application startup order:

Specifies to use application startup order weights to determine the application routing order.

Click the link to go to the Startup order page where you can specify the application order weight for each application on the target server. Lower weighted values take precedence.

Advanced application routing rules (DAR configuration):

Specifies to use routing rules when determining the application routing order.

Click the link to go to the DAR configuration file rules page where you can edit, import, or view the rules to be used by the SIP application router for this target server.

Application startup order settings:

Use this page to define the order in which Session Initiation Protocol (SIP) requests are routed to applications.

To view this administrative console page, click **Environment > SIP application routers > DefaultSIPApplicationRouter > *target* > Configure application startup order**.

Startup order weight:

Specifies to manually order the installed applications using the Startup Weight column in the Application order table.

The Startup order weight determines the order in which the SIP application router sends SIP requests to applications. These values also determine the startup order of applications after a server restart. The lower values start first.

Application name:

Specifies the name of the SIP application whose startup order weight you can modify.

SIP container custom properties:

You can add any of the following custom properties to the configuration settings for a Session Initiation Protocol (SIP) container.

To specify custom properties for a specific SIP container, navigate to the custom properties page, and then specify a value for the custom property.

Important: The custom properties are supported as the primary method of configuration. Therefore, if a custom property is set and then you set the corresponding setting in the administrative console, the custom property value is used.

1. In the administrative console, expand **Servers > Server Types > WebSphere application servers >** *server_name* to open the configuration tab for the server.
2. From **Container settings**, expand **SIP Container settings**, and click **SIP container**.
3. From **Additional properties**, select **Custom Properties** > **New**.
4. On the settings page, type the custom property to configure in the **Name** field, and then type the value of the custom property in the **Value** field.

5. Click **Apply** or **OK**.
6. Click **Save** on the console task bar to save your configuration changes.
7. Restart the server.

The following list of SIP container custom properties is provided with the product. These properties are not shown on the settings page for the container.

You can define the following SIP container custom properties that are provided with the product. These properties are not shown on the settings page for the container.

- “auth.int.enable” on page 2442
- “com.ibm.sip.sm.lnm.size” on page 2442
- “com.ibm.webspehere.sip.security.digest.ldap.cachecleanperiod” on page 2442
- “com.ibm.websphere.sip.security.tai.usercachecleanperiod” on page 2442
- “com.ibm.ws.sip.key.set” on page 2442
- “com.ibm.ws.sip.tai.DisableSIPBasicAuth” on page 2442

- “thread.message.queue.max.size” on page 2453
- “weight.overload.watermark” on page 2453

auth.int.enable:

Specifies the **auth-int** quality of protection (QOP) for digest authentication. Digest authentication defines two types of QOP: **auth** and **auth-int**. By default, **auth** is used. When this custom property is set to True, the highest level of protection is used, which is the **auth-int** QOP.

Data type	String
Default	False

com.ibm.sip.sm.lnm.size:

Specifies the number of logical names in the application server. Each SIP object that can be replicated, such as a SIP session, is associated with a logical name. All objects with the same logical name are replicated to the same back-up container. The proxy can route messages to the correct container using the logical name found in the message. The value must be greater than 1.

Data type	String
Default	10

com.ibm.webspehere.sip.security.digest.ldap.cachecleanperiod:

Specifies the clean Lightweight Directory Access Protocol (LDAP) cache period in minutes.

Data type	String
Default	120

com.ibm.websphere.sip.security.tai.usercachecleanperiod:

Specifies the clean security subject cache period in minutes.

Data type	String
Default	15

com.ibm.ws.sip.key.set:

Specifies the key to use for SIP flow token security. When a value is specified for this property, SIP flow token security is automatically enabled.

Data type String
Default There is no default value

com.ibm.ws.sip.tai.DisableSIPBasicAuth:

Specifies whether to allow basic authentication for SIP.

Data type String
Default False

DigestPasswordServerClass:

Specifies types of user registries that are supported, except LDAP. To configure DigestTAI without the LDAP user registry, complete the following steps.

1. Create a class that implements this interface: com.ibm.ws.sip.security.digest.DigestPasswordServer
2. Add the following property to the SIP container custom property:
   Default LdapPasswordServer
3. Ensure that all users declared by the impl class are declared in the user registry configured for the product security.

Data type String
Default impl

enable.system.headers.modify:

Specifies whether the application has access to headers that are otherwise restricted.

Data type String
Default False

end.of.service.replication: Specifies whether changes are buffered until the thread for a siplet is about to end. If the value is set to `true`, then each change is buffered until the thread for the siplet is about to end.

Data type Boolean
Default true

immediate.replication: Specifies whether each change is immediately sent to the Data Replication Service. When this property is set to `true`, when replication is issued from a non-SIP container thread, the replication is immediately performed on the calling thread. When this property is set to `false`, the changes are buffered, and replication does not occur until all changes are made.

Setting this property to true might have a negative impact on performance.

Data type Boolean
Default false

javax.servlet.sip.ar.dar.configuration:

Specifies the location of the default application router (DAR) properties file. The properties file defines the order in which the application router sends SIP requests to applications as described in Appendix C of the JSR 289 specification.

Data type	String
Default	Null

javax.servlet.sip.ar.spi.SipApplicationRouterProvider:

Specifies the custom application router implementation fully qualified class name as described in section 15.4.2 of the JSR 289 specification. The custom application router implementation class defines the order in which the application router sends SIP requests to applications.

Data type	String
Default	Null

javax.sip.bind.retries:

Specifies the amount of time, in milliseconds, between attempts to start the SIP channel if the SIP port is busy with another process during server startup.

Data type	String
Default	60

javax.sip.bind.retry.delay:

Specifies the delay, in milliseconds, between attempts to start the SIP channel if the SIP port is busy with another process during server startup.

Data type	String
Default	5000

javax.sip.detect.pre.escaped.params:

Specifies whether to prevent the container from re-escaping Uniform Resource Identifier (URI) parameters that were pre-escaped by the application.

Enabling this property provides the application with more control over escaping URI parameters, when calling the **javax.servlet.sip.SipFactory.createURI()** and the **javax.servlet.sip.SipURI.setParameter()** parameters.

By default, the container only escapes characters that it must encode according to the RFC 3261 25.1 specification. In some cases, however, escaping additional characters might be required. Due to a limitation in the JSR 116 (5.2.1) specification, the application cannot perform its own escaping. Because of this limitation, attempts by the application to encode URI parameters causes the container to re-encode the percent sign. If the value of this property is set to true, the container cannot re-encode the percent sign.

Setting the value to true is not in compliance with the JSR 116 (5.2.1) specification, but provides the application with greater control over URI parameter escaping. APAR PK37192 describes the problem and the workaround.

Data type	String
Default	False

javax.sip.force.connection.reuse:

Specifies whether to force reuse of inbound connections for outbound requests. This custom property is only relevant for stream transports, such as Transmission Control Protocol (TCP) and Transport Layer Security (TLS). Disabling this property causes the container to create a separate connection for outbound requests, even if an existing connection is already established to the same peer address. The connection is automatically reused if the top Via header in the inbound request contains an alias parameter. (http://www.ietf.org/internet-drafts/draft-ietf-sip-connect-reuse-07.txt)

Data type	String
Default	False

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.hide.message.body:

Specifies to hide message content in logs. Set the value of this property to `true` to remove the message body text from SIP messages printed in the log files. This property only affects the representation of the messages in log files.

Data type	String
Default	False

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.hide.message.headers:

Specifies to hide the specified message header field names in log files. The value of this property is a comma-separated list of header field names that you want removed from SIP messages printed in the log files. This property only affects the representation of the messages in log files.

Data type	String
Default	None

javax.sip.hide.request.uri:

Specifies to hide request URIs in log files. Set the value of this property to `true` to remove request URIs from SIP messages printed in the log files. This property only affects the representation of the messages in log files.

Data type	Boolean
Default	False

javax.sip.OUTBOUND_PROXY:

Specifies the fixed address for routing all outbound SIP messages. The format is *address:port/transport*, such as `1.2.3.4:5065/tcp`.

Note: Do not use this property if the container is fronted by an application server SIP proxy.

Data type	String
Default	null

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.PATH_MTU:

Specifies the maximum transmission unit, in bytes, for outbound User Datagram Protocol (UDP) requests. The SIP stack measures the size of a request before sending it out on the UDP channel. If the request is larger than the value specified for **PATH_MTU-200** (1300 bytes by default), then the transport is switched from UDP to TCP before transmission. Increase this value to send larger requests over the UDP channel; however, messages might be truncated or dropped. See the RFC 3261-18.1.1 specification for details.

Data type	String
Default	1500

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.stat.report.interval:

Specifies the amount of time, in milliseconds, for reporting dispatch and timer statistics to a system.out file. A value of zero indicates no report.

Data type	String
Default	0

javax.sip.trace.msg.in:

Specifies whether to print incoming messages to a system.out file.

Data type	String
Default	False

javax.sip.trace.msg.out:

Specifies whether to print outbound messages to a system.out file.

Data type	String
Default	False

javax.sip.transaction.invite.auto100:

Specifies whether to automatically reply to invite requests with a `100 Trying` response. Disabling this property might increase the number of invite retransmissions.

Data type	String
Default	True

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.transaction.timer.a:

Specifies, for UDP only, the amount of time, in milliseconds, before retransmitting invite requests for timer A for the RFC 3261 specification. This property is relevant for the invite client transaction.

Data type	String
Default	javax.sip.transaction.timer.t1

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.transaction.timer.b:

Specifies the amount of time, in milliseconds, for the invite client transaction timeout timer (timer B) for the RFC 3261 specification.

Data type	String
Default	64*javax.sip.transaction.timer.t1

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.transaction.timer.cancel:

Specifies the amount of timer, in milliseconds, for the timer to keep the cancelled client transaction in the proceeding state before completing the cancelled transaction for the RFC 3261 9.1 specification. This property is relevant for the invite client transaction.

Data type	String
Default	64*javax.sip.transaction.timer.t1

javax.sip.transaction.timer.d:

Specifies the wait time, in milliseconds, before retransmission of the invite response for timer D for the RFC 3261 specification. This property is relevant for the invite client transaction.

Data type	String
Default	32000

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.transaction.timer.e:

Specifies, for UDP only, the amount of time, in milliseconds, before the retransmission of the initial non-invite request for timer E for the RFC 3261 specification. This property is relevant for the non-invite client transaction.

Data type	String
Default	javax.sip.transaction.timer.t1

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.transaction.timer.f:

Specifies the amount of time, in milliseconds, for the non-invite transaction timeout timer (timer F) for the RFC 3261 specification. This property is relevant for the non-invite client transaction.

Data type	String
Default	64*javax.sip.transaction.timer.t1

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.transaction.timer.g:

Specifies the amount of time, in milliseconds, before retransmission of an initial invite response for timer G for the RFC 3261 specification. This property is relevant for the invite server transaction.

Data type	String
Default	javax.sip.transaction.timer.t1

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.transaction.timer.h:

Specifies the amount of time, in milliseconds, to wait for an acknowledgement (ACK) receipt for timer H for the RFC 3261 specification. This property is relevant for the invite server transaction.

Data type	String
Default	64*javax.sip.transaction.timer.t1

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.transaction.timer.i:

Specifies the amount of time in milliseconds to wait for an ACK retransmission for timer I for the RFC 3261 specification. This property is relevant for the invite server transaction.

Data type	String
Default	javax.sip.transaction.timer.t4

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.transaction.timer.invite.server:

Specifies the amount of time, in milliseconds, for the timer to keep the invite server transaction in the complete state. This timer is not defined in the RFC specification.

To avoid creating a new server transaction when a client retransmits an invite request, keep the completed server transaction for a period of time before removing invite retransmissions. This timer is started when the transaction changes to the terminated state. When the timer completes, the transaction is removed.

Data type	String
Default	32000

javax.sip.transaction.timer.j:

Specifies the amount of time in milliseconds to wait for non-invite request retransmission for timer J for the RFC 3261 specification. This property is relevant for the non-invite server transaction.

Data type String
Default 64*javax.sip.transaction.timer.t1

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.transaction.timer.k:

Specifies the amount of time, in milliseconds, to wait for non-INVITE response retransmissions for timer K for the RFC 3261 specification. This property is relevant for the non-invite client transaction.

Data type String
Default javax.sip.transaction.timer.t4

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.transaction.timer.non.invite.server:

Specifies the amount of time, in milliseconds, for an Application Programming Interface (API) timer for the application to respond to a non-invite request. This property is relevant for non-invite server transactions.

This timer is not defined in the RFC specification. This property is needed to stop the transaction if the application does not generate a final response to the request. The timer starts when the request arrives in the stack and stops when a response is generated by the application. If no response is generated before the timer stops, then the transaction completes.

Data type String
Default 34000

javax.sip.transaction.timer.t1:

Specifies the amount of time, in milliseconds, for a network round trip delay for timer T1 for the RFC 3261 specification. The value is used as a base for calculating some timers and is relevant for all types of transactions, such as client, server, invite, and non-invite transactions.

Data type String
Default 500

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.transaction.timer.t2:

Specifies the maximum time in milliseconds before retransmitting non-invite requests and invite responses for timer T2 for the RFC 3261 specification.

Data type	String
Default	4000

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

javax.sip.transaction.timer.t4:

Specifies the maximum amount of time, in milliseconds, for a message to remain in the network. This value is used as a base for calculating other timers for timer T4 for the RFC 3261 specification.

Data type	String
Default	5000

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

on.outgoing.message.replication: Specifies whether changes are buffered until a siplet issues a request.send() or response.send() call. If the value is set to `true`, then each change is buffered until a siplet issues a request.send() or response.send() call.

Data type	Boolean
Default	false

pws_atr_name:

Specifies the LDAP attribute name that stores the user password.

Data type	String
Default	userpassword

replicate.with.confirmed.dialog.only:

Specifies whether to replicate the application session, even when no dialogs are confirmed. If the value is set to `false`, then the application session is replicated immediately after the session is created. Otherwise, the application session is only replicated when an associated dialog is confirmed.

Data type	String
Default	False

sip.container.heartbeat.enabled:

Specifies whether or not SIP network outage detection is enabled for the SIP container. SIP network outage detection allows the SIP proxy to send keepalive messages to the SIP container if the value of this property is set to `true`.

If the value is set to `false` for the SIP container, then this property has no effect on the SIP proxy. However, if the value is set to `true` for the SIP container, the value should also be set to `true` for the SIP proxy to ensure that keepalive messages are answered at the SIP container and not presented to the application.

Data type	String
Default	true

sip.jsr289.parse.address:

Specifies to use the SIP Servlet Specification 1.1, JSR 289 required format for createRequest() and createAddress() methods.

Note: The JSR 289 API requires that for any SIP URI that contains address parameters, you must enclose the SIP URI in angle brackets. The default behavior of the sip.jsr289.parse.address property is compliant with JSR 289 and correctly parses the address parameter as if it belongs to the SIP address. For example, when the property is set to `false`, the SIP address, `sip:fred@acme.com;param1=1`, is converted to `<sip:fred@acme.com;param1=1>`. When the property is set to `true`, the SIP address `sip:fred@acme.com;param1=1`, is converted to `<sip:fred@acme.com;>param1=1`.

Data type	String
Default	True

SIP_RFC3263_nameserver:

Specifies whether to allow a SIP URI to be resolved through Domain Name System (DNS) into the IP address, port, and transport protocol of the next hop.

The value of the property is a string containing one or two address and port tuples, where two tuples are separated by a space. The following examples specify a one address and port tuple or a two address and port tuple.

dottedDecimalAddress@.port

hostname.domain@port

IPV6address@port

The following example values represent a single tuple.

- 1.2.3.4@53
- example.com@53
- a:b:c::d@53

The following example values represent two tuples separated by a space.

- 1.2.3.4@53 example.com@53
- a:b:c::d@53 9.32.211.14@53

Data type	String
Default	null

depfeat: This custom property is deprecated. Do not use this custom property unless you are running in a mixed cell environment that includes at least one core group that contains a mixture of Version 7.0 and Version 6.x processes.

mixv: If you are running in a mixed cell environment, and you have core groups that contain a mixture of Version 7.0 and Version 6.x processes, you must continue to use this custom property.

thread.message.queue.max.size:

Specifies the maximum number of events allowed in the container threads queue. When this number is exceeded, the proxy server is notified that the container is overloaded and requests for new sessions are not accepted. Instead, the container returns an error message that indicates that the container is temporarily unavailable.

This value represents the total number of messages for all queues and reflects the state of the CPU. When the CPU approaches 100%, the maximum value for this custom property is reached quickly. Configure your system to limit the queue size and prevent the queue from reaching this threshold.

Data type	String
Default	1000

weight.overload.watermark:

Specifies the threshold value for the internal weight calculated by the container. When the container calculates the internal weight to be higher than the value specified, an overloaded container becomes available for service again.

This custom property represents a percentage of the maximum internal weight, such as 30 percent when the default value is set. When the high-water mark, or maximum threshold, is exceeded, the container waits until the weight drops below the maximum weight. This value cannot exceed `10`.

Data type	String
Default	3

Default application router rule collection:

Use this page to view or modify default application router (DAR) routing rules or import a new DAR configuration file. The DAR is a Session Initiation Protocol (SIP) application router that you can use to select the order in which SIP applications are triggered.

To view this administrative console page, click **Environment > SIP application routers > DefaultSIPApplicationRouter > *target* > Configure routing rules**.

The DAR configuration file contains the routing definitions for the application routing order of the DAR. You can upload a new DAR configuration file and view the definitions in the existing DAR configuration file. You can also use the New, Delete, Move up, and Move down buttons to edit rules individually. Use the **Method** menu list to filter the list of displayed rules by method name. Select **All Methods** to view all rules currently in the DAR configuration file.

Table 230. Button descriptions. This table shows button descriptions.

Button	Resulting action
New	Click to add a new DAR rule.

Table 230. Button descriptions (continued). This table shows button descriptions.

Button	Resulting action
Delete	Click to delete the selected rules.
Move Up / Move Down	Click to move the selected rule up or down in the list of rules. Rules must remain grouped by the method name; rules only move up or down within the method group. For example, if you try to move up an INVITE method, but the previous method is an ACK method, then this INVITE method is already at the top of the INVITE method group, and cannot move any higher.
Import	Click to open the file import window. Browse to the new DAR configuration file. **Attention:** Importing a new configuration file overwrites all existing rules.

Method:

Specifies the name of the SIP method used in the request.

Application:

Specifies the name of the application that the application router sends the SIP request to.

Subscriber identifier:

Specifies the identity of the subscriber that the DAR returns. The DAR can return any header in the SIP request. For example, if you specify `DAR:From` , the SIP URI is returned in the From header. The DAR can also return any string.

Routing region:

Specifies the routing region, which can be any of the following strings:
- ORIGINATING
- TERMINATING
- NEUTRAL

Route modifier:

Specifies the route modifier, which can be any of the following values:
- ROUTE
- ROUTE_BACK
- NO_ROUTE

Default application router rule settings

Use this page to edit the details of an application router rule.

To view this administrative console page, click **Environment > SIP application routers > DefaultSIPApplicationRouter > *target* > Configure routing rules**. Select a routing rule to edit or click **New**.

Routing rules are used to determine how the default SIP application router routes SIP requests to the installed applications.

Method:

Specifies the name of the SIP method in the request.

Select a method from the existing method list, or specify a new method name.

Application:

Specifies the name of the application that the application router sends the request to.

Subscriber identifier:

Specifies the identity of the subscriber that the DAR returns. The DAR can return any header in the SIP request. For example, if you specify `DAR:From` , the SIP URI is returned in the From header. The DAR can also return any string.

Select a subscriber identifier from the list of existing identifiers, or specify a new subscriber identifier name.

Routing region:

Specifies the routing region, which can be any of the following strings:

- ORIGINATING
- TERMINATING
- NEUTRAL

SIP URI:

Specifies the SIP URI that indicates the route as returned by the application router. This value can be an empty string.

Route modifier:

Specifies the route modifier, which can be any of the following values:

- ROUTE
- ROUTE_BACK
- NO_ROUTE

State info:

Specifies the stateInfo object, which the application router uses internally. For more information about this value, see the SIP servlet specification.

Configuring multihomed hosting

The SIP container can accept from the SIP proxy a list of outbound interfaces and expose it to any SIP application.

Before you begin

Multihomed hosting is configured at the WebSphere SIP proxy after the multihomed environment is set up. The multihome topology may include setting up multiple networks (routers, switches, etc.), multiple load balancers (if more than one proxy server needs to be configured for each virtual IP), and multiple network cards on each of the available proxy servers. After you install the network cards and configure the loopback addresses, set up a separate SIP proxy channel chain in each SIP proxy for each available network interface.

Attention: You can only configure the SIP proxy server to support multiple interfaces. The SIP container does not support this capability.

About this task

Multihoming allows you to have a single application communicate with different user agent clients (UAC) and user agent servers (UAS) on different networks.

The application queries the SIP container to determine the list of available outbound interfaces using standard procedures defined by JSR 289. This is done through a context attribute that is maintained in the container (through protocol exchanges with all the available SIP proxies). This attribute is javax.servlet.sip.SipServlet.OUTBOUND_INTERFACES, which is defined to be `javax.servlet.sip.outboundInterfaces`. This attribute contains all the available interfaces. The sample code in the Example section shows how to access the attribute from the application.

After the interfaces on each SIP proxy are configured, follow the steps in the procedure to control the routing of outbound messages. If more than one proxy is being used, it is important that each proxy be configured identically.

When an application does not specify an interface to use for sending outbound requests, the default interfaces are used by the proxy. It is recommended that you set the default interfaces for every protocol. See step 5 for more information.

The administrator can optionally set three SIP proxy custom properties that define the chain name that define the appropriate interface to use if the SIP application does not call the setOutboundInterface method. If these custom properties are not set and the setOutboundInterface method is not used, the interface that will be used for outbound requests cannot be definitively determined.

The following procedure applies to a topology that contains a single proxy setup for multihomed hosting with more than one network interface.

Procedure

1. In the administrative console, expand **Servers > Server Types** and click **WebSphere proxy servers > *proxy_name***.
2. Under **Proxy Settings**, expand **SIP Proxy Server Settings** and click **SIP proxy server transports**.
3. On the Transport Chain panel, delete existing transport chain or chains that contain proxy host names that use an asterisk (*).
4. Add new transport chain names and specify the IP address or host name associated with the interface that the chain is configured to use. Proxy multihomed configurations require you to configure a transport for each proxy interface. When using proxy servers with a load balancer, ensure a transport for TCP exists along with the desired transport type for SIP traffic. For example, when a proxy server uses two interfaces, then a minimum of six proxy transport chains are required. Each proxy interface will have a UDP transport chain (2) configured using the load balancer cluster alias IP address, TCP transport chain (2), and specific transport chain (2) of desired protocol (UDP, TLS, etc.) to run SIP traffic.
   a. On the Transport chain panel, click **New**. The Create New Transport Chain wizard initializes. During the transport chain creation process, add a unique Transport chain name and select the proxy protocol template (UDP, TCP, or Secure) from the Transport chain template menu.
   b. Click **Next**.
   c. Select the **Use existing port** or **Create a new port** option. For new ports, provide the port name, host name, and port number. For the Host value, specify the IP address or specific host name. Do not use an asterisk (*) for the Host value.
   d. Click **Next** for Step 2.
   e. Review the summary of actions and click **Finish** for Step 3.
   f. At the top of the panel, click **Save** to save the changes to the master configuration and resynchronize with the nodes, if applicable.

5. Specify the default chain name to use on the proxy server. From the SIP proxy settings panel, custom properties can be set up to specify the appropriate default interface for each protocol. These interfaces are used to send outbound requests when an application does not specify which interface to use.
   a. In the administrative console, expand **Servers > Server Types** and click **WebSphere proxy servers > *proxy_name***.
   b. Under **Proxy Settings** , expand **SIP Proxy Server Settings** and click **SIP proxy settings > Custom properties**.
   c. Enter the appropriate chain name previously configured in step 4 (not the interface or host name) to configure the transports section of the SIP proxy settings. There is one custom property for each transport type.

Custom Property Name	Description
defaultUDPChainName	The default UDP chain name to use when setOutboundInterface is not called.
defaultTCPChainName	The default TCP chain name to use when setOutboundInterface is not called.
defaultTLSChainName	The default TLS chain name to use when setOutboundInterface is not called.

6. Recycle the proxy server.

Results

You have successfully configured SIP multihomed hosting, which enables your applications to route outbound SIP requests through more than a single outbound interface.

Example

The following sample code demonstrates how to acquire the available outbound interfaces and set the appropriate outbound interface on the session object.

```
....
import javax.servlet.sip.SipServlet;
import javax.servlet.sip.SipSession;
....

protected void doInvite(SipServletRequest req1) throws ServletException, IOException
{
 ...
 // This block of code handles setting of the outbound interface.
         SipSession sipSession = req1.getSession();
 javax.servlet.ServletContext  context = getServletContext();
 java.util.List list = (java.util.List)context.getAttribute(javax.servlet.sip.SipServlet.
OUTBOUND_INTERFACES);
 SipURI uri = getProtocolInterface ("udp", list);

 if (uri != null)
 {
  InetSocketAddress inetSocketAddr = new InetSocketAddress(uri.getHost(), uri.getPort());
  sipSession .setOutboundInterface(inetSocketAddr);
 }
 ...
}

// This method simply pulls out the first interface in the list for the specified protocol
private SipURI getProtocolInterface(String transport, List outboundInterfaceList)
{
 SipURI uri = null;
 Iterator iterator = outboundInterfaceList.iterator();
```

```
 while (iterator.hasNext())
 {
  SipURI tempUri = (SipURI)iterator.next();

  if (tempUri.getTransportParam().equals(transport) == true)
  {
   uri = tempUri;
   break;
  }
 }

 return (uri);
}
```

Multihomed hosting:

SIP can support the ability to route outbound SIP requests through more than a single interface with the multihomed host feature of JSR 289.

In a multihomed host environment, the SIP container has the ability to select a particular outbound interface for routing messages. The SIP container can accept from the SIP proxy a list of outbound interfaces and expose it to any SIP application. This functionality is for applications that require tighter control over the outgoing request flow.

The following two methods can be used to select the outbound interface to use when sending requests, as defined in section 14.2 of the JSR 289 specification:

- `setOutboundInterface(java.net.InetAddress address)`
- `setOutboundInterface(java.net.InetSocketAddress address)`

A SIP application can obtain a list of available of SIP URIs it can send outbound requests on from the ServletContext attribute "javax.servlet.sip.outboundInterfaces," which is defined with the static string `javax.servlet.sip.SipServlet.OUTBOUND_INTERFACES`.

The application must set the interface on the Proxy, the ProxyBranch, or the SipSession objects before any outbound requests are sent. The interface is passed back in the attribute for outbound interfaces. The container then notifies the proxy which interface to send the outbound request on. Routing of non-request messages is controlled by other means, such as headers. For instance, a response message always flows through the same interface that the request arrived on.

Modifying the outbound routing of a request can affect all of the following SIP headers that are inserted into the outgoing SIP request, and subsequent responses in the dialog:

- Via header
- Contact headers
- Record-Route and Route headers
- Path header

Three SIP proxy custom properties specify the default chain names that define the appropriate interface to use for outbound requests. See the information on configuring multihomed hosting.

SIP with multihomed host is only supported in a distributed environment and must be configured at the WebSphere SIP proxy. A stand-alone SIP container does not support this capability.

Configuring multiple proxy servers using a load balancer in a multihomed environment

You can configure multiple proxy servers with multiple network interfaces using a load balancer in a multihomed environment.

Before you begin

Communications Enabled Applications (CEA) enables you to have multiple network interfaces on multiple proxy servers using a load balancer.

In a multihome environment, you need to define multiple virtual IP (VIP) alias addresses at the proxy server, and you need to define the proxy transport chains for each VIP alias address.

Note: Do not use an asterisk (*) for the transport chain names. Instead, use host names and IP addresses for the transport chains.

About this task

The following setup includes configuring a load balancer with two clusters, and two proxy servers with two VIP alias addresses defined. Ensure that the following steps are repeated for both proxy servers.

Procedure

1. In the administrative console, expand **Servers > Server Types** and click **WebSphere proxy servers > *proxy_name***.
2. Under **Proxy Settings**, expand **SIP Proxy Server Settings** and click **SIP proxy settings**.
3. Under Load balancer health checking, set the Load balancer members for IP address 1 and IP address 2. The IP address of the load balancer is used to source the SIP health checks.
4. Under Container facing network interface, specify the User Datagram Protocol (UDP) interface. The UDP interface specifies the network interface for all UDP data that goes to and from the backend SIP containers.
5. Click **Custom properties** and set the default protocol chain name types for each protocol type (UDP, TCP, and TLS). Specify the default chain name to use on the proxy server. From the SIP proxy settings panel, custom properties can be set up to specify the appropriate default interface for each protocol. These interfaces are used to send outbound requests when an application does not specify which interface to use.
   a. In the administrative console, expand **Servers > Server Types** and click **WebSphere proxy servers > *proxy_name***.
   b. Under **Proxy Settings** , expand **SIP Proxy Server Settings** and click **SIP proxy settings > Custom properties**.
   c. Enter the appropriate chain name to configure the transports section of the SIP proxy settings. There is one custom property for each transport type.

Custom Property Name	Description
defaultUDPChainName	The default UDP chain name to use when setOutboundInterface is not called.
defaultTCPChainName	The default TCP chain name to use when setOutboundInterface is not called.
defaultTLSChainName	The default TLS chain name to use when setOutboundInterface is not called.

6. In the administrative console, expand **Servers > Server Types** and click **WebSphere proxy servers > *proxy_name***.
7. Under **Proxy Settings**, expand **SIP Proxy Server Settings** and click **SIP proxy server transports**.
8. On the Transport Chain panel:
   a. Add two TCP transport chains using the host name or IP address for each network interface.
   b. Add two UDP transport chains using the host name or IP address for each network interface.

c. Add two UDP transport chains using the VIP alias addresses of the proxy servers so that the load balancer can communicate with the proxy servers. These two unique VIP alias addresses must be the same on both proxy servers.

9. Recycle the proxy server.

Results

You have successfully configured multihomed network interfaces for two proxy servers using a load balancer.

Chapter 26. Administering Startup beans

This page provides a starting point for finding information about startup beans.

Startup beans allow business logic to run when an application starts or stops.

Using startup beans

There are two types of startup beans: application startup beans and Module startup beans.

About this task

Note: The capabilities provided with startup singleton session beans (EJB 3.1 specification) causes the WebSphere Application Server proprietary startup beans function to be deprecated.

A module startup bean is a session bean that is loaded when an EJB Jar file starts. Module startup beans enable Java Platform Enterprise Edition (Java EE) applications to run business logic automatically, whenever an EJB module starts or stops normally. An application startup bean is a session bean that is loaded when an application starts. Application startup beans enable Java EE applications to run business logic automatically, whenever an application starts or stops normally.

Startup beans are especially useful when used with asynchronous bean features. For example, a startup bean might create an alarm object that uses the Java Message Service (JMS) to periodically publish heartbeat messages on a well-known topic. This enables clients or other server applications to determine whether the application is available. Refer to the Enabling an application to wait for a messaging engine to start article if you are using the default JMS provider.

Procedure

1. For Application startup beans, use the home interface, com.ibm.websphere.startupservice.AppStartUpHome, to designate a bean as an Application startup bean. For Module startup beans, use the home interface, com.ibm.websphere.startupservice.ModStartUpHome, to designate a bean as a Module startup bean.
2. For Application startup beans, use the remote interface, com.ibm.websphere.startupservice.AppStartUp, to define start() and stop() methods on the bean. For Module startup beans, use the remote interface, com.ibm.websphere.startupservice.ModStartUp, to define start() and stop() methods on the bean.

   The startup bean start() method is called when the module or application starts and contains business logic to be run at module or application start time.

   The start() method returns a boolean value. **True** indicates that the business logic within the start() method ran successfully. Conversely, **False** indicates that the business logic within the start() method failed to run completely. A return value of False also indicates to the Application server that application startup is aborted.

   The startup bean stop() methods are called when the module or application stops and contains business logic to be run at module or application stop time. Any exception thrown by a stop() method is logged only. No other action is taken.

   The start() and stop() methods must never use the TX_MANDATORY transaction attribute. A global transaction does not exist on the thread when the start() or stop() methods are invoked. Any other TX_* attribute can be used. If TX_MANDATORY is used, an exception is logged, and the application start is aborted.

   The start() and stop() methods on the remote interface use **Run-As** mode. **Run-As** mode specifies the credential information to be used by the security service to determine the permissions that a principal has on various resources. If security is on, the **Run-As** mode needs to be defined on all of the methods called. The identity of the bean without this setting is undefined.

There are no restrictions on what code the start() and stop() methods can run, since the full Application Server programming model is available to these methods.

3. Use an *optional* environment property integer, `wasStartupPriority`, to specify the start order of multiple startup beans in the same Java Archive (JAR) file. If the environment property is found and is the wrong type, application startup is aborted. If no priority value is specified, a default priority of `0` is used. It is recommended that you specify the priority property. Beans that have specified a priority are sorted using this property. Beans with numerically lower priorities are run first. Beans that have the same priority are run in an undefined order. All priorities must be positive integers. Beans are stopped in the opposite order to their start priority. The priority values for module startup beans and application startup beans are mutually exclusive. All modules will be started prior to the application being declared as "started" and therefore the start() methods for module startup beans within an application will be invoked prior to the start() methods for any application startup beans. Likewise, all application startup bean stop() methods for a specific Java Archive (JAR) file will be invoked prior to any module startup bean stop() methods for that JAR.
4. For module startup beans, the order in which EJB modules are started can be adjusted via the "Starting weight" value associated with each module
5. To control who can invoke startup bean methods via WebSphere Security do the following:
   a. Define the method permissions for the Start() and Stop() methods as you would for any EJB module. (See "Defining method permissions for EJB modules".)
   b. Ensure that the user that is mapped to the Security Role defined for the startup bean methods is the same user that is defined as the Server user ID within the User Registry.

What to do next

View the startup beans service settings.

Enabling startup beans in the administrative console

Enabling startup beans in the administrative console enables Java 2 Platform Enterprise Edition (J2EE) applications to run business logic automatically, whenever an application starts or stops normally.

About this task

Use the following steps to enable startup beans in the administrative console.

Procedure

1. Start the administrative console.
2. Select **Servers** > **Application Servers** > *server_name* > **Container Services** > **Startup beans service**.
3. Select the **Enable service at server startup** check box.
4. Click **Apply** to save the configuration.

What to do next

View the startup beans service settings.

Startup beans service settings

Use this page to enable startup beans that control whether application-defined startup beans function on this server. Startup beans are session beans that run business logic through the invocation of start and stop methods when applications start and stop. If the startup beans service is disabled, then the automatic invocation of the start and stop methods does not occur for deployed startup beans when the parent application starts or stops. This service is disabled by default. Enable this service only when you want to use startup beans. Startup beans are especially useful when used with asynchronous beans.

Note: The capabilities provided with startup singleton session beans (EJB 3.1 specification) causes the WebSphere Application Server proprietary startup beans function to be deprecated.

To view this administrative console page, click **Servers > Server types > WebSphere application servers >** *server_name*. Under **Container Settings**, expand **Container Services** then click **Startup beans service**.

Enable service at server startup

Specifies whether the server attempts to initiate the startup beans service.

Default
Cleared

Range

Selected
When the application server starts, it attempts to initiate the startup bean service automatically.

Cleared
The server does not try to initiate the startup beans service. All startup beans do not start or stop with the application. If you use startup beans on this server, then the system administrator must start the startup beans service manually or select this property, and then restart the server.

Chapter 27. Administering Transactions

This page provides a starting point for finding information about Java Transaction API (JTA) support. Applications running on the server can use transactions to coordinate multiple updates to resources as one unit of work, such that all or none of the updates are made permanent.

The product provides advanced transactional capabilities to help application developers avoid custom coding. It provides support for the many challenges related to integrating existing software assets with a Java EE environment. More introduction...

Administering the transaction service

You can view or change settings for the transaction service and manage active and prepared transactions. You can configure transaction properties to enable peer recovery of failed application servers in a cluster.

Procedure

- "Configuring transaction properties for an application server"
- "Managing active and prepared transactions" on page 2505
- "Managing transaction logging for optimum server availability" on page 2510
- "Displaying transaction recovery audit messages" on page 2514
- "Delaying the cancelling of transaction timeout alarms" on page 2515
- "Removing entries from the transaction partner log" on page 2515

Configuring transaction properties for an application server

You can view or change settings for the transaction service. For example, you can change the location or default file size of the transaction log files, change transaction timeout properties, or change heuristic-related properties.

About this task

The transaction service is a server runtime component that can coordinate updates to multiple resource managers to ensure atomic updates of data. Transactions are started and ended by applications or the container in which the applications are deployed.

You might undertake this task when you want to move the transaction logs to a different storage device, or when you have to change the transaction service settings. You must restart the application server to make configuration changes take effect.

Procedure

1. In the administrative console, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***. The properties of the application server, *server_name*, are displayed in the content pane.
2. Click **[Container Settings] Container Services** > **Transaction Service**. The Transaction Service settings page is displayed.
3. Ensure that the Configuration tab is displayed.
4. Optional: To change the directory in which transaction logs are written, type the full path name of the directory in the **Transaction log directory** field. You can check the current runtime value of **Transaction log directory** by clicking the **Runtime** tab.

   If you do not enter a value for the **Transaction log directory**, the application server assumes a default location in the appropriate profile directory.

Note: If you change the transaction log directory, apply the change and restart the application server as soon as possible, to minimize the risk of problems occurring before the application server is restarted. For example, if there is a problem and the server fails with in-flight transactions, when the server restarts, it uses the new log directory and cannot automatically resolve in-flight transactions that were recorded in the old log directory.

You can also specify a size for the transaction logs, as described in the following step.

5. Optional: To change the size of transaction log files, modify the **Transaction log directory** field to include a file size setting. Use one of the following formats, where *directory_name* is the name of the transaction log directory and *file_size* is the disk space allocation for the transaction log files, specified in kilobytes (*n*K) or megabytes (*n*M). The minimum transaction log file size that you can specify is 64K. If you specify a value that is less than 64K, or you do not specify a value for the file size, the default value of 1M is used.

```
;file_size   <!-- This format keeps the default directory -->
directory_name;file_size
dir://directory_name/directory_name;file_size
/directory_name/directory_name;file_size
```

In a non-production environment, you can turn transaction logging off by entering `;0` in the **Transaction log directory** field (do not enter a directory name). Do not turn transaction logging off in a production environment because this prevents recovery after a system failure, and therefore data integrity cannot be guaranteed.

For more information about transaction log sizes, see “Managing transaction logging for optimum server availability” on page 2510.

6. Optional: Review or change the value of transaction timeout properties:

Total transaction lifetime timeout

The number of seconds to allow for a transaction that is started on this server, before the transaction service initiates timeout completion. If a transaction does not begin completion processing before this timeout occurs, it is rolled back. A value of `0` (zero) indicates that this timeout does not apply, and therefore the maximum transaction timeout is used instead. Application components can override the total transaction lifetime timeout for their transactions by setting their own timeout value.

If you are running your messaging system in non-ASF mode, you must make sure that this property is correctly configured with **NON.ASF.RECEIVE.TIMEOUT** so that unwanted transaction timeouts are avoided. See the related links for more details.

Maximum transaction timeout

The number of seconds a transaction that is propagated into this application server can remain inactive before it is ended by the transaction service. This value also applies to transactions that are started in this server, if their associated applications do not set a transaction timeout and the total transaction lifetime timeout is set to `0` (zero).

This value must be equal to, or greater than, the total transaction lifetime timeout. A value of `0` (zero) indicates that this timeout does not apply. In this situation, transactions that are affected by this timeout never time out.

Client inactivity timeout

The number of seconds after which a client is considered inactive and the transaction service ends any transactions associated with that client. A value of `0` (zero) indicates that there is no timeout limit.

7. Optional: Review or change heuristic-related properties:

Heuristic retry limit

The number of times that the application server retries a completion signal, such as commit or rollback. Retries occur after a transient exception from a resource manager or remote partner, or if the configured asynchronous response timeout expires before all Web Services Atomic Transaction (WS-AT) partners have responded.

Heuristic retry wait
The number of seconds that the application server waits before retrying a completion signal, such as commit or rollback, after a transient exception from a resource manager or remote partner.

Enable logging for heuristic reporting
Select this option to enable the application server to log “about to commit one-phase resource” events from transactions that involve a one-phase commit resource and two-phase commit resources.

Heuristic completion direction
Select the direction used to complete a transaction that has a heuristic outcome; either the application server commits or rolls back the transaction, or depends on manual completion by the administrator.

The heuristic completion direction property specifies how a transaction is completed in the following situations:

- The transaction manager reports a heuristic outcome for a last participant support (LPS) resource.
- The heuristic retry limit is exceeded during the recovery of a subordinate server in a distributed transaction.
- The transaction is imported from a Java EE Connector Architecture (JCA) provider.

This property applies only to transactions that are in the situations just described.

Accept heuristic hazard
Select this option to specify that all applications on this server accept the possibility of a heuristic hazard occurring in a two-phase transaction that contains a one-phase resource. This setting configures last participant support (LPS) for the server. If you do not select this option, you must configure applications individually to accept the heuristic hazard.

8. Optional: To change the default WS-Transaction specification level to use for outbound requests that include a web Services Atomic Transaction (WS-AT) or Web Services Business Activity (WS-BA) coordination context, select the specification level from the **Default WS-Transaction specification level** list.
9. Review or change other configuration properties, to suit your requirements. For more information about the properties of the transaction service, see the topic about Transaction service settings.
10. Click **OK**, then save your changes to the master configuration.
11. Stop, then restart, the application server.

What to do next

If you change the transaction log directory configuration property to an incorrect directory name, the application server restarts, but cannot open the transaction logs. Change the configuration property to a valid directory name, then restart the application server.

If you are running the application server as non-root, modify the permissions on the new transaction log location. To use peer recovery of transactions on a shared device with non-root users, make sure that your non-root users and groups have matching identification numbers across machines.

Transaction service settings

Use this page to specify settings for the transaction service. The transaction service is a server runtime component that can coordinate updates to multiple resource managers to ensure atomic updates of data. Transactions are started and ended by applications or the container in which the applications are deployed.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Container Settings] Container Services** > **Transaction Service**.

Transaction log directory:

Specifies the name of a directory for this server where the transaction service stores log files for recovery. Optionally, you can specify the size of transaction log files.

Set this property to change the transaction log file directory for an application server only if the applications use distributed resources or XA transactions; for example, multiple databases and resources are accessed in a single transaction.

If you do not specify this directory during server configuration, the transaction service uses a default directory that is based on the installation directory: *app_server_root*/ tranlog/*cell_ name*/*node_ name*/*server_ name*.

When an application that runs on the application server accesses more than one resource, the application server stores transaction information in the product directory so that it can coordinate and manage the distributed transaction correctly. When there is a higher transaction load, storing persistent information in this way can slow the performance of the application server because it depends on the operating system and the underlying storage systems. To achieve better performance, designate a new directory for the log files on a separate, physically larger, storage system.

If your application server demonstrates one or more of the following symptoms, change the transaction log directory:
- CPU use remains low despite an increase in transactions
- Transactions fail with several timeouts
- Transaction rollbacks occur with the exception “Unable to enlist transaction”
- The application server stops in the middle of a run and must be restarted
- The disk that the application server is running on shows higher use

There are the following recommendations for a storage system for the log files:
- Store log files on a redundant array of independent disks (RAID)

  In RAID configurations, the task of writing data to the physical media is shared across the multiple drives. This technique yields more concurrent access to storage for persisting transaction information, and faster access to that data from the logs. Depending on the design of the application and storage subsystem, performance gains can range from 10% to 100%, or more in some cases.
- Do not store log files with the operation system I/O mode set to concurrent I/O (CIO)

  When you designate a transaction log directory, ensure that the file system uses only synchronous write-through and write serialization operations. Some operating systems, such as AIX JFS2, support an optional concurrent I/O (CIO) mode, where the file system does not enforce serialization of write operations. On these systems, do not use CIO mode for application server transaction recovery log files.

To specify the size of transaction log files, include a file size setting. Use one of the following formats, where *directory_name* is the name of the transaction log directory and *file_size* is the new disk space allocation for the transaction log files, specified in KB (*n*K) or MB (*n*M). The minimum transaction log file size that you can specify is 64K. If you specify a value that is less than 64K, or you do not specify a value for the file size, the default value of 1M is used.

```
;file_size   <!-- This format keeps the default directory -->
directory_name;file_size
dir://directory_name/directory_name;file_size
/directory_name/directory_name;file_size
```

For more information about transaction log sizes, see “Managing transaction logging for optimum server availability” on page 2510.

Data type String

Default	Directory name: *app_server_root*/tranlog/*cell_name*/*node_name*/*server_name* File size: 1MB
Recommended	Create a file system with at least three to four disk drives raided together in a RAID-0 configuration. Then, create the transaction log on this file system with the default size. When the server is running under load, check the disk input and output. If disk input and output time is more then 5%, consider adding more physical disks to lower the value.

Total transaction lifetime timeout:

The default maximum time, in seconds, allowed for a transaction that is started on this server before the transaction service initiates timeout completion. Any transaction that does not begin completion processing before this timeout occurs is rolled back.

This timeout is used only if the application component does not set its own transaction timeout.

The upper limit of this timeout is constrained by the maximum transaction timeout. For example, if you set a value of `500` for the total transaction lifetime timeout, and a value of `300` for the maximum transaction timeout, transactions will time out after 300 seconds.

If you set this timeout to `0`, the timeout does not apply and the value of the maximum transaction timeout is used instead.

Data type	Integer
Units	Seconds
Default	120
Range	0 to 2 147 483 647

Asynchronous response timeout:

Specifies the amount of time, in seconds, that the server waits for an inbound Web Services Atomic Transaction (WS-AT) protocol response before resending the previous WS-AT protocol message.

Data type	Integer
Units	Seconds
Default	30
Range	0 to 2 147 483 647

Client inactivity timeout:

Specifies the maximum duration, in seconds, between transactional requests from a remote client. Any period of client inactivity that exceeds this timeout results in the transaction being rolled back in this application server.

If you set this value to `0`, there is no timeout limit.

Data type	Integer
Units	Seconds
Default	60
Range	0 to 2 147 483 647

Maximum transaction timeout:

Specifies, in seconds, the upper limit of the transaction timeout for transactions that run in this server. This value should be greater than or equal to the value specified for the total transaction timeout.

This timeout constrains the upper limit of all other transaction timeout periods.

Table 231. Transaction timeout settings. The table shows how the different timeout settings apply to transactions running in the server.

Timeout setting	Transactions affected
Maximum transaction timeout	All transactions running in this server that are not affected by the total transaction lifetime timeout or an application component timeout. These transactions include transactions imported from outside this server, such as those imported from a client.
Total transaction lifetime timeout	All transactions that originated in this server that are not affected by an application component timeout, in other words, the associated application component does not set its own timeout.
Application component timeout	Transactions that are specific to an application component. You cannot set this transaction timeout using the administrative console. If the component is a container-managed bean, set this timeout in the deployment descriptor for the component. For example, you can use an assembly tool, such as the Rational Application Developer. If the component is a bean-managed bean, set this timeout programmatically by using the UserTransaction.setTransactionTimeout method.

If you set a timeout to `0`, that timeout does not apply, and is effectively disabled. If you set all timeouts to `0`, transactions never time out.

For example, consider the following timeout values:

Table 232. Example timeout values. The table lists different timeout settings and their values.

Timeout setting	Value
Maximum transaction timeout	360
Total transaction lifetime timeout	240
Application component timeout	60

In this example, transactions that are specific to the application component time out after 60 seconds. Other local transactions time out after 240 seconds, and any transactions that are imported from outside this server time out after 360 seconds. If you then change the application component timeout to `500`, application component transactions time out after 360 seconds, the value of the maximum transaction timeout. If you set the maximum transaction timeout to `0`, application component transactions time out after 500 seconds. If you remove the application component timeout, application component transactions time out after 240 seconds.

To determine the occurrence of a timeout quickly, and to prevent further resource locking, the application server prevents further transactional work on the transactional path where the timeout condition has taken place. This applies equally to attempting to undertake work under the current transaction context and to attempting to perform work under a different transactional context.

Data type Integer
Units Seconds
Default 300
Range 0 to 2 147 483 647

Heuristic retry limit:

Specifies the number of times that the application server retries a completion signal, such as commit or rollback. Retries occur after a transient exception from a resource manager or remote partner, or if the configured asynchronous response timeout expires before all Web Services Atomic Transaction (WS-AT) partners have responded.

If the application server abandons the retries, the resource manager or remote partner is responsible for ensuring that the resource or partner branch of the transaction is completed appropriately. The application server raises (on behalf of the resource or partner) an exception that indicates a heuristic hazard. If a commit request was made, the transaction originator receives an exception on the commit operation; if the transaction is container-initiated, the container returns a remote exception or Enterprise JavaBeans (EJB) exception to the EJB client.

During recovery of a subordinate server in a distributed transaction, when the number of heuristic retries is exceeded, the heuristic completion direction property specifies how the transaction is completed.

Data type	Integer
Default	0
Range	0 to 2 147 483 647 A value of 0 (the default) means try again indefinitely.

Heuristic retry wait:

Specifies the number of seconds that the application server waits before retrying a completion signal, such as commit or rollback, after a transient exception from a resource manager or remote partner.

Data type	Integer
Default	0
Range	0 to 2 147 483 647 A value of 0 means that the application server determines the retry wait; the server doubles the retry wait after every 10 failed retries.

Enable logging for heuristic reporting:

Specifies whether the application server logs about-to-commit-one-phase-resource events from transactions that involve both a one-phase commit resource and two-phase commit resources.

This property enables logging for heuristic reporting. If applications are configured to allow one-phase commit resources to participate in two-phase commit transactions, reporting of heuristic outcomes that occur at application server failure requires extra information to be written to the transaction log. If enabled, one additional log write is performed for any transaction that involves both one-phase and two-phase commit resources. No additional records are written for transactions that do not involve a one-phase commit resource.

Data type	Check box
Default	Cleared

Range

Cleared
The application server does not log "about to commit one-phase resource" events from transactions that involve a one-phase commit resource and two-phase commit resources.

Selected
The application server does log "about to commit one-phase resource" events from transactions that involve a one-phase commit resource and two-phase commit resources.

Heuristic completion direction:

Specifies the direction that is used to complete a transaction that has a heuristic outcome; either the application server commits or rolls back the transaction, or depends on manual completion by the administrator.

The heuristic completion direction property specifies how a transaction is completed in the following situations:

- The transaction manager reports a heuristic outcome for a last participant support (LPS) resource.
- The heuristic retry limit is exceeded during the recovery of a subordinate server in a distributed transaction.
- The transaction is imported from a Java EE Connector Architecture (JCA) provider.

This property applies only to transactions that are in the situations just described.

Data type Drop-down list
Default ROLLBACK
Range

COMMIT
The application server heuristically commits the transaction.

ROLLBACK
The application server heuristically rolls back the transaction.

MANUAL
The application server depends on an administrator to manually complete or roll back transactions with heuristic outcomes.

Accept heuristic hazard:

Specifies whether all applications on this server accept the possibility of a heuristic hazard occurring in a two-phase transaction that contains a one-phase resource. This setting configures last participant support (LPS) for the server. Last participant support is an extension to the transaction service that enables a single one-phase resource to participate in a two-phase transaction with one or more two-phase resources.

If the Accept heuristic hazard option is not selected, you must configure applications individually to accept the heuristic hazard. You can configure applications either when they are assembled, or following deployment by using the Last participant support extension pane.

Data type Check box
Default Cleared

Range

Selected
All applications deployed on the server accept the increased risk of an heuristic outcome.

Cleared
Applications must be individually configured to accept the increased risk of an heuristic outcome.

Enable file locking:

Specifies whether the use of file locks is enabled when opening the transaction service recovery log.

If you enable this setting, a file lock will be obtained before accessing the transaction service recovery log files. File locking is used to ensure that, in a highly available WebSphere Application Server deployment, only one application server can access a particular transaction service recovery log at any one time. This setting has no effect in a standard deployment where you have not configured high availability support.

Attention: This setting requires a compatible network file system, such as Network File System (NFS) version 4, to operate correctly.

Data type Check box
Default Selected

Enable transaction coordination authorization:

Specifies whether the secure exchange of transaction service protocol messages is enabled.

This setting has no effect unless you enable WebSphere Application Server security on the server.

Data type Check box
Default Selected

Default WS-Transaction specification level:

Specifies the default WS-Transaction specification level to use for outbound requests that include a Web Services Atomic Transaction (WS-AT) or Web Services Business Activity (WS-BA) coordination context.

You can choose from WS-Transaction 1.0, WS-Transaction 1.1 or WS-Transaction 1.2. For details of these specifications, see the topics about WS-AT support or WS-BA support in the application server.

The default WS-Transaction specification level is used if a level cannot be determined from the provider policy (the WS-Transaction WS-Policy assertion). This could be, for example, if the policy assertion is not available either from the WSDL of the target web service or from the WS-Transaction policy type of the client, or if the policy assertion is available but more than one specification level is applicable.

Data type Drop-down list
Default 1.0

External WS-Transaction HTTP(S) URL prefix:

Select or specify the external WS-Transaction HTTP(S) URL prefix.

Select or specify one of these fields if you are using an intermediary node, such as an HTTP server or Proxy Server for WebSphere, to send requests that comply with the Web Services Atomic Transaction (WS-AT) or Web Services Business Activity (WS-BA) protocols.

If WebSphere Application Server security is enabled and transaction coordination authorization is enabled, the HTTPS prefix is used. Otherwise, the HTTP prefix is used.

If the intermediary node is not a Proxy Server, the prefix must be unique for each server.

Select prefix:

Select this option to select the external endpoint URL information to use for WS-AT and WS-BA service endpoints from the list.

Data type Drop-down list
Default None

Specify custom prefix:

Select this option to specify the external endpoint URL information to use for WS-AT and WS-BA service endpoints in the field.

Use one of the following formats for the prefix, where *host_name* and *port* represent the intermediary node that is an HTTP or HTTPS proxy for the server.

`http://host_name:port`

`https://host_name:port`

Data type String
Default None

Manual transactions:

Specifies the number of transactions that await manual completion by an administrator.

If there are transactions awaiting manual completion, you can click the **Review** link to display a list of those transactions on the Transactions needing manual completion panel.

Data type Integer
Default 0

Retry transactions:

Specifies the number of transactions with some resources being retried.

If there are transactions with resources being retried, you can click the **Review** link to display a list of those transactions on the Transactions retrying resources panel.

Data type Integer
Default 0

Heuristic transactions:

Specifies the number of transactions that have completed heuristically.

If there are transactions that have completed heuristically, you can click the **Review** link to display a list of those transactions on the Transactions with heuristic outcome panel.

Data type	Integer
Default	0

Imported prepared transactions:

Specifies the number of transactions that are imported and prepared but not yet committed.

If there are transactions that have been imported and prepared but not yet committed, you can click the **Review** link to display a list of those transactions on the Transactions imported and prepared panel.

Data type	Integer
Default	0

Additional Properties:

Under Additional Properties you can click the **Custom properties** link to display or change custom properties for your WebSphere Application Server transaction service.

You use **Custom properties** to specify whether or not information messages are displayed on the administrative console and written to the `SystemOut.log` file upon transaction service recovery.

To find out more about WebSphere Application Server transaction service custom properties, see the related link.

Transactions needing manual completion:

Use this page to review transactions that need manual completion.

It is unusual for transactions to require manual completion. A transaction needs manual completion in the following circumstances:

1. An application was exploiting the last participant support to coordinate a single one-phase capable resource and one or more two-phase capable resources.
2. A failure occurred during the commit of the one-phase capable resource.
3. The transaction service heuristic completion direction is set to **Manual**, in the transaction service settings.

An administrator reviewing transactions in this state can review the outcome of any one-phase resources, by using facilities provided by the specific resource manager, then use this page to complete the transaction accordingly.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > [Content pane] *server_name* > **[Container Settings] Container Services** > **Transaction Service** > **Runtime** > **Manual transactions - Review**.

To list the resources used by a transaction, click the transaction local ID in the list displayed.

To act on one or more of the transactions listed, select the check boxes next to the transactions that you want to act on, then use the buttons provided.

Local ID

The local identifier of the transaction.

Global ID
The global identifier of the transaction.

Buttons

Commit
Heuristically commit the selected transactions.

Rollback
Heuristically roll back the selected transactions.

Transactions retrying resources:

Use this page to review transactions with resources being retried.

If the transaction manager has prepared resources, but has lost contact with the resource managers before committing them or aborting them, then the transaction manager retries the commit or rollback requests to the affected resource managers. The number of times and frequency that the transaction manager retries such commit or rollback requests is configured on the **Heuristic retry limit** and **Heuristic retry wait** properties of the transaction service settings.

An administrator can use this page to make the transaction service abandon the retries of one or more transactions. If a resource manager cannot be contacted, WebSphere Application Server relegates that resource manager to an in-doubt (prepared) state. The administrator then needs to use mechanisms specific to the resource manager to resolve the in-doubt status.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers >** [Content pane] *server_name* **> [Container Settings] Container Services** > **Transaction Service** > **Runtime** > **Retry transactions - Review**.

To list the resources used by a transaction, click the transaction local ID in the list displayed.

To act on one or more of the transactions listed, select the check boxes next to the transactions that you want to act on, then use the buttons provided.

Local ID
The local identifier of the transaction.

Status
The status of the transaction, shown as an integer value. The values correspond to the following status:

0 - active
1 - marked for rollback
2 - prepared
3 - committed
4 - rolled back
5 - unknown
6 - none
7 - preparing
8 - committing
9 - rolling back

Global ID
The global identifier of the transaction.

Buttons

Finish Stop retrying resources for the selected transactions.

Transactions with heuristic outcome:

Use this page to review transactions that completed with a heuristic outcome.

The page is provided for information purposes only. After you have reviewed the information in this page, then the only action required is to remove the transactions from the list. If you do not remove a transaction from the list, it is kept in the list for three days or until the server is shut down, whichever occurs first.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** [Content pane] *server_name* [Container Settings] **Container Services** > **Transaction Service** > **Runtime** > **Heuristic transactions - Review**.

To list the resources used by a transaction, click the transaction local ID in the list displayed.

To act on one or more of the transactions listed, select the check boxes next to the transactions that you want to act on, then use the buttons provided.

Local ID
The local identifier of the transaction.

Heuristic outcome
The outcome of the transaction.

Global ID
The global identifier of the transaction.

Buttons

Clear Remove the selected transactions from the list.

Transactions imported and prepared:

Use this page to review transactions that have been imported and prepared but not yet committed.

Under normal circumstances no administrative action is required for any of the transactions listed on this page. This page lists those transactions that are in a prepared state, but are being directed by an external transaction manager (for example, another WebSphere application server) from a transaction context that has been propagated.

Under aberrant circumstances, however, an administrator can configure WebSphere Application Server to resolve the transactions listed on this page independent of the external transaction manager. (This step might be necessary if, for example, the external transaction manager has become unavailable for an unacceptable period of time.)

Note: If the completion direction (commit or rollback) chosen administratively differs from the eventual direction of the external transaction manager, then the overall outcome of the transaction is not atomic and data corruption can result.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** [Content pane] *server_name* > **[Container Settings] Container Services** > **Transaction Service** > **Runtime** > **Imported prepared transactions - Review**.

To list the resources used by a transaction, click the transaction local ID in the list displayed.

To act on one or more of the transactions listed, select the check boxes next to the transactions that you want to act on, then use the buttons provided.

Local ID
The local identifier of the transaction.

Global ID
The global identifier of the transaction.

Buttons

Commit
Heuristically commit the selected transactions.

Rollback
Heuristically roll back the selected transactions.

Transaction resources:

Use this page to review resources used by a transaction.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** [Content pane] *server_name* > **[Container Settings] Container Services** > **Transaction Service** > **Runtime** > *transaction_type local_ID*.

Where:

- *transaction_type* is one of:
  - **Manual transactions - Review**
  - **Retry transactions - Review**
  - **Heuristic transactions - Review**
  - **Imported prepared transactions - Review**
- *local_ID* is the local ID of the transaction (as an active link in the list of transactions).

The details displayed depend on the resource provider.

Transaction service custom properties

WebSphere Application Server allows you to configure a number of custom properties for transaction services.

Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

Transaction service custom properties can be specified in the administrative console. To use any of these custom properties click on **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Container Settings] Container Services** > **Transaction Service** > **[Additional Properties] Custom Properties**.

You can define the following transaction service custom properties:

- DELAY_CANCELLING_ALARMS
- DISABLE_RECOVERY_AUDIT_LOGGING
- REMOVE_PARTNER_LOG_ENTRY

DELAY_CANCELLING_ALARMS: If the before completion stage of a transaction process is likely to include processes that could either take a long time to complete or could fail, then you might want the transaction to time out.

By default, transaction timeout alarms are cancelled prior to the before completion phase of the transaction begins. The DELAY_CANCELLING_ALARMS custom property allows the before completion phase of the transaction to be encompassed within the transaction timeout period. To do this, set the custom property on the application server.

Table 233. DELAY_CANCELLING_ALARMS custom properties. The table includes the data type, acceptable values, and default for the property.

Data type	Boolean
Acceptable values	TRUE, FALSE
Default	FALSE

DISABLE_RECOVERY_AUDIT_LOGGING: You can control whether information messages are displayed on the administrative console and written to the `SystemOut.log` file upon transaction service recovery. To do this, set the DISABLE_RECOVERY_AUDIT_LOGGING custom property for the transaction service for the server.

On distributed platforms the default is for information messages to appear both on the administrative console and in the `SystemOut.log` file during the recovery of transaction services. If you do not want these messages to be displayed you can use the DISABLE_RECOVERY_AUDIT_LOGGING custom property.

Table 234. DISABLE_RECOVERY_AUDIT_LOGGING custom properties. The table includes the data type, acceptable values, and default for the property.

Data type	Boolean
Acceptable values	TRUE, FALSE
Default	FALSE

REMOVE_PARTNER_LOG_ENTRY: You can remove entries from the transaction partner log file. To do this, set the REMOVE_PARTNER_LOG_ENTRY custom property for the transaction service on the server that owns the partner log.

As part of the transaction recovery process, the partner log is checked to establish which resources are needed. If you want to remove certain entries from the partner log, such as a resource that no longer exists, set this custom property on the application server that owns the transaction partner log containing the entries you want to remove.

The REMOVE_PARTNER_LOG_ENTRY custom property is effective only when both of the following situations apply.

- The application server is started in recovery mode.
- The application server has no transactions that currently require recovery. You can establish this by checking the `SystemOut.log` file.

Table 235. REMOVE_PARTNER_LOG_ENTRY custom properties. The table includes the data type, acceptable values, and default for the property.

Data type	Integer
Acceptable values	(one or more comma-delimited integer recovery ID)
Default	(null)

Managing active and prepared transactions

Use this task to manage active and prepared transactions that might need administrator action.

About this task

Under normal circumstances, transactions should run and complete (commit or roll back) automatically, without the need for intervention. However, in some circumstances, you might have to resolve a

transaction manually. For example, you might want to roll back a transaction that has become stuck polling a resource manager that you know will not become available again within the required timeframe.

Note: If you choose to complete a transaction on an application server, it is recorded as having completed in the transaction service logs for that server, so will not be eligible for recovery during server start up. If you complete a transaction, you are responsible for cleaning up any in-doubt transactions on the resource managers affected.

You can use the administrative console to display a snapshot of all the transactions in an application server that are in the following states:

Manual transactions
Transactions awaiting administrative completion. For each transaction, the local id or global id is displayed. You can choose to display information on each resource (specifically, which resource manager it is associated with) associated with the transaction. You can also choose to commit or roll back transactions in this state.

Retry transactions
Transactions with some resources being retried. For each transaction, the local id or global id is displayed, and whether the transaction is committing or rolling back. You can choose to display information on each resource (specifically, which resource manager it is associated with) associated with the transaction. You can also choose to finish (stop retrying) transactions in this state.

Heuristic transactions
Transactions that have completed heuristically. For each transaction, the local id or global id and the heuristic outcome is displayed. You can choose to display information on each resource (specifically, which resource manager it is associated with) associated with the transaction. You can also choose to clear the transaction from the list.

Imported prepared transactions
Transactions that have been imported and prepared but not yet committed. For each transaction, the local id or global id is displayed. You can choose to display information on each resource (specifically, which resource manager it is associated with) associated with the transaction. You can also choose to commit or roll back transactions in this state.

To manage the active and prepared transactions for an application server, use the administrative console to complete the following steps:

Procedure

1. Display the Transaction Service runtime page for application server:
   a. In the navigation pane, click **Servers** > **Server Types** > **WebSphere application servers**.
   b. In the content pane, click the name of the application server.
   c. In the content pane, click the **Runtime** tab.
   d. Under Additional Properties, click **Transaction Service**.

   The page displays values for the runtime properties of the transaction service, including the number of transactions in the active and prepared states.
2. To display a snapshot of the transactions in a specific state, click **Review** in the field label.
3. Optional: To display information about the resources associated with a transaction, click the name of the transaction.
4. Optional: To act on a transaction, select the check box provided on the entry for the transaction, then click one of the buttons provided. Alternatively, to act on all transactions, select the check box in the header of the transactions table, then click a button.

Managing active and prepared transactions by using wsadmin scripting

You can use wsadmin scripting to manage active and prepared transactions that might need administrator action.

Before you begin

Before you start this task, the wsadmin scripting client must be running.

About this task

In normal circumstances, transactions should run and complete (commit or roll back) automatically, without the need for intervention. However, in some circumstances, you might have to resolve a transaction manually. For example, you might want to roll back a transaction that is stuck polling a resource manager that you know will not become available again in the required time frame.

Note: If you choose to complete a transaction on an application server, it is recorded as having completed in the transaction service logs for that server, so it is not eligible for recovery during server start up. If you complete a transaction, you are responsible for cleaning up any in-doubt transactions on the resource managers affected.

For more information about the TransactionService and Transaction MBeans, see the application programming interface (API) documentation.

Procedure

- You can use the TransactionService Managed Bean (MBean) to list transactions in various states by invoking one of the following methods:

  listOfTransactions
  Lists all non-completed transactions. Never attempt to alter the state of active transactions (for example, by using commit or rollback).

  listManualTransactions
  Lists transactions awaiting administrative completion. You can commit or roll back transactions in this state.

  listRetryTransactions
  Lists transactions with some resources being retried. You can finish (stop retrying) transactions in this state.

  listHeuristicTransactions
  Lists transactions that have completed heuristically. You can clear these transactions from the list.

  listImportedPreparedTransactions
  Lists transactions that have been imported and prepared but not yet committed. You can commit or roll back transactions in this state.

  Each entry in the returned list contains the following attributes:
  - **Local Transaction Identifier**
  - **Status**, which can be interpreted by calling getPrintableStatus on the Transaction MBean.
  - **Global Transaction Identifier**
  - **Heuristic Outcome**, which can take one of the following values:
    - 8 (HEURISTIC_COMMIT)
    - 9 (HEURISTIC_ROLLBACK)
    - 10 (HEURISTIC_MIXED)
    - 11 (HEURISTIC_HAZARD)

- You can use the TransactionService MBean to gather more information about the properties of the transaction service, by obtaining the following attributes:

  transactionLogDirectory
  The directory for this server where the transaction service stores log files for recovery.

  totalTranLifetimeTimeout
  The default maximum time, in seconds, allowed for a transaction that is started on this server before the transaction service initiates timeout completion. Any transaction that does not begin completion processing before this timeout occurs is rolled back. This value applies only to container-managed transaction (CMT) beans.

  asyncResponseTimeout
  The time, in seconds, that the server waits for an inbound Web Services Atomic Transaction (WS-AT) protocol response before resending the previous WS-AT protocol message.

  enableFileLocking
  Specifies whether the use of file locks is enabled when opening the transaction service recovery log.

  enableProtocolSecurity
  Specifies whether the secure exchange of transaction service protocol messages is enabled.

  clientInactivityTimeout
  The maximum duration, in seconds, between transactional requests from a remote client. Any period of client inactivity that exceeds this timeout results in the transaction being rolled back in this application server.

  heuristicRetryLimit
  The number of times that the application server retries a completion signal, such as commit or rollback. Retries occur after a transient exception from a resource manager or remote partner, or if the configured asynchronous response timeout expires before all Web Services Atomic Transaction (WS-AT) partners have responded.

  heuristicRetryWait
  The number of seconds that the application server waits before retrying a completion signal, such as commit or rollback, after a transient exception from a resource manager or remote partner.

  propogatedOrBMTTranLifetimeTimeout
  The upper limit of the transaction timeout, in seconds, for transactions that run in this server. This value must be greater than or equal to the total transaction timeout.

  LPSHeuristicCompletion
  The action to use to complete a transaction that has an heuristic outcome. Either the application server commits or rolls back the transaction, or the administrator must complete the transaction manually.

- You can use the Transaction MBean to commit, roll back, or finish a transaction, or remove a transaction from the list of heuristically completed transactions, depending on the state of the transaction, by invoking one of the following methods:

  commit
  Heuristically commits the transaction.

  rollback
  Heuristically rolls back the transaction.

  finish Stops retrying resources for the transaction.

  removeHeuristic
  Clears the transaction from the list.

- You can use the Transaction MBean to gather more information about a transaction, by invoking the following methods:

  getPrintableStatus
  Return the transaction status.

  getGlobalTranName
  Get the global identifier for the transaction.

  listResources
  List the resources for the transaction.

Example

The following script is an example of how to use the TransactionService and Transaction MBeans to work with manual transactions. Run the script only against an application server, and not against the deployment manager or node agent.

Example Jacl script:

```
# get the TransactionService MBean
set servicembean [$AdminControl queryNames type=TransactionService,*]

# get the Transaction MBean
set mbean [$AdminControl queryNames type=Transaction,*]

set input 0
while {$input >= 0} {
        # invoke the listManualTransactions method
        set tranManualList [$AdminControl invoke $servicembean listManualTransactions]

        if {[llength $tranManualList] > 0} {
                puts "----Manual Transaction details---------------"
                set index 0
                foreach tran $tranManualList {
                        puts "   Index= $index tran= $tran"
                        incr index
                }
                puts "----End of Manual Transactions ---------------"
                puts "Select index of transaction to commit/rollback:"
                set input [gets stdin]
                if {$input < 0} {
                        puts "No index selected, exiting."
                } else {
                        set tran [lindex $tranManualList $input]
                        set commaPos [expr [string first "," $tran ]-1]
                        set localTID [string range $tran 0 $commaPos]
                        puts "Enter c to commit or r to rollback Transaction $localTID"
                        set input [gets stdin]
                        if {$input=="c"} {
                                puts "Committing transaction=$localTID"
                                $AdminControl invoke $mbean commit $localTID
                        }
                        if {$input=="r"} {
                                puts "Rolling back transaction=$localTID"
                                $AdminControl invoke $mbean rollback $localTID
                        }
                }
        } else {
                puts "No Manual transactions found, exiting"
                set input -1
        }
        puts " "

}
```

Example Jython script:

```
import sys
def wsadminToList(inStr):
        outList=[]
        if (len(inStr)>0 and inStr[0]=='[' and inStr[-1]==']'):
                tmpList = inStr[1:-1].split(" ")
```

```
        else:
                tmpList = inStr.split("\n")  #splits for Windows or Linux
        for item in tmpList:
                item = item.rstrip();        #removes any Windows "\r"
                if (len(item)>0):
                        outList.append(item)
        return outList
#endDef

servicembean = AdminControl.queryNames("type=TransactionService,*" )
mbean = AdminControl.queryNames("type=Transaction,*" )
input = 0

while (input >= 0):
        tranList = wsadminToList(AdminControl.invoke(servicembean, "listManualTransactions" ))

        tranLength = len(tranList)
        if (tranLength > 0):
                print "----Manual Transaction details---------------"
                index = 0
                for tran in tranList:
                        print "   Index=" , index , " tran=" , tran
                        index = index+1
                #endFor
                print "----End of Manual Transactions ---------------"
                print "Select index of transaction to commit/rollback:"
                input = sys.stdin.readline().strip()
                if (input == ""):
                        print "No index selected, exiting."
                        input = -1
                else:
                        tran = tranList[int(input)]
                        commaPos = (tran.find(",") -1)
                        localTID = tran[0:commaPos+1]
                        print "Enter c to commit or r to rollback transaction ", localTID
                        input = sys.stdin.readline().strip()
                        if (input == "c"):
                                print "Committing transaction=", localTID
                                AdminControl.invoke(mbean, "commit", localTID )
                        #endIf
                        elif (input == "r"):
                                print "Rolling back transaction=", localTID
                                AdminControl.invoke(mbean, "rollback", localTID )
                        #endIf
                        else:
                                input = -1
                        #endelse
                #endElse
        else:
                print "No transactions found, exiting"
                input = -1
        #endElse
        print " "

#endWhile
```

Managing transaction logging for optimum server availability

You can manage transaction logging to optimize the availability of your application servers.

About this task

The transaction service writes information to the transaction log for every global transaction that involves two or more resources, or that is distributed across multiple servers. The transaction log is stored on disk and is used by the transaction service for recovery after a system or server crash. The transaction log for each application server consists of multiple subdirectories and files held in a single directory. To change the directory that an application server uses to store the transaction log, change the transaction log directory in the transaction service settings.

When a global transaction is completed, the information in the transaction log is no longer required, and the information is marked for deletion. The redundant information is garbage collected and intervals, and

the space is reused by new transactions. The log files are created with a fixed size at server startup, so no further disk space allocation is required during the lifetime of the server.

If all the log space is in use when a transaction needs to save information, the transaction is rolled back and the message `CWWTR0083W: The transaction log is full. Transaction rolled back.` is reported to the system error log. No more transactions can commit until more log space is made available when existing active transactions complete.

The default disk space allocation for the transaction logs is 1M. For global transactions that involve only XA resources and that are either local to an application server or are distributed between enterprise beans running in remote application servers, the default disk space allocation is suitable for peak workloads of up to 4000 concurrent two-phase commit transactions. For global transactions that involve Web Services Atomic Transaction (WS-AT) transactions or interoperable OTS transactions, the default disk space allocation is suitable for peak workloads of up to 250 concurrent two-phase commit transactions. For higher workloads, consider using a larger transaction log. To change the disk space allocation for the transaction log files, change the transaction log directory in the transaction service settings.

You can monitor the number of concurrent global transactions by using the performance monitoring counters for transactions. The “Global transaction commit time” counter is a measure of how long a transaction takes to complete and, therefore, how long the log is in use by a transaction. If this value is high, then transactions are taking a long time to complete, which can be due to resource manager or network failures. If you ensure that this value is low, the log is more efficiently used and unlikely to become full.

Use the following tasks to manage transaction logging to optimize the availability of your application servers:

Procedure

- “Configuring transaction aspects of servers for optimum availability.” Use this task to configure the transaction properties for an application server to help transactions to complete or recover more quickly.
- “Moving a transaction log from one server to another” on page 2513 Use this task if you have to move a transaction log between servers.
- “Restarting an application server on a different host” on page 2514 Use this task to restart the application server if you move a transaction log between hosts.
- “Configuring transaction properties for an application server” on page 2491 Use this task to change the directory or the disk space allocation for the transaction log files.

Configuring transaction aspects of servers for optimum availability

You can configure transaction-related aspects of application servers to optimize the availability of those servers. This helps your transactions to complete or recover more quickly. After changing transaction-related properties of an application server, you must restart the server.

About this task

To configure transaction-related aspects of application servers for optimum availability, complete the following steps:

Procedure

1. Store the transaction log files on a fast disk in a highly-available file system, such as a RAID device. The transaction log might have to be accessed by every global transaction and be used for transaction recovery after a crash. Therefore, the disk the log files are being written to should be on a highly-available file system, such as a RAID device.

   The performance of the disk also directly affects the transaction performance. In general, a global transaction makes two disk writes, one after the prepare phase when the outcome of the transaction is

known (this information is forced to disk) and a further disk write at transaction completion. Therefore, the transaction logs should be placed on the fastest disks available.

In order for automatic failover of transaction log recovery to work in a WebSphere Application Server cluster topology, network mounted devices must be used for the transaction logs, on a fast disk in a highly-available file system, such as a RAID device, that each cluster member can access.

2. Mirror the transaction log files by using hardware disk mirroring or dual-ported disks. If log files have been mirrored or can be recovered, these log files can be used when restarting a failed server, or they can be moved to another machine and another server can be started to undertake recovery.

   You can configure hardware disk mirroring or dual-ported disks by using the administrative console to specify the appropriate file system directory for the transaction logs.

3. Specify the optimum location of the transaction log directory for application servers.

   By default, an application server places transaction log files in a subdirectory of the installed WebSphere Application Server, where the subdirectory name is the same as the server name.

   For example, the default directory for an application server named `server1` is

   ```
   /QIBM/UserData/WebSphere/AppServer/was_version/Base/profiles/profile_name/tranlog/server1
   ```

   where *was_version* indicates the version number for this installation of IBM WebSphere Application Server. For example `V6` for WebSphere Application Server Version 6.

   You can define a specific location for the transaction log directory for an application server by setting the **Transaction Log Directory** property for the server. If the directory for the transaction logs has not been created at application server start up, the directory structure is created for you.

   Note: If you change the transaction log directory, apply the change and restart the application server as soon as possible, to minimize the risk of problems occurring before the application server is restarted. For example, if a problem causes the server to fail (with in-flight transactions), the server next starts with the new log directory and cannot automatically resolve in-flight transactions that were recorded in the old log directory.

4. Never allow more than one application server to concurrently use the same set of log files. Because the transaction logs record the state of global transactions within a server, if the logs become lost or corrupt, then transactions that are in the prepared state before failure can leave resources in an in-doubt state and prevent further updates or access to the resources by other users or servers. These transactions might have to be manually resolved by either committing or rolling back the transactions at the affected resource managers. The failed server can then be cold-started, which creates new empty transaction logs.

   If log files have been mirrored or can be recovered, these log files can be used when restarting a failed server, or they can be moved to another machine and another server can be started to undertake recovery, as described in the related tasks.

   Never allow more than one application server to concurrently use the same set of log files, because each server will destroy the information recorded by the other, resulting in corrupt log files that are unusable for future recovery purposes.

5. Configure application servers to always use the same listening port address at each startup. If you are running distributed transactions between multiple application servers, for example non-WebSphere EJB or Corba servers, the remote object references saved in the transaction log have to be redirected to the originating server on recovery.

   You must handle the redirection of remote object references so that transaction recovery can complete. For example, you must do this if an application server is deployed on WebSphere Application Server and runs distributed transactions with non-WebSphere EJB or Corba servers.

   In particular, the default restart action of an application server is to use a different listening port address to the port when the server shuts down. This prevents transaction recovery from completing. To overcome this, you must configure application servers to always use the same listening port address at each startup (see the ORB property com.ibm.CORBA.ListenerPort in the topic about Object

Request Broker custom properties). You might have to make similar configuration changes to other application servers involved in transactions, so that you can access those servers during recovery.

Moving a transaction log from one server to another

You can move the transaction logs for an application server to another server.

About this task

The following steps explain how to move transaction logs from one application server to another.

Note: The transaction service does not allow transaction logs to be moved from one server to another in a high availability (HA) environment. In such scenarios, WebSphere Application Server dynamically controls which server is assigned ownership of the recovery logs. For this reason, the following steps are not applicable when the **Enable failover of transaction log recovery** option has been set on the administrative console.

Procedure

1. Move all the transaction log files for the application server. The transaction log directory for each server contains a number of files and subdirectories. When moving transaction logs from one server to another you must move all of the files and subdirectories together as a single unit; otherwise recovery might not complete resulting in data inconsistency.
2. Follow the relevant step below, depending on your server configuration:
   a. Optional: For a server configuration where there are no distributed transactions, move the transaction logs to any server that has access to the same resource managers. For a single server or network-deployed server configuration where it is known there are no distributed transactions present in the logs, the transaction logs can be moved to any server (on any node) that has access to the same resource managers as the original server. For example, the server needs communication and valid security access to databases or message queues.

      If the server is in a different cell from the original server, you must ensure that there is a Java Authentication and Authorization Service (JAAS) alias available to the server that was used by the original server for accessing XA resources. In this case you should use wsadmin to construct the aliases, because if you use the administrative console to create the alias, then the node name gets prefixed to the alias.

      All the transaction log files for the original server must be moved to a directory accessible by the new server. This can be accomplished by either renaming the transaction log directory or copying all the contents to the new server transaction log directory before starting the new server.

   b. Optional: For a network-deployed server configuration where there are distributed transactions, move the transaction logs to a server that has the same name and host IP address, and access to the same resource managers. For a network-deployed server configuration, when it is known there are distributed transactions present in the logs, there are more restrictions. Distributed transactions that access multiple servers log information about each server involved in the transaction. This information includes the server name and the IP address of the machine on which the server is running. When recovery is taking place on server restart, the server uses this information to contact the distributed servers and similarly, the distributed servers try to contact the server with the same original name. Therefore, if a server fails and the logs have to be recovered on an alternative server, the alternative server must have the same name and host IP address as the original server. The alternative server also must have access to the same resource managers as the original server. For example, the server needs communication and valid security access to databases or message queues.

      Note: All servers within a cell must have unique names.

   Note: To complete transaction recovery, the application server uses the resource manager configuration information in the transaction logs. However, for the application server to continue

to do new work with the same resource managers, the server must have an appropriate resource manager configuration (as for the original server).

Restarting an application server on a different host

As part of restarting an application server on a different host, you move all the transaction logs to the new host.

About this task

Moving transactions logs to a different host is similar to moving logs from one server to another, as described in “Moving a transaction log from one server to another” on page 2513.

This involves moving an original application server on one host to an alternative server, which has access to the same resource managers, on another host. For a network-deployed server configuration, the alternative server must have the same name and host IP address as the original server.

Note: To complete transaction recovery, the application server uses the resource manager configuration information in the transaction logs. However, for the application server to continue to do new work with the same resource managers, the server must have an appropriate resource manager configuration (as for the original server).

To restart an application server on a different host, complete the following steps:

Procedure

1. Ensure that the alternative application server is stopped.
2. Move all the transaction logs for the original server to the alternative application server, as described in “Moving a transaction log from one server to another” on page 2513.
3. Restart the alternative application server.

Displaying transaction recovery audit messages

You can choose whether information messages are displayed on the administrative console and written to the `SystemOut.log` file upon transaction service recovery. To do this, set the DISABLE_RECOVERY_AUDIT_LOGGING custom property for the transaction service for the server.

About this task

Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

On distributed platforms the default is for information messages to appear both on the administrative console and in the `SystemOut.log` file during the recovery of transaction services. If you do not want these messages to be displayed you can use the DISABLE_RECOVERY_AUDIT_LOGGING custom property.

Procedure

1. In the administrative console, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Container Settings] Container Services** > **Transaction Service** > **[Additional Properties] Custom Properties**.
2. Click **New**.
3. Enter the values required, depending on the operating system:

- To suppress the information messages, type DISABLE_RECOVERY_AUDIT_LOGGING in the **Name** field, and TRUE in the **Value** field.

4. Click **Apply** or **OK**.
5. Save your changes to the master configuration.
6. Restart the server in recovery mode.

Delaying the cancelling of transaction timeout alarms

If the before completion stage of a transaction process is likely to include processes that could either take a long time to complete or could fail, then you might want the transaction to time out.

About this task

By default, transaction timeout alarms are cancelled prior to the before completion phase of the transaction begins. The DELAY_CANCELLING_ALARMS custom property allows the before completion phase of the transaction to be encompassed within the transaction timeout period. To do this, set the custom property on the application server.

Procedure

1. In the administrative console, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Container Settings] Container Services** > **Transaction Service** > **[Additional Properties] Custom Properties**.
2. Click **New**.
3. Type DELAY_CANCELLING_ALARMS in the **Name** field, and TRUE in the **Value** field.
4. Click **Apply** or **OK**.
5. Save your changes to the master configuration.
6. Restart the server in recovery mode.

Removing entries from the transaction partner log

You can remove entries from the transaction partner log file. To do this, set the REMOVE_PARTNER_LOG_ENTRY custom property for the transaction service on the server that owns the partner log.

About this task

As part of the transaction recovery process, the partner log is checked to establish which resources are needed. If you want to remove certain entries from the partner log, such as a resource that no longer exists, set this custom property on the application server that owns the transaction partner log containing the entries you want to remove.

The REMOVE_PARTNER_LOG_ENTRY custom property is effective only when both of the following situations apply.

- The application server is started in recovery mode.
- The application server has no transactions that currently require recovery. You can establish this by checking the SystemOut.log file.

Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using SystemOut.log , SystemErr.log, trace.log, and activity.log files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

Procedure

1. In the administrative console, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Container Settings] Container Services** > **Transaction Service** > **[Additional Properties] Custom Properties**.
2. Click **New**.
3. Type `REMOVE_PARTNER_LOG_ENTRY` in the **Name** field, and in the **Value** field, type one or more comma-delimited integer recovery IDs to be removed.
4. Click **Apply** or **OK**.
5. Save your changes to the master configuration.
6. Restart the server in recovery mode.

Chapter 28. Administering web applications

This page provides a starting point for finding information about web applications, which are comprised of one or more related files that you can manage as a unit, including:

- HTML files
- Servlets can support dynamic web page content, provide database access, serve multiple clients at one time, and filter data.
- Java ServerPages (JSP) files enable the separation of the HTML code from the business logic in web pages.

IBM extensions to the JSP specification make it easy for HTML authors to add the power of Java technology to web pages, without being experts in Java programming. More introduction...

Deploying JavaServer Pages and JavaServer Faces files

JSP class loading settings

You can configure a JavaServer Pages (JSP) class to be loaded by either the JSP engine's class loader or by the web module's class loader.

By default, a JSP class is loaded by a unique instance of the JSP engine's class loader. The JSP engine's class loader enables reloading at runtime of a JSP class when the JSP source or one of its dependents is modified. This allows you to reload a single JSP class when necessary, without affecting any other loaded JSP classes.

JSP classes are loaded by the web module's class loader under either of the following scenarios.

1. The JSP engine configuration parameter useFullPackageNames is set to true, and the JSP file is configured as a servlet in the `web.xml` file using the <servlet-class> scenario in the table below.
2. The JSP engine configuration parameters useFullPackageNames and disableJspRuntimeCompilation are both set to true. In this case, you do not need to configure a JSP file does as a servlet in the `web.xml` file.

Configuring JSP files as Servlets

You can configure a JSP file as a servlet in the `web.xml` file. There are two ways to do this. They are described in the table below.

Before you configure a JSP file as a servlet, consider the following.

1. Reloading capability - If runtime reloading of JavaServer Pages files is desired, requests for JavaServer Pages files must be handled by the JSP engine. The <servlet-class> scenario in the table below disables runtime JSP file reloading, while the <jsp-file> scenario is compatible with reloading.
2. Reducing the number of class loaders - If you do not require runtime reloading of modified JSP pages and you want to reduce the number of class loader instances, then you can use the <servlet-class> scenario in the table below. Similarly, scenario 2 in section 1 above can be used without having to configure a JSP file as a servlet.

Table 236. Example: Configure a JSP file as a servlet in the `web.xml` file.. Configure a JSP file as a servlet

Scenario	Example	compatible with runtime reloading	multiple class loaders used?	useFullPackageNames

Table 236. Example: Configure a JSP file as a servlet in the web.xml file. (continued). Configure a JSP file as a servlet

<jsp-file>	<servlet> <servlet-name>jspOne</servlet-name> <jsp-file>jspOne.jsp</jsp-file> </servlet>	Yes	Yes	Can be true or false
<servlet-class>	<servlet> <servlet-name>jspTwo</servlet-name> <servlet-class>_ibmjsp.jspTwo</servlet-class> </servlet>	No	No	Must be true

The JSP batch compiler tool helps you configure JavaServer Pages files as servlets. When useFullPackageNames is true, the JSP batch compiler generates <servlet> and <servlet-mapping> elements for each JSP file that it successfully translates and compiles. The elements are written to a web.xml fragment file named generated_web.xml which is located in the binaries WEB-INF directory of a web module processed by the JSP file batch compiler (this directory is located within the deployed application's ear file). You can copy and paste all or some of these elements into the web.xml file to configure JavaServer Pages files as servlets.

Take note of the location of the web.xml that is used by the application server. The application specific configuration is obtained from either the application binaries (the application's ear file) or from the configuration repository. If an application is deployed into WebSphere Application Server with the flag Use Binary Configuration set to true, then the WEB-INF/web.xml file is looked for in a web module's binaries directory, not in the configuration repository. Below are examples of these two locations.

- An example of a configuration repository directory is *profile_root*/config/cells/*cellName*/applications/*enterpriseAppName*/deployments/*deployedName*/*webModuleName*
- An example of an application binaries directory is: *profile_root*/installedApps/*nodeName*/*EnterpriseAppName*/*WebModuleName*/

If the JSP batch compiler is executed on a pre-deployed application then the web.xml file is in the web module's WEB-INF directory.

JavaServer Pages (JSP) runtime reloading settings

JavaServer Pages files can be translated and compiled at run time when the JSP file or its dependencies are modified. This is known as JSP reloading.

Note: Use an assembly tool, such as Rational Application Developer, to modify IBM extension and binding files. You can convert extension and binding files within modules from XMI to XML using the IBM Bindings and Extensions Conversion Tool for Multi-Platforms.

JSP reloading is enabled through the **reloadEnabled** JSP engine parameter in the WEB-INF/ibm-web-ext.xmi or WEB-INF/ibm-web-ext.xml file.

ibm-web-ext.xmi example:

```
<jspAttributes xmi:id="JSPAttribute_1" name="reloadEnabled" value="true"/>
```

ibm-web-ext.xml example:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
   xmlns="http://websphere.ibm.com/xml/ns/javaee"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
      version="1.0">
```

```
   <jsp-attribute name="trackDependencies" value="true" />
   <jsp-attribute name="disableJspRuntimeCompilation" value="true" />
   <jsp-attribute name="reloadEnabled" value="true"/>

   <reload-interval value="5"/>
   <auto-encode-requests value="false"/>
   <auto-encode-responses value="false"/>
   <enable-directory-browsing value="false"/>
   <enable-file-serving value="false"/>
   <pre-compile-jsps value="false"/>
   <enable-reloading value="true"/>
   <enable-serving-servlets-by-class-name value="false" />
</web-ext>
```

Note: For IBM extension and binding files, the .xmi or .xml file name extension is different depending on whether you are using a pre-Java EE 5 application or module or a Java EE 5 or later application or module. An IBM extension or binding file is named ibm-*-ext.xmi or ibm-*-bnd.xmi where * is the type of extension or binding file such as app, application, ejb-jar, or web. The following conditions apply:

- For an application or module that uses a Java EE version prior to version 5, the file extension must be .xmi.
- For an application or module that uses Java EE 5 or later, the file extension must be .xml. If .xmi files are included with the application or module, the product ignores the .xmi files.

However, a Java EE 5 or later module can exist within an application that includes pre-Java EE 5 files and uses the .xmi file name extension.

The `ibm-webservices-ext.xmi`, `ibm-webservices-bnd.xmi`, `ibm-webservicesclient-bnd.xmi`, `ibm-webservicesclient-ext.xmi`, and `ibm-portlet-ext.xmi` files continue to use the .xmi file extensions.

The following table contains suggested reload settings for production and development environments.

Table 237. Suggested reload settings for production and development environments.. Reload settings

	Settings	
Configuration Attribute	**Production Environment**	**Development Environment**
reloadEnabled	false	true
reloadInterval	n/a (ignored if reloadEnabled is false)	approximately 5 seconds
trackDependencies	n/a (ignored if reloadEnabled is false)	true Alternatively, set this to false to improve response time if dependencies are not changing
disableJspRuntimeCompilation	true - Alternatively, set this to false if JSP files are not pre-compiled and therefore need to be compiled on the first request.	false

The default for the **reloadEnabled** parameter is true. If the **reloadEnabled** parameter is set to true, a JSP file is reloaded at run time if the JSP file and its class file do not have the same timestamp. In addition, if **trackDependencies** is set to true then the JSP file is reloaded if the timestamp of any of its dependencies has changed since the JSP class file was last generated. If the **reloadEnabled** parameter is set to false, a JSP file is still compiled if necessary on the first request to it unless the parameter **disableJspRuntimeCompilation** is true. For example, when **disableJspRuntimeCompilation** is false and **reloadEnabled** is false, a JSP file is compiled on the first request if the class file is outdated. It would not compile on subsequent requests, even if the JSP source file is modified or the class file is deleted,, unless **reloadEnabled** is true.

Reload interval

The reload interval is set through the **reloadInterval** JSP engine parameter.

`ibm-web-ext.xmi` example:

```
<jspAttributes xmi:id="JSPAttribute_1" name="reloadInterval" value="5"/>
```

ibm-web-ext.xml example:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
   xmlns="http://websphere.ibm.com/xml/ns/javaee"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
      version="1.0">

   <jsp-attribute name="trackDependencies" value="true" />
   <jsp-attribute name="disableJspRuntimeCompilation" value="true" />
   <jsp-attribute name="reloadInterval" value="5"/>

   <reload-interval value="5"/>
   <auto-encode-requests value="false"/>
   <auto-encode-responses value="false"/>
   <enable-directory-browsing value="false"/>
   <enable-file-serving value="false"/>
   <pre-compile-jsps value="false"/>
   <enable-reloading value="true"/>
   <enable-serving-servlets-by-class-name value="false" />
</web-ext>
```

If reloading is enabled, the **reloadInterval** parameter value determines the delay between checks to see if a JSP file is outdated. For example, if **reloadInterval** is 5, the JSP engine checks to see if a JSP file is outdated only when the last such check was done more than five seconds prior to the current request for the JSP file. Once the **reloadInterval** is exceeded, reload checking is performed and the reload interval timer is reset to 0 for that JSP file. The larger the **reloadInterval**, the less frequently the JSP engine checks for the need to reload a JSP file.

Dependency tracking

Dependency tracking is set through the **trackDependencies** JSP engine parameter.

ibm-web-ext.xmi example:

```
<jspAttributes xmi:id="JSPAttribute_1" name="trackDependencies" value="true"/>
```

ibm-web-ext.xmi example:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
   xmlns="http://websphere.ibm.com/xml/ns/javaee"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
      version="1.0">

   <jsp-attribute name="trackDependencies" value="true" />
   <jsp-attribute name="disableJspRuntimeCompilation" value="true" />
   <jsp-attribute name="reloadInterval" value="5"/>

   <reload-interval value="5"/>
   <auto-encode-requests value="false"/>
   <auto-encode-responses value="false"/>
   <enable-directory-browsing value="false"/>
   <enable-file-serving value="false"/>
   <pre-compile-jsps value="false"/>
   <enable-reloading value="true"/>
   <enable-serving-servlets-by-class-name value="false" />
</web-ext>
```

If reloading is enabled, the **trackDependencies** parameter value determines whether the JSP engine tracks modifications to the requested JSP file dependencies as well as to the JSP file itself. The three types of dependencies tracked by the JSP engine are:

- files statically included in the JSP file
- tag files that are referenced in the JSP file (excluding tag files that are in JAR files)
- TLDs that are referenced in the JSP file (excluding TLDs that are in JAR files)

Dependency tracking information is always included in the generated class file even if **trackDependencies** is false. The information is not used by the JSP engine or batch compiler unless the **trackDependencies** parameter is true. This means that you can enable dependency tracking without having to recompile JSP files.

For example, the toplevel.jsp file statically includes the footer.jspf file. When the toplevel.jsp file is compiled, the path to the footer.jspf file and its timestamp are stored in the toplevel.jsp's class file. As a result, the footer.jspf file is modified and the toplevel.jsp file is requested. Now that the reload interval for the toplevel.jsp file has been exceeded, the JSP engine compares the timestamp stored in the class file with the footer.jspf file timestamp on disk. Because the timestamps are different, the toplevel.jsp file is compiled, picking up the modification to the footer.jspf file. In order for dependency tracking to work, the **trackDependencies** value must be set to true at the time a JSP file is requested at run time or is processed by the batch compiler.

Disabling compilation

Disablement of run time compilation of JavaServer Pages is set via the disableJspRuntimeCompilation JSP engine parameter.

ibm-web-ext.xmi example:

```
<jspAttributes xmi:id="JSPAttribute_1" name="disableJspRuntimeCompilation" value="true"/>
```

ibm-web-ext.xml example:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
   xmlns="http://websphere.ibm.com/xml/ns/javaee"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
      version="1.0">

   <jsp-attribute name="trackDependencies" value="true" />
   <jsp-attribute name="disableJspRuntimeCompilation" value="true" />
   <jsp-attribute name="reloadInterval" value="5"/>

   <reload-interval value="5"/>
   <auto-encode-requests value="false"/>
   <auto-encode-responses value="false"/>
   <enable-directory-browsing value="false"/>
   <enable-file-serving value="false"/>
   <pre-compile-jsps value="false"/>
   <enable-reloading value="true"/>
   <enable-serving-servlets-by-class-name value="false" />
</web-ext>
```

If the **disableJspRuntimeCompilation** parameter is set to true, the JSP engine at run time does not translate and compile JSP files; the JSP engine loads only precompiled class files. JSP source files do not need to be present in order for the class files to be loaded. With this option set to true, an application can be installed without JSP source, but must have precompiled class files. There is a web container custom property of the same name that can be used to determine the behavior of all web modules installed in a server. If both the web container custom property and the JSP engine option are set, the JSP engine option takes precedence. Setting the **disableJspRuntimeCompilation** parameter to true automatically sets **reloadEnabled** to false.

Reload processing sequence

The processing sequence pertaining to JSP file reloading when **trackDependencies** is false is shown in Figure 1.

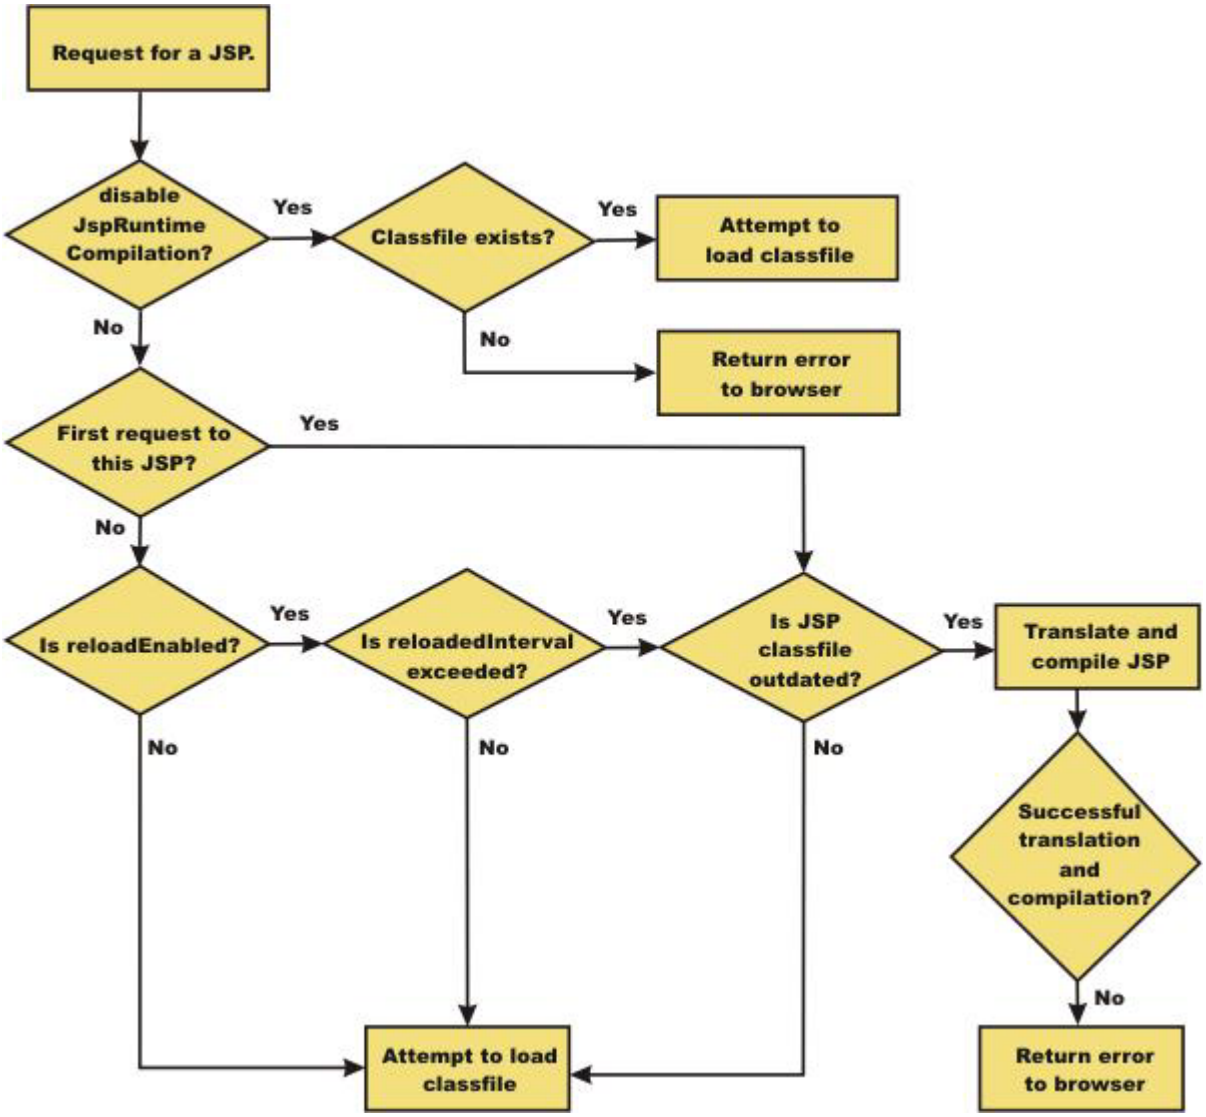

Figure 40. Reload processing sequence when **trackDependencies** *is false.*

When **trackDependencies** is true, the JSP engine does additional file system processing to determine if any of a JSP file's dependencies have changed since the JSP file was last translated and compiled. Figure 2 shows the additional processes that are performed on the 'No' path of flow chart labeled "is JSP class file outdated?". You can see that the path taken when disableJspRuntimeCompilation is true is the most efficient path.

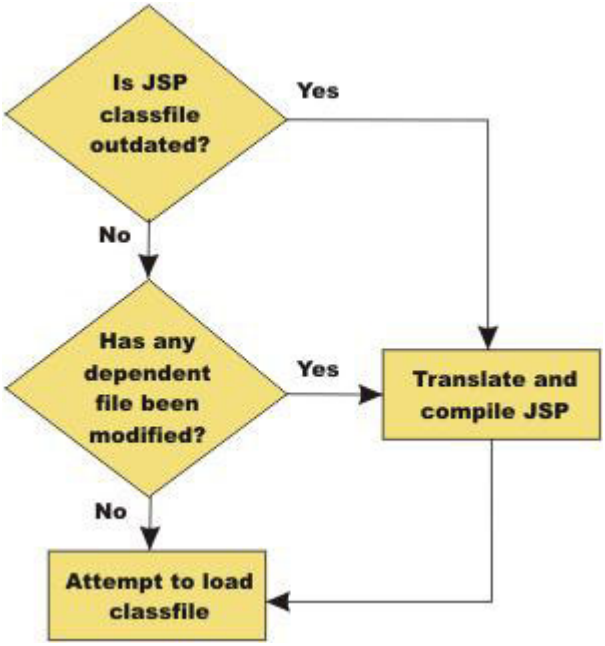

Figure 41. Additional reload processing performed when **trackDependencies** *is true.*

JSP and JSF option settings

Use this panel to configure the class reloading of web modules such as JavaServer Pages (JSP) files and to select a JSF implementation to use with this application.

To view this administrative console panel, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **JSP and JSF options**. This panel is the same as the **Provide JSP reloading options for web modules** panel on the application installation and update wizards.

The following note applies to the files with a .xmi extension in this topic:

Note: For IBM extension and binding files, the .xmi or .xml file name extension is different depending on whether you are using a pre-Java EE 5 application or module or a Java EE 5 or later application or module. An IBM extension or binding file is named ibm-*-ext.xmi or ibm-*-bnd.xmi where * is the type of extension or binding file such as app, application, ejb-jar, or web. The following conditions apply:

- For an application or module that uses a Java EE version prior to version 5, the file extension must be .xmi.
- For an application or module that uses Java EE 5 or later, the file extension must be .xml. If .xmi files are included with the application or module, the product ignores the .xmi files.

However, a Java EE 5 or later module can exist within an application that includes pre-Java EE 5 files and uses the .xmi file name extension.

The `ibm-webservices-ext.xmi`, `ibm-webservices-bnd.xmi`, `ibm-webservicesclient-bnd.xmi`, `ibm-webservicesclient-ext.xmi`, and `ibm-portlet-ext.xmi` files continue to use the .xmi file extensions.

Web module

Specifies the name of a web module in the installed or deployed application.

URI
Specifies the location of the module that is relative to the root of the application (EAR file).

JSP enable class reloading
Specifies whether to enable class reloading when JSP files are updated.

A web container reloads JSP files only when the IBM extension reloadEnabled in the jspAttributes of the `ibm-web-ext.xmi` file is set to `true`.

Java Platform, Enterprise Edition 5 (Java EE 5) applications IBM extension files are in `.xml` file format. For applications versions earlier than Java EE 5, they are in the `.xmi` file format.

JSP reload interval in seconds
Specifies the number of seconds to scan the application file system for updated JSP files. The default is the value of the reloading interval attribute in the IBM extension (`META-INF/ibm-web-ext.xmi`) file of the web module.

To enable reloading, specify a value greater than zero (for example, 1 to 2147483647). The default reload interval is 5. To disable reloading, specify zero (0). The range is from 0 to 2147483647.

The reloading interval attribute takes effect only if class reloading is enabled.

Java EE 5 applications IBM extension files are in `.xml` file format. For applications versions earlier than Java EE 5, they are in the `.xmi` file format.

Sun Reference Implementation 1.2
Select this option to use the Sun Reference Implementation 1.2 JSF implementation.

If you change the JSF implementation that you are using for your application, you must delete any previously compiled JSP files. If you precompiled your application, you must recompile. If you did not precompile, but have already requested JSP files from this application, you must delete the JSP files from the temp directory of your profile.

You can set the JSF engine configuration parameter, com.ibm.ws.jsf.JSF_IMPL_CHECK, to true to automatically mark the JSP files to recompile at application startup.

MyFaces 2.0
Select this option to use the MyFaces JSF implementation. This is the default JSF implementation.

If you change the JSF implementation that you are using for your application, you must delete any previously compiled JSP files. If you precompiled your application, you must recompile. If you did not precompile, but have already requested JSP files from this application, you must delete the JSP files from the temp directory of your profile.

You can set the JSF engine configuration parameter, com.ibm.ws.jsf.JSF_IMPL_CHECK, to true to automatically mark the JSP files to recompile at application startup.

In a mixed-version cell, a V7 node uses MyFaces 1.2 if the MyFaces selection is toggled, while a V8 node uses MyFaces 2.0. For WebSphere Application Server versions before V7 (for example, V6.1 and earlier), this toggle is ineffective because JSF implementation switching was not supported before V7.

JSP run time compilation settings
By default, the JavaServer Pages (JSP) engine translates a requested JSP file, compiles the `.java` file, and loads the compiled servlet into the run time environment. You can change the JSP engine default behavior by indicating that a JSP file must not be translated or compiled at run time, even when a `.class` file does not exist.

If run time compilation is disabled, you must precompile the JSP files, which provides the following advantages:
- Reduces compilation related disk operations.
- Minimizes disk storage requirements necessary for handling temporary `.java` files generated during a run time compilation.
- Allows you to not include the JSP source files in the application.
- Allows verification that a JSP file compiled successfully before deploying and installing the application in the product

You can disable run time JSP file compilation on a global or an individual web application basis:
- To disable the translation and compilation of JSP files for all Web applications, in the administrative console, click **Servers > Server Types > WebSphere application servers >** *server_name*. Then, in the Container Settings section, click **Web container settings > Web container > Custom properties**.

  If the disableJspRuntimeCompilation property appears in the list of defined custom properties, but is set to `false`, click the property name, and then set the property to `true`.

  If this property is not included in the list of defined custom properties, click **New**, and then specify `disableJspRuntimeCompilation` in the **Name** field and `true` in the **Value** field.

  Valid settings for this property are `true` or `false`. When this property is set to `true`, translation and compilation of the JSP files is disabled at run time for all web applications.
- To disable the translation and compilation of JSP files for a specific web application, set the JSP engine initialization parameter disableJspRuntimeCompilation to `true`. This setting, if enabled, determines the run time behavior of the JSP engine and overrides the web container custom property setting.

  Set this parameter through the **JavaServer Pages attribute assembly settings** page when assembling applications.

  Valid values for this setting are `true` or `false`. If this parameter is set to `true`, then, for that specific web application, translation and compilation of the JSP files is disabled at run time, and the JSP engine only loads precompiled files.
- If neither the web container custom property nor the JSP parameter is set, the first request for a JSP file results in the translation and compilation of the JSP file when the `.class` file does not exist or is outdated. Subsequent requests for the file also result in translations and compilations, but only if the following conditions are met:
  - Translations are required because the `.class` file is outdated.
  - Reloading is enabled for the web module.
  - Reload interval is exceeded.

If you disable run time compilation and a request arrives for a JSP file that does not have a matching .class file, the JSP engine returns the following 404 error to the browser:

```
Error 404: SRVE0200E: Servlet [org.apache.jsp._jsp1]: Could not find required servlet class - _jsp1.class
```

In this case, an exception is written to the System Out (SYSOUT) and First Failure Data Capture (FFDC) logs. .

If a JSP file has a matching .class file but that file is out of date, the JSP engine still loads the .class file into memory.

Provide options to compile JavaServer Pages settings

Use this page to specify options to be used by the JavaServer Pages (JSP) compiler.

This administrative console page is a step in the application installation and update wizards. To view this page, you must select **Precompile JavaServer Pages files** on the **Select installations options** page. Thus, to view this page, click **Applications** > **New Application** > **New Enterprise Application** > ***application_path*** > **Next** > **Detailed - Show me all installation options and parameters** > **Next** > **Next** or **Continue** > **Precompile JavaServer Pages files** > **Next** > **Step: Provide options to compile JSPs**.

You can specify the JSP compiler options on this page only when installing or updating an application that contains web modules. After the application is installed, you must edit the JSP engine configuration parameters of a web module `WEB-INF/ibm-web-ext.xmi` file to change its JSP compiler options.

Note: For IBM extension and binding files, the .xmi or .xml file name extension is different depending on whether you are using a pre-Java EE 5 application or module or a Java EE 5 or later application or module. An IBM extension or binding file is named ibm-*-ext.xmi or ibm-*-bnd.xmi where * is the type of extension or binding file such as app, application, ejb-jar, or web. The following conditions apply:

- For an application or module that uses a Java EE version prior to version 5, the file extension must be .xmi.
- For an application or module that uses Java EE 5 or later, the file extension must be .xml. If .xmi files are included with the application or module, the product ignores the .xmi files.

However, a Java EE 5 or later module can exist within an application that includes pre-Java EE 5 files and uses the .xmi file name extension.

The `ibm-webservices-ext.xmi`, `ibm-webservices-bnd.xmi`, `ibm-webservicesclient-bnd.xmi`, `ibm-webservicesclient-ext.xmi`, and `ibm-portlet-ext.xmi` files continue to use the .xmi file extensions.

Web module
Specifies the name of a module within the application.

URI
Specifies the location of the module relative to the root of the application (EAR file).

JSP class path
Specifies a temporary class path for the JSP compiler to use when compiling JSP files during application installation. This class path is not saved when the application installation is complete and is not used when the application is running. This class path is used only to identify resources outside of the application which are necessary for JSP compilation and which will be identified by other means (such as shared libraries) after the application is installed. In network deployment configurations, this class path is specific to the deployment manager machine.

To specify that multiple web modules use the same class path:
1. In the list of web modules, select the **Select** check box beside each web module that you want to use a particular class path.
2. Expand **Apply Multiple Mappings**.
3. Specify the desired class path.
4. Click **Apply**.

Use full package names
Specifies whether the JSP engine generates and loads JSP classes using full package names.

When full package names are used, precompiled JSP class files can be configured as servlets in the `web.xml` file, without having to use the `jsp-file` attribute. When full package names are not used, all JSP classes are generated in the same package, which has the benefit of smaller file-system paths.

When the options useFullPackageNames and disableJspRuntimeCompilation are both `true`, a single class loader is used to load all JSP classes, even if the JSP files are not configured as servlets in the `web.xml` file.

This option is the same as the useFullPackageNames JSP engine parameter.

JDK source level
Specifies the source level at which the Java compiler compiles JSP Java sources. Valid values are `13`, `14`, and `15`. The default value is `13` for pre-Java EE 5 web modules, which specifies source level 1.3 and `15` for Java EE 5 and later web modules.

Disable JSP runtime compilation
Specifies whether a JSP file should never be translated or compiled at run time, even when a `.class` file does not exist.

When this option is set to `true`, the JSP engine does not translate and compile JSP files at run time; the JSP engine loads only precompiled class files. JSP source files do not need to be present in order to load class files. You can install an application without JSP source, but the application must have precompiled class files.

For a single web application class loader to load all JSP classes, this compiler option and the **Use full package names** option both must be set to `true`.

This option is the same as the disableJspRuntimeCompilation JSP engine parameter.

Administering web applications

Modifying the default web container configuration
A web container handles requests for servlets, JavaServer Pages (JSP) files, and other types of files that include server-side code. The web container creates servlet instances, loads and unloads servlets, creates and manages request and response objects, and performs other servlet management tasks. The web server plug-ins, provided by the product, help supported web servers to pass servlet requests to web containers.

About this task

If the property to start servlets during application server startup is enabled, part of its startup process calls the Servlet.init method on its servlets when you start the web container. Therefore, when the web container starts and calls the init method, other components such as Naming and Work Load Management might not be fully started yet. As a result, application server related calls may not work because all of the application server components might not be ready yet. Once the application server is 'ready for e-business', it is completely ready. If application server related calls fail during Servlet.init method, you can either:

- Start the servlet manually when the server is ready for e-business instead of starting the servlet upon startup or
- You can choose not to make application server related calls in the servlet's init method.

The web container is created initially with default properties values suitable for simple web applications. However, these values might not be appropriate for more complex web applications.

Your application is considered complex if it requires any of the following features:
- Additional virtual host aliases
- Servlet caching
- Persistent HTTP session support
- Session tracking support with URL rewriting
- Special web container transport chain settings
- Asynchronous or remote dispatching
- No request or response pooling

Make the following configuration changes if you have a complex application:

Procedure

1. In the administrative console, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***. Then under web container settings, click on one of the following:
   a. **Web container**, if your web application requires a virtual host, other than the default_host, or requires servlet caching.
   b. **Web container transport chains**, if you need to reconfigure your HTTP connections.
2. If your application handles special client request loads, in the administrative console, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***. Then under Additional Properties, click **Thread pools** to modify your thread pool settings.
3. If your application requires global settings for internal servlets for web application archive (WAR) files packaged by third-party tools, in the administrative console, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **Web Container Settings** > **Web container**. Then under Additional Properties, click **Custom properties** and enter the appropriate custom property.

Web container settings

Use this page to configure the web container settings.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **Web Container Settings** > **Web container**.

Default virtual host:

Specifies a virtual host that enables a single host machine to resemble multiple host machines. Resources associated with one virtual host cannot share data with resources associated with another virtual host, even if the virtual hosts share the same physical machine.

Select a virtual host option:

default_host
The product provides a default virtual host with some common aliases such as the machine IP address, short host name, and fully qualified host name. The alias comprises the first part of the path for accessing a resource such as a servlet. For example, it is `localhost:9080` in the request `http://localhost:9080/myServlet`.

admin_host
This virtual host option is another name for the application server; also known as *server1* in the base installation. This process supports the use of the administrative console.

proxy_host
The virtual host called proxy_host, includes default port definitions, port 80 and 443, which are typically initialized as part of the proxy server initialization. Use this proxy host as appropriate with routing rules associated with the proxy server.

Enable servlet caching:

Specifies that if a servlet is started once and it generates output to be cached, a cache entry is created containing not only the output, but also side effects of the invocation. These side effects can include calls to other servlets or JavaServer Pages (JSP) files, as well as metadata about the entry, including timeout and entry priority information.

Portlet fragment caching requires that servlet caching is enabled. Therefore, enabling portlet fragment caching automatically enables servlet caching. Disabling servlet caching automatically disables portlet fragment caching.

Disable servlet request and response pooling:

Specifies to disable the pooling of servlet request and servlet response objects that are pooled by the web container. When you disable pooling of servlet request and servlet response objects, new servlet request and servlet response objects are created for each request.

When you disable pooling of servlet request and servlet response objects, new servlet request and servlet response objects are created for each request, which can negatively affect performance, but provides protection from any unforeseen pooling bugs.

Number of timeout threads:

Specifies the number of threads that are available to handle asynchronous servlet timeout operations per server.

The default of two might be too low if you have many applications using asynchronous servlets that often have timeouts.

Default timeout:

Specifies the default asynchronous servlet timeout for the server.

The default of 30 seconds can be lowered if responses are not being received quickly enough and there is a viable fall back in the error case. You can raise the value if too many timeouts are being received and the longer timeout produces responses in an acceptable manner to the client. The units are in millisecond, so multiply the number by 1000 to convert to seconds. To configure at a higher granularity, you must use the AsyncContext setTimeout method programmatically.

Use thread pool to start Runnable objects:

Select this option to use the same thread pool where the request originates. This option does not propagate any context from the original request.

Use a work manager to start Runnable objects:

Select this option to use an Asynchronous Beans work manager to start the runnable. This option is the default selection. The work manager option propagates any context that is configured for the selected work manager. This option also requires selecting the JNDI name of the work manager that you will use.

Considerations when using a work manager:

- The context that is propagated is configurable under Resources > Asynchronous Beans > Work managers. You can also create new work managers on the same panel.
- The WebSphere Application Server default Work Manger is used unless you specify otherwise. This might not be desirable as other components might be using the work manager and effectively decreasing the number of threads that are available at one time.
- To make changes to the work manager settings, it is recommended that you create a work manager so changes to defaults do not affect other components.
- If you have a work manager configured to throw exceptions when the work queue is full, then an exception of type IllegalStateException is thrown to the caller of start(Runnable) and the caller is responsible for handling the exception.

Programmatic session cookie configuration collection

Use this page to secure cookies by prohibiting programmatic configuration.

To view this administrative console page at the web container level, click **Security > Global security > Programmatic session cookie configuration**.

Cookie domain:

Specifies the domain where the cookie is used. Use the asterisk (*) symbol as a wild card, for example, *.ibm.com.

Cookie name:

Specifies an alphanumeric name for the cookie, for example, **JSESSIONID**. Use the asterisk (*) symbol as a wild card.

Cookie path:

Specifies the directory in the domain where the cookie is valid; for example, **/path_name**. Use the asterisk (*) symbol as a wild card.

Web container custom properties

You can configure name-value pairs of data, where the name is a property key and the value is a string value that you can use to set internal system configuration properties. Defining a new property enables you to configure a setting beyond that which is available in the administrative console. The following is a list of some of the available web container custom properties.

To specify web container custom properties:

1. In the administrative console click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **Web Container Settings** > **Web container**.
2. Under **Additional Properties** select **Custom Properties**.
3. On the Custom Properties page, click **New**.
4. On the settings page, enter the name of the custom property that you want to configure in the **Name** field and the value that you want to set it to in the **Value** field.
5. Click **Apply** or **OK**.
6. Click **Save** on the console task bar to save your configuration changes.
7. Restart the server.

The following is a list of custom properties provided with the Application Server. The topics, JavaServer Pages specific web container custom properties and HTTP transport custom properties, are listed in a separate topic.

You can use the Custom properties page to define the following properties for use by the Java virtual machine.

- “BodyContentBuffSize” on page 2532
- com.ibm.ws.jsf.disablealternatefacesconfigsearch
- “com.ibm.ws.jsp.enableDefaultIsELIgnoredInTag” on page 2532
- “com.ibm.ws.jsp.getWriterOnEmptyBuffer” on page 2532
- “com.ibm.ws.jsp.limitBuffer” on page 2533
- “com.ibm.ws.jsp.throwExceptionForAddELResolver” on page 2533
- “com.ibm.ws.webcontainer.assumefiltersuccessonsecurityerror” on page 2533
- “com.ibm.ws.webcontainer.channelwritetype” on page 2533
- “com.ibm.ws.webcontainer.checkEDRinGetRealPath” on page 2534
- “com.ibm.ws.webcontainer.copyattributeskeyset” on page 2534
- “com.ibm.ws.webcontainer.disableSetCharacterEncodingAfterParametersRead” on page 2534
- “com.ibm.ws.webcontainer.disableSystemAppGlobalListenerLoading” on page 2535
- “com.ibm.ws.webcontainer.disablexPoweredBy” on page 2535

- “com.ibm.ws.webcontainer.disallowAllFileServing” on page 2535
- “com.ibm.ws.webcontainer.disallowserveservletsbyclassname” on page 2535
- “com.ibm.ws.webcontainer.discernUnavailableServlet” on page 2535
- “com.ibm.ws.webcontainer.dispatcherRethrowSER” on page 2536
- “com.ibm.ws.webcontainer.dispatcherRethrowSError” on page 2536
- “com.ibm.ws.webcontainer.donotservebyclassname” on page 2536
- “com.ibm.ws.webcontainer.enabledefaultservletrequestpathelements” on page 2536
- “com.ibm.ws.webcontainer.enableErrorExceptionTypeFirst” on page 2537
- “com.ibm.ws.webcontainer.enableJspMappingOverride” on page 2537
- “com.ibm.ws.webcontainer.enableMultiReadOfPostData” on page 2537
- “com.ibm.ws.webcontainer.extractHostHeaderPort and trusthostheaderport” on page 2537
- “com.ibm.ws.webcontainer.finishresponseonclose” on page 2538
- “com.ibm.ws.webcontainer.ForceDifferentCookiePaths” on page 2538
- “com.ibm.ws.webcontainer.HTTPOnlyCookies” on page 2538
- “com.ibm.ws.webcontainer.ignoreinjectionfailure” on page 2539
- “com.ibm.ws.webcontainer.ignoreInvalidQueryString” on page 2539
- “com.ibm.ws.webcontainer.IgnoreSessiononStaticFileRequest” on page 2539
- “com.ibm.ws.webcontainer.invokeFilterInitAtStartup” on page 2539
- “com.ibm.ws.webcontainer.invokeFiltersCompatibility” on page 2539
- “com.ibm.ws.webcontainer.invokerequestlistenerforfilter” on page 2540
- “com.ibm.ws.webcontainer.KeepUnreadPostDataAfterResponseSentToClient” on page 2540
- “com.ibm.ws.webcontainer.logServletContainerInitializerClassloadingErrors” on page 2540
- “com.ibm.ws.webcontainer.mapFiltersToAsterisk” on page 2540
- “com.ibm.ws.webcontainer.normalizerequesturi” on page 2541
- “com.ibm.ws.webcontainer.parseUTF8PostData” on page 2541
- “com.ibm.ws.webcontainer.provideQStringToWelcomeFile” on page 2541
- “com.ibm.ws.webcontainer.SendResponseToClientAsPartOfSendRedirect” on page 2542
- “com.ibm.ws.webcontainer.SendResponseToClientWhenResponseIsComplete” on page 2542
- “com.ibm.ws.webcontainer.ServeWelcomeFileFromExtendedDocumentRoot” on page 2542
- “com.ibm.ws.webcontainer.ServletDestroyWaitTime” on page 2542
- “com.ibm.ws.webcontainer.setUnencodedHTMLinsendError” on page 2542
- “com.ibm.ws.webcontainer.suppressheadersinrequest” on page 2543
- “com.ibm.ws.webcontainer.suppressHtmlRecursiveErrorOutput” on page 2543
- “com.ibm.ws.webcontainer.suppressLastZeroBytePackage” on page 2543
- “com.ibm.ws.webcontainer.suppressServletExceptionLogging” on page 2543
- “com.ibm.ws.webcontainer.throwMissingJspException” on page 2544
- “com.ibm.ws.webcontainer.webgroupvhostnotfound” on page 2544
- “com.ibm.ws.webcontainer.xPoweredBy” on page 2544
- “com.ibm.wsspi.jsp.convertAttrValueToString” on page 2544
- “com.ibm.wsspi.jsp.disableElCache” on page 2544
- “com.ibm.wsspi.jsp.disableResourceInjection” on page 2544
- “com.ibm.wsspi.jsp.disableTldSearch” on page 2545
- “com.ibm.wsspi.jsp.enabledoublequotesdecoding” on page 2545
- “DebugSessionCrossover” on page 2545
- “DecodeUrlAsUTF8” on page 2546

- “enableInProcessConnections” on page 2546
- “fileServingEnabled, directoryBrowsingEnabled, and serveServletsByClassnameEnabled” on page 2546
- “ForceSessionIdLengthCheck” on page 2547
- “ForceSessionInvalidationMultiple” on page 2547
- “httpsIndicatorHeader” on page 2547
- “HttpSessionIdReuse” on page 2548
- “listeners” on page 2548
- “prependSlashToResource” on page 2548
- “trusted” on page 2549

BodyContentBuffSize: The size of the body content buffer for a JavaServer Pages (JSP) file can affect the performance of some applications. By default, the body content buffer size is 512 bytes. However, you can use the BodyContentBuffSize custom property to set a different buffer value.

Name	Default value
BodyContentBuffSize	512

com.ibm.ws.jsf.disablealternatefacesconfigsearch: Disables MyFaces searching for META-INF/*.faces-config.xml for all web applications on a server.

Name	Default value
com.ibm.ws.jsf.disablealternatefacesconfigsearch	false

com.ibm.ws.jsp.enableDefaultIsELIgnoredInTag: Typically Expression Language (EL) expressions in tag files get evaluated before the tag files a JavaServer Page (JSP) is compiled. However, under certain conditions these EL expressions in a tag file do not get evaluated if the <el-ignored> attribute is set to true.

To ensure that EL expressions are always evaluated, set the com.ibm.ws.jsp.enableDefaultIsELIgnoredInTag custom property to `true`. The default value for this property is false.

Name	Default value
com.ibm.ws.jsp.enableDefaultIsELIgnoredInTag	false

com.ibm.ws.jsp.getWriterOnEmptyBuffer: The dynamic cache service uses flushes to determine when one cacheable web fragment, such as a JSP include or a c:import, ends and the next web fragment begins. If you set the com.ibm.wsspi.jsp.usecdatatrim custom property to `true` for your JSP engine, all of the white space and extra lines in the generated Java code are stripped out. In this situation, there might not be any content to write before the first flush. If the generated Java code contains text or other code before the first flush then normal dynamic cache service processing occurs.

If you set the com.ibm.wsspi.jsp.usecdatatrim custom property to `true`, and are using the dynamic cache service, you must also set the com.ibm.ws.jsp.getWriterOnEmptyBuffer custom property to `true`. This custom property requires the JSP Engine to call the flush function when it reaches the end of the first cachable web fragments even if there is not any data to flush. The default value for this property is false.

Name	Default value
com.ibm.ws.jsp.getWriterOnEmptyBuffer	false

com.ibm.ws.jsp.limitBuffer: The body content buffer size of the tag bodies for a JavaServer Pages (JSP) file are reused to optimize performance. If the size of a tag body increases beyond the default body content buffer size, the buffer is resized to accommodate the tag body. However, the buffer is not reset to the default size after serving a request. As a result, the heap memory that is used by org.apache.jasper.runtime.BodyContentImpl implementation might increase over time. You can configure the body content buffer size by setting an integer value for the BodyContentBuffSize custom property. For more information, see "BodyContentBuffSize" on page 2532.

Use the com.ibm.ws.jsp.limitBuffer custom property to deallocate large body content buffer sizes and create a buffer with the default buffer size.

Name	Default value
com.ibm.ws.jsp.limitBuffer	false

com.ibm.ws.jsp.throwExceptionForAddELResolver: Set the com.ibm.ws.jsp.throwExceptionForAddELResolver property to `true` if you do not want to allow an ELResolver to be registered from a servlet or a filter after the application has received a request from the client. When this property is set to true, an IllegalStateException is thrown as specified by the JSP (Java Server Pages) specification for addELResolver() method of the JspApplicationContext interface.

The default value for this property is false.

Name	Default value
com.ibm.ws.jsp.throwExceptionForAddELResolver	false

com.ibm.ws.webcontainer.assumefiltersuccessonsecurityerror: When a request is received for a static file which does not exist, the web container calls defined servlet filters. If the filters do no successfully complete, a 404 error code is set. In a situation where application security is enabled, a security check is performed as part of filter invocation. Typically if the security check fails the web container considers the filters to have failed and still sets a 404 error code instead of the 401 error code that indicates the failure of a security check. The 404 error code enables the requester to access the static file without logging on.

You can set the com.ibm.ws.webcontainer.assumefiltersuccessonsecurityerror custom property to `true`, to prevent the 401 error code from being replaced with a 404 error code, and ensure that a user must enter a valid user ID and password before they can access a static file.

Name	Default value
com.ibm.ws.webcontainer.assumefiltersuccessonsecurityerror	false

com.ibm.ws.webcontainer.channelwritetype:

By default, the web container uses asynchronous writes to write response data in chunks up to the response buffer size. For larger responses that are greater than the response buffer size, the web container continues to buffer response data into memory while waiting for an asynchronous write of a response data chunk to complete. This process can result in part of a large response held in memory, which can lead to high memory usage and potentially an out of memory error. An application server hang might also occur when a server is simultaneously processing more requests than web container-defined threads.

If the com.ibm.ws.webcontainer.channelwritetype property is set to `sync`, synchronous writing is used, otherwise asynchronous writing is used by default. With synchronous writing, response data are written synchronously in chunks of up to the value of responsebuffersize and no response data are buffered into memory while waiting for a synchronous write of a response data chunk to complete. As a result, the approximate maximum amount of response data that is held in memory is equal to the responsebuffersize

multiplied by the number of web container threads. The maximum number of requests that can be processed simultaneously by the web container is limited by the number of web container threads. Additional requests are queued, waiting for a request that is in process to complete.

The responsebuffersize web container custom property defines the maximum amount of response data written by the web container in a single chunk, and is 32k by default. As a result, it is used to change the number of writes needed by the web container to send complete response data. However, if an application flushes response data, any response data held by the web container is immediately written irrespective of the responsebuffersize.

Use the following name-value pair to write chunks of data using synchronous writes.

Name	Default value
com.ibm.ws.webcontainer.channelwritetype	none

com.ibm.ws.webcontainer.checkEDRinGetRealPath: The ServletContext.getRealPath() Java Servlet API does not return the correct path for a requested resource when the resource exists in an extendedDocumentRoot path and does not exist in the installed application path. If you want the ServletContext.getRealPath() Java Servlet API to look for the requested resource in the extendedDocumentRoot path if the resource is not found in the installed application path, set the com.ibm.ws.webcontainer.checkEDRinGetRealPath custom property to `true`.

When this property is set to true, and the requested resource is also not found in the extendedDocumentRoot path, a null value is returned.

Name	Default value
com.ibm.ws.webcontainer.checkEDRinGetRealPath	false

com.ibm.ws.webcontainer.copyattributeskeyset: This custom property addresses a situation where the request.getAttributeNames method returns a list of values. If a servlet modifies the list using the request.removeAttribute method, subsequent calls to the nextElement method causes a java.util.ConcurrentModificationException exception. To enable a servlet to modify the list, set the `com.ibm.ws.webcontainer.copyattributeskeyset` custom property to true. When you set this custom property to true, a copy of the list of attributes is returned, which enables the servlet to modify the list without resulting in a java.util.ConcurrentModificationException exception when the nextElement method is called.

Name	Default value
com.ibm.ws.webcontainer.copyattributeskeyset	false

com.ibm.ws.webcontainer.disableSetCharacterEncodingAfterParametersRead: The web container processes a setCharacterEncoding(String) method of the ServletRequest API even if it is called after the post data is parsed. According to the Java Servlet Specification, the web container should ignore a setCharacterEncoding(String) method if the method is called after the data is parsed.

If you want the web container to ignore a setCharacterEncoding(String) method if the method is called after the data is parsed, add the com.ibm.ws.webcontainer.disableSetCharacterEncodingAfterParametersRead custom property to your web container configuration settings and set this property to `true`.

The default value for this property is false.

Name	Default value
com.ibm.ws.webcontainer.disableSetCharacterEncodingAfterParametersRead	false

com.ibm.ws.webcontainer.disableSystemAppGlobalListenerLoading:

If a system application is the first to start, and the application attempts to load a global listener in a shared library that is associated with the server classloader, the application does not load that listener and prevents the listener from being loaded or invoked by a later non-system application. Set the com.ibm.ws.webcontainer.disableSystemAppGlobalListenerLoading custom property to true to prevent system applications from loading global listeners. When this property is set to `true`, the system application does not attempt to load the global listeners and later non-system applications can load them from a shared library associated with a server class loader.

Name	Default value
com.ibm.ws.webcontainer.disableSystemAppGlobalListenerLoading	false

com.ibm.ws.webcontainer.disablexPoweredBy:

Note: When you configure server security, you can turn off the X-Powered-By header if you do not want to reveal which server you are running. Use this custom property to disable the X-Powered-By header, which prevents the header from being sent on the HTTP response. The default value is false. However, set this property to `true`, if you want to disable this header.

Name	Default value
com.ibm.ws.webcontainer.disablexPoweredBy	false

com.ibm.ws.webcontainer.disallowAllFileServing:

Use the com.ibm.ws.webcontainer.disallowAllFileServing custom property to disable file serving on all applications on a specific application server.

You can enable file serving on a global level across a given application server by using the fileServingEnabled custom property. However, the fileServingEnabled property is overridden by the specific deployment information of each application. Therefore, the current fileServingEnabled custom property only applies as a backup in case an application does not define the fileServingEnabled setting itself.

To globally override this setting on a specific application server to prevent the application server from serving static files regardless of their individual deployment settings, set the com.ibm.ws.webcontainer.disallowAllFileServing web container custom property to `true` using the following name-value pair.

Name	Default value
com.ibm.ws.webcontainer.disallowAllFileServing	false

com.ibm.ws.webcontainer.disallowserveservletsbyclassname:

When the serveServletsByClassnameEnabled property is enabled, it is possible to access servlets directly, resulting in a possible security exposure. Define the following custom property to disallow the use of the serveServletsByClassnameEnabled property across the entire application server level.

Name	Default value
com.ibm.ws.webcontainer.disallowserveservletsbyclassname	false

com.ibm.ws.webcontainer.discernUnavailableServlet: Typically, when the web container receives an UnavailableException, it cannot determine whether the exception was issued from a servlet or a dispatched resource. Therefore, the web container automatically marks the servlet unavailable even if it is the dispatched resource that is unavailable.

If you are running on Version 7.0.0.5 or later, and have set the com.ibm.ws.webcontainer.discernUnavailableServlet custom property to true, any UnavailableException that is issued from a dispatched resource is placed in a wrapper. This wrapper enables the web container to determine whether the exception was issued from the servlet or a dispatched resource. If the exception is not issued by the servlet, the web container does not mark the servlet unavailable.

Name	Default value
com.ibm.ws.webcontainer.discernUnavailableServlet	false

com.ibm.ws.webcontainer.dispatcherRethrowSER: Typically, the RequestDispatcher does not propagate exceptions thrown from dispatched servlets, including JavaServer Pages, back to the servlet doing the dispatching. If you want the RequestDispatcher to throw exceptions back to the servlet doing the dispatching, add the com.ibm.ws.webcontainer.dispatcherRethrowSER custom property to the settings for the web container, and set the property to `true`.

Name	Default value
com.ibm.ws.webcontainer.dispatcherRethrowSER	false

Note: The com.ibm.ws.webcontainer.dispatcherRethrowSError custom property supersedes the com.ibm.ws.webcontainer.dispatcherRethrowSER custom property. When you enable the com.ibm.ws.webcontainer.dispatcherRethrowSError custom property by setting its value to `true`, the com.ibm.ws.webcontainer.dispatcherRethrowSER custom property is also set to true.

com.ibm.ws.webcontainer.dispatcherRethrowSError: When a JavaServer Page (JSP) file contains a compilation error, the runtime error is caught and handled directly by the container. Exceptions are not propagated and addressed by the dispatched JSP resource. With the com.ibm.ws.webcontainer.dispatcherRethrowSError custom property, exceptions are propagated back to the dispatched JSP resource.

Name	Default value
com.ibm.ws.webcontainer.dispatcherRethrowSError	false

Note: The com.ibm.ws.webcontainer.dispatcherRethrowSError custom property supersedes the com.ibm.ws.webcontainer.dispatcherRethrowSER custom property. When you enable the com.ibm.ws.webcontainer.dispatcherRethrowSError custom property by setting its value to `true`, the com.ibm.ws.webcontainer.dispatcherRethrowSER custom property is also set to true.

com.ibm.ws.webcontainer.donotservebyclassname:

The com.ibm.ws.webcontainer.donotservebyclassname custom property specifies a list of classes that cannot be served by the class name.

Name	Default value
com.ibm.ws.webcontainer.donotservebyclassname	none

com.ibm.ws.webcontainer.enabledefaultservletrequestpathelements: To correctly map a request to a default servlet, you must determine the proper servlet path and PathInfo values. The following table shows the affects on the Servlet Path and PathInfo values when you set the `com.ibm.ws.webcontainer.enabledefaultservletrequestpathelements` custom property to a true or false value.

Table 238. Servlet Path and PathInfo values. Values for Servlet Path and PathInfo

Value	Servlet Path value	PathInfo value
true	Set to the contents of the URI after the Context Path	Set to a null value

Table 238. Servlet Path and PathInfo values (continued). Values for Servlet Path and PathInfo

Value	Servlet Path value	PathInfo value
false (Default)	Set to an empty string	Set based on the contents of the URI after the Context Path

com.ibm.ws.webcontainer.enableErrorExceptionTypeFirst: When an exception occurs, the Web container searches for an error page to handle that exception. The default searching order is:

1. Any matching error-code error page
2. Any matching exception-type error page

The matched error-code page is always returned even if there is also a matching exception type error page defined in the web.xml file. To have the Web container search and use the exception-type before the error-code, set this property to `true`.

Name	Default value
com.ibm.ws.webcontainer.enableErrorExceptionTypeFirst	false

com.ibm.ws.webcontainer.enableJspMappingOverride: When a url-pattern is defined in the jsp-property-group of the web.xml, file, it is typically mapped to, and handled by the JavaServer Page (JSP) engine. If you have applications that must override this mapping so that they can handle and serve the JSP content themselves, set the com.ibm.ws.webcontainer.enableJspMappingOverride property to `true`.

Name	Default value
com.ibm.ws.webcontainer.enableJspMappingOverride	false

com.ibm.ws.webcontainer.enableMultiReadOfPostData: Set the com.ibm.ws.webcontainer.enableMultiReadOfPostData custom property to `true` if you want to enable multiple reads of post data. When this property is set to true, the post data can be read multiple times as either an InputStream or Reader, and as parameters.

When the web container is enabled for multiple reads of post data, you can set up an application to complete the following actions if you want that application to re-read post data from the beginning using either an InputStream or Reader:

1. Obtain the InputStream or Reader
2. Read the data
3. Close the InputStrean or Reader

If either the first or third action does not occur, the next read of the post data is not reset to the beginning of that data.

The web container automatically completes this sequence if an application re-reads the post data as parameters.

Name	Default value
com.ibm.ws.webcontainer.enableMultiReadOfPostData	false

com.ibm.ws.webcontainer.extractHostHeaderPort and trusthostheaderport: The getServerPort method relies on the getVirtualPort method of the channel, which returns a port number in the following order:

1. Port number from the request URL
2. Port number from the request host header

This order is compliant with HTTP/1.1 RFC but not with the Java Servlet Specification Version 2.4 API, which requires the port number from the host header to be returned first, if any, or the request URL. The correct returned URL for the above example is: `http://ProxyServer:8888`. The web container was modified to return a port number from the host header, if any, or the URL port that accepted the client connection. You must set the trusthostheaderport and the com.ibm.ws.webcontainer.extractHostHeaderPort custom property to true to return the port number from the request host header first. For example, set these properties in the web.xml file using:

```
trusthostheaderport = true
com.ibm.ws.webcontainer.extractHostHeaderPort = true
```

Or you can set these properties as web container custom properties in the administrative console using the following two sets of name-value pairs:

Name	Default value
com.ibm.ws.webcontainer.extractHostHeaderPort	false
trusthostheaderport	false

com.ibm.ws.webcontainer.finishresponseonclose:

Use the com.ibm.ws.webcontainer.finishresponseonclose custom property to indicate that you want the web container to close a connection when a servlet calls close() on a writer or output stream.

Typically, when a servlet calls close() on a writer or output stream, the web container sends the data that has been written to the writer or output stream to the client, and then waits for the servlet service() method to finish before it closes the connection. This delay might be interpreted as a response completion delay, especially if a servlet service() method does not complete until sometime after the writer or output stream is closed.

Name	Default value
com.ibm.ws.webcontainer.finishresponseonclose	false

com.ibm.ws.webcontainer.ForceDifferentCookiePaths:

Note: When you configure an application to use a cookie to track the session, the default path for the cookie is set to the context root of the application. Therefore, the cookie is only sent to requests that are made to this application. To change the default path to be "/" (forward slash), such that the cookie is sent to requests for any application in this domain, set the ForceDifferentCookiePaths session manager custom property.

Name	Default value
com.ibm.ws.webcontainer.ForceDifferentCookiePaths	false

com.ibm.ws.webcontainer.HTTPOnlyCookies: The com.ibm.ws.webcontainer.HTTPOnlyCookies custom property provides a level of defense against a client-side script accessing a protected cookie and acquiring its content. When you use this custom property, you can prevent Java scripts that run in a browser from accessing all cookies or a particular list of cookies of your choosing. The HTTPOnly attribute is added to each cookie specified in this custom property and enables protection from client-side script access.

gotcha: Specifying com.ibm.ws.webcontainer.HTTPOnlyCookies with no operands means that the HTTPOnly attribute will NOT be added to any cookie, and any client-side Java script running in a browser can access the content of any cookies.

You can specify the following values for this property:

* - An asterisk value means that all cookies are given the HTTPOnly attribute.

A comma delimited list of the specific cookies that are given the HTTPOnly attribute. The HTTPOnly attribute is only given to cookies that are on this list.

The following examples illustrate how to specify these two settings:

```
com.ibm.ws.webcontainer.HTTPOnlyCookies=*
com.ibm.ws.webcontainer.HTTPOnlyCookies=cookieName1,Account3Cookie,JsessionID
```

Note: Cookie names used in specifying com.ibm.ws.webcontainer.HTTPOnlyCookies are case-insensitive.

Name	Default value
com.ibm.ws.webcontainer.HTTPOnlyCookies	none

com.ibm.ws.webcontainer.ignoreinjectionfailure: If a resource or Enterprise JavaBeans (EJB) injection fails during the servlet initialization process, an error message is written to the server log files. However, the error message is not propagated to the client. In addition, the servlet is put into service and it is not reinitialized until its application is restarted. During this time, if a request is received that references the resource, which previously failed to inject, a NullPointerException exception results. Similarly, this problem can occur during the filter and listener initialization processes.

The com.ibm.ws.webcontainer.ignoreinjectionfailure custom property enables you to specify whether to propagate these error messages and whether to put a servlet into service. By default, the custom property is set to `false`, which retains the previously described behavior. To enable the propagation of these injection exceptions to the client and to not put the servlet into service, you must leave this custom property set to `false`.

Name	Default value
com.ibm.ws.webcontainer.ignoreinjectionfailure	false

com.ibm.ws.webcontainer.ignoreInvalidQueryString: When the web container encounters an encoding character in a query string pair that is not valid, it throws an IllegalArgumentException exception and, by default, ignores the entire query string. In applications where every field in the query string is an essential resource, it might not be desirable to ignore the entire query string. If you set the com.ibm.ws.webcontainer.ignoreInvalidQueryString custom property to `true`, the web container ignores query string pairs that are not valid and continues to process valid query string pairs.

Name	Default value
com.ibm.ws.webcontainer.ignoreInvalidQueryString	false

com.ibm.ws.webcontainer.IgnoreSessiononStaticFileRequest: The web container accesses a session for the static file requests involving filters. This action can result in a performance degradation, for example, when running with database session persistence. If you set the com.ibm.ws.webcontainer.IgnoreSessiononStaticFileRequest custom property to `true`, the web container cannot access a session for the static files requests involving filters.

Name	Default value
com.ibm.ws.webcontainer.IgnoreSessiononStaticFileRequest	false

com.ibm.ws.webcontainer.invokeFilterInitAtStartup: The com.ibm.ws.webcontainer.invokeFilterInitAtStartup custom property enables the web container to invoke the init method and initialize a filter during the startup process for an application.

Name	Default value
com.ibm.ws.webcontainer.invokeFilterInitAtStartup	false

com.ibm.ws.webcontainer.invokeFiltersCompatibility:

You might need to use a custom servlet filter with web applications to map files from a one URI to another URI that points to a particular resource. For example, you might map URIs that start with *my_company* to the *my_company*/external directory. Without enabling the *com.ibm.ws.webcontainer.invokeFiltersCompatibility* custom property, the web container does not call any custom servlet filters.

When this custom property is set to true, the web container calls custom servlet filters before looking for welcome files. Also, if the web container cannot find a resource, it calls the custom servlet filters before creating a FileNotFoundException exception. This change enables the web container to verify whether the custom servlet filters modify the path to a resource.

Name	Default value
com.ibm.ws.webcontainer.invokeFiltersCompatibility	false

com.ibm.ws.webcontainer.invokerequestlistenerforfilter: If a web application has defined the listener in the web deployment descriptor xml file, then you must set the com.ibm.ws.webcontainer.invokerequestlistenerforfilter custom property to `true` to have ServletRequestListener invoked when a request is about to enter the filter for that web application.

According to the Java Servlet Specification, a ServletRequestListener should be invoked if a request is about to enter the filter for a web application that has defined the listener in the web deployment descriptor xml file.

Name	Default value
com.ibm.ws.webcontainer.invokerequestlistenerforfilter	false

com.ibm.ws.webcontainer.KeepUnreadPostDataAfterResponseSentToClient: This property indicates whether post data is available to read after the client response is completed, following either the completion of a forward request completes, or a return from a sendRedirect. If this property is set to `true`, post data is available to read after the client response is completed either after a forward request completes, which is the default behavior, or on a return from a sendRedirect,, which occurs when the com.ibm.ws.webcontainer.SendResponseToClientAsPartOfSendRedirect custom property is set to `true`. However, setting this property to `true` requires unread post data to be held in memory until the target resource completes, and increases memory usage.

Name	Default value
com.ibm.ws.webcontainer.KeepUnreadPostDataAfterResponseSentToClient	false

com.ibm.ws.webcontainer.logServletContainerInitializerClassloadingErrors:

Note: When examining the classes of an application to see if they match any of the criteria that is specified by the HandlesTypes annotation of a ServletContainerInitializer, the container might run into class loading problems if one or more of the optional application JAR files are missing. Because the container does not decide whether these types of class loading failures prevent the application from working correctly, it ignores the failures and provides a configuration option that logs them.

Setting this property to true turns on logging.

Name	Default value
com.ibm.ws.webcontainer.logServletContainerInitializerClassloadingErrors	false

com.ibm.ws.webcontainer.mapFiltersToAsterisk:

When processing a request, the web container recognizes servlet mappings to "*" as the same as servlet mappings to "/*". To provide the same behavior with filter mapping, set the com.ibm.ws.webcontainer.mapFiltersToAsterisk custom property to `true`. Setting the com.ibm.ws.webcontainer.mapFiltersToAsterisk custom property to `true` causes the web container to recognize filter mappings to "*" as a filter mapping to "/*". This custom property is not case-sensitive.

Name	Default value
com.ibm.ws.webcontainer.mapFiltersToAsterisk	false

com.ibm.ws.webcontainer.normalizerequesturi: Typically, request URI 404 errors do not occur if a request URI is submitted from a browser, because most modern browsers automatically normalizes a request URI before calling WebSphere Application Server. Therefore, by default, the web container does not normalize a request URI before trying to resolve that URI to an application and servlet mapping.

A request URI, that includes `/./` or `/../` as part of an application context, that has not been normalized, might fail with a 404 error. Similarly, a request URI, that includes `/./`" or `/../` as part of a servlet path, that has not been normalized, fails to match a servlet mapping, which also results in a 404 error, even though the URI is normalized before resolving the URI to a JavaServer Pages (JSP) or static file.

You can set the com.ibm.ws.webcontainer.normalizerequesturi custom property to `true` and the web container normalizes these types of request URIs.

Name	Default value
com.ibm.ws.webcontainer.normalizerequesturi	false

com.ibm.ws.webcontainer.parseUTF8PostData:

If the web container attempts to process a request that includes UTF-8 post data that is not URL encoded, the target resource accesses the post data as parameters. However, the UTF-8 data is not decoded correctly and the result data might be lost.

To resolve this issue, set the com.ibm.ws.webcontainer.parseUTF8PostData custom property to true. When the web container processes parameters, it detects UTF-8 post data that is not URL encoded and includes the data in the parameter values.

To use this function, you must set the value to true.

Name	Default value
com.ibm.ws.webcontainer.parseUTF8PostData	false

com.ibm.ws.webcontainer.provideQStringToWelcomeFile: Typically, when a request is initially sent to the context root of the application, the request is forwarded to a welcome file. If a query string is included in an initial request, it is unavailable to the welcome file if you included the request.getQueryString() attribute in the welcome file. However, the query string is available to the welcome file if you included the javax.servlet.forward.query_string attribute in the welcome file.

If you must use the request.getQueryString() attribute, instead of the javax.servlet.forward.query_string attribute, to make the query string available to the welcome file, add the com.ibm.ws.webcontainer.provideQStringToWelcomeFile custom property to your web container configuration and set the property to `true`.

Name	Default value
com.ibm.ws.webcontainer.provideQStringToWelcomeFile	false

com.ibm.ws.webcontainer.SendResponseToClientAsPartOfSendRedirect: This property indicates whether a response is completed as part of a a sendRedirect request. If this property is set to `true`, a response is completed as part of a sendRedirect request, and any post data associated with the request is not available for a read on return from sendRedirect.

The default value is false.

Name	Default value
com.ibm.ws.webcontainer.SendResponseToClientAsPartOfSendRedirect	false

com.ibm.ws.webcontainer.SendResponseToClientWhenResponseIsComplete: This property indicates whether a response is completed on return from a forward request.

If this property is set to `false`, a response is not completed on return from a forward request. Instead, it is delayed until the target resource completes. Post data is available for a read after the forward completes.

Name	Default value
com.ibm.ws.webcontainer.SendResponseToClientAsPartOfSendRedirect	true

com.ibm.ws.webcontainer.ServeWelcomeFileFromExtendedDocumentRoot: Typically, the first time the web container handles a request for a static welcome page that is not a JavaServer Pages (JSP) file, the web container does not search the ExtendedDocumentRoot for the welcome file unless the request for that welcome file is fully-qualified. If the request is fully-qualified, the web container serves the welcome file, and the context root of the application displays the welcome file. If the request for the static welcome file is not fully-qualified, the web container returns a 404 error, which indicates that the web container did not find the welcome file.

After the web container successfully serves a welcome file, the web container creates a mapping for that welcome file. The web container then uses this mapping to handle future requests for the welcome file, thereby eliminating the need for subsequent requests to be fully-qualified.

If you want the web container to always search an application defined ExtendedDocumentRoot for a welcome file, even if the request is not fully-qualified, you can add the com.ibm.ws.webcontainer.ServeWelcomeFileFromExtendedDocumentRoot custom property to your web container settings, and set this property to `true`.

Name	Default value
com.ibm.ws.webcontainer.ServeWelcomeFileFromExtendedDocumentRoot	false

com.ibm.ws.webcontainer.ServletDestroyWaitTime: By default, when an application is stopped the web container waits up to 60 seconds for each active request for a resource of that application to complete. You can now define the com.ibm.ws.webcontainer.ServletDestroyWaitTime web container custom property to control the amount of time that the web container waits for an active request to complete when the owning application is stopped.

Set the com.ibm.ws.webcontainer.ServletDestroyWaitTime custom property to an integer value, which specifies the number of seconds to wait for a request to complete. The default value is 60 seconds.

Name	Default value
com.ibm.ws.webcontainer.ServletDestroyWaitTime	60

com.ibm.ws.webcontainer.setUnencodedHTMLinsendError: Typically, the web container encodes the specified error messages before formatting them, to prevent Cross-Site Scripting (XSS) attacks on the

client if the application does not sanitize these messages. However the Java Servlet Specification for the sendError(int, String) method, indicates that the server should create the response to look like an HTML-formatted server error page.

If you do not want the web container to encode the specified error messages before formatting them, add the com.ibm.ws.webcontainer.setUnencodedHTMLinsendError custom property to your web container configuration settings, and set the property to `true`.

Name	Default value
com.ibm.ws.webcontainer.setUnencodedHTMLinsendError	false

com.ibm.ws.webcontainer.suppressheadersinrequest: The com.ibm.ws.webcontainer.suppressheadersinrequest custom property can be used to suppress the inclusion of request headers that start with special characters, such as "$" or "_". Some applications do not handle request headers that start with special characters.

The value specified for this custom property is a delimited list of the header prefixes that you want to be suppressed.

Example:

```
com.ibm.ws.webcontainer.suppressheadersinrequest=$WS,_WS
```

Name	Default value
com.ibm.ws.webcontainer.suppressheadersinrequest	none

com.ibm.ws.webcontainer.suppressHtmlRecursiveErrorOutput:

During a recursive error that an application-specified error page cannot handle, the stack trace and error message are output as an HTML page. This information includes class names and program information that the application developer does not want expose to the user.

You can set the com.ibm.ws.webcontainer.suppressHtmlRecursiveErrorOutput web container custom property to suppress the HTML output of the error text, without changing the internal logging of the message. Set the custom property com.ibm.ws. webcontainer.suppressHtmlRecursiveErrorOutput to `true` to disable the HTML output of the error message to the user and present the user with blank page with a 500 error code.

Name	Default value
com.ibm.ws.webcontainer.suppressHtmlRecursiveErrorOutput	false

com.ibm.ws.webcontainer.suppressLastZeroBytePackage: Typically, the last zero byte chunk is used to indicate, to a client, the end of the response data in a chunked encoded transmission. Some applications use this last zero to determine when the response data is completely received, and they can start processing it. If an error occurs in the application after the response headers are sent, the last chunk of data is still sent to the client. The client might not realize that an error has occurred, and attempt to process incomplete data.

If you set the com.ibm.ws.webcontainer.suppressLastZeroBytePackage custom property to `true`, if an error occurs in the application after the response headers are sent, the last chunk of data is not sent to the client.

Name	Default value
com.ibm.ws.webcontainer.suppressLastZeroBytePackage	false

com.ibm.ws.webcontainer.suppressServletExceptionLogging:

If a servlet creates an exception, it is logged to the system console. If you do not want the web container to log servlet- created exceptions, add the com.ibm.ws.webcontainer.suppressServletExceptionLogging custom property to the web container configuration settings, and set the property to `true`.

Name	Default value
com.ibm.ws.webcontainer.suppressServletExceptionLogging	false

com.ibm.ws.webcontainer.throwMissingJspException:

Set the com.ibm.ws.webcontainer.throwMissingJspException custom property to `true` to create a FileNotFoundException when a resource that is included by a JSP file is missing. If this property is not set to `true`, an error page displays.

Name	Default value
com.ibm.ws.webcontainer.throwMissingJspException	false

com.ibm.ws.webcontainer.webgroupvhostnotfound: Error message SRVE0017W states "Web Group not found: {0}", and error message SRVE0255 states "A WebGroup/Virtual Host to handle {0} has not been defined". These messages might be returned when the application that is called to process the request serviced by IBM WebSphere Application Server is not found. You can use the com.ibm.ws.webcontainer.webgroupvhostnotfound custom property to change the text of these messages to text that is more suitable for your environment.

Name	Default value
com.ibm.ws.webcontainer.webgroupvhostnotfound	none

com.ibm.ws.webcontainer.xPoweredBy:

Note: This custom property enables you to configure the value of the X-Powered-By header, which supplies the implementation information of the server.

Name	Default value
com.ibm.ws.webcontainer.xPoweredBy	Servlet/3.0

com.ibm.wsspi.jsp.convertAttrValueToString:

Set the com.ibm.wsspi.jsp.convertAttrValueToString web container custom property to `true` to convert start and end attributes of the repeat tag to strings before they are used.

Name	Default value
com.ibm.wsspi.jsp.convertAttrValueToString	false

com.ibm.wsspi.jsp.disableElCache:

Set the com.ibm.wsspi.jsp.disableElCache web container custom property to `true` to disable the commons-el expression cache if you are experiencing out of memory conditions because the hash maps are held by the expression evaluator.

Name	Default value
com.ibm.wsspi.jsp.disableElCache	false

com.ibm.wsspi.jsp.disableResourceInjection: The resource injection feature accesses resources in applications differently than it did in earlier versions of the product, and causes the compiled method

output to be larger than it was previously. If you have large JSP files that in earlier releases pushed the 65535 byte limit in the translated service method, they might now exceed this limit, causing the compile to fail.

If you encounter this situation, you can either break a large JSP file into smaller JSP files, and use <jsp:include> statements to combine them after they are compiled, or you can add the com.ibm.wsspi.jsp.disableResourceInjection custom property to your web container settings to disable the resource injection function during the JSP translation process. When the com.ibm.wsspi.jsp.disableResourceInjection custom property is set to `true`, the resource injection function is disabled for all applications.

If you only want to disable the resource injection function for specific applications, you can add the disableResourceInjection JSP attribute to the ibm-web-ext.xmi files for those specific applications.

Name	Default value
com.ibm.wsspi.jsp.disableResourceInjection	false

com.ibm.wsspi.jsp.disableTldSearch: The *com.ibm.wsspi.jsp.disableTldSearch* custom property can be used to improve application startup time. By default, when an application starts, the JSP engine searches the application installation directories for the taglib descriptor (TLD) files. This search process might increase the startup time for large applications with many files and directories. To disable this search process, set this property to `true`.

Name	Default value
com.ibm.wsspi.jsp.disableTldSearch	false

com.ibm.wsspi.jsp.enabledoublequotesdecoding:

Set the com.ibm.wsspi.jsp.enabledoublequotesdecoding web container custom property to decode an encoded double quote character if it is embedded in a script function within a JavaServer Pages (JSP) file.

The JSP Container does not decode an encoded double quote character during the translation of a JSP file. Instead, there is a dependency on the browser to decode it. However, when an encoded double quote character exists inside a script function of a tag, the browser cannot decode it. Thus, when this custom property is not set, the encoded double quote character causes the script function to malfunction.

When you set this custom property, the value affects all of your deployed applications. If you want to affect an individual application, set the `enableDoubleQuotesDecoding` JSP attribute to `true` within the `ibm-web-ext.xmi` file in your application.

Name	Default value
com.ibm.wsspi.jsp.enabledoublequotesdecoding	false

DebugSessionCrossover:

The *DebugSessionCrossover* custom property enables code to perform additional checks to verify that only the session associated with the request is accessed or referenced. Messages are logged if any discrepancies are detected.

Note: The use of the *DebugSessionCrossover* property as a web container custom property is deprecated. You can now define it as a session management custom property.

To enable session data crossover detection, set this property to `true`

Name	Default value
DebugSessionCrossover	false

Refer to the HTTP session problems article for additional information.

DecodeUrlAsUTF8:

The UTF-8 encoded URL feature, which provides UTF-8 encoded Uniform Resource Locators (URLs) to support the double-byte characters in URLs is enabled by default. You can prevent the web container from explicitly decoding URLs in UTF-8 and have them use the ISO-8859 standard as per the current HTTP specification by by setting this custom property to `false`.

Name	Default value
DecodeUrlAsUTF8	true

enableInProcessConnections:

Use the enableInProcessConnections custom property to reduce response times and to reduce the number of threads that are used to service a request, which reduces the potential for a deadlock.

There is an optimized communication path between a web services client application and a web container that are located in the same application server process. Requests from the web services client that are normally sent to the web container using a network connection are delivered directly to the web container using an optimized local path. The local path is available because the web services client application and the web container are running in the same process. This optimized communication path is disabled by default. Before enabling this property, make sure that wild cards are not specified for the web container ports. Use specific ports for the web container when the optimized communication path is enabled.

To enable the optimized communication path, set this property to `true`.

Name	Default value
enableInProcessConnections	false

Refer to the Web services client to web container optimized communication topic for additional information.

fileServingEnabled, directoryBrowsingEnabled, and serveServletsByClassnameEnabled:

fileServingEnabled, directoryBrowsingEnabled, and similar properties are global settings for internal servlets. Web application archive (WAR) files that are packaged using third-party tools cannot specify behavior for the services that are exposed by the web container internal servlets.

You can use the fileServingEnabled, directoryBrowsingEnabled, and serveServletsByClassnameEnabled properties to globally enable and disable the fileServing, directoryBrowsing, and serveServletsByClassname functions for internal servlets for all web applications at the web container level.

- Setting the fileServingEnabled, property to `false` disables the fileServing function.
- Setting the directoryBrowsingEnabled, property to `true` enables the directoryBrowsing function.
- Setting the serveServletsByClassnameEnabled property to `true` enables the serveServletsByClassnameEnabled function.

Name	Default value
fileServingEnabled	true
directoryBrowsingEnabled	false

Name	Default value
serveServletsByClassnameEnabled	false

Settings that are defined in an assembly tool take precedence over the global settings that are set through the custom properties at the web container level.

Web application deployment extensions continue to hold configuration information for the services that are provided by the internal servlets, and take precedence over the global settings that are set through the custom properties at the web container level.

ForceSessionIdLengthCheck: Newly-generated session IDs are, by default, 23 characters in length, unless you use the HttpSessionIdLength custom property to specify a different maximum length for your session IDs.

When an incoming request has a session ID that is longer than the expected session ID length, and whose prefix is identical to a pre-existing session ID, the longer ID is used to return a new session. If the length of the session ID on the incoming request is larger then the maximum length specified for your system, such that it exceeds the width of the ID column in the session table column that is used in database persistence, an SQL0302 error occurs.

To prevent the occurrence of these SQL0302 errors, you can add the ForceSessionIdLengthCheck custom property to your web container custom properties and set it to `true`. When this custom property is set to true, the length of a session ID cannot exceed 23 characters. If an incoming request has a session ID that is longer than 23 characters, the first 23 characters are used to return a new session.

Name	Default value
ForceSessionIdLengthCheck	false

ForceSessionInvalidationMultiple:

The *ForceSessionInvalidationMultiple* custom property indicates whether the session manager should wait indefinitely for a request to complete before attempting to invalidate the session, or attempt to invalidate a session after the specified time limit has elapsed.

- If you specify 0 (zero) for this custom property, the session manager waits indefinitely until a request is complete before attempting to invalidate the session.

  If your requests normally are not bound by a response time limit, specify 0 for this property.
- If you specify a positive integer, such as 1, 2, or 3 for this custom property, even if a session is not known to have completed, the session manager attempts to invalidate the session if the indicated time period since the last access occurred has elapsed. This time period is the result of multiplying the value specified for this property and the value specified for the Session Timeout property. For example, if you specify 2 minutes for the Session Timeout property and 2 for the ForceSessionInvalidationMultiple property, the session manager attempts to invalidate the session after 4 minutes.

  If you want to invalidate your sessions after a certain amount of time has elapsed, specify the appropriate positive integer for this property.

Name	Default value
ForceSessionInvalidationMultiple	1

httpsIndicatorHeader:

The custom property *httpsIndicatorHeader* manages HTTPS requests that are forwarded to an application server from an SSL offloader that is used in front of WebSphere Application Server. When an HTTPS request is received by an SSL offloader it is redirected over HTTP to an application server using

WebSphere Application Server. The SSL offloader adds a header indicating the original request was over HTTP. The httpsIndicatorHeader property specifies the request header key name added by the SSL box. The application server checks this indicator to determine if SSL is required. If it determines the request is SSL over HTTP, an HTTPS scheme is chosen.

Name	Default value
httpsIndicatorHeader	none

HttpSessionIdReuse:

The custom property *HttpSessionIdReuse* determines whether the session manager can use the session ID sent from a browser to preserve session data across web applications that are running in an environment that is not configured for session persistence. In a multi-JVM environment, that is not configured for session persistence, setting this property to `true` enables the session manager to use the same session information for all of a user requests, even if the web applications that are handling these requests are governed by different JVM files. The default value for this property is `false`.

Note: The use of the HttpSessionIdReuse property as a web container custom property is deprecated. You should now define this functionality as a session management custom property.

To enable the session manager to use the session ID sent from a browser to preserve session data across web applications that are running in an environment that is not configured for session persistence, set this property to `true`.

Name	Default value
HttpSessionIdReuse	false

listeners:

The servlet specification supports applications registering listeners for servlet-related events on an individual application basis through the `web.xml` descriptor. However, using the listeners custom property, you can enable a server to listen to servlet events across web applications.

To implement global listening, a listener is registered at the web container level and is propagated to all of the installed and new web applications. This global behavior of internal servlet listeners is controlled by the listeners custom property by using the following name-value pair format.

`listeners=`*`listener_class`*

Name	Default value
listeners	none

The value for this property is a string, specifying a comma-separated list of listener classes. The listener that is supplied must implement standard listener classes from the Java Servlet API or IBM listener extension classes.

prependSlashToResource:

WebSphere Application Server 5.x supports Uniform Resource Locators (URLs) without leading front slashes (/) . To preserve compatibility, you can set this custom property to `true`. When this property is set to `true`, the web container ignores the specification and consider URLs without the leading front slash, use the following name-value pair.

Name	Default value
prependSlashToResource	false

trusted: The **trusted** custom property enables the application server to use inbound private headers from the web server plug-in. These inbound private headers notify the application server about the connection to the web server. When you set the custom property to **true**, the application server uses the asserted information on the client certificates. These client certificates are used by the end user to connect to the web server and establish the client information, which is treated as the certificate for the end user. Then, the application server uses the certificate information for authentication purposes when client certificate authentication is used or when the application code accesses the javax.net.ssl.peer_certificates certificates. Because this information is asserted, it is insecure and potentially vulnerable to an attacker that is able to connect directly to the application server and bypass the web server.

Important: If you allow direct connections to the application server and use client certificates, you must set this custom property to **false**.

Name	Default value
trusted	true

Web module deployment settings

Use this page to configure an instance of web module deployment.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Manage Modules** > ***Web_module_instance***.

URI:

Specifies the relative location of the module within the application enterprise archive (EAR) file.

Alternate deployment descriptor:

Specifies the alternate deployment descriptor for the module as defined in the application deployment descriptor according to the Java Platform, Enterprise Edition (Java EE) specification.

Starting weight:

Specifies the order that modules are started. Lower weighted modules are started before higher weighted modules.

If the application deployment descriptor specifies the `<initialize-in-order>true</initialize-in-order>` element, the default starting weights reflect the order that is specified in the deployment descriptor. Otherwise, the defaults are determined based on module type (RAR modules start before EJB modules, which start before web modules).

Class loader order:

Specifies whether the class loader searches in the parent class loader or in the application class loader first to load a class. The standard for development kit class loaders and product class loaders is `Classes loaded with parent class loader first`. By specifying `Classes loaded with application class loader first`, your application can override classes contained in the parent class loader, but this action can potentially result in ClassCastException or LinkageErrors if you have mixed use of overridden classes and non-overridden classes.

The options are `Classes loaded with parent class loader first` and `Classes loaded with local class loader first (parent last)`. The default is to search in the parent class loader before searching in the application class loader to load a class.

Data type String
Default Classes loaded with parent class loader first

Context root for web modules settings

Use this page to specify the context root for web modules during or after installation of an application onto a WebSphere Application Server deployment target.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Context root for web modules**. This page is the same as the Context root for web modules page on the application installation and update wizards.

Web Module:

Specifies the name of a web module in the application that you are installing or that you are viewing after installation.

URI:

Specifies the location of the module relative to the root of the application EAR file.

Context Root:

Specifies the context root of the web application (WAR).

A context root for each web module is defined in the application deployment descriptor during application assembly. Use this field to assign a different context root to a web module. The context root is combined with the defined servlet mapping (from the WAR file) to compose the full URL that users type to access the servlet. For example, if the context root is `/gettingstarted` and the servlet mapping is `MySession`, then the URL is `http://host:port/gettingstarted/MySession`.

Environment entries for web modules settings

Use this page to configure the environment entries of Web modules such as servlets and JavaServer Pages (JSP) files.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Environment entries for web modules**. This page is the same as the Environment entries for web modules page on the application installation and update wizards.

Module:

Specifies the name of a web module.

URI:

Specifies the location of the module relative to the root of the application (EAR file).

Name:

Specifies the name of the environment entry that you are editing or viewing. The environment entry is the `env-entry` property in the web module.

Type:

Specifies a data type for the environment entry defined by the `env-entry` property in the web module.

Description:

Specifies information on the environment entry.

Value:

Specifies an editable value for the environment entry defined by the `env-entry` property in the web module.

The lookup name is displayed in the **Value** column if the lookup name is configured in the application metadata. The lookup name is not editable. If you do not specify a value on this page, the lookup name is used for the value.

Web container troubleshooting tips

Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

If you are having problems starting a web module, or accessing resources within a particular web module:

- View the JVM logs and process logs for the application server which hosts the problem web modules, and look for messages in the JVM output file which indicate that the web module has started successfully. You should see messages similar to the following:

```
WebContainer  A SRVE0161I: IBM WebSphere Application Server - Web Container.
Copyright IBM Corp. 1998-2002
WebContainer  A SRVE0169I: Loading Web Module: [module_name]
ApplicationMg A WSVR0221I: Application started: [application_name]
HttpTransport A SRVE0171I: Transport http is listening on port [port_number]
[server_name] open for e-business in profile_root/logs/[server_name]/SystemOut.log
```

- For specific problems that can cause servlets, HTML files, and JavaServer Pages (JSP) files not to be served, refer to the topic, web resource (JSP file, servlet, HTML file, image) does not display .
- For a detailed trace of the run-time behavior of the web container, enable trace for the component com.ibm.ws.webcontainer using `com.ibm.ws.webcontainer*=all`.

If application server related calls fail during Servlet.init method, you can either:

- Initialize the servlet manually by making a single request to that servlet in your browser when the server is ready for e-business instead of starting the servlet upon startup or
- You can choose not to make application server related calls in the servlet's init method.

If the property to start servlets during application server startup is enabled, part of its startup process calls the Servlet.init method on its servlets when you start the web container. Therefore, when the web container is starts and calls the init method, other components such as Naming and Work Load Management may not be fully started yet. As a result, application server related calls may not work since all of the application server components may not be ready yet. Once the application server is 'ready for e-business', it is completely ready.

If none of these steps fixes your problem, check to see if the problem has been identified and documented by looking at the available online support (hints and tips, tech notes, and fixes). If you do not find your problem listed there contact IBM support.

For current information available from IBM Support on known problems and their resolution, refer to the IBM Support page.

IBM Support has documents that can save you time gathering information needed to resolve this problem. Before opening a PMR, see the IBM Support page.

Disabling servlet pooling: Best practices and considerations

This topic provides usage examples of when you may want to disable servlet pooling. You may want to disable request and response pooling if your application is creating threads inside of the application or if you are concerned about the web container reusing request and response objects.

Disabling request and response pooling

- Application is creating threads inside of the application.

  The Servlet 2.4 specification states the following:

  > **SRV.4.10 Lifetime of the Request Object** Each request object is valid only within the scope of a servlet's service method, or within the scope of a filter's doFilter method. Containers commonly recycle request objects in order to avoid the performance overhead of request object creation. The developer must be aware that maintaining references to request objects outside the scope described above is not recommended as it may have indeterminate results.
  >
  > **SRV.5.6 Lifetime of the Response Object** Each response object is valid only within the scope of a servlet's service method, or within the scope of a filter's doFilter method. Containers commonly recycle response objects in order to avoid the performance overhead of response object creation. The developer must be aware that maintaining references to response objects outside the scope described above may lead to non-deterministic behavior.

- If you are concerned about the web container reuse of reusing request and response objects. Since these objects are reused, there is the potential for two requests in two separate applications to have access to the same request or response object as described in the Thread Safety section of Servlet 2.4.

  > **SRV.2.3.3.3 Thread Safety** Implementations of the request and response objects are not guaranteed to be thread safe. This means that they should only be used within the scope of the request handling thread.
  >
  > References to the request and response objects should not be given to objects executing in other threads as the resulting behavior may be nondeterministic. If the thread created by the application uses the container-managed objects, such as the request or response object, those objects must be accessed only within the servlet's service life cycle and such thread itself should have a life cycle within the life cycle of the servlet's service method because accessing those objects after the service method ends may cause undeterministic problems. Be aware that the request and response objects are not thread safe. If those objects were accessed in the multiple threads, the access should be synchronized or be done through the wrapper to add the thread safety, for instance, synchronizing the call of the methods to access the request attribute, or using a local output stream for the response object within a thread.

It is important to note that disabling pooling prevents the web container from recycling the servlet request and servlet response objects for subsequent requests. This creates additional overhead as a result of an increase in request and response object creation and the subsequent garbage collection of these discarded objects.

JavaServer Pages specific web container custom properties

You can configure name-value pairs of data, where the name is a property key and the value is a string value that you can use to set internal system configuration properties. You can define a new property to configure a setting beyond what is available in the administrative console. This topic includes a list of the available JavaServer Pages custom properties. The JavaServer Pages custom properties are case-sensitive.

You can use the following JSP file-specific web container custom properties:

- "com.ibm.ws.jsp.getparameterreturnemptystring" on page 2553
- "com.ibm.ws.jsp.jdksourcelevel" on page 2553
- "com.ibm.wsspi.jsp.allowjspoutputelementmismatch" on page 2553

- “com.ibm.wsspi.jsp.allowtaglibprefixusebeforedefinition”
- “com.ibm.wsspi.jsp.allowtaglibprefixredefinition” on page 2554
- “com.ibm.wsspi.jsp.allowunmatchedendtag” on page 2554
- “com.ibm.wsspi.jsp.evalquotedandescapedexpression” on page 2554
- “com.ibm.wsspi.jsp.modifyPageContextVariable” on page 2555
- “com.ibm.wsspi.jsp.recompilejsponrestart” on page 2555
- “com.ibm.wsspi.jsp.usecdatatrim” on page 2555
- “com.ibm.wsspi.jsp.usescriptvardupinit” on page 2556
- “com.ibm.wsspi.jsp.usestringcast” on page 2556
- com.ibm.wsspi.jsp.reusepropertygroupconfigoninclude

com.ibm.ws.jsp.getparameterreturnemptystring:

This property is for returning an empty string for actions not set in a JSP file. If a JSP file contains an action and that property has not been set, the JSP engine returns null on WebSphere Application Server Versions 6.0 and 6.1. However, in WebSphere Application Server Version 5.1 an empty string is returned. This custom property was added to provide backwards compatibility. When it is set to true, the value returned on a call to jsp:getProperty is an empty string instead of null for Versions 6.0 and 6.1.

Name com.ibm.ws.jsp.getparameterreturnemptystring

Value true

com.ibm.ws.jsp.jdksourcelevel:

This property is for setting the JDK source level through the administrative console. A JSP engine parameter can be configured for different levels of JDK. However, setting a JSP parameter requires that you set the jdksourcelevel JSP attribute in the web extension file for each web module. However, you can use the com.ibm.ws.jsp.jdksourcelevel custom property to set the JSP attribute globally using the web container custom property. If this attribute is also defined in the web extension file, the property defined in the web extension file supersedes the custom property for that particular application. This custom property is not case-sensitive. The default value is 16.

Name com.ibm.ws.jsp.jdksourcelevel

Value 13, 14, 15, or 16

com.ibm.wsspi.jsp.allowjspoutputelementmismatch:

CTS requirements in previous releases were not applicable to the product, therefore the JSP container supported multiple occurrences of properties in the jsp:output element. In the current release, CTS compliance requires that the JSP container strictly enforces rules about multiple occurrences of properties in the jsp:output element. You can use the com.ibm.wsspi.jsp.allowjspoutputelementmismatch custom property to relax the enforcement of the rule for compatibility with earlier versions.

Name com.ibm.wsspi.jsp.allowjspoutputelementmismatch

Value true

com.ibm.wsspi.jsp.allowtaglibprefixusebeforedefinition:

CTS compliance requires that a tag library directive that defines a prefix must occur before that prefix is used in a custom tag. This rule was not enforced in previous releases because CTS requirements were not required. However, you can use the `com.ibm.wsspi.jsp.allowtaglibprefixusebeforedefinition` custom property to relax the enforcement of the rule for compatibility with earlier versions.

Name com.ibm.wsspi.jsp.allowtaglibprefixusebeforedefinition

Value true

com.ibm.wsspi.jsp.allowtaglibprefixredefinition:

CTS compliance requires that if a tag library prefix is already defined with a different URI within a JSP, the product must create a translation error. This rule was not enforced in previous releases because CTS requirements were not required. However, you can use the com.ibm.wsspi.jsp.allowtaglibprefixredefinition custom property to relax the enforcement of the rule for compatibility with earlier versions.

Name com.ibm.wsspi.jsp.allowtaglibprefixredefinition

Value true

com.ibm.wsspi.jsp.allowunmatchedendtag:

In Version 5 of the product, improper termination of end tags was ignored whereas in Version 6, a translation exception is created. This change of behavior in Version 6 causes problems to users who are migrating their applications, which had improperly terminated end tags, to Version 6. In Version 6, to facilitate migration, a web container property, com.ibm.wsspi.jsp.allowunmatchedendtag, and a JSPAttribute, allowUnmatchedEndTag), are provided. You can enable these properties provides the Version 5 behavior.

Name com.ibm.wsspi.jsp.allowunmatchedendtag

Value true

com.ibm.wsspi.jsp.evalquotedandescapedexpression:

This property is for compiling functions that contain an expression. The JSP translation code was modified to handle escape characters and quotations properly when determining whether to evaluate an expression or to treat it as a literal string. To apply this behavior globally across all web applications, add the following name-value pair as a web container custom property.

Name com.ibm.wsspi.jsp.evalquotedandescapedexpression

Value true

To enable this new behavior for a single application, you must also add the evalquotedandescapedexpression JSP attribute to the `ibm-web-ext.xmi` or `ibm-web-ext.xml` file of the failing application and set the value to `true`.

The following example code shows the attribute in an XMI format:

```
&ltjspAttributes xmi:id="JSPAttribute_1" name="evalquotedandescapedexpression" value="true"/>
```

Note: The attribute ID value must be unique.

The following example code shows the attribute in the `ibm-web-ext.xml` file:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
 xmlns="http://websphere.ibm.com/xml/ns/javaee"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
 version="1.0">
 <jsp-attribute name="evalquotedandescapedexpression" value="true" />

 <reload-interval value="3"/>
 <auto-encode-requests value="true"/>
 <auto-encode-responses value="true"/>
 <enable-directory-browsing value="true"/>
 <enable-file-serving value="true"/>
 <pre-compile-jsps value="true"/>
```

```
 <enable-reloading value="true"/>
 <enable-serving-servlets-by-class-name value="true" />

</web-ext>
```

Note: Use an assembly tool, such as Rational Application Developer, to modify IBM extension and binding files. You can convert extension and binding files within modules from XMI to XML using the IBM Bindings and Extensions Conversion Tool for Multi-Platforms.

Note: For IBM extension and binding files, the .xmi or .xml file name extension is different depending on whether you are using a pre-Java EE 5 application or module or a Java EE 5 or later application or module. An IBM extension or binding file is named ibm-*-ext.xmi or ibm-*-bnd.xmi where * is the type of extension or binding file such as app, application, ejb-jar, or web. The following conditions apply:

- For an application or module that uses a Java EE version prior to version 5, the file extension must be .xmi.
- For an application or module that uses Java EE 5 or later, the file extension must be .xml. If .xmi files are included with the application or module, the product ignores the .xmi files.

However, a Java EE 5 or later module can exist within an application that includes pre-Java EE 5 files and uses the .xmi file name extension.

The `ibm-webservices-ext.xmi`, `ibm-webservices-bnd.xmi`, `ibm-webservicesclient-bnd.xmi`, `ibm-webservicesclient-ext.xmi`, and `ibm-portlet-ext.xmi` files continue to use the .xmi file extensions.

com.ibm.wsspi.jsp.modifyPageContextVariable:

During the translation phase of a tag file that is compiled, the JSP container implicitly uses the pageContext variable for the PageContext object. The use of the pageContext variable as an implicit variable name in tag files does not comply with the JSP Specification.

If compilation errors occur for applications that use a local pageContext variable in their tag file, set the com.ibm.wsspi.jsp.modifyPageContextVariable custom property to `true` to remove the use of the pageContext variable name in the generated Java code for tag files.

Name com.ibm.wsspi.jsp.modifyPageContextVariable

Value true

com.ibm.wsspi.jsp.recompilejsponrestart:

This property forces JSP files that were compiled at run time to be recompiled every time the application is restarted. This property is helpful if you switch the underlying JSF implementation. This property is best used on development environments.

Name com.ibm.wsspi.jsp.recompilejsponrestart

Value true

com.ibm.wsspi.jsp.usecdatatrim:

You can use the com.ibm.wsspi.jsp.usecdatatrim custom property to trim the text before creating CDATA section which eliminates the extra white spaces addedUsers Affected: WebSphere Application Server Version 6.0 users who are migrating their applications from Version 5 to Version 6 and whose JSPs use nesting tags in separate lines. Problem Description: JSP files that use nesting tags have extra lines in the code generated for this section. In Version 6, you could eliminate the extra spaces by appending all the lines into one using: '' The extra line is added in the Java code generated because the text is not trimmed

before creating the CDATA section. Therefore, a switch is provided to enable the trimming of the text before creating the CDATA section. You can set the JSP attribute, useCDataTrim, at the web module level or set the com.ibm.wsspi.jsp.usecdatatrim web container property at the web container level using the following name-value pair.

Name com.ibm.wsspi.jsp.usecdatatrim

com.ibm.wsspi.jsp.usescriptvardupinit:

The code generated for a JSP file assumed that the same tag variables to be declared two or more times in an If-Else condition, even if the variable had a page scope. The com.ibm.wsspi.jsp.usescriptvardupinit custom property enables this feature for all the applications deployed on a particular server. If the compatibility feature is required only for a specific application, enable the useScriptVarDupInit JSP attribute. If both the options are set, then the JSP attribute takes preference over the web container custom property.

Name com.ibm.wsspi.jsp.usescriptvardupinit

Value true

com.ibm.wsspi.jsp.usestringcast:

The com.ibm.wsspi.jsp.usestringcast property explicitly adds a String cast to the relative path before inclusion when you migrate Version 5.1 applications. In Version 6.0.x, the generated Java source for the JSP file did not add the "implicit" cast, for return types of type String when the request.getAttribute method is called. When a JSP file includes a resource whose relative path does not evaluate to a String, then the include fails as the include takes only a String as a relative path of the resource. You can set the com.ibm.wsspi.jsp.usestringcast custom property, which would affect all the deployed applications or you can set the property as a JSPAttribute, useStringCast, in the extensions file, which affects only the application for which the property is set.

Name com.ibm.wsspi.jsp.usestringcast

Value true

com.ibm.wsspi.jsp.reusepropertygroupconfigoninclude:

Note: Most properties that are defined in a JSP property group apply to an entire translation unit, for example, the requested JSP file that is matched by its URL pattern and all the files it includes using the include directive. The exceptions are the page-encoding and is-xml properties, which apply separately to each JSP file that is matched by its URL pattern. To revert the behavior to a setting before WebSphere Application Server Version 8.0, set the custom property to `true` to apply the two property values to the entire translation unit.

Name com.ibm.wsspi.jsp.reusepropertygroupconfigoninclude

Value false

Configuring JSP engine parameters

Learn about how to add, change or delete JSP engine configuration parameters.

About this task

The following note applies to the file references with a .xmi extension in this topic:

Note: For IBM extension and binding files, the .xmi or .xml file name extension is different depending on whether you are using a pre-Java EE 5 application or module or a Java EE 5 or later application or

module. An IBM extension or binding file is named ibm-*-ext.xmi or ibm-*-bnd.xmi where * is the type of extension or binding file such as app, application, ejb-jar, or web. The following conditions apply:

- For an application or module that uses a Java EE version prior to version 5, the file extension must be .xmi.
- For an application or module that uses Java EE 5 or later, the file extension must be .xml. If .xmi files are included with the application or module, the product ignores the .xmi files.

However, a Java EE 5 or later module can exist within an application that includes pre-Java EE 5 files and uses the .xmi file name extension.

The `ibm-webservices-ext.xmi`, `ibm-webservices-bnd.xmi`, `ibm-webservicesclient-bnd.xmi`, `ibm-webservicesclient-ext.xmi`, and `ibm-portlet-ext.xmi` files continue to use the .xmi file extensions.

WebSphere Application Server does not support the modification of deployment descriptor extension parameters through the Administrative Console or through administrative scripting.

Note: Use an assembly tool, such as Rational Application Developer, to modify IBM extension and binding files. You can convert extension and binding files within modules from XMI to XML using the IBM Bindings and Extensions Conversion Tool for Multi-Platforms.

To add, change or delete JSP engine configuration parameters, complete the following steps:

Procedure

1. Open the `WEB-INF/ibm-web-ext.xmi` or `WEB-INF/ibm-web-ext.xml` file.

   JSP engine configuration parameters are stored in a web module's configuration directory or in a web modules's binaries directory in the `WEB-INF/ibm-web-ext.xmi` or `WEB-INF/ibm-web-ext.xml` file. Open the `WEB-INF/ibm-web-ext.xmi` or `WEB-INF/ibm-web-ext.xml` file from:

   - The configuration directory, as in the following examples:

     profile_root/config/cells/*cellName*/applications/*enterpriseAppName*/deployments/*deployedName*/*webModuleName*/WEB-INF/ibm-web-ext.xmi

     profile_root/config/cells/*cellName*/applications/*enterpriseAppName*/deployments/*deployedName*/*webModuleName*/WEB-INF/ibm-web-ext.xml
   - The binaries directory if an application was deployed into WebSphere Application Server with the flag "Use Binary Configuration" set to true. Example of a binaries directory is:

     profile_root/installedApps/*nodeName*/*applicationName*.ear/applicationName.war/WEB-INF/ibm-web-ext.xmi

     profile_root/installedApps/*nodeName*/*applicationName*.ear/applicationName.war/WEB-INF/ibm-web-ext.xml
2. Edit the `WEB-INF/ibm-web-ext.xmi` or `WEB-INF/ibm-web-ext.xml` file.
   - To add configuration parameters to the `WEB-INF/ibm-web-ext.xmi` file, use the following format:

     ```
     xmi:id="JSPAttribute_6" name="parametername" value="parametervalue"/>
     ```
   - To add configuration parameters to the `WEB-INF/ibm-web-ext.xml` file, use the following format:

     ```
     <jsp-attribute name="parametername" value="parametervalue"/>
     ```
   - To delete configuration parameters, either delete the line from the file, or enclose the statement with `<!-- -->` tags.
3. Save the file.
4. Restart the Enterprise Application. It is not necessary to restart the server for parameter changes to take effect. However, some JSP engine configuration parameters affect the Java source code that is generated for a JSP. If such a parameter is changed, then you must retranslate the JSP files in the web module to regenerate Java source. You can use the batch compiler to retranslate all JSP files in a web module. The batch compiler uses the JSP engine configuration parameters that you have set in the `ibm-web-ext.xmi` or `ibm-web-ext.xml` file, unless you specifically override them. The topic, JSP engine configuration parameters, identifies the parameters that affect the generated Java source.

Example

The following is a sample of the WEB-INF/ibm-web-ext.xmi file. The lines in bold text are JSP engine configuration parameters.

```
<?xml version="1.0" encoding="UTF-8"?>
<webappext:WebAppExtension xmi:version="2.0" xmlns:xmi=http://www.omg.org/XMI
   xmlns:webappext="webappext.xmi" xmlns:webapplication="webapplication.xmi" xmi:id="WebAppExtension_1"
   reloadInterval="9" reloadingEnabled="true" defaultErrorPage="error.jsp" additionalClassPath=""
   fileServingEnabled="true" directoryBrowsingEnabled="false" serveServletsByClassnameEnabled="true"
   autoRequestEncoding="true" autoResponseEncoding="false"
   <webApp href="WEB-INF/web.xml#WebApp_1"/>
   <jspAttributes xmi:id="JSPAttribute_1" name="useThreadTagPool" value="true"/>
   <jspAttributes xmi:id="JSPAttribute_2" name="verbose" value="false"/>
   <jspAttributes xmi:id="JSPAttribute_3" name="deprecation" value="false"/>
   <jspAttributes xmi:id="JSPAttribute_4" name="reloadEnabled" value="true"/>
   <jspAttributes xmi:id="JSPAttribute_5" name="reloadInterval" value="5"/>
   <jspAttributes xmi:id="JSPAttribute_6" name="keepgenerated" value="true"/>
   <!--<jspAttributes xmi:id="JSPAttribute_7" name="trackDependencies" value="true"/> -->

</webappext:WebAppExtension>
```

The following is a sample of the WEB-INF/ibm-web-ext.xml file. The lines in bold text are JSP engine configuration parameters.

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
   xmlns="http://websphere.ibm.com/xml/ns/javaee"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
      version="1.0">

   <default-error-page uri="error.jsp"/>
   <jsp-attribute name="useThreadTagPool" value="true" />
   <jsp-attribute name="verbose" value="false" />
   <jsp-attribute name="deprecation" value="false" />
   <jsp-attribute name="reloadEnabled" value="true" />
   <jsp-attribute name="reloadInterval" value="5" />
   <jsp-attribute name="keepgenerated"  value="true" />
   <jsp-attribute name="trackDependencies" value="true" />
   <reload-interval value="9"/>
   <auto-encode-requests value="true"/>
   <auto-encode-responses value="false"/>
   <enable-directory-browsing value="false"/>
   <enable-file-serving value="false"/>
   <pre-compile-jsps value="false"/>
   <enable-reloading value="true"/>
   <enable-serving-servlets-by-class-name value="true"/>
</web-ext>
```

Attention: The integer **n** in **JSPattribute_n** has to be unique within the file.

JSP engine

The WebSphere Application Server JavaServer Pages (JSP) engine is the implementation of the JavaServer Pages Specification.

WebSphere Application Server Version 8.0 supports the JSP 2.1 specification.

The JSP engine

- Validates JSP source, both classic and XML styles
- Translates JSP source to Java classes
- Compiles Java classes, reporting any errors
- Generates Java classes for any tag files that are used by the JSP
- Interfaces with the web container to load JSP class files

- Supports JSP batch compilation, JSP compilation during application installation, and JSP compilation during the build process of customer applications, through an Ant task.
- Loads class files, and manage life-cycle (reloading, unloading as necessary)
- Supports debugging of JavaServer Pages files through support for JSR 45 (Debugging Support for Other Languages)

JSP engine configuration parameters

In WebSphere Application Server, you can configure the JavaServer Pages (JSP) engine configuration parameters for optimal performance in a production server environment and for the needs of developers in a development environment.

The JSP engine parameters are case sensitive. If the value specified for a parameter is comprised of two or more words separated by spaces, you must add quotation marks around the value. Some parameters affect the Java source that is generated for a JSP or tag file. These parameters are identified by the statement "This parameter requires regeneration of Java source." This statement indicates that if the configuration parameter is modified, the new value for the parameter does not have any effect until the JSP files are retranslated and the Java sources are recompiled.

Note: Use an assembly tool, such as Rational Application Developer, to modify IBM extension and binding files. You can convert extension and binding files within modules from XMI to XML using the IBM Bindings and Extensions Conversion Tool for Multi-Platforms.

compileWithAssert:

Specifies whether the generated Java classes should contain support for the Developer Kit, Java Technology Edition 1.4 Assertion facility. The effect of setting this parameter to true is that the –source 1.4 option is passed to the Java compiler. The default for this parameter is `false`. This parameter requires regeneration of Java source.

classdebuginfo:

Indicates whether the compiler includes debugging information in the generated class file. When you set this parameter to true, the –g option is passed to the Java compiler. The default for this parameter is `false`. This parameter requires regeneration of Java source.

convertAttrValueToString:

Specifies whether to convert start and end attributes of the repeat tag to strings before they are used. The default for this parameter is `false`. This parameter requires regeneration of Java source.

deprecation:

Specifies whether the compiler generates deprecation warnings when compiling the generated Java source. When you set this parameter to true, the -deprecation option is passed to the Java compiler. The default for this parameter is `false`. This parameter requires regeneration of Java source.

disableElCache:

Set the com.ibm.wsspi.jsp.disableElCache web container custom property to `true` to disable the commons-el expression cache if you are experiencing out of memory conditions because the hash maps are held by the expression evaluator. The default for this parameter is `false`.

disableJspRuntimeCompilation:

If this option is set to true, the JSP engine at runtime does not translate and compile JSP files; the JSP engine loads only precompiled class files. JSP source files do not need to be present in order to load

class files. When this option is set to true, you can install an application without JSP source, but the application must have precompiled class files. There is a web container custom property with the same name that is used to determine the behavior of all web modules installed in a server. If both the web container custom property and the JSP engine option are set, the JSP engine option takes precedence. The default for this parameter is `false`.

disableTldSearch:

Set this option is set to `true` to prevent the JSP engine from searching the application installation directories for the taglib descriptor (TLD) files when an application starts. If this option is set to false, when an application starts, the JSP engine searches the application installation directories for the TLD files. The default for this parameter is `false`.

There is a web container custom property, com.ibm.wsspi.jsp.disableTldSearch, that can be used to specify whether, when an application starts, the JSP engines in all web modules installed in a server do not search the application installation directories for the TLD files. If conflicting values are set for the web container custom property and the JSP engine option, the setting for the JSP engine option takes precedence.

Note: This option is only available in version levels 7.0.0.3, and higher.

evalQuotedAndEscapedExpression:

Set this option to true to handle escape characters and quotations properly when determining whether to evaluate an expression.

During the translation phase of a JSP compile, expressions are evaluated by the JSP engine. Characters, such as the escape character (\) or nested quotations, single or double, causes the JSP file translation to fail. For example, when you use functions that contain an expression such as

```
<input type="text" value="${fn:substring('1234567', 0,4)}"/>
```

Because of the double quote directly before the fn:substring statement, the JSP file fails to compile because the translator did not add the function mapper to the generated Java class. Also, if a dollar sign ($) was escaped using the backslash (\$), the translator still attempts to evaluate the expression instead of treating it as a literal string. To handle escape characters and quotations properly, you must set evalQuotedAndEscapedExpression to `true` in the `ibm-web-ext.xmi` or `ibm-web-ext.xml` file of the failing application.

The following code sample shows an entry in the `ibm-web-ext.xmi` file:

```
<jspAttributes xmi:id="JSPAttribute_1"
name="evalQuotedAndEscapedExpression" value="true"/>
```

The following code sample shows an entry in the `ibm-web-ext.xml` file:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
   xmlns="http://websphere.ibm.com/xml/ns/javaee"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
      version="1.0">
   <file-serving-attribute name="extendedDocumentRoot" value="true" />
   <jsp-attribute name="evalQuotedAndEscapedExpression" value="true" />
   <jsp-attribute name="extendedDocumentRoot" value="/opt/extDocRootDir" />
   <jsp-attribute name="extendedDocumentRoot" value="${MY_CUSTOM_VARIABLE}" />

   <reload-interval value="3"/>
   <auto-encode-requests value="false"/>
   <auto-encode-responses value="false"/>
   <enable-directory-browsing value="false"/>
   <enable-file-serving value="true"/>
```

```
   <pre-compile-jsps value="false"/>
   <enable-reloading value="true"/>
   <enable-serving-servlets-by-class-name value="false" />
</web-ext>
```

To apply this behavior globally across all web applications, you can set the com.ibm.wsspi.jsp.evalQuotedAndEscapedExpression web container custom property to true.

extendedDocumentRoot:

Use the extended document root facility when applications require access to files outside of the application web application archive (WAR) directory. This facility enables you to configure an application with one or more directory paths from which you can serve static files and JSP files. You can use this attribute when an application requires access to files that exist outside of the web application archive (WAR) directory. For example, if several applications require access to a set of common files, you can place the common files in a directory to which you can link each application as an extended document root directory.

To configure an application with an extended document root, add an extendedDocumentRoot attribute as a file-serving attribute to the `ibm-web-ext.xmi` or `ibm-web-ext.xml` file for the application. The value of this attribute is a comma-delimited list of directories that serve as the root directory location for the static files.

The following entry is an example within the `ibm-web-ext.xmi` file:

```
<fileServingAttributes xmi:id="FileServingAttribute_1" name="extendedDocumentRoot" value="/opt/extDocRootDir"/>
```

The following examples are based on the previous entry in the `ibm-web-ext.xmi` file with the attribute set to the `/opt/extDocRootDir` value:

- A request for the http://localhost:9080/*context_root*/sample.html resource requires that the `sample.html` file is located in the `/opt/extDocRootDir/sample.html` directory structure.
- A request for the http://localhost:9080/*context_root*/myDir/sample.gif resource requires that the `sample.gif` file is located in the `/opt/extDocRootDir/myDir/sample.gif` directory structure.

The following entry is an example within the `ibm-web-ext.xml` file:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
   xmlns="http://websphere.ibm.com/xml/ns/javaee"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
      version="1.0">
   <file-serving-attribute name="extendedDocumentRoot" value="/opt/extDocRootDir" />
   <jsp-attribute name="evalQuotedAndEscapedExpression" value="true" />
   <jsp-attribute name="extendedDocumentRoot" value="/opt/extDocRootDir" />
   <jsp-attribute name="extendedDocumentRoot" value="${MY_CUSTOM_VARIABLE}" />
   <reload-interval value="3"/>
   <auto-encode-requests value="false"/>
   <auto-encode-responses value="false"/>
   <enable-directory-browsing value="false"/>
   <enable-file-serving value="true"/>
   <pre-compile-jsps value="false"/>
   <enable-reloading value="true"/>
   <enable-serving-servlets-by-class-name value="false" />
</web-ext>
```

Important: To serve static files from an extended document root directory, you must enable file serving.

To configure an application with an extended document root from which JSP files are served, add an extendedDocumentRoot attribute as a JSP attribute to the `ibm-web-ext.xmi` or `ibm-web-ext.xml` file. The value of this attribute is a comma-delimited list of directories that serve as the root directory location for the JSP files.

The following entry is an example within the `ibm-web-ext.xmi` file:

```
<jspAttributes xmi:id="JSPAttribute_1" name="extendedDocumentRoot" value="/opt/extDocRootDir"/>
```

The following example shows the entry within the `ibm-web-ext.xml` file:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
   xmlns="http://websphere.ibm.com/xml/ns/javaee"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
      version="1.0">
   <file-serving-attribute name="extendedDocumentRoot" value="/opt/extDocRootDir" />
   <jsp-attribute name="evalQuotedAndEscapedExpression" value="true" />
   <jsp-attribute name="extendedDocumentRoot" value="/opt/extDocRootDir" />
   <jsp-attribute name="extendedDocumentRoot" value="${MY_CUSTOM_VARIABLE}" />
   <reload-interval value="3"/>
   <auto-encode-requests value="false"/>
   <auto-encode-responses value="false"/>
   <enable-directory-browsing value="false"/>
   <enable-file-serving value="true"/>
   <pre-compile-jsps value="false"/>
   <enable-reloading value="true"/>
   <enable-serving-servlets-by-class-name value="false" />
</web-ext>
```

You can also use an extendedDocumentRoot attribute to define a WebSphere variable on multiple nodes to the appropriate directory.

`ibm-web-ext.xmi` example:

```
<jspAttributes xmi:id="JSPAttribute_2" name="extendedDocumentRoot"
    value="${MY_CUSTOM_VARIABLE}"/>
```

`ibm-web-ext.xml` example:

```
 <jsp-attribute name="extendedDocumentRoot"
    value="${MY_CUSTOM_VARIABLE}" />
```

where *MY_CUSTOM_VARIABLE* is the WebSphere variable that you want to define on multiple nodes.

The following example shows a `ibm-web-ext.xmi` file that defines an extended document root both as a file-serving attribute and a JSP attribute:

```
<?xml version="1.0" encoding="UTF-8"?>
<com.ibm.ejs.models.base.extensions.webappext:WebAppExtension xmi:version="2.0"
xmlns:xmi="http://www.omg.org/XMI"
xmlns:com.ibm.ejs.models.base.extensions.webappext="webappext.xmi" xmi:id="WebAppExtension_1"
          reloadInterval="3"
          reloadingEnabled="true"
          fileServingEnabled="true">
      <webApp href="WEB-INF/web.xml#WebApp_ID"/>
      <fileServingAttributes xmi:id="FileServingAttribute_1" name="extendedDocumentRoot"
       value="/opt/extDocRootDir"/>
      <jspAttributes xmi:id="JSPAttribute_1" name="extendedDocumentRoot"
       value="/opt/extDocRootDir"/>
<com.ibm.ejs.models.base.extensions.webappext:WebAppExtension>
```

The following example shows a `ibm-web-ext.xml` file that defines an extended document root both as a file-serving attribute and a JSP attribute:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-ext
   xmlns="http://websphere.ibm.com/xml/ns/javaee"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-web-ext_1_0.xsd"
      version="1.0">
   <file-serving-attribute name="extendedDocumentRoot" value="/opt/extDocRootDir" />
   <jsp-attribute name="evalQuotedAndEscapedExpression" value="true" />
   <jsp-attribute name="extendedDocumentRoot" value="/opt/extDocRootDir" />
   <jsp-attribute name="extendedDocumentRoot" value="${MY_CUSTOM_VARIABLE}" />
```

```
   <reload-interval value="3"/>
   <auto-encode-requests value="false"/>
   <auto-encode-responses value="false"/>
   <enable-directory-browsing value="false"/>
   <enable-file-serving value="true"/>
   <pre-compile-jsps value="false"/>
   <enable-reloading value="true"/>
   <enable-serving-servlets-by-class-name value="false" />
</web-ext>
```

If the request is a valid partial request for a welcome file, a 404 error is returned. If the JSP file is located inside a JAR file and the reloadEnabled attribute value is true, the time stamp of the JAR file is used for isOutDated checks for recompile purposes. The default for this parameter is null.

Note: For IBM extension and binding files, the .xmi or .xml file name extension is different depending on whether you are using a pre-Java EE 5 application or module or a Java EE 5 or later application or module. An IBM extension or binding file is named ibm-*-ext.xmi or ibm-*-bnd.xmi where * is the type of extension or binding file such as app, application, ejb-jar, or web. The following conditions apply:

- For an application or module that uses a Java EE version prior to version 5, the file extension must be .xmi.
- For an application or module that uses Java EE 5 or later, the file extension must be .xml. If .xmi files are included with the application or module, the product ignores the .xmi files.

However, a Java EE 5 or later module can exist within an application that includes pre-Java EE 5 files and uses the .xmi file name extension.

The `ibm-webservices-ext.xmi`, `ibm-webservices-bnd.xmi`, `ibm-webservicesclient-bnd.xmi`, `ibm-webservicesclient-ext.xmi`, and `ibm-portlet-ext.xmi` files continue to use the .xmi file extensions.

ieClassId:

Indicates the Java plug-in COM class ID for Internet Explorer.

The `<jsp:plugin>` tags use this value. The default classid is `clsid:8AD9C840-044E-11D1-B3E9-00805F499D93`

javaEncoding:

Specifies the encoding that is used when the `.java` file is generated, and when it is compiled by the Java compiler. Set this parameter when the page encoding of your JSP pages is not UTF-8 compatible. When javaEncoding is set, the encoding is passed to the Java compiler through the -encoding argument. Note that encoding is not supported by Jikes. The default is UTF-8. This parameter requires regeneration of Java source.

jdkSourceLevel:

This JSP engine parameter was introduced in WebSphere Application Server version 6.1 to support JDK 5. Use this parameter instead of the compileWithAssert parameter, although compile WithAssert still works in version 6.1.

The default value for this parameter is 16. This parameter requires regeneration of Java source. The following are jdkSourceLevel paramater values:

- **13** - This value will disable all new language features of JDK 1.4, JDK 5.0 and JDK 6.0.

- **14** - This value will enable the use of the assertion facility and will disable all new language features of JDK 5.0 and JDK 6.0.
- **15** - This value will enable the use of the assertion facility and will disable all new language features of JDK 6.0.
- **16** - This value will enable the use of the new features of JDK 6.0.

jsp.file.extensions:

For JSP files with extensions other than the four standard extensions, *.jsp, *.jspx, *.jsw, and *.jsv, you can configure this the extensions using this parameter. These extensions are added to the standard extensions.

The preferred method for doing this is to create a `<jsp-property-group>` in web.xml, and add a `<url-pattern>` tag for each extension.

The JSP engine can handle a list of file extensions that is separated by a colon or semi-colon. For example, *.ext1;*.ext2:*.extn

keepgenerated:

Indicates that the Java files generated by the JSP compiler during the translation phase of the processing are retained. The default for this parameter is `false`. This parameter requires regeneration of Java source.

keepGeneratedclassfiles:

Indicates that the class files generated by the JSP compiler during the translation phase of the processing are retained. The default for this parameter is `true`. This parameter requires regeneration of Java source.

modifyPageContextVariable:

During the translation phase of a tag file that is compiled, the JSP container implicitly uses the pageContext variable for the PageContext object. The use of the pageContext variable as an implicit variable name in tag files does not comply with the JSP Specification. If compilation errors occur for applications that use a local pageContext variable in their tag file, set the modifyPageContextVariable attribute to`true` to remove the use of the pageContext variable name in the generated Java code for tag files.

recompileJspOnRestart:

Determines whether a JSP file is retranslated and recompiled after application startup for the first time the file is requested. If recompileJspOnRestart is false, a JSP file is still compiled, if necessary, on the first request to that JSP file unless the parameter disableJspRuntimeCompilation is true. The default for this parameter is false.

reloadEnabled:

Determines whether or not a JSP file is translated and compiled at runtime if the JSP file or its dependencies (see trackDependencies) are modified.

If reloadEnabled is false, a JSP file is still compiled, if necessary, on the first request to it unless the parameter disableJspRuntimeCompilation is true. The default for this parameter is `false`.

If this JSP engine parameter is not specified, the equivalent web container parameter for web module class reloading is used. However, for an application whose deployment descriptor is at the Servlet 2.2 level, the default is true. This is done for the support of applications being migrated from WebSphere Application Server Version 4.x.

reloadInterval:

If reloading is enabled, reloadInterval determines the delay between checks to see if a JSP file is outdated.

For example, if reloadInterval is 5, the JSP engine checks to see if a JSP file is outdated only when the last such check was done more than 5 seconds prior to the current request for the JSP file. The larger the reloadInterval, the less frequently the JSP engine checks for the need to reload a JSP file. If this JSP engine parameter is not specified, the equivalent web container parameter for web module class reloading is used. However, for an application whose deployment descriptor is at the Servlet 2.2 level, the default is 5 seconds. This is done for the support of applications being migrated from WebSphere Application Server Version 4.x.

reusePropertyGroupConfigOnInclude:

Note: Most properties that are defined in a JSP attribute group apply to an entire translation unit, for example, the requested JSP file that is matched by its URL pattern and all the files it includes using the include directive. The exceptions are the page-encoding and is-xml properties, which apply separately to each JSP file that is matched by its URL pattern. To revert the behavior to a setting prior to WebSphere Application Server Version 8.0, set the attribute to `true` to apply the two property values to the entire translation unit.

scratchdir:

Specifies the directory where the generated class files are created.

The system property com.ibm.websphere.servlet.temp.dir is used to set the scratchdir option on a server-wide basis. The JSP engine scratchdir parameter takes precedence over the system property com.ibm.websphere.servlet.temp.dir. The default for this parameter is *profile_root*/`temp`. This parameter requires regeneration of Java source.

gotcha: Do not specify a directory path that places the JSP temporary directory at the same level or underneath the configuration temporary directory. The default location for the configuration temporary directory is *profile_home*/config/temp.

For example, if you change the location of the JSP temporary directory to also be *profile_home*/config/temp. or if you place the JSP temporary directory underneath the configuration temporary directory at *profile_home*/config/temp/temp, processing errors occur.

trackDependencies:

If reloading is enabled, trackDependencies determines whether the JSP engine tracks modifications to the requested JavaServer Pages files dependencies as well as to the JSP file itself.

The dependencies tracked by the JSP engine are :

1. files statically included in the JSP file
2. tag files referenced in the JSP file (excluding tag files that are in JARs)
3. TLD files referenced in the JSP file (excluding TLDs that are in JARs)

The default is false.

useFullPackageNames:

If useFullPackageNames is true, the JSP engine generates and loads JSP classes using full package names.

The default is to generate all JSP classes in the same package. (For more information, refer to the Packages and directories for generated .java and .class files topic). The JSP engine's class loader knows how to load JSP classes when they are all in the same package.

The default method of generating all JSP classes in the same package has the benefit of generating smaller file-system paths. Full package names has the benefit of enabling the configuration of precompiled JSP class files as servlets in the `web.xml` file without the use of the jsp-file attribute, resulting in a single class loader, the web application's class loader, that is used to load all such JSP classes. Similarly, when the JSP engine's configuration attributes useFullPackageNames and disableJspRuntimeCompilation are both true, a single class loader is used to load all JSP classes, even if the JSP files are not configured as servlets in the `web.xml` file.

When useFullPackageNames is set to true, the batch compiler generates a `generated_web.xml` file in the web module's `WEB-INF` directory. This file contains servlet configuration information for each JSP file that was successfully translated and compiled. The information can optionally be copied into the web module `web.xml` file so that the JSP files are loaded as servlets by the web container. Note that if a JSP file is configured as a servlet in this way, no reloading of the JSP file is done at runtime if the JSP file is modified. This is because the JSP file is treated as a regular servlet and requests for it do not pass through the JSP engine. This parameter requires regeneration of Java source.

useImplicitTagLibs:

The JSP engine implicitly recognizes tsx and jsx as tag library prefixes for tag libraries supplied by the JSP engine. If tsx or jsx are used as prefixes for a customer's tag library, the customer's tag library overrides the implicit tag library. However, the implicit tag library is still cached by the JSP engine. Explicitly setting this parameter to false tells the engine not to cache the implicit tag library, and save resources. The default for this parameter is true.

The default URL for the tsx tags is http://websphere.ibm.com/tags/tsx. The default URI for the jsx tags is http://websphere.ibm.com/tags/jsx.

You might need to define the tsx or jsx tag library prefix with a different URI than its default URI. Also, you might need to define the same library prefix with a different URI. In these two situations, you can set the com.ibm.wsspi.jsp.allowtaglibprefixredefinition custom property to avoid translation errors. For more information, see the documentation about JavaServer Pages custom properties.

useInMemory:

Specifies that the JSP engine translate and compile Java code in the system memory.

When this option is not set, the JSP engine must perform the following steps:

1. Write the translated Java file to the file system
2. Load the Java file from the file system
3. Compile the code into a class file
4. Write the class to the file system
5. Load the class file into a classloader.

Note: No .class file or .java file will be written to the system disk. For debugging or creating a JAR file from precompiled JSP code, you will need to disable this option.

useJikes:

Specifies whether Jikes is used for compiling Java sources.

NOTE: Jikes is not shipped with WebSphere Application Server. The default for this parameter is false. This parameter requires regeneration of Java source.

usePageTagPool:

*Enables or disables the reuse of custom tag handlers on an individual JavaServer Pages basis. The default for this parameter is false. This parameter requires regeneration of Java source.

useThreadTagPool:

When thread-level tag handler pooling is used, tag handlers may be reused among separate occurrences of a custom action across all JSP pages in a single web module across separate requests. The default for this parameter is `false`. This parameter requires regeneration of Java source.

Enabling custom tag handler reuse might reveal problems in the tag handler code with regard to the tag's ability to be reused. A custom tag handler should always do two things:

- The release method of the tag handler should reset its state and release any private resources that it might have used. The JSP engine ensures the release method is called before the tag handler is garbage collected.
- In the doEndTag method, all instance states associated with this instance must be reset.

verbose:

Indicates that the compiler generates verbose output when compiling the generated Java source code. The effect of setting this parameter to true is that the -verbose option is passed to the Java compiler. The default for this parameter is false. This parameter requires regeneration of Java source.

*Enabling custom tag handler reuse might reveal problems in the tag handler code with regard to the tag's ability to be reused. A custom tag handler should always do two things:

- The release method of the tag handler should reset its state and release any private resources that it might have used. The JSP engine ensures the release method is called before the tag handler is garbage collected.
- In the doEndTag method, all instance states associated with this instance must be reset.

  CAUTION:
  When using page or thread tag pooling, the doEndTag method is not called in the case of an exception, and if there is service state that must be cleared, then the TryCatchFinally interface should be implemented.

JavaServer Pages troubleshooting tips

Use this tips to troubleshoot problems with JavaServer Pages.

JavaServer Pages source code shown by the web server

If you share the document root of the WebSphere Application Server with the web server document root, a security exposure can result as the web server might display the JavaServer Pages (JSP) source file as plain text.

Problem

You can use the WebSphere Web server plug-in set of rules to determine whether a given request will be handled by the WebSphere Application Server. When an incoming request fails to match those rules, the web server plug-in returns control to the web server so that the web server can fulfill the request. In this case, the unknown host header causes the web server plug-in to return control to the web server because the rules do not indicate that the WebSphere Application Server should handle it. Therefore, the web server looks for the request in the web server document root. Since the JSP source file is stored in the document root of the web server, the web server finds the file and displays it as plain text.

Suggested solution

Move the WebSphere Application Server JSP source file outside of the web server document root. Then, when this request comes in with the unknown host header, the plug-in returns control to the web server and the JSP source file is not found in the document root. Therefore, the web server returns a `404 File Not Found` error rather than the JSP source file.

Problems displaying double-byte character set (DBCS) characters when using the @include directive

JavaServer Pages files that use the @include directive might experience problems when displaying double-byte character set (DBCS) characters. Some applications that are migrated to WebSphere Application Server Version 6.0 and above might need to be modified to comply with the JSP 2.0 specification as a result of backwards compatibility issues. The JSP 2.0 specification requires that each statically included resource must set a page encoding or content type because the character encoding for each file is determined separately, even if one file includes another using the include directive.

Problems using the JavaServer Pages (JSP) engine

If you are having difficulty using the JavaServer Pages (JSP) engine, try these steps:

1. Determine whether other resources such as `.html` files or servlets are being requested and displayed correctly. If they are not, the problem probably lies at a deeper level, such as with the HTTP server.
2. If other resources are being displayed correctly, determine whether the JSP processor has started normally:
   - Browse the JVM logs of the server hosting the JSP files you are trying to access. The following messages indicate that the JSP processor has started normally:

     ```
     Extension Processor [class com.ibm.ws.jsp.webcontainerext.JSPExtensionProcessor]
     was initialized successfully.
     Extension Processor [class com.ibm.ws.jsp.webcontainerext.JSPExtensionProcessor]
     has been associated with patterns [*.jsp *.jspx *.jsw *.jsv ].
     ```

     If the JSP processor fails to load, you will see a message such as

     ```
     No Extension Processor found for handling JSPs.
     JSP Processor not defined. Skipping : jspfilename.
     ```

     in the *root_dir*/logs/*server_name*/SystemOut.log file
3. If the JSP engine has started normally, the problem may be with the JSP file itself.
   - The JSP may have invalid JSP syntax and could not be processed by the JSP Processor. Examine the *root_dir*/logs/*server_name*/SystemOut.log file of the target application for invalid JSP directive syntax messages. Errors similar to the following in a browser indicate this kind of problem:

     ```
     Message: /filename.jsp(2,1)JSPG0076E: Missing required attribute page for jsp
                 element jsp:include
     ```

     This example indicates that line 2, column 1 of the named JavaServer Pages file is missing a mandatory attribute for the jsp:include action. Similar messages are displayed for other syntax errors.
   - Examine the target application server's `SystemErr.log` files for problems with invalid Java syntax. Errors similar to `Message: Unable to compile class for JSP` in a browser indicate this kind of problem.

     The error message output from the Javac compiler will be found in the `SystemErr.log` file. It might look like:

```
JSPG0091E: An error occurred at line: 2 in the file: /myJsp.jsp
JSPG0093E: Generated servlet error: c:\WASROOT\temp\ ...
test.war\_myJsp.java:16: myInt is already defined in com.ibm.ws.jsp20._myJsp
int myInt = 122; String myString = "number is 122"; static int myStaticInt=22;
int myInt=121;
        ^  1 error
```

Correct the error in the JSP file and retry the file.

- Examine the log files for the target application for problems with invalid Java syntax. Errors similar to `Message: Unable to compile class for JSP` in a browser indicate this kind of problem.

  The error message output from the Javac compiler will be found in the SystemErr.log. It might look like:

```
JSPG0091E: An error occurred at line: 2 in the file: /myJsp.jsp
JSPG0093E: Generated servlet error: c:\WASROOT\temp\ ...
test.war\_myJsp.java:16: myInt is already defined in com.ibm.ws.jsp20._myJsp
int myInt = 122; String myString = "number is 122"; static int myStaticInt=22;
int myInt=121;
        ^  1 error
```

  Correct the error in the JSP file and retry the file.

Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

JavaServer Pages fail to compile when using precompile

Symptom

JavaServer Pages fail to compile during deployment through the administrative console when precompile is selected.

```
SystemErr R com.ibm.websphere.management.exception.AdminException:
ADMA0021E: Error in compiling jsps - xyz.war (rc=1)
```

Problem

JavaServer Pages fail to compile during deployment through the administrative console when precompile is selected when there is a dependency on another Java archive (JAR) file that is not available on any class path.

Suggested solution

You may use wsadmin scripting to precompile JSP files during enterprise application deployment. However if you want to use the administrative console, then compile all JSP files before packaging the application.

1. Add the dependent JAR to the application server.
   a. Click **Servers > Application servers > *server1* > Java and Process Management > Process Definition > Java Virtual Machine** in the console navigation.
   b. Add fully qualified dependent JAR in class path field.
   c. Click OK.
   d. Restart application server.

JSPG0089E: Mismatch found between page directive encoding Shift_JIS and xml prolog encoding UTF-8

Symptom

The following error appears:

```
JSP Processing Error

HTTP Error Code: 500

Error Message: /test.jsp(2,1) /test.jsp(2,1) JSPG0089E: Mismatch found between
page directive encoding Shift_JIS and xml prolog encoding UTF-8
```

Problem

The pageEncoding attribute in the jsp:directive.page element is not UTF-8.

Suggested solution

JavaServer Pages must specify a prolog that matches the encoding specified in the page directive. For example,

```
<?xml version="1.0" encoding="Shift_JIS"?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.0">
<jsp:directive.page language="java" contentType="text/html";
 charset=Shift_JIS" pageEncoding="Shift_JIS"/>
<jsp:text>XXXXXjsp:text>XXXXX>
</jsp:root>
```

For additional information, see section JSP.4.1, Page Character Encoding, in the JavaServer Pages specification and section 4.3.3 and appendix F.1 of the Extensible Markup Language (XML) specification

If none of these steps solves the problem, check to see if the problem is identified and documented using the links in the topic, Diagnosing and fixing problems: Resources for learning. If you do not see a problem that resembles yours, or if the information provided does not solve your problem, contact IBM support for further assistance.

For current information available from IBM Support on known problems and their resolution, see the IBM Support page. The IBM Support page contains documents that can save you time gathering information needed to resolve this problem.

Backing up and recovering servlets

Servlet source and class files, user profile data, Hypertext Transfer Protocol (HTTP) configuration, and administrative configuration should be considered for backup when using servlets. You should consider saving your HTTP configuration because changes to the HTTP configuration are often made to enable WebSphere Application Server to serve servlets and JSP requests, and to enable WebSphere Application Server security. You should consider backing up the user profile data if you use the User Profile function of WebSphere Application Server.

Procedure

- Backup servlet source and class files. Application code and configuration such as bindings, is located by default in the *profile_root*/`installedApps` directory. By saving this directory, you save your installed applications, including HTML, servlets, JavaServer Pages (JSP) files, and enterprise beans. Normally, each application is located in a separate subdirectory, so you can choose to save all applications or a subset.
  1. Save all installed applications. The commands below have been wrapped for display purposes. Enter each as a single command.

     ```
     SAV DEV('/QSYS.lib/wsalib.lib/wsasavf.file')
      OBJ(('/profile_root/installedApps'))
     ```

  2. Saves the sampleApp application only. The commands below have been wrapped for display purposes. Enter each as a single command.

     ```
     SAV DEV('/QSYS.lib/wsalib.lib/wsasavf.file')
      OBJ(('/profile_root/installedApps/cellName/sampleApp.ear'))
     ```

If you have located utility or general purpose classes in other directories, such as *profile_root*/lib/app or *profile_root*/lib/ext, be sure to include those locations in your backup plan as well.

- Save your HTTP configuration.

  Attention: The following information applies to IBM HTTP Server for iSeries (powered by Apache). If you are using Lotus Domino HTTP Server, see the Notes.net Documentation Library.

  1. Save the HTTP server instances for IBM HTTP Server for iSeries (powered by Apache). The HTTP server instances for IBM HTTP Server for iSeries (powered by Apache) are members of the QATMHINSTC file in the library QUSRSYS. An example save command for this file could be the following: SAVOBJ OBJ(QATMHINSTC) LIB(QUSRSYS) DEV(*SAVF) OBJTYPE(*FILE) SAVF(WSALIB/WSASAVF)
  2. Save the HTTP configurations for IBM HTTP Server for iSeries (powered by Apache). The HTTP configurations for IBM HTTP Server for iSeries (powered by Apache) are stored in the integrated file system in a subdirectory, chosen when the configuration was created. The recommended location is within the WebSphere instance directory. You can determine this file location by inspecting HTTP server instance member in the QATMHINSTC file in library QUSRSYS. An example save command for this file could be the following: SAV DEV('/QSYS.lib/wsalib.lib/wsasavf.file') OBJ(('*profile_root*/profile/apache/conf') ('*profile_root*/profile/htdocs')) where profile is the name of your instance. The default instance name is default.

Backing up and recovering JavaServer Pages files

JavaServer Pages source and generated servlet classes, Hypertext Transfer Protocol (HTTP) configuration, and administrative configuration should be considered for backup when using JavaServer Pages files.

Procedure

- Save installed applications. Application code and configuration such as bindings, is located by default in the *profile_root*/installedApps directory. By saving this directory, you save your installed applications, including HTML, servlets, JavaServer Pages (JSP) files, and enterprise beans. Normally, each application is located in a separate subdirectory, so you can choose to save all applications or a subset.

  1. Save all installed applications. The command below has been wrapped for display purposes. Enter the following as a single command, with a space between the end of DEV parameter and OBJ.

     ```
     SAV DEV('/QSYS.lib/wsalib.lib/wsasavf.file')
        OBJ(('/profile_root/installedApps'))
     ```

  2. Save the sampleApp application only. The command below has been wrapped for display purposes. Enter the following as a single command with a space between the end of DEV parameter and OBJ.

     ```
     SAV DEV('/QSYS.lib/wsalib.lib/wsasavf.file')
        OBJ(('/profile_root/installedApps/cellName/sampleApp.ear'))
     ```

- Save and restore your JSP files. When JSP files are run, a servlet class is generated, compiled, and then run. When saving and restoring your JSP files, you can elect to save only the JSP source or the generated files as well.
  - If you save and restore only the JSP source, the servlet source and class files are regenerated when they are invoked. This is a simpler, smaller save and restore operation. Note that regeneration slows the first requests, and default optimization is done on the generated Java programs.
  - If you save and restore the source and generated files, no regeneration is done. If you have optimized Java programs to levels other than the default, this optimization is preserved.

Example

WebSphere Application Server places the generated files (*.class, .java*, and optionally, *.dat*) in a temporary directory under the WebSphere Application Server instance. For example, the default instance stores the generated files in this directory:

/profile_root/temp/*node_name/application_server/enterprise_app/web_module*

In this example:

- *profile* is the name of your instance. The default instance name is default.
- *node_name* is the name of the iSeries server or partition on which your WebSphere Application Server instance is running
- *application_server* is the name of your WebSphere Application Server
- *enterprise_app* is the name of the enterprise application to which the JSP file belongs
- *web_module* is the web module that contains your JSP file.

Attention: A `.dat` file is a helper file used by the generated servlet.

Administering RRD applications

Remote request dispatcher

Remote Request Dispatcher (RRD) is a pluggable extension to the web container for application frameworks, servlets, and JavaServer Pages to include content from outside of the current Java virtual machine (JVM) for the resource, as part of the response sent to the client.

Remote request dispatcher is an extensible infrastructure for other components and stack products to add custom extensions like generators and handlers, to the RRD extension. The remote request dispatcher extension enhances the standard Java Platform, Enterprise Edition (Java EE) `javax.servlet.RequestDispatcher` implementation to be aware of locating remote resources using web services to communicate between machines within a WebSphere Application Server, Network Deployment (ND) core group. The remote request dispatcher extension reports any errors that occur on the remote server back to the originating server. It can also use SSL for secure communications and WS-Security security context propagation between servers. See the rrdSecurity.props file topic for more information.

RRD portlet support carries forward the remote request dispatcher concept to portlets and enhances the portlet container for invocation of portlets outside of the current JVM resource.

By using the RRD extension, you can share request load across multiple machines and JVMs by including remote servers within the cell. If RRD resource is memory or processor intensive, the calling resource is not affected as much as a standard RequestDispatcher running within the same JVM. RRD solves this problem by separating resources into a different JVM.

Capabilities

- Requests on remote server are treated as include requests. Filters and request listeners are started as if the dispatch type is INCLUDE.
- Serializable request attributes and query parameters are sent to remote server.
- Security context is sent to a remote server through LTPA tokens.
- Servlet parameters and OutputStream

  Request parameters are passed to remote server.
- Response headers that are set by the remotely included resource are ignored similar to includes on a local server. Internal headers such as Set-Cookie can still be set and are propagated back.
- All original request headers are passed to remote server
  - Similar to the plug-in for WebSphere Application Server.
  - Method calls return the state as if they are on local server. For example, getServer returns the local server name or isSecure returns whether the request to the ‘local' server has been secure.
- Cookies and sessions
  - Cookies are passed to the remote server as part of headers.

  - Sessions in local and remote servers use the same cookie or session ID for a given client which is similar to includes in the same server. If a session exists on a remote server, the session cookie contains the information for both the servers to maintain the affinity to the remote server.
- Exceptions
  - If there is an exception on the remote server, the server returns an RRD-specific web services fault which wraps the original exception created by the application.
  - Attempt to recreate the original exception on the local server if the exception class exists on both servers. If the original exception cannot be recreated, an RRD-specific ServletException is constructed and used instead.
  - The exception is recreated by the local server for error handling purposes.
- Dynamic cache

  When dynamic cache is enabled, caching is performed on the local and remote machine.
- Security

  You can use SSL to encrypt RRD messages between application servers. SSL is enabled by default, however, you must also pass security context needs through RRD to ensure that the security state is available in the remote machine. RRD uses WS-Security to pass this information, but this security context propagation is disabled by default. See the rrdSecurity.props file topic for additional information.

Asynchronous request dispatching settings

Asynchronous request dispatching settings

Use this page to enable the asynchronous request dispatcher (ARD), which enables servlets and JSP pages to make standard include calls concurrently on separate threads.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **Web Container Settings** > **Web container** > **Asynchronous request dispatching**.

Additionally, the initiation and the insertion of the include contents can be separated so that the include has more time to execute before it needs to be written to the response. ARD requires aggregation of the include contents with the original response. The application server can aggregate the contents in memory or the client browser can aggregate the contents through AJAX. Aggregation type is configurable at the application level.

Allow Asynchronous Request Dispatching:

Enables applications installed on this server to use asynchronous request dispatching.

Asynchronous include timeout:

Specifies the default timeout in milliseconds to complete asynchronous includes.

Data type	Integer
Units	Milliseconds
Default	60000
Range	

Maximum expired requests per minute:

Specifies the maximum percentage of expired response versus total response in one minute before switching to synchronous requests.

Data type	Integer

Units	Percentage
Default	15
Range	

Maximum memory size of results store:

Specifies the maximum size of store for client side requests.

Data type	Integer
Units	Megabytes
Default	100
Range	

Asynchronous request dispatching settings

Asynchronous request dispatching settings

Use this page to enable the asynchronous request dispatcher (ARD), which enables servlets and JSP pages to make standard include calls concurrently on separate threads.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **Web Container Settings** > **Web container** > **Asynchronous request dispatching**.

Additionally, the initiation and the insertion of the include contents can be separated so that the include has more time to execute before it needs to be written to the response. ARD requires aggregation of the include contents with the original response. The application server can aggregate the contents in memory or the client browser can aggregate the contents through AJAX. Aggregation type is configurable at the application level.

Allow Asynchronous Request Dispatching

Enables applications installed on this server to use asynchronous request dispatching.

Asynchronous include timeout

Specifies the default timeout in milliseconds to complete asynchronous includes.

Units	Milliseconds
Default	60000
Range	

Maximum expired requests per minute

Specifies the maximum percentage of expired response versus total response in one minute before switching to synchronous requests.

Data type	Integer
Units	Percentage
Default	15
Range	

Maximum memory size of results store

Specifies the maximum size of store for client side requests.

Data type	Integer
Units	Megabytes
Default	100
Range	

Administering RRD applications

Remote request dispatcher

Remote Request Dispatcher (RRD) is a pluggable extension to the web container for application frameworks, servlets, and JavaServer Pages to include content from outside of the current Java virtual machine (JVM) for the resource, as part of the response sent to the client.

Remote request dispatcher is an extensible infrastructure for other components and stack products to add custom extensions like generators and handlers, to the RRD extension. The remote request dispatcher extension enhances the standard Java Platform, Enterprise Edition (Java EE) `javax.servlet.RequestDispatcher` implementation to be aware of locating remote resources using web services to communicate between machines within a WebSphere Application Server, Network Deployment (ND) core group. The remote request dispatcher extension reports any errors that occur on the remote server back to the originating server. It can also use SSL for secure communications and WS-Security security context propagation between servers. See the rrdSecurity.props file topic for more information.

RRD portlet support carries forward the remote request dispatcher concept to portlets and enhances the portlet container for invocation of portlets outside of the current JVM resource.

By using the RRD extension, you can share request load across multiple machines and JVMs by including remote servers within the cell. If RRD resource is memory or processor intensive, the calling resource is not affected as much as a standard RequestDispatcher running within the same JVM. RRD solves this problem by separating resources into a different JVM.

Capabilities

- Requests on remote server are treated as include requests. Filters and request listeners are started as if the dispatch type is INCLUDE.
- Serializable request attributes and query parameters are sent to remote server.
- Security context is sent to a remote server through LTPA tokens.
- Servlet parameters and OutputStream

  Request parameters are passed to remote server.
- Response headers that are set by the remotely included resource are ignored similar to includes on a local server. Internal headers such as Set-Cookie can still be set and are propagated back.
- All original request headers are passed to remote server
  - Similar to the plug-in for WebSphere Application Server.
  - Method calls return the state as if they are on local server. For example, getServer returns the local server name or isSecure returns whether the request to the ‘local' server has been secure.
- Cookies and sessions
  - Cookies are passed to the remote server as part of headers.
  - Sessions in local and remote servers use the same cookie or session ID for a given client which is similar to includes in the same server. If a session exists on a remote server, the session cookie contains the information for both the servers to maintain the affinity to the remote server.
- Exceptions

- If there is an exception on the remote server, the server returns an RRD-specific web services fault which wraps the original exception created by the application.
- Attempt to recreate the original exception on the local server if the exception class exists on both servers. If the original exception cannot be recreated, an RRD-specific ServletException is constructed and used instead.
- The exception is recreated by the local server for error handling purposes.

- Dynamic cache

  When dynamic cache is enabled, caching is performed on the local and remote machine.
- Security

  You can use SSL to encrypt RRD messages between application servers. SSL is enabled by default, however, you must also pass security context needs through RRD to ensure that the security state is available in the remote machine. RRD uses WS-Security to pass this information, but this security context propagation is disabled by default. See the rrdSecurity.props file topic for additional information.

Configuring HTTP sessions

Configuring session management by level

When you configure session management at the web container level, all applications and the respective web modules in the web container normally inherit that configuration, setting up a basic default configuration for the applications and web modules below it. However, you can set up different configurations individually for specific applications and web modules that vary from the web container default. These different configurations override the default for these applications and web modules only.

About this task

An enterprise application can contain web modules, and so can an OSGi application. At the web container level and at the application level, the process for configuring HTTP sessions is the same whether the web module is part of an enterprise application or an OSGi application. For enterprise applications only, you can also configure HTTP sessions at the web module level.

Note: When you overwrite the default session management settings at the application level, all the web modules below the application inherit the new setting unless they too are set to overwrite these settings.

Note: Session management configuration is a post-deployment configuration and is tied to existing targets. If you change the target mapping after you configure session management, you must return to the session management configuration page in the administrative console or use wsadmin scripting and apply the changes. Apply the changes to module targets if session management is configured for a web module. Apply the changes to all targets if session management is configured for an application level.

Procedure

1. Open the administrative console.
2. Change the configuration for the web container, enterprise application, or web module level. The following substeps explain how to access the configuration panels for each of these levels.
   - Complete the following substeps for the web container level:
     a. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
     b. Under **Container Settings**, expand **Web Container Settings** and click **Web container**.
     c. Under **Additional Properties**, click **Session management**.
   - Complete the following substeps for the application level:

     If the application is an enterprise application:
     a. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.

b. Under **Web Module Properties**, click **Session management**.

If the application is an OSGi application:

a. Click **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***eba_asset_name***.

b. Under **Additional Properties**, click **Session management**.

- Complete the following substeps for the web module level, if the application is an enterprise application:
  a. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
  b. Under **Modules**, click **Manage Modules** > ***module_name***.
  c. Under Additional Properties, click **Session Management**.

3. Manage sessions by configuring session tracking, session timeouts and serializing access.
4. If you are working at the web module or application level and want these settings to override the inherited Session Management settings, under **General Properties** select **Override session management**.
5. Click **Apply** and **Save**.

Session management settings

Use this page to manage HTTP session support. This support includes specifying a session tracking mechanism, setting maximum in-memory session count, controlling overflow, and configuring session timeout.

To view this administrative console page at the web container level, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **Session management**.

Important:
You can override the session management settings at the application level.

Session tracking mechanism:

Table 239. HTTP session tracking mechanism. This table describes mechanisms for HTTP session management.

Mechanism	Function	Default
Enable SSL ID tracking	Specifies that session tracking uses Secure Sockets Layer (SSL) information as a session ID. Enabling SSL tracking takes precedence over cookie-based session tracking and URL rewriting. There are two parameters available if you enable SSL ID tracking: SSLV3Timeout and Secure Authentication Service (SAS). SSLV3Timeout specifies the time interval after which SSL sessions are renegotiated. This parameter is a high setting and modification does not provide any significant impact on performance. The SAS parameter establishes an SSL connection only if it goes out of the Java Virtual Machine (JVM) to another JVM. If all the beans are co-located within the same JVM, the SSL used by SAS does not hinder performance. These parameters are set by editing the `sas.server.properties` and `sas.client.props` files, located in the *product_installation_root*`/properties` directory, where *product_installation_root* is the directory where WebSphere Application Server is installed. **Important:** SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.	false (cleared)
Enable cookies	Specifies that session tracking uses cookies to carry session IDs. If cookies are enabled, session tracking recognizes session IDs that arrive as cookies and tries to use cookies for sending session IDs. If cookies are not enabled, session tracking uses Uniform Resource Identifier (URL) rewriting instead of cookies (if URL rewriting is enabled). Enabling cookies takes precedence over URL rewriting. Click **Enable cookies** to change these settings. Application level session management settings override the server level session management settings. Because session management is defined at the application level, enabling cookies for the administration console is handled in the `deployment.xml` file.	true (selected)

Table 239. HTTP session tracking mechanism (continued). This table describes mechanisms for HTTP session management.

Mechanism	Function	Default
Enable URL rewriting	Specifies that the session management facility uses rewritten URLs to carry the session IDs. If URL rewriting is enabled, the session management facility recognizes session IDs that arrive in the URL if the encodeURL method is called in the servlet.	false (cleared)
Enable protocol switch rewriting	This option is only available when **Enable URL rewriting** is selected. This option specifies that the session ID is added to a URL when the URL requires a switch from HTTP to HTTPS or from HTTPS to HTTP. If rewriting is enabled, the session ID is required to go between HTTP and HTTPS.	false (cleared)

Maximum in-memory session count:

Specifies the maximum number of sessions to maintain in memory for each web module.

The meaning differs depending on whether you are using in-memory or distributed sessions. For in-memory sessions, this value specifies the number of sessions in the base session table for a web module. Use the **Allow overflow** property to specify whether to limit sessions to this number for the entire session management facility or to allow additional sessions to be stored in secondary tables. For distributed sessions, this value specifies the size of the memory cache for sessions of each web module. When the session cache has reached its maximum size and a new session is requested, the session management facility removes the least recently used session from the cache to make room for the new one.

Note: Do not set this value to a number less than the maximum thread pool size for your server.

Allow overflow:

Specifies that the number of sessions in memory can exceed the value specified by the Max in-memory session count property. This option is valid only in non-distributed sessions mode.

Session timeout:

Specifies how long a session can go unused before it is no longer valid. Specify either `Set timeout` or `No timeout`. Specify the value in minutes greater than or equal to two.

The value specified in a web module deployment descriptor file takes precedence over the administrative console settings. However, the value of this setting is used as a default when the session timeout is not specified in a web module deployment descriptor. To preserve performance, the invalidation timer is not accurate to the second. When the write frequency is time-based, ensure that this value is least twice as large as the write interval.

Security integration:

Specifies that when security integration is enabled, the session management facility associates the identity of users with their HTTP sessions. Session security (security integration) is enabled by default.

Serialize session access:

Specifies that concurrent session access in a given server is not permitted.

Table 240. Serialize session access. This table describes mechanisms for serialize session access.

Mechanism	Function
Maximum wait time	Specifies the maximum amount of time a servlet request waits on an HTTP session before starting. This parameter is optional and expressed in seconds. The default is five seconds. Under normal conditions, a servlet request waits for access to an HTTP session and is notified by the request that currently owns the given HTTP session when the request finishes.

Table 240. Serialize session access (continued). This table describes mechanisms for serialize session access.

Mechanism	Function
Allow access on timeout	Specifies whether the servlet starts normally or stops processing from a timeout. The servlet starts normally when this box is checked. If this box is not checked, the servlet stops processing and error logs are generated.

Session recovery support

For session recovery support, WebSphere Application Server provides distributed session support in the form of database sessions. You can use session recovery support when the user's session data must be maintained across a server restart or when the user's session data is too valuable to lose through an unexpected server failure.

All the attributes set in a session must implement java.io.Serializable if the session requires external storage. In general, consider making all objects held by a session serialized, even if immediate plans do not call for session recovery support. If the website grows, and session recovery support becomes necessary, the transition occurs transparently to the application if the sessions only hold serialized objects. If not, a switch to session recovery support requires coding changes to make the session contents serialized.

Configuring session tracking

About this task

Review the Session tracking options to plan your approach to session management. To configure session tracking, complete the following:

Procedure

1. Go to the appropriate level of Session Management.
2. Specify the session tracking mechanism that you want to pass the session ID between the browser and the servlet:
   - To track sessions with cookies, click **Enable Cookies**.

     To change the cookie settings, click **Modify**.
   - To track sessions with URL rewriting, click **Enable URL Rewriting**.

     If you want to enable protocol switch rewriting, click **Enable protocol switch rewriting.**
   - To track sessions with SSL information, click **Enable SSL ID tracking**.

     Note: Session tracking using the SSL ID is deprecated in WebSphere Application Server version 7.0. You can reconfigure session tracking to use cookies or modify the application to use URL rewriting.
3. Click **Apply**.
4. Click **Save**.

Session tracking options

HTTP session support also involves session tracking. You can use cookies, URL rewriting, or Secure Sockets Layer (SSL) information for session tracking.

the following tracking methods are available:
- Session tracking with cookies
- Session tracking with URL rewriting
- Session tracking with Secure Sockets Layer (SSL) information

Session tracking with cookies: Tracking sessions with cookies is the default. No special programming is required to track sessions with cookies.

Session tracking with URL rewriting: An application that uses URL rewriting to track sessions must adhere to certain programming guidelines. The application developer needs to do the following:
- Program servlets to encode URLs
- Supply a servlet or JavaServer Pages (JSP) file as an entry point to the application

Using URL rewriting also requires that you enable URL rewriting in the session management facility.

Note: In certain cases, clients cannot accept cookies. Therefore, you cannot use cookies as a session tracking mechanism. Applications can use URL rewriting as a substitute.

Program session servlets to encode URLs

Depending on whether the servlet is returning URLs to the browser or redirecting them, include either the encodeURL method or the encodeRedirectURL method in the servlet code. Examples demonstrating what to replace in your current servlet code follow.

Rewrite URLs to return to the browser

Suppose you currently have this statement:

```
out.println("<a href=\"/store/catalog\">catalog<a>");
```

Change the servlet to call the encodeURL method before sending the URL to the output stream:

```
out.println("<a href=\"");
out.println(response.encodeURL ("/store/catalog"));
out.println("\">catalog</a>");
```

Rewrite URLs to redirect

Suppose you currently have the following statement:

```
response.sendRedirect ("http://myhost/store/catalog");
```

Change the servlet to call the encodeRedirectURL method before sending the URL to the output stream:

```
response.sendRedirect (response.encodeRedirectURL ("http://myhost/store/catalog"));
```

The encodeURL method and encodeRedirectURL method are part of the HttpServletResponse object. These calls check to see if URL rewriting is configured before encoding the URL. If it is not configured, the calls return the original URL.

You can also configure session support to enable protocol switch rewriting. When this option is enabled, the product encodes the URL with the session ID for switching between HTTP and HTTPS protocols.

gotcha: If you want to encode a URL, you must enable the AlwaysEncodeURL custom property and set the value to true.

Session management properties, like the session management configuration, can be configured at the server, application, or web module level. The following steps are for setting the custom properties for session management at the server level.

1. In the administrative console click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **Session management**.
2. Under **Additional Properties** select **Custom Properties**.
3. On the Custom Properties page, click **New**.
4. On the settings page, enter the property that you want to configure in the **Name** field and the value that you want to set it to in the **Value** field.
5. Click **Apply** or **OK**.

6. Click **Save** on the console task bar to save your configuration changes.
7. Restart the server.

Supply a servlet or JSP file as an entry point

The entry point to an application, such as the initial screen presented, may not require the use of sessions. However, if the application in general requires session support (meaning some part of it, such as a servlet, requires session support), then after a session is created, all URLs are encoded to perpetuate the session ID for the servlet (or other application component) requiring the session support.

The following example shows how you can embed Java code within a JSP file:

```
<%
response.encodeURL ("/store/catalog");
%>
```

Session tracking with SSL information (Deprecated):

Note: Session tracking using the SSL ID is deprecated in WebSphere Application Server version 7.0. You can configure session tracking to use cookies or URL rewriting.

No special programming is required to track sessions with Secure Sockets Layer (SSL) information.

To use SSL information, turn on **Enable SSL ID tracking** in the session management property page. Because the SSL session ID is negotiated between the web browser and HTTP server, this ID cannot survive an HTTP server failure. However, the failure of an application server does not affect the SSL session ID if an external HTTP server is present between WebSphere Application Server and the browser.

SSL tracking is supported for the IBM HTTP Server and iPlanet Web Servers only. You can control the lifetime of an SSL session ID by configuring options in the web server. For example, in the IBM HTTP Server, set the configuration variable SSLV3TIMEOUT to provide an adequate lifetime for the SSL session ID. An interval that is too short can cause a premature termination of a session. Also, some web browsers might have their own timers that affect the lifetime of the SSL session ID. These web browsers may not leave the SSL session ID active long enough to serve as a useful mechanism for session tracking. The internal HTTP Server of WebSphere Application Server also supports SSL tracking.

When using the SSL session ID as the session tracking mechanism in a cloned environment, use either cookies or URL rewriting to maintain session affinity. The cookie or rewritten URL contains session affinity information that enables the web server to properly route a session back to the same server for each request.

Serializing access to session data

The Servlet API supports concurrent access to a session in a given server instance. WebSphere Application Server provides an option to prevent the concurrent access to a session in a given server instance so that concurrent modification of a session does not occur in a given server instance.

About this task

Preventing concurrent access to a session is achieved by synchronizing the requests based on session. When this feature is turned on, a session is obtained for the request before invoking the servlet and requests are synchronized by locking the session for the servlet initiation time. Note that synchronization is based on the memory copy of session. So this feature cannot serialize requests across servers based on session when session affinity fails.

You can also use the serializing access to session data feature to synchronize session objects inside of servlets or JavaServer pages. Applications cannot synchronize session objects inside of their servlets or JavaServer Pages because a deadlock with the session manager may occur. The deadlock occurs

because the session manager does not expect the use of more than one locking mechanism. You can ensure that only one request can access the session at a time through the use of the configuration option, Allow serial access.

Use this feature only when concurrent modification of the same session data is possible and is not desirable by the application. This feature has overhead of serializing the requests based on a session.

Do the following to synchronize session access:

Procedure

1. Select the level of Session Management on which you want to serialize session access.
2. Under Serialize Session access, click **Allow serial access**.
3. In the Maximum wait time box, type the amount of time, in milliseconds, a servlet waits on a session before continuing execution. The default is 120000 milliseconds or two minutes.
4. Select **Allow access on timeout** if you want the servlet to gain access to the session and continue normal execution even if the session is still locked by another servlet. If you do not select this box, the servlet execution will abort when the session request times out.
5. Click **Apply**.
6. Click **Save**.

Cookie settings

Use this page to configure cookie settings for session management.

To view this administrative console page, click **Servers** > **Server types** > **WebSphere application servers** > ***server_name*** > **Session management** > **Enable cookies**.

Cookie name:

Specifies a unique name for the session management cookie. The servlet specification requires the name JSESSIONID. However, for flexibility, you can configure this value.

Restrict cookies to HTTPS sessions:

Specifies that the session cookies include the secure field. Enabling this feature restricts the exchange of cookies to HTTPS sessions only.

Set cookies as HTTP only to help prevent cross-site scripting attacks:

Specifies that session cookies include the HTTP only field. When checked, browsers that support the HTTP only attribute do not enable cookies to be accessed by client-side scripts. For security cookies, see the global security settings for web single sign-on (SSO).

Cookie domain:

Specifies the domain field of a session tracking cookie. This value controls whether a browser sends a cookie to particular servers. For example, if you specify a particular domain, session cookies are sent to hosts in that domain. The default domain is the server.

Cookie maximum age:

Specifies the amount of time that the cookie lives on the client browser. Specify that the cookie lives only as long as the current browser session, or to a maximum age. If you choose the maximum age option, specify the age in seconds. This value corresponds to the Time to Live (TTL) value described in the Cookie specification.

Default is the current browser session which is equivalent to setting the value to -1.

Cookie path:

Specifies that a cookie is sent to the URL designated in the path. Specify any string representing a path on the server. A slash (/) indicates root directory. Specify a value to restrict the paths to which the cookie is sent. By restricting paths, you prevent the cookie from going to certain URLs on the server. If you specify the root directory, the cookie is sent no matter which path on the given server is accessed.

Set the cookie path to match the context root for each application. This setting restricts the cookie from being sent to other applications and results in having different cookies created when accessing multiple applications.

Session management custom properties

You can specify additional settings for session management through setting custom properties.

Session management properties, like the session management configuration, can be configured at the server, application, or web module level. The following steps are for setting the custom properties for session management at the server level.

1. In the administrative console click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **Session management**.
2. Under **Additional Properties** select **Custom Properties**.
3. On the Custom Properties page, click **New**.
4. On the settings page, enter the property that you want to configure in the **Name** field and the value that you want to set it to in the **Value** field.
5. Click **Apply** or **OK**.
6. Click **Save** on the console task bar to save your configuration changes.
7. Restart the server.

You can use the custom properties page to define the following session management properties:

- “AlwaysEncodeURL” on page 2584
- “CloneSeparator” on page 2584
- “CloneSeparatorChange” on page 2584
- “DebugSessionCrossover” on page 2584
- “ForceSessionInvalidationMultiple” on page 2584
- “HideSessionValues” on page 2585
- “HttpSessionCloneId” on page 2585
- “HttpSessionIdLength” on page 2585
- “HttpSessionIdReuse” on page 2585
- “HttpSessionReaperPollInterval” on page 2585
- “NoAdditionalSessionInfo” on page 2586
- “OptimizeCacheIdIncrements” on page 2586
- “SecurityUserIgnoreCase” on page 2586

AlwaysEncodeURL:

The Servlet 2.5 specification specifies to not encode the URL on a response.encodeURL call if it is not necessary. To support backward compatibility when URL encoding is enabled, set the *AlwaysEncodeURL* custom property to `true` to call the encodeURL method. The URL is always encoded, even if the browser supports cookies.

CloneSeparator:

Use this property to specify a different character as the clone separator in session cookies. The value specified for this custom property must be a single character.

This property was set as a web container custom property in version 6.1 but must now be set as a session management custom property.

bprac: This property should only be used as a means to provide more flexibility if you have a situation where you cannot use either a colon (:), or a plus sign (+) as the clone separator in session cookies. You should understand the clone character requirements of other products running on your system before using this property to change the clone separator character.

The fact that any character can be specified as the value for this custom property does not imply that the character you specify will function correctly. This fact also does not imply that IBM is responsible for fixing any problem that might arise from using an alternative character.

CloneSeparatorChange:

Use this property to maintain session affinity. The clone ID of the server is appended to session identifier separated by colon. On some Wireless Application Protocol (WAP) devices, a colon is not allowed. Set this property to `true` to change clone separator to a plus sign (+).

DebugSessionCrossover:

The *DebugSessionCrossover* custom property enables code to perform additional checks to verify that only the session associated with the request is accessed or referenced. Messages are logged if any discrepancies are detected.

Set this property to `true` to enable session data crossover detection.

See article, HTTP session problems, for additional information.

ForceSessionInvalidationMultiple:

The *ForceSessionInvalidationMultiple* custom property indicates whether the session manager should wait indefinitely for a request to complete before attempting to invalidate the session, or should attempt to invalidate a session after the specified time limit has elapsed. The default value for this property is 1.

- If you specify 0 (zero) for this custom property, the session manager waits indefinitely until a request is complete before attempting to invalidate the session.

  If your requests normally are not bound by a response time limit, specify 0 for this property.
- If you specify a positive integer, such as 1, 2, or 3, for this custom property, even if a session is not known to have completed, the session manager attempts to invalidate the session, if the indicated time period since the last access occurred has elapsed. This time period is the result of multiplying the value specified for this property and the value specified for the Session Timeout property. For example, if you

specify 2 minutes for the Session Timeout property and 2 for the ForceSessionInvalidationMultiple property, the session manager attempts to invalidate the session after 4 minutes.

If you want to invalidate your sessions after a certain amount of time has elapsed, specify the appropriate positive integer for this property.

HideSessionValues:

The *HideSessionValues* custom property prevents the logging of session attribute values in session manager traces.

Applications store these session attribute values. However, you might not want to see these values in application server traces. Set this property to `true` if you do not want to see these values in application server traces.

HttpSessionCloneId:

Use this property to change the clone ID of the cluster member. Within a cluster, this ID must be unique to maintain session affinity. When set, this name overwrites the default name generated by WebSphere Application Server.

Default clone ID length: 40

HttpSessionIdLength:

Use this property to configure the session identifier length. Do not use an extremely low value; using a low value results in reduced number of combinations possible, thereby increasing risk of guessing the session identifier. In a cluster, all cluster members should be configured with same ID length. Allowed range: 8 to 128. Default length: 23.

HttpSessionIdReuse:

The custom property *HttpSessionIdReuse* determines whether the session manager can use the session ID sent from a browser to preserve session data across web applications that are running in an environment that is not configured for session persistence.

In a multi-JVM environment that is not configured for session persistence setting this property to `true` enables the session manager to use the same session information for all of a user's requests even if the web applications that are handling these requests are governed by different JVMs. The default value for this property is `false`. Set this property to `true` if you want to enable the session manager to use the session ID sent from a browser to preserve session data across web applications that are running in an environment that is not configured for session persistence.

HttpSessionReaperPollInterval:

Use this property to specify, in seconds, a wake-up interval for the process that removes invalid sessions. The value specified for this property overrides the default installation value, which is between 30 and 360 seconds, and ensures that the reaper process runs at a specific interval.

If the maximum inactive interval is less than 2 minutes, the reaper poll interval may be as short as 30 seconds.

If the maximum inactive interval is more than 15 minutes, the reaper poll interval can be as long as 6 minutes.

Because the default timeout and maximum inactive interval is 30 minutes, the reaper interval is usually between 5 and 6 minutes.

For example, you might want to use this property if you want the installation timed out sessions invalidated more frequently than 5 to 6 minutes. Specifying HttpSessionReaperPollInterval=120 ensures that sessions are invalidated within 2 minutes of timing out.

The minimum value for this property is 30 seconds. If a value less than the minimum is entered, the specified property is ignored and an appropriate value is automatically determined and used. The maximum inactive interval is the session timeout. The default is based on maximum inactive interval set in session management.

NoAdditionalSessionInfo:

Set this value to "true" to force removal of information that is not needed in session identifiers.

OptimizeCacheIdIncrements:

Set the *OptimizeCacheIdIncrements* custom property to true to make the session manager assess whether the in-memory session for a web module is older than the copy in persistent store. Setting this property resolves the continually increasing cache ID.

If HTTP session management is configured to use session persistence and the user's browser session is moving back and forth across multiple web applications you might see extra persistent store activity as the in-memory sessions for a web module are refreshed from the persistent store. As a result, the cache IDs are continually increasing and the in-memory session attributes are overwritten by those of the persistent copy. Set this property to `true` if you want to prevent the cache IDs from continually increasing.

If the configuration is a cluster, ensure that the system times of each cluster member is identical as possible.

SecurityUserIgnoreCase:

Set this property to `true` if you want the session security identity and the client security identity to be considered a match even if their cases are different.

When a user configures session security integration, the session manager compares the security identity of th session owner with the security identity of the client request. Because the matching criteria is case sensitive, if these two identities do not exactly match, an UnauthorizedSessionRequestException is sent back to the client.

If you have situations where you want the session security identity and the client security identity to be considered a match even if their cases are different, add the SecurityUserIgnoreCase custom property to your Web container configuration settings, and set the property to `true`. When this property is set to true, an UnauthorizedSessionRequestException does not occur if the session security identity and the client security identity are identical except for their cases. For example, when this property is set to true, the session security identity USER1 matches the client security identities User1 and user1.

Servlet21SessionCompatibility:

Set this custom property to true to enable global session behavior. In Servlet 2.2 and later, sessions are scoped at the Web module level. The default is **false**.

Note: This property is deprecated. The IBMApplicationSession method replaces the function of the Servlet21SessionCompatibility custom property.

SessionIdentifierMaxLength:

Use this value to set maximum length that a session identifier can grow.

This property helps to find out the condition and take appropriate action to address servers fail-over. When this is specified, message is logged when specified maximum length is reached. Allowed value: integer.

SessionRewriteIdentifier:

Use this property to change the key used with URL rewriting. Default key: jsessionid.

SessionTableName:

Use this custom property to set the database table name. Allowed value: String. The default value is SESSIONS.

Some applications may rely on method ejbCreate(...) to have created the entity bean in the database. For such a requirement, setting the JVM property *com.ibm.websphere.ejbcontainer.allowEarlyInsert* to **true** overrides the default behavior.

UseInvalidatedId:

Set this custom property to true to reuse the incoming ID if the session with that ID was recently invalidated. This is a performance optimization because it prevents checking the persistent store. The default value is **true**.

UseOracleBLOB:

The *UseOracleBLOB* custom property creates the HTTP session database table using the Binary Large Object (BLOB) data type for the medium column. This property increases performance of persistent sessions when Oracle databases are used. Due to an Oracle restriction, BLOB support requires use of the Oracle Call Interface (OCI) database driver for more than 4000 bytes of data. You must also ensure that a new sessions table is created before the server is restarted by dropping your old sessions table or by changing the datasource definition to reference a database that does not contain a sessions table.

To create a sessions table using the BLOB data type, use the following name-value pair:

Name	Value
UseOracleBLOB	true

UsingApplicationSessionsAndInvalidateAll:

When the invalidateAllSet method is called, not all IBMApplicationSessions objects are checked. If you are using both the IBMApplicationSessions object and the invalidateAll call, use the following name-value pair:

Name	Value
UsingApplicationSessionsAndInvalidateAll	true

UsingCustomSchemaName:

Use this property to ensure that the session manager successfully detects the sessions table on subsequent server startups.

Set this custom property to `true` if you are using DB2 for sessions persistence and the customSchema property is not set to the default value in the DB2 JDBC driver.

The default value is false.

Configuring session tracking for Wireless Application Protocol (WAP) devices

Applications that run in a web container use sessions to keep track of individual users. Because most Wireless Application Protocol (WAP) devices do not support cookies, you can configure WAP devices to use URL rewriting to track sessions.

About this task

On most WAP devices, the maximum URL length is 128 characters. With URL rewriting, a session identifier is added to the URL itself, effectively decreasing the space available for the actual URL and the number of parameters that can be sent on a request.

To reduce the length of session identifier, you can configure key (jsessionid), session ID length and clone ID. To make these configuration changes, complete the following steps.

Procedure

1. Open the administrative console.
2. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **Web Container Settings** > **Web container**.
3. Under Additional Properties, click **Custom properties**.
4. Add the appropriate properties from the following list:
   - HttpSessionIdLength
   - SessionRewriteIdentifier
   - HttpSessionCloneId
   - CloneSeparatorChange
   - NoAdditionalSessionInfo
   - SessionIdentifierMaxLength
5. Click **Apply** and **Save**.

Configuring for database session persistence

You can configure a database to collect session data for database session persistence.

About this task

To configure the session management facility for database session persistence, complete the following steps.

Procedure

1. Create and configure a JDBC provider.
2. Create a data source pointing to a database.

   Use the JDBC provider that you defined: **Resources > JDBC > JDBC Providers >** *JDBC_provider* **> Data Sources > New**. The data source should be non-JTA, for example, non-XA enabled. Note the JNDI name of the data source.

   Point to an existing database.
3. Verify that the correct database is listed under **Resources > JDBC Providers >** *JDBC_provider* **> Data Sources >** *datasource_name*. If necessary, contact your database administrator to verify the correct database name.
4. Go to the appropriate level of Session Management.
5. Under Additional Properties, click **Distributed Environment Settings**
6. Select and click **Database**.

7. Specify the Data Source JNDI name from a previous step. The database user ID and password are case-sensitive.
8. Specify the database user ID and password that is used to access the database and for table creation. When you created your data source, you might have specified a Container Managed Authentication Alias or a Component Managed Authentication Alias; however, these two settings are not used by the session manager for session persistence. The session manager uses the userId and password specified in this step for session persistence.
9. Optional: Append the schema name in the session User ID field if you want to have more than one instance of the session table.

   The session manager uses the schema name to qualify the session table name for all database operations. If only the userid is specified without the schema name, the schema name defaults to NULL and therefore a table name with NULL as the schema name, for example, NULL.SESSIONS, is created. You can create multiple session tables with different schema names, other than NULL, and access them separately by modifying the user name to contain the appropriate schema name.
10. Retype the password for confirmation.
11. Configure a table space and page sizes for DB2 session databases.
12. Switch to a multirow schema.
13. Click **OK**.
14. If you want to change the tuning parameters, click **Custom Tuning Parameters** under Additional properties.
15. Click **Apply**.
16. Click **Save**.

Switching to a multi-row schema

The multi-row schema configuration supports storing an unlimited amount of data that is only bounded by the database capacities in an application. The application can read individual fields instead of the whole record, which can help to improve performance by avoiding unnecessary Java object serialization. Configure the session management facility to store each attribute in a session object in its own row in the database by using the multi-row schema configuration.

About this task

The only practical limit that remains is the size of the session attribute object. The multi-row schema potentially has performance benefits in certain usage scenarios, such as when larger amounts of data are stored in the session but only small amounts are specifically accessed during a given servlet processing of an HTTP request. In such a scenario, avoiding unneeded Java object serialization is beneficial to performance.

In addition to allowing larger session records, using multi-row schema can yield performance benefits. However, it requires a little work to switch from single-row to multi-row schema, as shown in the following table.

By default, a single session maps to a single row in the database table used to hold sessions. With this setup, there are hard limits to the amount of user-defined, application-specific data that WebSphere Application Server can access.

Consider configuring direct single-row usage to one database and multi-row usage to another database while you verify which option suits your application needs. Do this in code by switching the data source used; then monitor performance.

Table 241. Choosing a single-row or multi-row schema configuration. Single-row or multi-row schema configuration

Programming issue	Application scenario
Reasons to use single-row	• You can read or write all values with just one record read and write. • This takes up less space in a database because you are guaranteed that each session is only one record long.
Reasons **not** to use single-row	2-megabyte limit of stored data per session.
Reasons to use multi-row	• The application can store an unlimited amount of data; that is, you are limited only by the size of the database and a 2-megabyte-per-record limit. • The application can read individual fields instead of the whole record. When large amounts of data are stored in the session but only small amounts are specifically accessed during servlet processing of an HTTP request, multi-row sessions can improve performance by avoiding unneeded Java object serialization.
Reasons **not** to use multi-row	If data is small in size, you probably do not want the extra overhead of multiple row reads when you can store everything in one row.

In the case of multi-row usage, design your application data objects not to have references to each other, to prevent circular references. For example, suppose you are storing two objects A and B in the session using HttpSession.put(..) method, and A contains a reference to B. In the multi-row case, because objects are stored in different rows of the database, when objects A and B are retrieved later, the object graph between A and B is different than stored. A and B behave as independent objects.

Procedure

1. Modify the Session Management facility properties to switch from single to multi-row schema.
2. Manually drop the table.

   To drop the table:
   a. Determine which data source configuration Session Management is using.
   b. In the data source configuration, look up the database name.
   c. Use the database facilities to connect to the database.
   d. Drop the SESSIONS table.

Configuring tablespace and page sizes for DB2 session databases

If you are using DB2 for session persistence, you can increase the page size to optimize performance for writing large amounts of data to the database. Page sizes of 8K, 16K, and 32K are supported.

About this task

To use a page size other than the default (4K), complete the following steps.

Procedure

1. If the SESSIONS table already exists, drop it from the DB2 database.
2. Create a new DB2 buffer pool and table space, specifying the same page size (8K, 16K or 32K) for both, and assign the new buffer pool to this table space.

```
DB2 Connect to session
DB2 CREATE BUFFERPOOL sessionBP SIZE 1000 PAGESIZE 8K
DB2 Connect reset
```

```
DB2 Connect to session
DB2 CREATE TABLESPACE sessionTS PAGESIZE 8K MANAGED BY SYSTEM
    USING ('D:\DB2\NODE0000\SQL00005\sessionTS.0') BUFFERPOOL sessionBP
DB2 Connect reset
```

Refer to DB2 product documentation for details.

3. Configure the correct table space name and page size in the Session Management facility. Page size is referred to as *row size* on the Session Management page.)

Results

When the product is restarted, the Session Management facility creates the new SESSIONS table in the specified tablespace based on the indicated page size.

Creating a table for session persistence

You can use a database table to collect and store session data. If you are using a database table for session persistence, you must create and define a database table that is associated with the application server.

About this task

Whenever the session manager is set for database persistence, the session manager creates a table for its use. If you want to expand the column size limits to make it more appropriate for your website, you can create the table externally. If the external table is specified as the target table in the session manager database persistence configuration, then during the session manager start up, the external table is used. In most cases it is better to let the session manager create the table during startup.

To create a table for collecting session data, do the following:

Procedure

Have your administrator create a database table for storing your session data using one of the following data definition language (DDL): For DB2:

```
CREATE TABLE <SchemaName>.sessions  (
  ID               VARCHAR(128) NOT NULL ,
  PROPID           VARCHAR(128) NOT NULL ,
  APPNAME          VARCHAR(128) NOT NULL,
  LISTENERCNT      SMALLINT ,
  LASTACCESS       BIGINT,
  CREATIONTIME     BIGINT,
  MAXINACTIVETIME  INTEGER ,
  USERNAME         VARCHAR(256) ,
  SMALL            VARCHAR(3122)  FOR BIT DATA ,
  MEDIUM           LONG VARCHAR FOR BIT DATA ,
  LARGE            BLOB(2M)
    )
```

For Oracle:

```
CREATE TABLE SESSIONS  (
  ID               VARCHAR(128) NOT NULL ,
  PROPID           VARCHAR(128) NOT NULL ,
  APPNAME          VARCHAR(128) NOT NULL,
  LISTENERCNT      SMALLINT ,
  LASTACCESS       INTEGER,
  CREATIONTIME     INTEGER,
  MAXINACTIVETIME  INTEGER ,
  USERNAME         VARCHAR(256) ,
  SMALL            RAW(2000),
  MEDIUM           LONG RAW ,
  LARGE            RAW(1)
  )
```

If the web container custom property UseOracleBLOB is set to true then:

```
CREATE TABLE SESSIONS  (
  ID              VARCHAR(128) NOT NULL ,
  PROPID          VARCHAR(128) NOT NULL ,
  APPNAME         VARCHAR(128) NOT NULL,
  LISTENERCNT     SMALLINT ,
  LASTACCESS      INTEGER,
  CREATIONTIME    INTEGER,
  MAXINACTIVETIME INTEGER ,
  USERNAME        VARCHAR(256) ,
  SMALL           RAW(2000),
  MEDIUM          BLOB,
  LARGE           RAW(1)
  )
```

Attention:

1. At run time, the session manager accesses the target table using the identity of the Java Platform, Enterprise Edition (Java EE) server in which the owning web application is deployed. Any web container that is configured to use persistent sessions must have both read and update access to the subject database table.
2. HTTP session processing uses the index defined using the `CREATE INDEX` statement to avoid database deadlocks. In some situations, such as when a relatively small table size is defined for the database, DB2 may decide not to use this index. When the index is not used, database deadlocks can occur. If database deadlocks occur, see the DB2 Administration Guide for the version of DB2 you are using for recommendations on how to calculate the space required for an index and adjust the size of the tables that you are using accordingly.
3. It might be necessary to tune DB2 to make efficient use of the sessions database table and to avoid deadlocks when accessing it. Your DB2 administrator should refer to the DB2 Administration Guide for specific information about tuning the version of DB2 that you are using.
4. During run time, the session manager may create an entry in the database for each web module of the application. This row of data is used internally for session management purposes, such as in session invalidation. Do not be concerned with this entry. It can be overlooked.

Database settings

Use this page to specify the settings for database session support.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **Session management** > **Distributed environment settings** > **Database**.

Datasource JNDI name:

Specifies the datasource description.

The JNDI name of the non-XA enabled datasource from which session management obtains database connections. For example, if the JNDI name of the datasource is "jdbc/sessions", specify "jdbc/sessions." The datasource represents a pool of database connections and a configuration for that pool (such as the pool size). The datasource must already exist as a configured resource in the environment.

User ID:

Specifies the user ID for database access.

Password:

Specifies the password for database access.

DB2 row size:

Specifies the table space page size configured for the sessions table, if using a DB2 database. Possible values are 4, 8, 16, and 32 kilobytes (KB). The default row size is 4KB.

The default row size is 4KB. In DB2, it can be updated to a larger value. This can help database performance in some environments. When this value is other than 4, you must specify table space name to use this property. For 4KB pages, the table space name is optional.

Table space name:

Specifies that table space to be used for the sessions table.

This value is required when the DB2 page size is other than 4KB.

Use multi row schema:

Specifies that each session data attribute is placed in a separate row in the database, allowing larger amounts of data to be stored for each session. This action can yield better performance when session attributes are very large and few changes are required to the session attributes. If use multi row schema is not enabled, instances of application data can be placed in the same row.

Configuring write contents

In session management, you can configure which session data is written to the database or to another WebSphere instance, depending on whether you are using database persistent sessions or memory to memory replication. You can either write only session data properties that have been updated through setAttribute method and removeAttribute method calls or you can write all session data properties.

About this task

This flexibility allows for fewer code changes for the JavaServer Pages (JSP) writer when the application will be operating in a clustered environment. The following options are available in Session Management for tuning what is written back:

- Write changed (the default) - Write only session data properties that have been updated through setAttribute method and removeAttribute method calls.
- Write all - Write all session data properties.

The **Write all** setting might benefit servlet and JSP writers who change Java objects' states that reside as attributes in HttpSession and do not call HttpSession.setAttribute method.

However, the use of **Write all** could result in more data being written back than is necessary. If this situation applies to you, consider combining the use of **Write all** with **Time-based write** to boost performance overall. As always, be sure to evaluate the advantages and disadvantages for your installation.

With either Write Contents setting, when a session is first created, complete session information is written, including all of the objects bound to the session.

Table 242. Single-row or multi-row schemas. When using database session persistence, in subsequent session requests, what is written to the database depends on whether a single-row or multi-row schema has been set for the session database, as shown in the following table.

Write Contents setting	Behavior with single-row schema	Behavior with multirow schema
Write changed	If any session attribute is updated, all objects bound to the session are written.	Only the session data modified through setAttribute method or removeAttribute method calls is written.

Table 242. Single-row or multi-row schemas (continued). When using database session persistence, in subsequent session requests, what is written to the database depends on whether a single-row or multi-row schema has been set for the session database, as shown in the following table.

Write Contents setting	Behavior with single-row schema	Behavior with multirow schema
Write all	All bound session attributes are written.	All session attributes that currently reside in the cache are written. If the session has never left the cache, all session attributes are written.

Procedure

1. Go to the appropriate level of Session Management. See the *Administering applications and their environment* PDF for more information.
2. Click Distributed environment settings
3. Click Custom tuning parameters.
4. Click Custom settings.
5. Select the appropriate write contents setting.
6. Click **OK**.

Configuring write frequency

In the session management facility, you can configure the frequency for writing session data to the database or to a WebSphere instance, depending on whether you use database distributed sessions or memory-to-memory replication. You can write session data using the end of service servlet, manual update or time based update options.

About this task

This flexibility enables you to weigh session performance gains against varying degrees of failover support. The following options are available in the Session Management facility for tuning write frequency:

- **End of service servlet**- Write session data at the end of the servlet service method call.
- **Manual update**- Write session data only when the servlet calls the IBMSession.sync method.
- **Time based** (the default) - Write session data at periodic intervals, in seconds (called the *write interval*).

When a session is first created, session information is always written at the end of the service call.

If you are using the time based write option, when a server shuts down, the server typically attempts to write the latest session data, that is in the session cache, to the persistent store, as part of the shutdown process.

Using the time based write or manual update options can result in the loss of data in failover scenarios because the backup copy of the session in the persistent store, such as a database, or another JVM, might not be in sync with the session in the session cache.

Procedure

1. Go to the appropriate level of Session Management. See the *Administering applications and their environment* PDF for more information.
2. Click Distributed environment settings
3. Click Custom tuning parameters.
4. Click Custom settings.
5. Select the method of write frequency that you want to use.
6. Click **OK**.

Chapter 29. Administering web services

This page provides a starting point for finding information about web services.

Web services are self-contained, modular applications that can be described, published, located, and invoked over a network. They implement a services oriented architecture (SOA), which supports the connecting or sharing of resources and data in a very flexible and standardized manner. Services are described and organized to support their dynamic, automated discovery and reuse.

Planning to use web services

You can plan to develop and implement web services based on a variety of Java programming models.

Before you begin

The JAX-WS Web services samples demonstrate the simple message exchange patterns using both synchronous and asynchronous invocation of web services in SOAP 1.1 and SOAP 1.2 environments. The samples are composed with web service standards such as WS-Addressing (WS-A) , WS-Reliable Messaging (WS-RM), and WS-Secure Conversation (WS-SC), which you can use to complete a broad range of interoperability tests. The samples demonstrate the use of JavaBeans artifacts and static service endpoints and proxy-based clients. Additionally, a sample is provided that demonstrates Message Transmission Optimization Mechanism (MTOM).

About this task

best-practices: IBM WebSphere Application Server supports the Java API for XML-Based Web Services (JAX-WS) programming model and the Java API for XML-based RPC (JAX-RPC) programming model. JAX-WS is the next generation web services programming model extending the foundation provided by the JAX-RPC programming model. Using the strategic JAX-WS programming model, development of web services and clients is simplified through support of a standards-based annotations model. Although the JAX-RPC programming model and applications are still supported, take advantage of the easy-to-implement JAX-WS programming model to develop new web services applications and clients.

You must re-write existing JAX-RPC applications if you want to take advantage of the features of the JAX-WS programming model.

Web services reflect the service-oriented architecture approach to programming. This approach is based on the idea of building applications by discovering and implementing network-available services, or by invoking the available applications to accomplish a task. Web services deliver interoperability, for example, web services applications provide a way for components created in different programming languages to work together as if they were created using the same language. Web services rely on existing transport technologies, such as HTTP, and standard data encoding techniques, such as Extensible Markup Language (XML), for invoking the implementation.

Procedure

1. Identify your goals and design web services to fit your e-business solution. Consider what you want to accomplish by using web services. Decide how web services fit into your current topology, applications and programming model. Determine how the Web services process requests on the server and how the clients manage and use the web service.
2. Design your web services for reliability, availability, manageability and security. For example, you want your web services to process a transaction in a reasonable time at all hours of the day and provide users with optimal security, such as authentication for buyers. Planning to use web services to work with WebSphere Application Server helps to meet these requirements.

3. Review the standards used in developing and deploying web services onto WebSphere Application Server. Development and deployment are based on a variety of Java programming models.
4. Decide what development and implementation tools to use. You can use a variety of manual development and implementation tasks. Whether you have an existing web service to implement or you want to develop your own from a JavaBeans implementation or from an Enterprise JavaBeans (EJB) module, you can choose different tasks respective to your resources. You can also use assembly tools to complete development and implementation tasks.
5. Install the application server. For detailed information on installing the application server, read about installing your application serving environment.
6. Review web services samples.

Results

You have a design plan for implementing web services applications into your business architecture.

Deploying web services

Deploying web services applications onto application servers

After assembling the artifacts required to enable the web module for web services into an enterprise archive (EAR) file, you can deploy the EAR file into the application server.

Before you begin

To deploy Java-based web services, you need an enterprise application, also known as an EAR file that is configured and enabled for web services.

A Java API for XML-Based Web Services (JAX-WS) application does not require additional bindings and deployment descriptors for deployment whereas a Java API for XML-based RPC (JAX-RPC) web services application requires you to add additional bindings and deployment descriptors for application deployment. JAX-WS is much more dynamic, and does not require any of the static data generated by the deployment step required for deploying JAX-RPC applications.

For JAX-WS web services, the use of the `webservices.xml` deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the `webservices.xml` deployment descriptor overrides any corresponding information that is specified by annotations.

Note: In a mixed node cell, you can only target a JAX-WS enabled enterprise beans module to a server using WebSphere Application Server Version 7.0 and later. However, you can target a JAX-WS enabled web application archives (WAR) module to a server using either WebSphere Application Server Version 7.0 and later or WebSphere Application Server Version 6.1 Feature Pack for Web Services

You can use the wsdeploy command with JAX-RPC applications to add WebSphere product-specific deployment classes to a web services-compatible enterprise application enterprise archive (EAR) file or an application client Java archive (JAR) file.

To install or deploy a JAX-WS application, you only need to install the JAX-WS enabled EAR file. If your web services application contains only JAX-WS endpoints, you do not need to run the wsdeploy command, as this command is used to process only JAX-RPC endpoints.

Ensure that you have installed the HTTP or Java Message Service (JMS) router module that was generated with the endptEnabler command onto the same target as your web services enterprise bean

JAR files. These HTTP or JMS router modules are included in your web services application and they need to use the runtime libraries of the application server.

About this task

This task is one of the steps in developing and implementing web services.

You can use either the administrative console or the wsadmin scripting tool to deploy an EAR file. If you are installing an application containing web services by using the wsadmin command, specify the `-deployws` option for JAX-RPC applications. If you are installing an application containing web services by using the administrative console, select **Deploy WebServices** in the Install New Application wizard. For more information about installing applications using the administrative console, see the installing enterprise application files with the console information.

If your JAX-RPC web services application was previously deployed with the wsdeploy command, it is not necessary to specify web services deployment during installation.

The following actions deploy the EAR file with the wsadmin command:

Procedure

1. Start *install_root*`/bin/wsadmin` from a command prompt.
2. Deploy the EAR file.
   - For JAX-WS web service applications, enter the `$AdminApp install` *EARfile* `"-usedefaultbindings"` command at the wsadmin prompt.
   - For JAX-RPC web service applications, enter the `$AdminApp install` *EARfile* `"-usedefaultbindings -deployws"` command at the wsadmin prompt.

Results

You have a web service installed onto your application server.

Note: While installing web services applications that contain a large number of enterprise beans onto the application server, you might receive out of memory errors. If you receive out of memory errors, increase the heap size of your Java Virtual Machine (JVM). Read about tuning the IBM virtual machine for Java documentation to learn more about tuning the application server environment.

What to do next

You can confirm that the web services application was deployed by entering the web service endpoint URL in a browser, then viewing an informative page. The information page contains the following information:

```
{http://webservice.pli.tc.wssvt.ibm.com}RetireWebServices
Hello! This is an Axis2 web service!
```

The first line of this information is variable, depending on your web service. The URI in the brackets is the namespace and the string that follows, in this example RetireWebServices, is the name of the port used to access the web service.

The next step you might want to consider is to apply security to your web service.

Provide options to perform the web services deployment settings

Use this page to specify options for web services deployment.

This administrative console page is a step in the application installation and update wizards.

To view this page, you must select **Deploy web services** on the **Select installation options** page.

To view this administrative console page, complete the following steps:

1. Click **Applications** > **New application** > ***application_path*** .
2. Select the option to **Show all installation options and parameters** .
3. Click **Next** to get to the **Step: Select installation options** page.
4. Select **Deploy web service**.
5. Click **Next** to get to the **Step: Provide options to perform the web services deployment** page.

You can specify the web services deployment options on this page only when installing or updating an application that uses web services.

The wsdeploy command is supported by Java API for XML-based RPC (JAX-RPC) applications. The Java API for XML-Based Web Services (JAX-WS) programming model that is implemented by the application server does not support the wsdeploy command. If your web services application contains only JAX-WS endpoints, you do not need to run the wsdeploy command, as this command is used to process only JAX-RPC endpoints.

The options that you specify set parameter values for the wsdeploy command. The wsdeploy command adds product-specific deployment classes to a web services-compatible enterprise archive (EAR) file or an application client Java archive (JAR) file. These classes include:

- Stubs
- Serializers and deserializers
- Implementations of service interfaces

The wsdeploy command is run during installation after you click **Finish** on the **Summary** page of the wizard.

Deploy web services option - Classpath:

Specifies entries to add to the CLASSPATH when the generated classes are compiled.

To specify the class paths of multiple entries, you need to separate the entries with a semicolon on Windows platforms and on Linux, Unix, and z/OS platforms, you need to use a colon to separate the entries. This is the same separator that is used with the CLASSPATH environment variable.

This option is the same as the wsdeploy command parameter `-cp` *`class_path`*.

Data type	String
Default	null

Deploy web services option - Extension Directories:

Specifies a directory that contains zipped or Java archive (JAR) files. All zipped and JAR files in this directory are added to the CLASSPATH used to compile the generated files.

This option is the same as the wsdeploy command parameter `-jardir` *`directory`*.

Data type	String
Default	null

wsdeploy command

Use the wsdeploy command to add WebSphere product-specific deployment classes to a web services-compatible enterprise application enterprise archive (EAR) file or an application client Java archive (JAR) file.

The wsdeploy command is supported by Java API for XML-based RPC (JAX-RPC) applications. The Java API for XML-Based Web Services (JAX-WS) programming model that is implemented by the application server does not support the wsdeploy command. If your web services application contains only JAX-WS endpoints, you do not need to run the wsdeploy command, as this command is used to process only JAX-RPC endpoints.

The deployment classes that are added by the wsdeploy tool to a web services-compatible EAR file or a JAR file include:
- Stubs
- Serializers and deserializers
- Implementations of service interfaces

This deployment step must be performed at least once, and can be performed more often. Deployment can be performed separately using the wsdeploy command, assembly tools, or when the application is installed. When using the wsadmin command for installation, specify the **-deployws** option.

The wsdeploy command operates as noted in the following list:
- Each module in the enterprise application or JAR file is examined.
- If the module contains web services implementations, indicated by the presence of the `webservices.xml` deployment descriptor, the associated Web Services Description Language (WSDL) files are located and the WSDL2Java command is run with the role deploy-server option.
- If the module contains web services clients, indicated by the presence of the client deployment descriptor, the associated WSDL files are located and the WSDL2Java command is run with the role deploy-client option.
- The files generated by the WSDL2Java command are compiled and repackaged.

See the WSDL2Java command for JAX-RPC applications command information to learn more about the files that are generated for deployment.

When the generated files are compiled, they can reference application-specific classes outside the EAR or JAR file, if the EAR or JAR file is not self-contained. In this case, use either the -jardir or -cp option to specify additional JAR or zip files to be added to CLASSPATH variable when the generated files are compiled.

wsdeploy command syntax

The command syntax is noted in the following example:

```
wsdeploy Input_filename Output_filename [options]
```

Required options:
- ***Input_filename***

  Specifies the path to the EAR or JAR file to deploy.
- ***Output_filename***

  Specifies the path of the deployed EAR or JAR file. If *output_filename* already exists, it is silently overwritten. The *output_filename* can be the same as the *input_filename*.

Other options:
- **-jardir** *directory*

  Specifies a directory that contains JAR or zip files. All JAR and zip files in this directory are added to the CLASSPATH used to compile the generated files. This option can be specified zero or more times.
- **-cp** *entries*

  Specifies entries to add to the CLASSPATH when the generated classes are compiled. Multiple entries are separated the same as they are in the CLASSPATH environment variable.
- **-codegen**

  Specifies to generate but not compile deployment code. This option implicitly specifies the -keep option.
- **-debug**

Includes debugging information when compiling, that is, use javac -g to compile.

- **-help**

  Displays a help message and exit.
- **-ignoreerrors**

  Do not stop deployment if validation or compilation errors are encountered.
- **-keep**

  Do not delete working directories containing generated classes. A message is displayed indicating the name of the working directory that is retained.
- **-novalidate**

  Do not validate the web services deployment descriptors in the input file.
- **-trace**

  Displays processing information, including the names of the generated files.
- **-compliancelevel** *level*

  Sets the JDK level for compiler compliance. Valid values include: 1.4, 5.0, 6.0 (default) and 7.0. This flag is optional.

Example The following example illustrates how the options are used with the wsdeploy command:

```
wsdeploy x.ear x_deployed.ear -trace -keep
Processing web service module x_client.jar.
Keeping directory: f:\temp\Base53383.tmp for module: x_client.jar.
Parsing XML file:f:\temp\Base53383.tmp\WarDeploy.wsdl
Generating f:\temp\Base53383.tmp\generatedSource\com\test\WarDeploy.java
Generating f:\temp\Base53383.tmp\generatedSource\com\test\WarDeployLocator.java
Generating f:\temp\Base53383.tmp\generatedSource\com\test\HelloWsBindingStub.java
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\WarDeploy.java.
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\WarDeployLocator.java.
Compiling f:\temp\Base53383.tmp\generatedSource\com\test\HelloWsBindingStub.java.
Done processing module x_client.jar.
```

Messages

- Flag *-f* is not valid.

  Option *f* was not recognized as a valid option.
- Flag *-c* is ambiguous.

  Options can be abbreviated, but the abbreviation must be unique. In this case, the wsdeploy command cannot determine which option was intended.
- Flag *-c* is missing parameter *-p*.

  A required parameter for an option is omitted.
- Missing *p* parameter.

  A required option is omitted.

JAX-WS application deployment model

The administration function of the product is enhanced to support installing and deploying Java Application Programming Interface (API) for XML Web Services (JAX-WS) applications like any other WebSphere Application Server applications.

A JAX-WS application is packaged as a web application archive (WAR) file or a WAR module within an Enterprise Archive (EAR) file. The JAX-WS application deployment model is similar to the Java API for XML Remote Protocol Call (JAX-RPC) web services application model. The main difference between them is that JAX-RPC web services application requires you to add additional bindings and deployment descriptors for application deployment. A JAX-WS application does not require additional bindings and deployment descriptors for deployment. You can deploy your JAX-WS applications as you would deploy any other WebSphere Application Server application.

JAX-WS web services is a rewrite of JAX-RPC web services. The table compares the web services stack for both JAX-WS and JAX-RPC web services.

JAX-RPC web services	JAX-WS web services
Bindings are proprietary	Bindings are based on the open source Java API for XML Bindings (JAXB)
Parsing is proprietary	Parsing is based on the open source Java Specification Request (JSR) 173
No Java annotations support	Support for Java annotations such as `@WebService`, `@WebMethod`, `@WebParam`, `@WebResult`, and `@SOAPBinding`
During deployment, some deployment descriptor files are created in a JAX-RPC based service and client. The following files are created on the services side, when it is an EJB based web service and EJB based module: • `webservices.xml` • <name_of_service>`_mapping.xml` • `ibm-webservices-bnd.xmi` • `ibm-webservices-ext.xmi` When the service is a JavaBeans-based or web module-based service, the following files and deployment descriptors are required: • `webservices.xml` • <name_of_service>`_mapping.xml` • In the `web.xml` file, there is no additional content • `ibm-webservices-bnd.xmi` • `ibm-webservices-ext.xmi` The `web.xml` exists in both EJB and JavaBeans based services. However, there is no additional content added to the file during deployment of a Web service application or module.	For JAX-WS web services, the use of the `webservices.xml` deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the `webservices.xml` deployment descriptor overrides any corresponding information that is specified by annotations.

Note: Starting with WebSphere Application Server Version 7.0 and later, Java EE 5 application modules (web application modules version 2.5 or above, or EJB modules version 3.0 or above) are scanned for annotations to identify JAX-WS services and clients. However, pre-Java EE 5 application modules (web application modules version 2.4 or before, or EJB modules version 2.1 or before) are not scanned for JAX-WS annotations, by default, for performance considerations. In the Version 6.1 Feature Pack for Web Services, the default behavior is to scan pre-Java EE 5 web application modules to identify JAX-WS services and to scan pre-Java EE 5 web application modules and EJB modules for service clients during application installation. Because the default behavior for WebSphere Application Server Version 7.0 and later is to not scan pre-Java EE 5 modules for annotations during application installation or server startup, to preserve backward compatability with the feature pack from previous releases, you must configure either the UseWSFEP61ScanPolicy property in the META-INF/MANIFEST.MF of a web application archive (WAR) file or EJB module or define the Java virtual machine custom property, com.ibm.websphere.webservices.UseWSFEP61ScanPolicy, on servers to request scanning during application installation and server startup. To learn more about annotations scanning, see the JAX-WS annotations information.

Using a third-party JAX-WS web services engine

In certain situations you might need to set up a third-party JAX-WS web services engine. For example, you must set up a third-party JAX-WS web services engine if you need to deploy applications that use a single runtime across various application servers such as WebSphere Application Server, JBoss, and WebLogic, or if you want to build JAX-WS web services applications using third party JAX-WS run-times such as CXF, Axis2, and Metro.

Before you begin

Use of a third-party JAX-WS runtime has limitations. It also requires mandatory configuration changes, and in some cases, it requires manual intervention to resolves issues that occur during deployment and when you run the application. These limitations and issues vary based on the third-party JAX-WS runtime you decide to use. You should understand the limitations for the third-party JAX-WS runtime you are preparing to use before you configure your system to use that implementation.

The following limitations exist regardless of which third-party JAX-WS implementation you use:

- The WebSphere Application Server runtime restricts usage of application modules that use both the JAX-WS implementation provided with WebSphere Application Server, and an external JAX-WS implementation in the same application EAR file. You must use either the JAX-WS implementation provided with WebSphere Application Server or the external implementation in a single application EAR file. This limitation ensures that the runtime WebSphere Application Server does not conflict with the external third-party JAX-WS implementation.
- You must remove any conflicting JAR files from your application library before you deploy an application that uses an external JAX-WS implementation. Most of the external third-party JAX-WS runtimes include some JAR file libraries that are already installed on WebSphere Application Server. This situation causes conflicts in your application library.
- After an application that uses a third-party JAX-WS runtime is deployed on WebSphere Application Server, it is not recognized as a service client or provider. Therefore, you cannot attach application level policy sets to these applications. You must rely on external runtimes support quality of service. Following is a list of WebSphere Application Server features that are not available if you decide to deploy and run application that uses third-party JAX-WS implementations:
  - WS-Security, WS-RM, and WS-Transactions policy sets
  - WSDM
  - JNDI lookup to retrieve JAX-WS Service or Port Instance.

gotcha: Even though IBM supports the enablement of third party JAX-WS runtimes to run on WebSphere Application Server, and ensures the successful deployment of applications that use such runtimes, IBM does not provide support for resolving JAR file conflict problems, or any problem that a stack trace indicates is in the third party code.

About this task

When you deploy an application EAR file with a third-party JAX-WS implementation on WebSphere Application Server, the WebSphere Application Server runtime must ensure the use of the third-party engine, and disable the use of the existing WebSphere Application Server JAX-WS web services engine.

WebSphere Application Server does not claim support for any of the third-party JAX-WS runtimes, but has tested the deployment and execution of applications that use such runtimes.

You must complete the following steps before you can use an external JAX-WS runtime in an application.

Procedure

1. Set the class loader policy to `Classes loaded with local class loader first (parent last)` at the module level.

   Changing the class loader policy to parent last ensures that the external third-party JAX-WS runtime and their dependent library JAR files are first in the class loader search path, thereby ensuring that the third-party implementation is used instead of the WebSphere Application Server.

   a. In the administrative console, click **Applications > Application Types > WebSphere enterprise applications >** *application_name* **> Class loading and update detection**.

   b. Under Class reloading options, select **Override class reloading settings for web and EJB modules** .

c. Under Class loader order, select **Class loader order** property to `Classes loaded with local class loader first (parent last)`.

a. Click **OK**, and then **Save** to save your changes.

2. Turn off web services annotation scanning.

   Annotation scanning can be turned off at the application level or at the server level.

   To turn off annotation scanning at the application level, set the DisableIBMJAXWSEngine property in the META-INF/MANIFEST.MF of a WAR file or EJB module to true. Example:

```
Manifest-Version: 1.0
DisableIBMJAXWSEngine: true
```

   To turn off web services annotation scanning at the server level:

   a. In the administrative console, go to the Custom properties page for the Java virtual machine.

      Servers > Server Types > WebSphere application servers > *server_name*, and then, under Server Infrastructure, click **Java and process management > Process definition > Java virtual machine > Custom properties**

   b. Set the **com.ibm.websphere.webservices.DisableIBMJAXWSEngine** property to `true`

      If this property does not already exist for your configuration, click **New**, and add `com.ibm.websphere.webservices.DisableIBMJAXWSEngine` in the **Name** field and `true` in the **Value** field.

Results

What to do next

- Deploy and run an application EAR file with a third-party JAX-WS implementation on WebSphere Application Server.

Deploying web services client applications

After you have created an enterprise archive (EAR) file for the web services client application, you can deploy the web services client application into the Application Server.

Before you begin

To deploy a Java-based web services client, you need an enterprise application, also known as an enterprise archive (EAR) file that is configured and enabled for web services.

A Java API for XML-Based Web Services (JAX-WS) application is packaged as a web application archive (WAR) file or a WAR module within an Enterprise Archive (EAR) file. A JAX-WS application does not require additional bindings and deployment descriptors for deployment whereas a Java API for XML-based RPC (JAX-RPC) web services application requires you to add additional bindings and deployment descriptors for application deployment. JAX-WS is much more dynamic, and does not require any of the static data generated by the deployment step required for deploying JAX-RPC applications. For JAX-RPC web services clients, you must configure the client deployment descriptors.

About this task

You can use either the administrative console or the wsadmin scripting tool to deploy an EAR file. If you are installing an application containing web services by using the wsadmin command, specify the `-deployws` option for JAX-RPC applications.

Use the wsdeploy command only with JAX-RPC applications. The wsdeploy command is not applicable for JAX-WS applications.

If you are installing an application containing web services by using the administrative console, select **Deploy WebServices** in the Install New Application wizard. Read about installing a new application for more information on using the administrative console.

The following actions deploy the EAR file with the wsadmin command:

Procedure

1. Start *install_root*/bin/wsadmin from a command prompt.
2. Deploy the EAR file.
   - For JAX-WS web service applications, enter the `$AdminApp install` *EARfile* `"-usedefaultbindings"` command at the wsadmin prompt.
   - For JAX-RPC web service applications, enter the `$AdminApp install` *EARfile* `"-usedefaultbindings -deployws"` command at the wsadmin prompt.

Results

You have a deployed a web service client in the application server runtime environment.

What to do next

Test the web services client. You can now test a web services-enabled managed client EAR file or an unmanaged client JAR file.

Making deployed web services applications available to clients

You can publish WSDL files to the file system. If you are a client developer or a system administrator, you can use WSDL files to enable clients to connect to web services.

Before you begin

The publish WSDL administrative console panel supports both JAX-RPC and JAX-WS services. The publish WSDL panel generates a compression file that contains WSDL files for all modules in an application that contains JAX-WS or JAX-RPC web services. Read about providing the HTTP endpoint URL information to learn how the URL information affects the content of the published WSDL.

To publish a Web Services Description Language (WSDL) file you need an enterprise application, also known as an enterprise archive (EAR) file, that contains a Web services-enabled module and has been deployed into WebSphere Application Server. To learn how to deploy web services, see the deploying web services applications onto application servers information.

About this task

The purpose of publishing the WSDL file is to provide clients with a description of the web service, including the URL identifying the location of the service.

After installing a web services application, and optionally modifying the endpoint information, you might need WSDL files containing the updated endpoint informations to make deployed web services application to be available to clients.

Before you publish a WSDL file, you can configure web services to specify endpoint information in the form of URL fragments to enable full URL specification of WSDL ports. Refer to the tasks describing configuring endpoint URL information.

The WSDL files for each web services-enabled module are published to the file system location you specify. You can provide these WSDL files to clients that want to invoke your Web services.

You can specify endpoint information for HTTP ports, for Java Message Service (JMS) ports, or you can directly access enterprise beans that are acting as web services.

Procedure

1. Configure the web services client bindings.
2. Configure the URL endpoint information for HTTP bindings. Do one of the following depending on what kind of bindings you are using:
   - Configure the URL endpoint information for JMS bindings.
3. Externalize or publish the WSDL file out of the application. You can complete this task in the following ways:
   - Publish a WSDL file with the wsadmin tool.

What to do next

Apply security to your web services. To learn more, see the securing web services applications using message level security information.

Configuring web services client bindings

When a web services application is deployed into WebSphere Application Server, an instance is created for each application or module. The instance contains deployment information for the web module or Enterprise JavaBeans (EJB) module, including client bindings.

Before you begin

Deploy a web service into your WebSphere Application Server instance. Read about deploying web services applications onto application servers.

You must know the topology of the URL endpoint address of the web services servers and which web service the client depends upon. You can view the deployment descriptors in the administrative console to find the topology information. To learn more, see the View web services server deployment descriptors information.

About this task

The client bindings define the Web Services Description Language (WSDL) file name and preferred ports. The relative path of a web service in a module is specified within a compatible WSDL file that contains the actual URL to be used for requests. The address is only needed if the original WSDL file did not contain a URL, or when a different address is needed. For a service endpoint with multiple ports, you need to define an alternative WSDL file name.

The following steps describe how to edit bindings for a web service after these bindings are deployed on a server. When one web service communicates with another web service, you must configure the client bindings to access the downstream web service.

To configure client bindings through the administrative console:

Procedure

1. Open the administrative console.
2. Click **Applications** > **Enterprise Applications** > *application_instance* > **Manage Modules** > *module_instance* > **Web services client bindings**.
3. Find the web service you want to update.

   The web services are listed in the **Web Service** field.
4. Select the WSDL file name from the drop down box in the WSDL file name field.

5. Click **Edit** in the Preferred port mappings field to configure the default port to use.
   a. Specify the port type and the preferred ports in the Port type and Preferred ports fields.

      Configuring the preferred port enables you to select an optimal port implementation use non-SOAP protocols. See the RMI-IIOP web services using JAX-RPC information to learn more about using non-SOAP protocols.
   b. Click **Apply** and **OK**.
6. Click **Edit** in the Port information field to configure the request timeout, the overridden endpoint, and the overridden binding namespace for a port.

   Configuring the request timeout accommodates complex topologies that can have multiple cascaded Web services that involve multiple hops or long-running services.

   You can configure Timeout values based on observed behavior of the overall system as integration proceeds. For example, a web service client might time out because of changing network conditions or the performance of an external web service. When you have applications containing web services clients that timeout, you can change the request time out values for the clients.

   You can specify an endpoint URL to override the current endpoint. A client invoking a request on this port uses this endpoint instead of the endpoint specified in the WSDL file. You can specify the **Overridden endpoint URL** value for both Java API for XML-Based Web Services (JAX-WS) clients and Java API for XML-based RPC (JAX-RPC) clients.

   Note: The **Overridden endpoint URL** field is applicable for both JAX-WS and JAX-RPC clients. The other fields on this administrative console page are only applicable for JAX-RPC clients.
   a. Click **Apply** and **OK**.

Results

Your web service client bindings are configured.

What to do next

Now you can finish any other configurations, start or restart the application, and verify the expected behavior of the web service.

Web services client bindings:

The client bindings define the Web Services Description Language (WSDL) file name, preferred ports and other port information. Use this page to specify the client bindings and the port mappings for the web services in a module.

A web service can specify the relative path within the module of a compatible WSDL file containing the actual URL to be used for requests. The relative path only needs to be specified if the original WSDL file does not contain a URL or when a different URL is needed. For a service endpoint with multiple ports defined, a preferred mapping specifies the default port to use for a port type.

To view this administrative console page, complete the following steps:
1. Click **Applications > Application Types > WebSphere enterprise applications >** ***application_name*** .
2. Click **Manage modules >** ***URI_file_name*** **> web services client bindings** .

This administrative console page applies only to Java API for XML-based RPC (JAX-RPC) applications.

Web service:

Identifies the name of this web service. A module can contain one or more web services.

EJB:

Identifies the name of the EJB for the EJB modules.

WSDL file name:

Specifies the WSDL file name, which is relative to the module. Locate the WSDL file name in the drop down menu.

Preferred port mappings:

Specifies and manages the preferred port type mapping for a web service when a particular port type is requested.

Click **Edit** to edit the preferred port mapping information on the **Preferred port mappings** panel.

Port information:

Specifies additional configuration information for the ports of this web service.

Click **Edit** to edit the port information on the **Port information** panel. You can set a request timeout, override an endpoint and override a binding namespace for each client port.

Preferred port mappings:

Use this page to view and manage a preferred portType mapping for a web service.

This administrative console page applies only to Java API for XML-based RPC (JAX-RPC) applications.

When you have multiple ports that reference the same portType (service endpoint interface), a preferred port specifies the port to use when the `Service.getPort(Class SEI)` method is called with only the service endpoint interface.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Manage Modules** > ***module instance*** > **Web services client bindings** > **Edit** > ***preferred_port_instance***.

portType:

Specifies the portType.

The preferred port and the portType values are both of the type `java.xml.namespace.QName`.

Preferred port:

Specifies the preferred port to be associated with a particular portType. The `Service.getPort(Class)` method returns the preferred port associated with the specified service endpoint interface class (portType).

The preferred ports available are listed, as well as a value of `None`, which indicates no preferred port is selected.

Web services client port information:

Use this page to specify a request timeout, override an endpoint, and override a binding namespace for a web services client port.

A web service can have multiple ports. You can view and configure the port attributes for each defined web service port. The web services are listed on the web services client bindings panel.

To view this page, click **Applications** > **Application Types** > **WebSphere enterprise applications** ***application_name*** > **Manage Modules** > ***module_instance*** > **Web services client bindings** > **Edit** .

This administrative console panel applies to both Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services. The **Overridden endpoint URL** field is the only field supported for JAX-WS clients. The other fields are not applicable for JAX-WS clients.

Port:

Specifies the name of a port.

Request timeout:

Specifies the time, in seconds, that a web service client waits for a request to complete on this port. If a timeout is not specified, the default request timeout for the client to wait is `300` seconds. If the value is set at `0` (zero), the timeout used is the default value for the underlying transport mechanism. This field is supported only for JAX-RPC clients.

A typical use for this setting is to customize the client's behavior when it is configured to use a JMS transport to access a web service to make it wait longer for an expected completion. Depending upon network conditions, or the nature of a web service implementation, it might be necessary to tune the timeout.

Overridden endpoint URL:

Specifies the name of an endpoint that is used to override the current endpoint. A client invoking a request on this port uses this endpoint instead of the endpoint specified in the WSDL file. This field is supported for both JAX-WS and JAX-RPC clients.

If an assembled application contains a web service client that is statically bound, the client is locked into using the implementation (service end point) identified in the WSDL file used during development. Overriding the endpoint is an alternative to configuring the deployed WSDL attribute.

The overridden endpoint URI attribute is specified on a per port basis. It does not require an alternative WSDL file within the module. The overridden endpoint URI takes precedence over the deployed WSDL attribute. The client uses this value for the service end point URI or SOAP address, instead of the value in the static client bindings.

Note: You can edit this field if you have managed clients or a mixture of both managed and unmanaged clients. You cannot edit the field if you have unmanaged clients only.

If you do not want a request by an unmanaged JAX-WS client service to be sent to the endpoint URL that is specified in this field, you can specify the `com.ibm.ws.websvcs.unmanaged.client.dontUseOverriddenEndpointUri` Java virtual machine (JVM) system property. For more information about this custom property, read about the Java virtual machine custom properties.

Overridden binding:

Specifies the WSDL file binding namespace URI to use with this port, instead of the namespace in the WSDL file. This binding does not need to exist in the WSDL file. A client invoking a request on this port

uses this binding instead of the binding specified in the WSDL file. An overridden binding namespace cannot be specified unless an overridden endpoint is specified. This field is supported only for JAX-RPC clients.

Configuring endpoint URL information for HTTP bindings

Configuring a service endpoint is necessary to connect Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services clients to any web services among the components being assembled or to any external web services.

Before you begin

You can develop an HTTP accessible Java API for XML-based remote procedure call (JAX-RPC) or Java API for XML Web Services (JAX-WS) web service when you have an existing JavaBeans object to enable as a web service. For additional information, see the using HTTP to transport web services requests information.

You can use either the administrative console or property files to configure and manage HTTP endpoint URL fragments. To learn about using property files to set and manage the URL fragments, see the information about working with web services endpoint URL fragment property files.

This task describes using the administrative console to configure endpoint URL information for HTTP bindings.

About this task

You can specify HTTP URL prefixes for web services that are accessed through HTTP by using the Provide HTTP endpoint URL information panel in the administrative console. The HTTP URL prefixes provide location specific information and are used to form complete endpoint URLs that are included within published WSDL files.

Note: The Provide HTTP panel in the administrative console displays modules that contain Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services. You can use the Provide HTTP panel to provide URL information for both types of web services, however, the panel does not indicate which type of service that you are working with.

To configure these prefixes with the administrative console:

Procedure

1. Open the administrative console.
2. Click **Applications** > **Enterprise Applications** > *application_instance* > **Provide HTTP endpoint URL information**.
3. Specify the URL prefixes for the web service.

   In this step you specify the protocol (HTTP or HTTPS), as well as the *host_name* and *port_number* used in the endpoint URL. You can select a prefix from a predefined list, by selecting the default HTTP URL prefix, or you can use a custom HTTP URL prefix.

   a. Select **Default HTTP URL prefix** or **Custom HTTP URL Prefix**.

      If you select the default HTTP URL prefix, a list provides you with a choice of endpoint URL prefixes. The list is a combination of two sets of ports in the module: the virtual host ports and the application server ports. Use a prefix from this list if the application server of the web service is accessed directly. Select a value and also select the check box of the modules to use the prefix.

      If you want to use a custom HTTP URL prefix, type the value in the field. Select the check box to use in the prefix.

      If you configure a custom HTTP URL prefix, , you must also configure the custom JVM property, `com.ibm.ws.webservices.enableHTTPPrefix` in the administrative console and set the value to `true`.

You must restart the application server after this custom property has been defined so that this property is used by the system. Setting this custom JVM property is required so the custom HTTP endpoint prefix information is correctly displayed in the ?WSDL query that is returned from the browser and the URL field of the WSDL file that is returned to the client. If this custom property is not defined with the value of `true`, the custom HTTP URL prefix is not reflected in the WSDL file that the service returns to the client. To learn how to configure this custom JVM property, see the documentation on configuring additional HTTP transport properties using the JVM custom property panel in the administrative console.

Note: The `com.ibm.ws.webservices.enableHTTPPrefix` custom property applies to JAX-RPC web services applications only.

b. Click **Apply**.

The URL prefix, whether default or custom, is copied to the selected module HTTP URL prefix field.

c. Click **OK**. The URL information is saved to your workspace.

Results

You have specified the partial URL information that is used to form the target endpoint addresses in the WSDL files that are published using the Publish WSDL files panel.

What to do next

Configure any other URL endpoint information for Java Message Service (JMS) bindings and direct Enterprise JavaBeans (EJB) access. Then publish the WSDL files to make the deployed web services application available to clients.

Provide HTTP endpoint URL information:

Use this page to specify endpoint URL prefix information for web services accessed by HTTP. Prefixes are used to form complete endpoint addresses included in published Web Services Description Language (WSDL) files.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Provide HTTP endpoint URL information**.

You can specify a portion of the endpoint URL to be used in each web service module. In a published WSDL file, the URL defining the target endpoint address is found in the location attribute of the port's `soap:address` element.

This administrative console page applies for Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services.

In addition to the using the administrative console, you can use property files to configure and manage HTTP endpoint URL fragments. To learn about using property files to set and manage the URL fragments, see the information about working with web services endpoint URL fragment property files.

Specify endpoint URL prefixes for web services:

Specifies the *protocol* (either http or https), *host_name*, and *port_number* to be used in the endpoint URL.

You can select a prefix from a predefined list using the **HTTP URL prefix** or **Custom HTTP URL prefix** field.

The URL prefix format is *protocol://host_name:port_number*, for example, `http://myHost:9045`. The actual endpoint URL that is contained in a published WSDL file consists of the prefix followed by the module's context-root and the web service url-pattern, for example, `http://myHost:9045/services/myService`.

Select default HTTP URL prefix:

Specifies the drop down list associated with a default list of URL prefixes. This list is the intersection of the set of ports for the module's virtual host and the set of ports for the module's application server. Use items from this list if the web services application server is accessed directly.

To set an HTTP endpoint URL prefix, select **Select default HTTP URL prefix** and select a value from the drop down list. Select the check box of the modules that are to use the prefix and click **Apply**. When you click **Apply**, the entry in the **Select default HTTP URL prefix** or **Select custom HTTP URL prefix** fields, depending on which is selected, is copied into the **HTTP URL prefix** field of any module whose check box is selected.

Select custom HTTP URL prefix:

Specifies the *protocol*, *host*, and *port_number* of the intermediate service if the web services in a module are accessed through an intermediate node, for example the web services gateway or an IHS server.

To set a custom HTTP endpoint URL prefix, you must also configure the custom JVM property, `com.ibm.ws.webservices.enableHTTPPrefix` in the administrative console and set the value to `true`. Setting this custom JVM property is required so the custom HTTP URL is correctly populated in the URL field of the WSDL file that is returned to the client. If this custom JVM property is not configured, the custom HTTP URL prefix is not in the URL field in the copy of the WSDL file that the service returns to the client. To learn how to configure this custom JVM property, see the documentation on configuring additional HTTP transport properties using the JVM custom property panel in the administrative console. You must restart the application server after this custom property has been defined so that this property is used by the system.

After the `com.ibm.ws.webservices.enableHTTPPrefix` custom JVM property is configured, select **Select custom HTTP URL prefix** and enter a value. Select the check box of the modules that are to use the prefix and click **Apply**. When you click **Apply**, the entry in the **Select default HTTP URL prefix** or **Select custom HTTP URL prefix** fields, depending on which is selected, is copied into the **HTTP endpoint URL prefix** field of any module whose check box is selected.

Note: The `com.ibm.ws.webservices.enableHTTPPrefix` custom property applies to JAX-RPC web services applications only.

Configuring endpoint URL information for JMS bindings

WebSphere Application Server supports the use of the Java Message Service (JMS) API to transport web services requests, as an alternative to using HTTP.

Before you begin

The application server supports use of the Java Message Service (JMS) API to transport web services requests, as an alternative to HTTP transport. Read about using the Java Message Service (JMS) to transport web services requests to learn more about how web service clients and servers can communicate through JMS queues and topics instead of through HTTP connections.

You can use either the administrative console or property files to configure and manage JMS endpoint URL fragments. To learn about using property files to set and manage the URL fragments, see the information about working with web services endpoint URL fragment property files.

This task describes using the administrative console to configure endpoint URL information for JMS bindings.

About this task

Configuring a service endpoint is necessary to connect web service clients to any web services among the components being assembled or to any external web services. You can configure the endpoint URL information for JMS during application installation

In this task, enter the JMS endpoint URL prefix to use for each web service-enabled Enterprise JavaBeans (EJB) Java archive (JAR) file that belong to the application. The JMS endpoint URLs are included in the Web Services Description Language (WSDL) files published for clients to use.

You can specify HTTP URL prefixes for web services that are accessed through HTTP by using the Provide HTTP endpoint URL information panel in the administrative console. These prefixes are used to form complete endpoint addresses that are included in WSDL files when published.

You can specify JMS URL prefixes by using the Provide JMS and EJB endpoint URL information panel in the administrative console during or after application installation.

This task applies for Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services.

To configure JMS URL prefixes:

Procedure

1. Open the administrative console.
2. Click **Applications** > **Enterprise Applications** > ***application_instance*** > **Provide JMS and EJB endpoint URL information**.
3. Locate the list of web services modules that are accessible through JMS transport.
4. Type the JMS URL fragment in the **URL fragment** field. Enter a URL fragment that is a prefix to the initial URL part that is obtained by examining the deployment information of the Web service. See the usage scenario following this task for more information.

   The value that you enter is used to define the location attribute of the port soap:address element within the WSDL file that is published using the *application_name*_ExtendedWSDLFiles.zip or the *application_name*_WSDLFiles.zip file on the Publish WSDL zip files panel.

Results

You have a web service that is accessible through the JMS transport and configured with JMS bindings.

Example

Suppose an application called StockQuoteService contains an EJB JAR file that is named StockQuoteEJB, which contains one or more web services that are accessible through the JMS transport.

See the using SOAP over Java Message Service to transport web services information to review the example that defines a queue with the Java Naming and Directory Interface (JNDI) name of jms/StockQuote_Q, and a connection factory with the JNDI name of jms/StockQuote_CF, for your application.

In this example, you specify the following string as the JMS URL prefix within the Provide JMS and EJB endpoint URL information panel:

```
jms:/queue?destination=jms/StockQuote_Q&connectionFactory=jms/StockQuote_CF
```

The WSDL publisher uses this partial URL string to produce the actual JMS URL for each port component that is defined in the module. The `targetService=<port_name>` string is added to the end of the JMS URL, for example:

```
jms:/queue?destination=jms/StockQuote_Q&connectionFactory=jms/StockQuote_CF&targetService=getQuote
```

The published WSDL file is used by clients to invoke the web service.

What to do next

Publish the WSDL files to make the deployed web services application available to clients.

Provide JMS and EJB endpoint URL information:

Use this page to specify Java Message Service (JMS) and Enterprise JavaBeans (EJB) endpoint URL fragments for web services accessed through SOAP and Java Message Service (JMS) or directly as enterprise beans. Fragments are used to form complete endpoint addresses included in published Web Services Description Language (WSDL) files.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Provide JMS and EJB endpoint URL information**.

You can specify a fragment of the endpoint URL to be used in each web service module. In a published WSDL file, the URL defining the target endpoint address is found in the location attribute of the port's `soap:address` element.

If you are using web services modules that are configured to use JMS or configured to access enterprise beans directly, these modules are listed on this panel.

This administrative console page applies for Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services.

In addition to the using the administrative console, you can use property files to configure and manage JMS and EJB endpoint URL fragments. To learn about using property files to set and manage the URL fragments, see the information about working with web services endpoint URL fragment property files.

URL fragment for JMS:

Specifies a URL fragment for web services accessed through a JMS transport. You can enter a value that is used to define the `soap:address` of a web service. When WSDL files are published, a URL is formed using this fragment and is contained in the WSDL files.

The URL fragment that is entered as a value is a prefix to which the targetService property is appended to form a complete JMS URL endpoint. The default value is obtained by examining the installed service's deployment information, for example, `jms:jndi:jms/MyQueue&jndiConnectionFactoryName=jms/MyCF`.

This information is obtained from the configured JMS endpoint for the web service, which is a Message Driven Bean (MDB) defined by the **endpointEnabler** command-line tool. You can modify the URL fragment, for example, by adding properties. The URL fragment is combined with the targetService property to form the complete URL, for example, `jms:jndi:jms/MyQueue&jndiConnectionFactoryName=jms/MyCF&priority=5&targetService=GetQuote`.

URL fragment for EJB:

Specifies a URL fragment for web services accessed through an EJB binding. You can enter a value used to define the location attribute of the port's `generic:address` element of a Web service. This port address

is contained in the WSDL compression file when the compression file is published using the *application_name_ExtendedWSDLFiles*.zip field on the **Publish WSDL zip file** panel.

The URL fragment value entered is a suffix, which is appended to the initial part of the URL obtained by examining the web service's deployment information. For example, the following URL fragment can be obtained from the EJB's deployment information: wsejb:/com.acme.sample.MyStockQuoteHome?jndiName=ejb/MyStockQuoteHome.

In this case, you can enter the following information in the URL fragment field, jndiProviderURL=corbaloc:iiop:myhost.mycompany.com:2809, which results in this endpoint URL, wsejb:/com.acme.sample.MyStockQuoteHome?jndiName=ejb/MyStockQuoteHome&jndiProviderURL=corbaloc:iiop:myhost.mycompany.com:2809.

Configuring endpoint URL information to directly access enterprise beans

WebSphere Application Server supports directly accessing an enterprise bean as a web service, as an alternative to using HTTP or Java Message Service (JMS) to transport requests between the server and the client. The Enterprise JavaBeans (EJB) module that is used as a web service contains a Web Services Description Language (WSDL) file that contains EJB bindings.

Before you begin

To learn more about the process of directly accessing an enterprise bean as a web service, see the using WSDL EJB bindings to invoke an EJB from a JAX-RPC web services client.

You can use either the administrative console or property files to configure and manage EJB endpoint URL fragments. To learn about using property files to set and manage the URL fragments, see the information about working with web services endpoint URL fragment property files.

This task describes using the administrative console to configure endpoint URL information to directly access enterprise beans.

About this task

Configuring a service endpoint is necessary to connect web service clients to any web services among the components being assembled or to any external web services.

You can specify web address endpoints of the enterprise bean for web services that are accessed directly by EJB bindings using the Provide JMS and EJB endpoint web address information panel in the administrative console.

If you have modules that are configured for using direct EJB access, the modules are listed on the Provide JMS and EJB endpoint web address information panel in the administrative console. The EJB endpoint is only available in the WSDL that is found in the *application_name*_ExtendedWSDLfiles.zip file.

You can specify a fragment of the endpoint web address for the web services in each module.

To configure the web address endpoints of the enterprise bean with the administrative console:

Procedure

1. Open the administrative console.
2. Click **Applications** > **Enterprise Applications** > ***application_instance*** > **Provide JMS and EJB endpoint URL information**.
3. Locate the list of EJB modules.
4. Select the application module.
5. Type the web address fragment in the **URL fragment** field.

Enter a web address fragment that is a suffix to the initial web address part that is obtained by examining the web service deployment information. See the example following this task for more information.

The value that you enter is used to define the location attribute of the port generic:address element within the WSDL file that is published using the *application_name*_ExtendedWSDLFiles.zip file name link on the Publish WSDL zip files panel. The zip file names are listed as links on the panel.

6. Click **OK**.
7. Click **Save**.

Results

You have configured endpoints of the enterprise bean for Web services that are accessed directly by EJB bindings.

Example

The following example illustrates a web address fragment to enter in the URL fragment field.

The following web address information can be obtained from the deployment descriptor of an enterprise bean:

```
wsejb:/com.acme.sample.MyStockQuoteHome?jndiName=ejb/MyStockQuoteHome
```

Enter the following web address fragment in the URL fragment field:

```
jndiProviderURL=corbaloc:iiop:myhost.mycompany.com:2089
```

The results are shown in the following example:

```
wsejb:/com.acme.sample.MyStockQuoteHome?jndiName=ejb/MyStockQuoteHome&jndiProviderURL=
corbaloc:iiop:myhost.mycompany.com:2089
```

What to do next

Provide a description of the web service to the service requestor by publishing WSDL files. To learn more, read about making deployed web services applications available to clients.

Publishing WSDL files using the administrative console

You can publish a Web Services Description Language (WSDL) file using the WebSphere Application Server administrative console.

Before you begin

Before completing this task, you need to install or deploy the web service. After deployment, configure the URL endpoint tasks for your transport:

- Configure endpoint URL information for HTTP bindings
- Configure endpoint URL information for JMS bindings
- Configure endpoint URL information to directly access enterprise beans

About this task

By publishing a WSDL file, you are providing clients with a description of the web service, including the URL identifying the location of the service.

The WSDL files in each web services-enabled module are published to the file system location you specify. You can provide these WSDL files in the development and configuration process of the web service clients so they can invoke your web services.

This task applies for Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services.

To learn about more ways to publish WSDL files, see the making deployed web services applications available to clients information.

To publish an application's WSDL file with the administrative console:

Procedure

1. Open the administrative console.
2. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
3. Under Web Services Properties, click **Publish WSDL files**. This takes you to the **Publish WSDL zip files** page.
4. Click the WSDL compression file to download. The compression file contains the application's published WSDL files. The compression file `ExtendedWDLFiles.zip` contains EJB binding information. It can also contain JMS or HTTP binding information. The compression file `WSDLFiles.zip` only contains JMS or HTTP binding information.

What to do next

Apply security to your web services. To learn more, see the securing web services applications using message level security information.

Publish WSDL compressed files settings:

Use this page to publish Web Services Description Language (WSDL) files.

This administrative console page applies for Java API for XML-Based Web Services (JAX-WS) and Java API for XML-based RPC (JAX-RPC) web services.

The publish WSDL panel generates a compressed file that contains WSDL files for all modules in an application that contains a JAX-WS or JAX-RPC web service. Read about providing the HTTP endpoint URL information to learn how the URL information affects the content of the published WSDL.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Publish WSDL files**.

When you click **OK**, a panel showing one or several compressed file names displays. Each compressed file contains a WSDL file that represents the web services-enabled modules in the application. When you select a compressed file to publish, a dialogue displays from which you can choose where to create the compressed file. Within the published compressed files, the directory structure is *`application_name`*`/`*`module_name`*`/[META-INF|WEB-INF]/wsdl/`*`wsdl_file_name`*.

In a published WSDL file, the location attribute of a port's `soap:address` element contains the endpoint URL through which the web service is accessed. Using the **Provide HTTP endpoint URL information** and the **Provide JMS and EJB endpoint URL information** panels, configure the endpoint URLs to be used for the web services in each module.

application_name_WSDLFiles.zip:

Specifies the *`application_name`*`_WSDLFiles.zip` file containing the WSDL that describes web services that are accessible by standard SOAP-based ports.

application_name_ExtendedWSDLFiles.zip:

Specifies the *application_name*_ExtendedWSDLFiles.zip file containing the WSDL file that describes the web services available, including SOAP-based and non-SOAP based (for example, EJB) ports.

If there are no web services configured for direct EJB access, this compressed file name is not displayed. Do not use this compressed file if you want to produce a WSDL file compliant to standards.

Publishing WSDL files using a URL

You can publish a Web Services Description Language (WSDL) file using a URL.

Before you begin

Before you can publish a WSDL file using a URL, ensure the web services-enabled application is installed and running.

The files referenced by the <wsdl-file> element in the webservices.xml might import other WSDL or XML Schema Definition (XSD) files. Typically, all WSDL or XSD files are initially placed into the META-INF/wsdl directory when using Enterprise JavaBeans (EJB) or the WEB-INF/wsdl directory when using JavaBeans. If your WSDL or XSD files are not placed in one of these directories, the file referenced by the <wsdl-file> and its imported files are copied to the wsdl directory for publishing purposes.

There are two different forms of URL query strings. The first appends /wsdl to the service and returns only HTTP and JMS bindings. The second appends /extwsdl to the service and returns the extended WSDL file, including HTTP, JMS, and EJB bindings. If a WSDL file contains only EJB bindings and the /wsdl query is used, an error message displays in the browser saying there are no HTTP or JMS bindings in the WSDL file. The error message suggests using the /extwsdl query instead. Publishing a WSDL file using a URL requires that the application have a web module; either provided by the application or in the form of an HTTP router module. If an EJB application contains a WSDL file with only JMS or EJB Web service bindings, the endptEnabler command can be used to add an HTTP router module to the application.

Note: Only HTTP URLs are supported for publishing.

About this task

To publish a WSDL file using a URL:

Procedure

1. Retrieve the outer-most WSDL file. The outer-most WSDL file is the WSDL file defined by the <wsdl-file> element in the webservices.xml file.

   Each web service has an endpoint address, like http://example.com/services/stockquote. You can retrieve the outer-most WSDL file (defined by the <wsdl-file> element within the webservices.xml file) by appending the string "/wsdl" or "/wsdl/" to the endpoint address, for example, http://example.com/services/stockquote/wsdl.
2. Retrieve the imported WSDL files. When the outer-most WSDL file imports other WSDL or XSD files, these imported files can be retrieved by appending the relative path to the URL, which is used to retrieve the outer-most WSDL file. This is also true for WSDL files that import other files. This process is similar to the use of relative hyperlinks in HTML documents. If an HTML document contains a hyperlink to other documents, the relative path is appended to create the URL to access the hyperlinked documents.

Example

Suppose you have an application with the following directory structure:

```
<module-root>/
 WEB-INF/
  webservices.xml    /* the <wsdl-file> element points to "WEB-INF/wsdl/fooImpl.wsdl"*/
  web.xml
```

```
ibm-webservices-bnd.xml

wsdl/
 fooImpl.wsdl   /* imports foo.wsdl which is an interface wsdl */
 foo.wsdl       /* type definition for the interface */
```

If the SOAP address for the foo service is `http://examples.com:9080/services/foo`, the simple way to retrieve the foo service's outer-most WSDL is with the following form: `http://examples.com:9090/services/foo/wsdl` or `http://examples.com:9090/services/foo/wsdl/`. The URL is redirected to `http://examples.com:9090/services/foo/wsdl/fooImpl.wsdl`, where `fooImpl.wsdl` is the name of the outer-most WSDL file.

Since the `fooImpl.wsdl` file has the import `<import namespace="http://examples.com/foo" location="a/b/foo.wsdl>`, use the URL `http://examples.com:9090/services/foo/wsdl/a/b/foo.wsdl` to obtain the `foo.wsdl` file.

Running an unmanaged web services JAX-RPC client

WebSphere Application Server Version 8.0 and the Application Client for WebSphere Application Server Version 8.0 provides a thin Java Platform, Standard Edition 6 (Java SE 6) web services client runtime implementation that is based on the Java API for XML-based RPC (JAX-RPC) 1.1 specification. The Thin Client for JAX-RPC with WebSphere Application Server is a stand-alone Java SE 6 client environment that enables running unmanaged JAX-RPC web services client applications in a non-WebSphere environment to invoke web services that are hosted by the application server.

Before you begin

Note: You can use the Thin Client for JAX-RPC with WebSphere Application Server as a stand-alone client run time in a pure Java SE environment, or within an OSGi environment. The Thin Client for JAX-RPC is not supported when running within WebSphere Application Server or WebSphere Application Client environments. In this version of the application server, with the exception of the Administration Thin Client, other Thin Client run times provided with the application server can also reside in the CLASSPATH and coexist with the Thin Client for JAX-RPC.

Before you can set up a JAX-RPC unmanaged client environment you will need to obtain the Thin Client for JAX-RPC Java archive (JAR) file. To obtain the Thin Client for JAX-RPC, you must either install the application server or the application client.

The Thin Client for JAX-RPC JAR file, `com.ibm.ws.webservices.thinclient_8.0.0.jar`, is located in the *app_server_root*`\runtimes` directory. Refer to the license agreements to ensure correct usage and for limitations on copies of the Thin Client for JAX-RPC outside of the WebSphere environment.

The Thin Client for JAX-RPC is supported in the following environments:

- IBM Software Development Kits (SDKs) Version 6.0
- Sun Java Development Kit (JDK) Version 6.0 that are provided by IBM
- non-IBM SDKs Version 6.0 with this limitation:
  - Xerces limitation on non-IBM SDKs

    If you are using a non-IBM SDK, because of dependencies with the Xerces implementation, you will need to download Xerces-J version 2.6.2 and set it in the classpath before attempting to run the Thin Client for JAX-RPC.
  - Equinox 3.6 OSGi runtime environments

About this task

Note: WS-Addressing is not supported for JAX-RPC web services in an unmanaged client environment. If you need to use WS-Addressing, or a web service standard that relies on WS-Addressing, such as

WS-Notification, you must use the Thin Client for Java API for XML-based Web Services (JAX-WS) instead. To learn how to setup and run the Thin Client for JAX-WS, see the Thin Client for JAX-WS documentation.

Procedure

1. Configure the path. You can add the Java `bin` directories to your path by typing:
2. Configure the classpath.

```
export CLASSPATH=.:<your_web_services_thin_client_install_directory>/com.ibm.ws.webservices.thinclient_8.0.0.jar:
<your_application_jars>;$CLASSPATH
```

   - If you are using a non-IBM SDK, obtain a Xerces `xml-apis.jar` and `xercesImpl.jar` from the Xerces web site and configure the classpath definition.

```
export CLASSPATH=.:<your_Xerces_install_directory>/xml-apis.jar:<your_Xerces_install_directory>
\xercesImpl.jar:$CLASSPATH
```

3. Configure SSL for the client.
   a. Add the following system properties to the Java command:

```
-Dcom.ibm.SSL.ConfigURL=file:///home/sample/ssl.client.props
```

   You can obtain the `ssl.client.props` file from the WebSphere Application Server installation and modify the file to suit your environment. You must, at a minimum, update the location of the `com.ibm.ssl.keyStore` and `com.ibm.ssl.trustStore` key files in the `ssl.client.props` file to the match location of your target environment. For example, use these SSL configuration settings when running the application with a Sun JRE:

```
com.ibm.ssl.protocol=SSL
com.ibm.ssl.trustManager=SunX509
com.ibm.ssl.keyManager=SunX509
com.ibm.ssl.contextProvider=SunJSSE

com.ibm.ssl.keyStoreType=JKS
com.ibm.ssl.keyStoreProvider=SUN
com.ibm.ssl.keyStore=/home/user1/etc/key.jks

com.ibm.ssl.trustStoreType=JKS
com.ibm.ssl.trustStoreProvider=SUN
com.ibm.ssl.trustStore=/home/user1/etc/trust.jks
```

   The key store file and trust store file must be created using the Java keytool utility before the application runs. The automatic key file generation is not supported with a non-IBM product JRE.

4. Enter the following command to run your client application:

```
$JAVA_HOME/bin/java -Dcom.ibm.SSL.ConfigURL=file:///home/sample/ssl.client.props <your_client_application>
```

Results

You have set up an unmanaged JAX-RPC client runtime environment that can be used to invoke web services hosted on a WebSphere Application Server.

Running an unmanaged web services JAX-WS client

WebSphere Application Server provides a thin Java Platform, Standard Edition 6 (Java SE 6) web services client runtime implementation that is based on the Java API for XML-based Web Services (JAX-WS) 2.2 specification. The Thin Client for JAX-WS with WebSphere Application Server is a stand-alone Java SE 6 client environment that enables running unmanaged JAX-WS web services client applications in a non-WebSphere environment to invoke web services that are hosted by the application server.

Before you begin

Note: You can use the Thin Client for JAX-WS with WebSphere Application Server as a stand-alone client run time in a pure Java SE environment, or within an OSGi environment. The Thin Client for JAX-WS is not supported running within WebSphere Application Server or WebSphere Application Client environments. In this version of the application server, with the exception of the

Administration Thin Client, other Thin Client run times provided with the application server can also reside in the CLASSPATH and coexist with the Thin Client for JAX-WS.

Before you set up a JAX-WS unmanaged client execution environment, obtain the Thin Client for JAX-WS Java archive (JAR) file. To obtain the Thin Client for JAX-WS, install WebSphere Application Server Version 8.0 or the Application Client for WebSphere Application Server Version 8.0. The Thin Client for JAX-WS JAR file, `com.ibm.jaxws.thinclient_8.0.0.jar`, is located in the *app_server_root*`\runtimes` directory.

Copy the Thin Client for JAX-WS, `com.ibm.jaxws.thinclient_8.0.0.jar` file and the `endorsed_apis_8.0.0.jar` files, to other machines to create a lightweight client environment that enables communications with the product. Copies of the Thin Client for JAX-WS are subject to the same terms and conditions of the license agreement for the WebSphere product where you obtained the Thin Client for JAX-WS. Refer to the license agreements for correct usage and other limitations.

The Thin Client for JAX-WS is supported in the following environments:

- IBM Software Development Kits (SDKs) Version 6.0
- non-IBM SDKs V6.0 with the following limitation:
  - Xerces limitation on non-IBM SDKs

    You must download Xerces-J Version 2.6.2, and add the file to the classpath when setting up the Thin Client for JAX-WS environment.
  - WS-SecurityKerberos on non-IBM SDKs

    WS-SecurityKerberos is not supported with the Sun JDK or other non-IBM SDKs. Applications running in a Thin Client for JAX-WS environment that make use of WS-Security message level protection and use Kerberos security tokens as described in the Web Services Security Kerberos Token Profile 1.1 specification, do not correctly work on non-IBM JDKs. This limitation exists because of a dependancy on the IBM JGSS provider that is only available within IBM SDKs.
- Equinox 3.6 OSGi runtime environments

About this task

Set up a Thin Client for JAX-WS environment by completing the following steps.

Procedure

1. Copy the Thin Client for JAX-WS JAR file, `com.ibm.jaxws.thinclient_8.0.0.jar`, to other machines to create a lightweight client environment.
2. Use the Java Endorsed Standards Override Mechanism to override APIs that are available in the JDK on your system.

   Because the Thin Client for JAX-WS with WebSphere Application ServerVersion 8.0 requires APIs that are more current than what is available in JDKs to support JAX-WS 2.2 and JAXB 2.2 implementations, you must override the default JDK APIs in use by your system by using the Java Endorsed Standards Override Mechanism.

   Copy the *app_server_root*`\runtimes\endorsed\endorsed_apis_8.0.0.jar` file into the default directory, `JAVA_JRE\lib\endorsed`. Alternatively, you can use the `java.endorsed.dirs` property to specify a directory of your choice. If you choose to use an alternative directory, it is a best practice to only include the `endorsed_apis` JAR file.
3. Configure the path. Enter the following command to add the Java `bin` directories to your path:
4. Configure the classpath.
   - Add the Thin Client for JAX-WS JAR file to the classpath definition.

Important: If the Thin Client is to use the Java Message Service (JMS), then **all** the JAR files that are required must be in the classpath for JMS and for the client so that entries exist for all the required files. Otherwise, required files will not be identified as installed and ready for use.

```
export CLASSPATH=.:<your_jax-ws_thin_client_install_directory>/com.ibm.jaxws.thinclient_8.0.0.jar:
<your_application_jars>;$CLASSPATH
```

- If you are using a non-IBM SDK, obtain a Xerces `xml-apis.jar` file and `xercesImpl.jar` file from the Xerces website, and configure the classpath definition.

```
export CLASSPATH=.:<your_Xerces_install_directory>/xml-apis.jar:<your_Xerces_install_directory>
\xercesImpl.jar:$CLASSPATH
```

5. Configure SSL for the client.
   a. Add the following system properties to the Java command:

```
-Dcom.ibm.SSL.ConfigURL=file:///home/sample/ssl.client.props
```

   You can obtain the `ssl.client.props` file from the WebSphere Application Server installation and modify the file to suit your environment. You must, at a minimum, update the location of the `com.ibm.ssl.keyStore` and `com.ibm.ssl.trustStore` key files in the `ssl.client.props` file to the match location of your target environment. For example, use these SSL configuration settings when running the application with a Sun JRE:

```
com.ibm.ssl.protocol=SSL
com.ibm.ssl.trustManager=SunX509
com.ibm.ssl.keyManager=SunX509
com.ibm.ssl.contextProvider=SunJSSE

com.ibm.ssl.keyStoreType=JKS
com.ibm.ssl.keyStoreProvider=SUN
com.ibm.ssl.keyStore=/home/user1/etc/key.jks

com.ibm.ssl.trustStoreType=JKS
com.ibm.ssl.trustStoreProvider=SUN
com.ibm.ssl.trustStore=/home/user1/etc/trust.jks
```

   The key store file and trust store file must be created using the Java keytool utility before the application runs. The automatic key file generation is not supported with a non-IBM product JRE.

6. Run your client application:
   - Enter the following command if you have copied the `endorsed_apis_8.0.0.jar` file into the `JAVA_JRE\lib\endorsed` default directory; for example:

```
$JAVA_HOME/bin/java -Dcom.ibm.SSL.ConfigURL=file:///home/sample/ssl.client.props <your_client_application>
```

   - Enter the following command if you have copied the `endorsed_apis_8.0.0.jar` file into a directory other than the default `JAVA_JRE\lib\endorsed` directory; for example:

```
$JAVA_HOME/bin/java
-Djava.endorsed.dirs=<directory_that_includes_endorsed_apis_8.0.0.jar>
-Dcom.ibm.SSL.ConfigURL=file:///home/sample/ssl.client.props <your_client_application>
```

Results

You have set up an unmanaged JAX-WS client runtime environment to invoke web services hosted on a WebSphere Application Server.

Testing web services-enabled clients

Once you have developed, assembled, deployed and configured your web service, you can test to confirm your web service runs in the application server environment.

Before you begin

Before testing your web services Java client to confirm your web service runs in the WebSphere Application Server environment, verify that the server endpoint specified in the client Web Services Description Language (WSDL) file is running and available.

About this task

Tests are run differently depending on whether the client module is in a Java EE container or if the client is running in the Thin Client for Java API for XML-based RPC (JAX-RPC) with WebSphere Application Server application environment or the Thin Client for Java API for XML-Based Web Services (JAX-WS) with WebSphere Application Server application environment.

Procedure

1. Test an unmanaged client JAR file by running your application with the **java** command.

   For JAX-WS applications:

```
"$JAVA_HOME/bin/java"
-Djava.endorsed.dirs=<your_jax-ws_thin_client_install_directory>/endorsed_apis_8.0.0.jar
-classpath
"<your_JAX-WS_thin_client_install_directory>/runtimes/com.ibm.jaxws.thinclient_8.0.0.jar:
<list_of_your_application_jars_and_classes>"
<fully_qualified_class_name_to_run> <your_application_parameters>
```

   The unmanaged client application runs.

2. Test a managed JAX-RPC client EAR file or an unmanaged JAX-WS client EAR file.
   a. Run your client application with the **launchClient** command. The following example illustrates the use of this command:

```
launchClient clientEar
```

Results

You have a web services-enabled client that is tested. Now you can add security measures to the web service. Security measures are optional.

Administering deployed web services applications

You can administer deployed web services applications using the administrative console.

Before you begin

Before you can administer a web service application, you need to deploy your web service application.

About this task

You can use the administrative console to administer Java API for XML-Based Web Services (JAX-WS) service provider or service client applications or Java API for XML-based RPC (JAX-RPC) web services.

Procedure

- Administer service providers. You can administer your service providers using the following ways:
  - View service providers at the cell level using the administrative console. You can view the details of your service provider, manage the policy sets for the service, its endpoints and operations, and assign bindings for the policy set attachment at the cell level.
  - View service providers at the application level using the administrative console. You can view the details of your service provider, manage the policy sets for the service, its endpoints and operations, and assign bindings for the policy set attachment at the application level.
  - Manage policy sets and bindings for service providers. You can view the details of your service provider, manage the policy sets for the service, its endpoints and operations, and assign bindings for the policy set attachment.
  - Manage policy sets and bindings for service providers at the application level using the administrative console. You can manage policy sets for the provider, its endpoints, and operations, and assign bindings for the policy set attachment at the application level.

  - View WSDL document using the administrative console . You can view the WSDL document for your JAX-WS application.
- Administer service clients. You can administer your service clients using the following ways:
  - View service clients at the cell level . Your application server instance can have one or more applications deployed on it that contain service clients. You can view a list of your service clients at the cell level using the administrative console.
  - View service clients at the application level . Your application server instance can have one or more applications deployed on it that contains service clients. You can view the service client names that are referenced in an application.
  - Manage policy sets and bindings for service clients. You can view details of your service client reference, manage the policy sets for the service, its endpoints and operations, and assign bindings for the policy set attachment.
  - Manage policy sets and bindings for service clients at the application level. You can manage policy sets for your service client applications or its service references, endpoints, or operations and assign bindings for the policy set attachment at the application level.
- View the deployment descriptors.. View the web services server and client deployment descriptors for a deployed web services application. You can view the bindings in the deployment descriptors. The deployment descriptors are required for JAX-RPC web services. You can optionally use the `webservices.xml` deployment descriptor to augment or override application metadata specified in annotations within your JAX-WS web services.
- Configure the scope of a web service port..**(JAX-RPC applications only)** When a web service application is deployed into WebSphere Application Server, an instance is created for each application or module. The instance contains deployment information for the web module or enterprise bean module, including implementation scope and client bindings information. There are three levels of scope that you can set: application, session and request.
- Suppress the compensation service Not all web servers are configured to handle SOAP messages containing CoordinationContext elements. WebSphere Application Server allows you to configure a custom property for the compensation service which processes a predefined list of Enterprise Java Beans for which no CoordinationContext should be sent on web service requests.

Overview of service and endpoint listeners

Using the administrative function of this product, you can control throughput by starting and stopping individual service listeners and endpoint listeners. When you stop a service listener, this causes any associated endpoint listeners to stop listening to any new inbound requests and the application server rejects any new incoming requests for that service. Additionally, resources become free that can be used to service requests that are already being processed for the service or to service new incoming requests for other services.

Service listener

The service listener can be started or stopped. When a service listener is stopped, all the endpoints for the service are stopped and new inbound requests are no longer processed. The endpoints for the service send out 404 error message response code to indicate that the service listener is currently stopped and cannot service new inbound requests. When the service listener is started, all the endpoints for the service resume processing of new inbound requests.

Endpoint listener

The endpoint listener can be started or stopped. When a service endpoint listener is stopped, the specific endpoint stops listening to any new inbound request. The requests that are already being processed are not affected. The endpoint sends out a 404 error message response code to indicate that the endpoint is currently stopped and cannot service a new, inbound request. When the endpoint listener is started, the specific endpoint resumes listening on new inbound requests. The state of a particular service endpoint does not impact the listening function of other endpoints for the same service.

Administration of service and endpoint listeners

The administration function of the product is enhanced to support service and endpoint listeners. You can use MBeans such as EndpointManager and the EndpointCentralManager to invoke service and endpoint listeners.

After an application containing a web service is installed, you want to verify that the service is installed correctly. You also want to monitor its service listener state, and update the listener state as needed to control the throughput. One option is to use the collection view of service providers in the administrative console of the product to locate the service provider of interest and observe its listener state.

If you do not want the listener state, then select the service and choose to start or stop the service listener. As the system starts or stops the service listener, the status indicator for the service is updated to show that it is started or stopped. This scenario helps you to throttle back traffic to a specific service as needed but leaves the containing application and other services in the application running. See service providers at the cell level using the administrative console. You can also reference service providers at the application level using the administrative console.

Important: You can only start or stop the service listener using the administrative console.

Another option is to use MBeans. With MBeans, you can invoke the startListener or stopListener operations in the EndpointCentralManager MBean or EndpointManager MBean to start or stop the listener service. The administrative console option does not expose the function of starting or stopping the listening state of a specific endpoint in a service. However, the MBeans option provides this capability. You can use scripting to invoke the MBean operations to start or stop the endpoint listener.

EndpointCentralManager MBean

There is an EndpointCentralManager MBean instance in the deployment manager, AdminAgent, and stand-alone server. The EndpointCentralManager MBean provides the administrative convenience to start and stop the service or endpoint listeners across all the deployment targets such as the cluster members in a cluster. You do not have to know the target servers for the service application.

EndpointManager MBean

There is an EndpointManager MBean instance for each web services application module in a server. This MBean instance is created when the application module is started. The MBean instance is deleted when the module is stopped. The MBean provides the start and stop operations to change the service and endpoint listener state. The MBean can also send a Java Management Extension (JMX) notification whenever the listener state has changed.

Viewing service providers at the cell level using the administrative console

You can use this administrative console page to view and manage your service providers at the cell level.

Before you begin

Before completing this task, you need to install one or more Java API for XML-Based Web Services (JAX-WS).

About this task

You can view a list of your installed service providers, such as JAX-WS web services providers in a cell. You can start or stop the service listener.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation

to learn more about the valid roles for the application server.

Procedure

1. Open the administrative console.
2. In the navigation pane, expand **Services > Service providers**.
3. Locate the web service of interest by name and the associated deployed asset in Deployed Asset column.
4. [Optional] Click the service of interest in the Name column to view the detail of the service and manage the policy sets and bindings for that service.
5. Click **Start Listener** or **Stop Listener** to start or stop the service listener. Starting the service listener makes all the endpoints for the service provider available and ready to receive messages. Stopping the listener makes all the endpoints for the service provider unavailable.

Results

When you finish this task, you have viewed the service providers at the cell level. You have also started or stopped the service listener.

What to do next

Proceed to view service providers at the application level using the administrative console.

Service providers collection at the cell level

Use this page to view and manage service providers at the cell level. Java Application Programming Interface (API) for XML-Based Web Services (JAX-WS) service providers are displayed in this view. Java API for XML Remote Procedure Call (JAX-RPC) service providers are not displayed in this view.

To view a service provider using this administrative console page, perform the following steps:

1. Expand **Services** > **Service Providers**.
2. Locate the service of interest by name in the Name column.
3. Click the service of interest in the Name column.
4. View the detail of the service.

To change the listening state of a service, perform the following steps:

1. Select the service of interest, and click **Start Listener** to start the listener service or click **Stop Listener** to stop the listener service. Starting the service listener makes all the endpoints for the service provider to be available and to receive messages. Stopping the listener makes all the endpoints for the service provider unavailable.
2. [Optional] Select the deployed asset link in the Deployed Asset column to access the deployed asset settings page.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Name:

Specifies the name of the service provider. The service, *QName* (`Java class javax.xml.namespace.QName`), is displayed when you hover your mouse pointer over the Name field.

Type:

Specifies the type of service, such as a JAX-WS web service and Web Services Notification (WSN) client service. You can filter by the type of service. If your service was migrated from the Feature Pack for Web Services, you can only filter by the name of the service.

Deployed Asset:

Represents a Java Platform, Enterprise Edition (Java EE) application or a WS-Notification service point.

Table 243. Type of deployed asset. Indicates the type of deployed asset.

	Java EE application
	WS-Notification Service point application

Status:

Indicates the status for the service listener.

Table 244. Status for the service listener. This table describes the status indicators for the deployed asset, service endpoints and service listener.

	Service endpoints are listening.
	Service endpoints are running, but the listener control is not supported because of the characteristics of this service; for example, the application is installed on a Feature Pack for Web Services server.
	Either the deployed asset is partially started or the service endpoints are listening on some, but not all the target servers.
	The deployed asset is partially started and the listener control is not supported.
	Service endpoints are not listening, but the deployed asset is running.
	Service endpoints are not listening because the deployed asset is not running.
	Service endpoints are not listening because the deployed asset is not running. Listener control is not supported.
	Deployed asset is partially stopped. Service endpoints are not listening.
	Deployed asset is partially stopped. Service endpoints are not listening. Listener control is not supported because of the characteristics of this service; for example, the application is installed on a Feature Pack for Web Services server.
	Status cannot be determined.

Viewing service providers at the application level using the administrative console

You can use this administrative console page to view and manage your service providers at the application level.

Before you begin

Before completing this task, you need to install a Java API for XML-Based Web Services (JAX-WS) web service.

About this task

You can view a list of your service providers, such as JAX-WS web services providers at the application level. You can start the service listener to make all the endpoints for the service to be available and to receive messages. You can also stop the service listener.

Procedure

1. Open the administrative console.

2. To view the service providers, click **Applications > Application Types > WebSphere enterprise applications** >*Service_provider_application_instance* > **Service providers**.
3. [Optional] Click a module that contains a service to view the module information.
4. Depending on the current application status, click **Start Listener** or **Stop Listener** to start or stop the service listener. Starting the service listener makes all the endpoints for the service available and ready to receive messages. Stopping the listener makes all the endpoints for the service unavailable. See Endpoint and service listeners overview.

Results

When you complete this task, you have viewed and managed the service providers at the application level.

What to do next

You can proceed to managing policy sets using the administrative console. You can click on a service provider to manage the policy sets and bindings for that service.

Service providers collection at the application level

Use this page to view and manage service providers at the application level.

To view a service provider using this administrative console page, perform the following steps:

1. Click **Applications > Application Types > WebSphere enterprise applications** >*Service_provider_application_instance* > **Service providers**.
2. Locate the service of interest by name in the Name column.
3. Click the service of interest in the Name column.
4. View the detail of the service.

To change the listening state of a service, perform the following steps:

1. Select the service of interest, and click **Start Listener**, to start the service listener or **Stop Listener**, to stop the service listener. Starting the service listener makes all the endpoints for the service provider to be available and to receive messages. Stopping the listener makes all the endpoints for the service provider to be unavailable.
2. [Optional] Click a module name in the Module column to access the module detail page.

Name:

Specifies the name of the service provider. The service *QName* (`Java class javax.xml.namespace.QName`) is displayed when you hover your mouse pointer over the Name field.

Type:

Specifies the type of service.

Module:

Specifies the name of the module that contains the service.

Status:

Indicates the status for the service listener.

Table 245. Status for the service listener. This table describes the status indicators for the deployed asset, service endpoints and service listener.

	Service endpoints are listening.

Table 245. Status for the service listener (continued). This table describes the status indicators for the deployed asset, service endpoints and service listener.

	Service endpoints are running, but the listener control is not supported because of the characteristics of this service; for example, the application is installed on a Feature Pack for Web Services server.
	Either the deployed asset is partially started or the service endpoints are listening on some, but not all the target servers.
	The deployed asset is partially started and the listener control is not supported.
	Service endpoints are not listening, but the deployed asset is running.
	Service endpoints are not listening because the deployed asset is not running.
	Service endpoints are not listening because the deployed asset is not running. Listener control is not supported.
	Deployed asset is partially stopped. Service endpoints are not listening.
	Deployed asset is partially stopped. Service endpoints are not listening. Listener control is not supported because of the characteristics of this service; for example, the application is installed on a Feature Pack for Web Services server.
	Status cannot be determined.

Viewing the detail of a service provider and managing policy sets using the administrative console

Use this administrative console task to view the detail of your service provider and to manage the policy sets for the service, its endpoints and operations. You can also use this page to manage policy sets and bindings or to access additional information for a Service Component Architecture (SCA) composition unit for service providers.

Before you begin

Before completing this task, you need to install one or more Java API for XML-Based Web Services (JAX-WS) or SCA artifacts.

About this task

You have developed a web service that contains all the necessary artifacts and deployed your web services application into your application server instance. Now, you can attach or detach policy sets and manage the associated bindings.

The policy set information is displayed in the Attached Policy Set column. If a policy set is directly attached, then the policy set name appears; for example, `WS-I RSP` is displayed. If there is no policy set attached, and a policy set is attached at a higher level, then the word *inherited* in parentheses is appended to the policy set name, as the following example demonstrates: `WS-I RSP (inherited)`. If there is no policy set attached directly or at a higher level, then `None` is displayed.

Every attachment of a policy set to a service artifact has an assigned binding. The binding information is displayed in the Binding column. The Binding column can contain the following values:

- Not applicable. There is no policy set attached, either directly or to a higher level service resource.
- *Binding_name* or Default. The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, `MyBindings1`. Default is displayed if a policy set is attached directly but the service resource uses the default bindings.
- *Binding_name* (inherited) or Default (inherited). A service resource inherits the bindings from an attachment to a higher level resource.

In Version 7.0 and later, there are two types of bindings, application specific bindings and general bindings.

Application specific binding

You can create application specific bindings only at a policy set attachment point. These bindings are specific to and constrained to the characteristics of the defined policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have very limited reuse across policy sets.

When you create an application specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding and fully configure the bindings for each policy that you have added. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application specific bindings.

For service providers, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service provider resources that have an attached policy set. See service providers policy sets and bindings collection. Similarly, for service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service client policy set and bindings collection.

General bindings

General bindings were introduced in Version 7.0. These bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust service attachments. Though general bindings are highly reusable, they are however not able to provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings:

- General provider policy set bindings
- General client policy set bindings

You can create general provider policy set bindings by accessing **Services > Policy sets > General provider policy set bindings** > **New** in the general provider policy sets panel or by accessing **Services > Policy sets > General client policy set bindings** > **New** in the general client policy set and bindings panel. See defining and managing service client or provider bindings. General provider policy set bindings might also be used for trust service attachments.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Procedure

1. Open the administrative console.
2. In the navigation pane, expand **Services > Service providers >***Service_provider_application_instance* **Service providers**.
3. [Optional] Use the **WSDL document** link under the **Additional Properties** section to view the Web Services Description Language (WSDL) for the service. The Application and Module links provide access to the application and module settings page.

   For SCA service providers, the **Additional Properties** section does not show the WSDL document link, instead, there is a composition unit link. Click **Composition unit** to see the composition unit detail page.
4. Select one or more service, endpoints and operations of interest and view the associated service, endpoints and operations.
5. Do one or more of the following actions:

- Click **Attach**, to attach a policy to a selected service, endpoint or operation.
- Click **Detach**, to detach a policy set from a list of attached policy sets for a service, endpoint or operation.

6. Click **Assign Binding** to select from a list of available bindings for the selected policy set attachment. All the bindings are listed along with the following options:

Table 246. Binding descriptions. Use the descriptions of the default bindings for the selected policy set attachment.

Bindings	Description
Default	Specifies the default binding for the selected service, endpoint or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the Default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used. For any policy set attachment, the runtime checks to see if the attachment includes a binding. If so, it uses that binding. If not, the runtime checks in the following order and uses the first available default binding: 1. Default general bindings for the server 2. Default general bindings for the domain in which the server resides 3. Default general bindings for the global security domain
New Application Specific Binding	Select this option to create a new application specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached.
Provider sample	Select this option to use the Provider sample binding.
Provider sample V2	Select this option to use the Provider sample V2 binding when you are using either the Kerberos V5 WSSecurity default or the TrustServiceKerberosDefault policy sets.
Saml Bearer Provider sample	Select this option to use the Saml Bearer Provider sample. The Saml Bearer Provider sample extends the Provider sample binding to support SAML Bearer token usage scenarios. You can use this sample with any of the SAML bearer token default policy sets.
Saml HoK Symmetric Provider sample	Select this option to use the Saml HoK Symmetric Provider sample. The Saml HoK Symmetric Provider sample extends the Provider sample binding to support SAML holder-of-key (HoK) symmetric key token usage scenarios. You can use this sample with one of the SAML HoK Symmetric key default policy sets: either SAML11 HoK Symmetric WSSecurity default or SAML20 HoK Symmetric WSSecurity default.

7. To close the drop down list for the assign binding action, click **Assign Binding**.

Results

When you finish this task, a policy set is attached, detached or a binding is assigned to the service artifact.

Example

You have configured a service provider, `EchoService12` in the application instance, WSSampleServicesSei. Now you want to attach the WS-Security policy to the `EchoService12Port` endpoint of the `EchoService12` service provider. First locate **`EchoService12`** in the Services > Service providers collection. Click the **`EchoService12`** service provider. Select the check box for the `columoService12Port` resource. Click **Attach** and select **WSSecurity** default policy from the list. Click **Save**, to save your changes to the master configuration.

What to do next

You can now proceed to manage policy sets and bindings for service providers at the application level using the administrative console.

Service provider settings

Use the Service provider settings page to manage the settings for your service providers. You can attach and detach policy sets to an application, its service, endpoints or operations. You can create new bindings,

or use bindings that you have already created for an attached policy set. You can view or change whether the service provider can share its current policy configuration.

Use the **WSDL document** link to view the Web Services Description Language (WSDL) for the service. The Application and Module links provide access to the application and module settings page.

To view this administrative console page, click **Services** > **Service providers** > ***service_provider_instance***.

You can also view this page by clicking **Applications** > **Application Types** > **WebSphere enterprise applications** > ***service_provider_application_instance*** > **Service providers** > ***service_provider_instance***.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Table 247. Button descriptions. Use the buttons to manage policy sets and policy set bindings for a service provider, its endpoints, or operations.

Bindings	Description
Attach Policy Set	Click this button to view a list of policy sets available for attachment to the selected service, endpoint, or operation. Select a policy set from the list to attach and it is attached to the selected service, endpoint, or operation. To close the menu list, click **Attach Policy Set**.
Detach Policy Set	Click this button to detach a policy set from a selected service, endpoint, or operation. After the policy set is detached, if there is no policy set attached to an upper level service resource, the **Attached Policy Set** column displays **None** and the **Binding** column displays **Not Applicable**. If there is a policy set attached to an upper level service resource, the **Attached Policy Set** column displays ***policy_set_name*** **(inherited)** and the binding used for the upper level attachment is applied. The binding name is displayed followed by **(inherited)**.

Table 247. Button descriptions (continued). Use the buttons to manage policy sets and policy set bindings for a service provider, its endpoints, or operations.

Bindings	Description
Assign Binding	Click this button to select from a list of available bindings for the selected policy set attachment. The options include the following: **Default** Specifies the default binding for the selected service reference, endpoint, or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application-specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used. For any policy set attachment, the run time checks to see if the attachment includes a binding. If so, it uses that binding. If not, the run time checks in the following order and uses the first available default binding: 1. Default general bindings for the server 2. Default general bindings for the domain in which the server resides 3. Default general bindings for the global security domain **New Application Specific Binding** Select this option to create a new application-specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached. **Provider sample** Select this option to use the Provider sample binding. **Provider sample V2** Select this option to use the Provider sample V2 binding when you are using either the Kerberos V5 WSSecurity default or the TrustServiceKerberosDefault policy sets. **Saml Bearer Provider sample** Select this option to use the Saml Bearer Provider sample. The Saml Bearer Provider sample extends the Provider sample binding to support SAML Bearer token usage scenarios. You can use this sample with any of the SAML bearer token default policy sets. **Saml HoK Symmetric Provider sample** Select this option to use the Saml HoK Symmetric Provider sample. The Saml HoK Symmetric Provider sample extends the Provider sample binding to support SAML holder-of-key (HoK) symmetric key token usage scenarios. You can use this sample with one of the SAML HoK Symmetric key default policy sets: either SAML11 HoK Symmetric WSSecurity default or SAML20 HoK Symmetric WSSecurity default. To close the menu list, click **Assign Binding**.

Service provider:

Specifies the name of the service provider that is displayed.

Policy Set Attachments:

Service/Endpoint/Operation:

Specifies the name of the service provider, endpoint, or operation that is contained in a service.

Attached Policy Set:

Specifies the policy set that is attached to a service provider, endpoint, or operation.

The Attached Policy Set column can contain the following values:

- **None**. No policy set is attached, either directly or to a higher-level service resource.
- ***Policy_set_name***. The name of the policy set that is attached directly to the service resource, for example, `WS-I RSP`.
- ***Policy_set_name* (inherited)**. The name of the policy set that is not attached directly to a service resource, but that is attached to a higher-level service resource.

When the value in the column is a link, click the link to view or change settings about the attached policy set.

Binding:

Specifies the binding configuration that is available for a service provider, endpoint, or operation.

The Binding column can contain the following values:
- **Not applicable**. No policy set is attached, either directly or to a higher-level service resource.
- ***Binding_name*** or **Default**. The binding name is displayed if a policy set is attached directly and an application specific binding or a general binding is assigned, for example, `MyBindings1`. **Default** is displayed if a policy set is attached directly but the service resource uses the default bindings.
- ***Binding_name* (inherited)** or **Default (inherited)**. A service resource inherits the bindings from an attachment to a higher-level resource.

When the value in the Binding column is a link, click the link to view or change settings about the binding.

About policy set bindings

In this release, there are two types of bindings: application-specific bindings and general bindings.

Application-specific bindings

You can create application-specific bindings only at a policy set attachment point. These bindings are specific to, and constrained by, the characteristics of the defined policy. Application-specific bindings can provide configuration for advanced policy requirements such as multiple signatures; however, these bindings are reusable only within an application. Also, application-specific bindings have very limited reuse across policy sets.

When you create an application-specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding, and fully configure the bindings for each policy that you add. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application-specific bindings.

For service providers, you can create application-specific bindings only by selecting **Assign Binding** > **New Application Specific Binding**, on the Service providers policy sets and bindings collection page, for service provider resources that have an attached policy set. Similarly, for service clients, you can create application-specific bindings only by selecting **Assign Binding** > **New Application Specific Binding**, on the Service clients policy sets and bindings collection page, for service client resources that have an attached policy set.

General bindings

You can configure general bindings to be used across a range of policy sets and they can be reused across applications and for trust service attachments. Although general bindings are highly reusable, they cannot provide configuration for advanced policy requirements such as multiple signatures. There are two types of general bindings: general provider policy set bindings and general client policy set bindings.

You can create general provider policy set bindings by clicking **Services** > **Policy sets** > **General provider policy set bindings** > **New** in the general provider policy sets panel, or by clicking **Services** > **Policy sets** > **General client policy set bindings** > **New** in the general client policy set and bindings panel. For details about defining and managing service client or provider bindings, see the related links. General provider policy set bindings might also be used for trust service attachments.

Policy Sharing:

Specifies whether the service provider can share its current policy configuration.

The Policy sharing column can contain the following values:

- **Not applicable**. The resource does not have a policy set attached, so there is no policy configuration to share.
- **Disabled**. The policy set of the resource cannot be shared. This is the default setting if a policy set is attached to a service.
- **Enabled**. The policy set of the resource can be shared.

When the value in the column is a link, click the link to view or change settings about how the policy configuration can be shared.

For a service, if the policy set is inherited from the parent application, the policy sharing value is also inherited, and you cannot change it. The value is not a link and it is followed by the term `inherited` in parentheses.

For an endpoint or operation, the value is not a link and it is followed by the term `inherited` in parentheses. The setting is inherited from the parent application or service and you cannot change it.

Managing policy sets and bindings for service providers at the application level using the administrative console

Use this administrative console task to manage policy sets for an application or its services, endpoints, and operations.

Before you begin

Before completing this task, you need to install one or more Java API for XML-Based Web Services (JAX-WS) and attach a policy set to each web service.

About this task

You have developed a web service that contains all the necessary artifacts and deployed your web services application into your application server instance. Now, you can attach or detach policy sets and manage the associated bindings.

The policy set information is displayed in the Attached Policy Set column. If a policy set is directly attached, then the policy set name appears; for example, `WS-I RSP` is displayed. If there is no policy set attached, and a policy set is attached at a higher level, then the word *inherited* in parentheses is appended to the policy set name, as the following example demonstrates: `WS-I RSP (inherited)`. If there is no policy set attached directly or at a higher level, then `None` is displayed.

Every attachment of a policy set to a service artifact has an assigned binding. The binding information is displayed in the Binding column. The Binding column can contain the following values:

- Not applicable. There is no policy set attached, either directly or to a higher level service resource.

- *Binding_name* or Default. The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, `MyBindings1`. Default is displayed if a policy set is attached directly but the service resource uses the default bindings.
- *Binding_name* (inherited) or Default (inherited). A service resource inherits the bindings from an attachment to a higher level resource.

In Version 7.0 and later, there are two types of bindings, application specific bindings and general bindings.

Application specific binding

You can create application specific bindings only at a policy set attachment point. These bindings are specific to and constrained to the characteristics of the defined policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have very limited reuse across policy sets.

When you create an application specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding and fully configure the bindings for each policy that you have added. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application specific bindings.

For service providers, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service provider resources that have an attached policy set. See service providers policy sets and bindings collection. Similarly, for service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service client policy set and bindings collection.

General bindings

General bindings were introduced in Version 7.0. These bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust service attachments. Though general bindings are highly reusable, they are however not able to provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings:

- General provider policy set bindings
- General client policy set bindings

You can create general provider policy set bindings by accessing **Services > Policy sets > General provider policy set bindings** > **New** in the general provider policy sets panel or by accessing **Services > Policy sets > General client policy set bindings** > **New** in the general client policy set and bindings panel. See defining and managing service client or provider bindings. General provider policy set bindings might also be used for trust service attachments.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Procedure

1. Open the administrative console.
2. **Applications > Application Types > WebSphere enterprise applications** >*Service_provider_application_instance* > **Service provider policy sets and bindings**.

[Optional] When you are accessing a business-level application, click **Business-level applications (BLA) > *My_BLA* > *BLA_instance*** > **Service provider policy sets and bindings**. Alternatively, click **Services > Service providers > *My_BLA* > *BLA_instance*** > **Service provider policy sets and bindings**.

3. Select the check box next to a service resource of interest.
4. Click **Attach** to attach a policy set to an application, service, endpoint or operation.
5. [Optional] Click **Detach** to detach a policy set from a list of attached policy sets for an application, service provider, endpoint or operation.
6. Click **Assign Binding** to select from a list of available bindings for the selected policy set attachment. All the bindings are listed along with the following options:

Table 248. Binding descriptions. Use the descriptions of the default bindings for the selected policy set attachment.

Bindings	Description
Default	Specifies the default binding for the selected service, endpoint or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the Default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used. For any policy set attachment, the runtime checks to see if the attachment includes a binding. If so, it uses that binding. If not, the runtime checks in the following order and uses the first available default binding: 1. Default general bindings for the server 2. Default general bindings for the domain in which the server resides 3. Default general bindings for the global security domain
New Application Specific Binding	Select this option to create a new application specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached.
Provider sample	Select this option to use the Provider sample binding.
Provider sample V2	Select this option to use the Provider sample V2 binding when you are using either the Kerberos V5 WSSecurity default or the TrustServiceKerberosDefault policy sets.
Saml Bearer Provider sample	Select this option to use the Saml Bearer Provider sample. The Saml Bearer Provider sample extends the Provider sample binding to support SAML Bearer token usage scenarios. You can use this sample with any of the SAML bearer token default policy sets.
Saml HoK Symmetric Provider sample	Select this option to use the Saml HoK Symmetric Provider sample. The Saml HoK Symmetric Provider sample extends the Provider sample binding to support SAML holder-of-key (HoK) symmetric key token usage scenarios. You can use this sample with one of the SAML HoK Symmetric key default policy sets: either SAML11 HoK Symmetric WSSecurity default or SAML20 HoK Symmetric WSSecurity default.

7. To close the drop down list for the assign binding action, click **Assign Binding**.

Results

When you finish this task, a policy set is attached or detached, and a binding is assigned to the service artifact.

Example

If you have configured a service provider application instance, `app1` and you want, for example, to attach the`Username WSSecurity default` policy set to your application, first locate `app1` application in the **Applications > Application Types > WebSphere enterprise applications**. Click `app1` > **Service provider policy sets and bindings** under the Web Services Properties section. Select the check box next to the `app1` service application. Click **Attach** and select `Username WSSecurity default` policy set. Click **Save**, to save your changes to the master configuration. You are returned to the **Applications > Application Types > WebSphere enterprise applications** page.

To assign a binding to the attached policy set, click app1 > **Service provider policy sets and bindings**. Select the check box next to the app1 service application and click **Assign Binding**. Select **Provider sample** binding from the list. Click **Save**, to save your changes to the master configuration.

What to do next

You can proceed to view service providers at the cell level using the administrative console.

Service provider policy sets and bindings collection

Use this page to attach and detach policy sets to an application, a service provider, its endpoints, or operations. You can select the default bindings, create new application-specific bindings, or use bindings that you created for an attached policy set. You can view or change whether the service provider can share its current policy configuration.

This page provides detail information for an application and its associated web service providers, endpoints, and operations. You can view and manage policy set attachments and bindings information using this page.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***Service_provider_application_instance*** > **Service provider policy sets and bindings**.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Table 249. Binding descriptions. Use the descriptions of the default bindings for the selected policy set attachment.

Bindings	Description
Attach Policy Set	Click this button to view a list of policy sets available for attachment to the selected service, endpoint, or operation. Select a policy set from the list to attach and it is attached to the selected service, endpoint, or operation. To close the menu list, click **Attach Policy Set**.
Detach Policy Set	Click this button to detach a policy set from a selected service, endpoint, or operation. After the policy set is detached, if there is no policy set attached to an upper level service resource, the **Attached Policy Set** column displays **None** and the **Binding** column displays **Not Applicable**. If there is a policy set attached to an upper level service resource, the **Attached Policy Set** column displays ***policy_set_name*** **(inherited)** and the binding used for the upper level attachment is applied. The binding name is displayed followed by **(inherited)**.

Table 249. Binding descriptions (continued). Use the descriptions of the default bindings for the selected policy set attachment.

Bindings	Description
Assign Binding	Click this button to select from a list of available bindings for the selected policy set attachment. The options include the following: **Default** Specifies the default binding for the selected service reference, endpoint, or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application-specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used. For any policy set attachment, the run time checks to see if the attachment includes a binding. If so, it uses that binding. If not, the run time checks in the following order and uses the first available default binding: 1. Default general bindings for the server 2. Default general bindings for the domain in which the server resides 3. Default general bindings for the global security domain **New Application Specific Binding** Select this option to create a new application-specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached. **Provider sample** Select this option to use the Provider sample binding. **Provider sample V2** Select this option to use the Provider sample V2 binding when you are using either the Kerberos V5 WSSecurity default or the TrustServiceKerberosDefault policy sets. **Saml Bearer Provider sample** Select this option to use the Saml Bearer Provider sample. The Saml Bearer Provider sample extends the Provider sample binding to support SAML Bearer token usage scenarios. You can use this sample with any of the SAML bearer token default policy sets. **Saml HoK Symmetric Provider sample** Select this option to use the Saml HoK Symmetric Provider sample. The Saml HoK Symmetric Provider sample extends the Provider sample binding to support SAML holder-of-key (HoK) symmetric key token usage scenarios. You can use this sample with one of the SAML HoK Symmetric key default policy sets: either SAML11 HoK Symmetric WSSecurity default or SAML20 HoK Symmetric WSSecurity default. To close the menu list, click **Assign Binding**.

Application/Service/Endpoint/Operation:

Specifies the name of the application and the associated service providers, endpoints or operations.

The Application/Service/Endpoint/Operation column lists the service application and the service providers, endpoints, or operations that the application contains.

Attached Policy Set:

Specifies the policy set that is attached to a service provider, endpoint, or operation.

The Attached Policy Set column can contain the following values:

- **None**. No policy set is attached, either directly or to a higher-level service resource.
- ***Policy_set_name***. The name of the policy set that is attached directly to the service resource, for example, WS-I RSP.

- ***Policy_set_name* (inherited)**. The name of the policy set that is not attached directly to a service resource, but that is attached to a higher-level service resource.

When the value in the column is a link, click the link to view or change settings about the attached policy set.

Binding:

Specifies the binding configuration that is available for a service provider, endpoint, or operation.

The Binding column can contain the following values:

- **Not applicable**. No policy set is attached, either directly or to a higher-level service resource.
- ***Binding_name*** or **Default**. The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, `MyBindings1`. **Default** is displayed if a policy set is attached directly but the service resource uses the default bindings.
- ***Binding_name* (inherited)** or **Default (inherited)**. A service resource inherits the bindings from an attachment to a higher-level resource.

When the value in the Binding column is a link, click the link to view or change settings about the binding.

About policy set bindings

In this release, there are two types of bindings: application-specific bindings and general bindings.

Application-specific bindings

You can create application-specific bindings only at a policy set attachment point. These bindings are specific to, and constrained by, the characteristics of the defined policy. Application-specific bindings can provide configuration for advanced policy requirements such as multiple signatures; however, these bindings are reusable only within an application. Also, application-specific bindings have very limited reuse across policy sets.

When you create an application-specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding, and fully configure the bindings for each policy that you add. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application-specific bindings.

For service providers, you can create application-specific bindings only by selecting **Assign Binding** > **New Application Specific Binding**, on the Service providers policy sets and bindings collection page, for service provider resources that have an attached policy set. Similarly, for service clients, you can create application-specific bindings only by selecting **Assign Binding** > **New Application Specific Binding**, on the Service clients policy sets and bindings collection page, for service client resources that have an attached policy set.

General bindings

You can configure general bindings to be used across a range of policy sets and they can be reused across applications and for trust service attachments. Although general bindings are highly reusable, they cannot provide configuration for advanced policy requirements such as multiple signatures. There are two types of general bindings: general provider policy set bindings and general client policy set bindings.

You can create general provider policy set bindings by clicking **Services** > **Policy sets** > **General provider policy set bindings** > **New** in the general provider policy sets panel, or by clicking **Services** >

Policy sets > **General client policy set bindings** > **New** in the general client policy set and bindings panel. For details about defining and managing service client or provider bindings, see the related links. General provider policy set bindings might also be used for trust service attachments.

Policy Sharing:

Specifies whether the service provider can share its current policy configuration.

The Policy sharing column can contain the following values:

- **Not applicable**. The resource does not have a policy set attached, so there is no policy configuration to share.
- **Disabled**. The policy set of the resource cannot be shared. This is the default setting if a policy set is attached to a service.
- **Enabled**. The policy set of the resource can be shared.

When the value in the column is a link, click the link to view or change settings about how the policy configuration can be shared.

For a service, if the policy set is inherited from the parent application, the policy sharing value is also inherited, and you cannot change it. The value is not a link and it is followed by the term `inherited` in parentheses.

For an endpoint or operation, the value is not a link and it is followed by the term `inherited` in parentheses. The setting is inherited from the parent application or service and you cannot change it.

Viewing WSDL documents for service providers using the administrative console

You can locate and view a Web Services Description Language (WSDL) document from the administrative console.

Before you begin

Before completing this task, you need to install or deploy a Java API for XML Web Services (JAX-WS) application. Read about the JAX-WS application deployment model.

About this task

JAX-WS integration with the WebSphere Application Server provides the option to view a Web Services Description Language (WSDL) document that is associated with your web service using the administrative console.

A web service application that contains all the necessary artifacts has been developed and deployed to the Application Server. Now you can view the WSDL document for each service using the administrative console.

Procedure

1. Open the administrative console.
2. In the navigation pane, expand **Services** > **Service providers**.
3. Select a web service of interest in the **Service providers** collection view.
4. Click the **WSDL document** link to view the WSDL document.

Results

When you finish this task, you have viewed the WSDL document for a service artifact.

What to do next

You can attach and detach policy sets and configure bindings information for your application. See managing policy sets and bindings for service providers at the application level using the administrative console.

Viewing service clients at the cell level using the administrative console

You can view all your service clients at the cell level using the administrative console.

Before you begin

Before completing this task, you need to install one or more Java API for XML-Based Web Services (JAX-WS).

About this task

You can view a list of your service clients, such as JAX-WS Web services clients using the administrative consolel.The Name column displays the service client references. The Deployed Asset column displays the name of the deployed asset that contains the service client.

Procedure

1. Open the administrative console.
2. In the navigation pane, expand **Services** > **Service clients**.
3. View the web service client of interest in the Name column and the associated application in the Deployed Asset column. For JAX-WS (WSN) references, the name of the containing WS-Notification service that is a part of the System Integration (SI) is displayed. Hovering over this name displays the Bus:<busName>.

Results

When you complete this task, you have viewed the service clients at the cell level.

What to do next

Proceed to view service clients at the application level using the administrative console. Click each service to see and manage the policy sets and bindings associated with a particular service.

Service client collection at the cell level

Use this page to view and manage service clients at the cell level. Server-based Java API for XML-Based Web Services (JAX-WS) service clients are the only clients that are displayed in this view. Java API for XML-based RPC (JAX-RPC) service clients are not displayed in this view.

To view this administrative console page, click **Services** > **Service clients**. Select the service name link in the Name column to access the service client settings page. Select the deployed asset link in the Deployed Asset column to access the deployed asset settings page.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Name:

Specifies the name of the service client, which is the name of the service provider that is referenced by the client. The full `QName`, Java class `javax.xml.namespace.QName`, is displayed when you hover the mouse pointer over the **Name** field.

If a web services reference has been defined for a service client, the **Name** field contains the name of the service reference under the corresponding service client. The full name of the service reference in name-value pair format is displayed when you hover the mouse pointer over the **Name** field.

Type:

Specifies the type of service such as a JAX-WS client service and Web Services Notification (WSN) client service. You can filter by the type of service.

Deployed Asset:

Represents a Java Platform, Enterprise Edition (Java EE) application or a WS-Notification service. For JAX-WS or WSN clients, the name of the containing WS-Notification service that is a part of the System Integration (SI) is displayed. Hovering over this name displays the Bus:<busName>.

Table 250. Type of deployed asset and service broker. This table describes the representations for the types of deployed assets.

	Java EE application
	WS-Notification service

Viewing service clients at the application level using the administrative console

You can view your installed service clients for an application using this task.

Before you begin

Before completing this task, you need to install a Java API for XML-based Web Services (JAX-WS) web service.

About this task

You can view a list of your service client references.

Your application server instance can have one or more applications deployed on it that contain service clients. This task enables you to view the service names that are referenced in an application.

Procedure

1. Open the administrative console.
2. View the service clients in an application by expanding **Applications > Application Types > WebSphere enterprise applications** >*Service_client_application_instance* > **Service clients**.

   [Optional] When you are accessing a business-level application, click **Services > Service clients > *BLA_client_instance***.
3. Select a client from the Name column to view the client and to manage the policy sets and bindings associated with it.
4. [Optional] Select a module name from the Module column to access the module detail page.

5. [Optional] In the **Additional Properties** section, click **Composition unit**, to see the composition unit detail page.

Results

When you finish this task, you have viewed service clients at the application level.

What to do next

You can now proceed to managing policy sets using the administrative console.

Service clients collection at the application level

Use this page to view and manage service clients at the application level.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***Service_client_application_instance*** > **Service client**.

Name:

Specifies the name of the service client. The service *QName*, `Java class javax.xml.namespace.QName`, is displayed when you hover your mouse pointer over the **Name** field. If a web services reference has been defined for a service client, the **Name** field contains the name of the service reference under the corresponding service client. The full name of the service reference in name-value pair format is displayed when you hover the mouse pointer over the **Name** field.

Type:

Specifies the type of service such as a Java API for XML-Based Web Services (JAX-WS) web service. You can filter by the type of service.

Module:

Specifies the name of the module that contains the service. Selecting a module name accesses the module detail page.

Viewing detail of a service client and managing policy sets using the administrative console

Use this administrative console task to view the detail of your service client reference and to manage the policy sets for the service, its endpoints and operations.

Before you begin

Before completing this task, you need to install one or more Java API for XML-based Web Services (JAX-WS) web services, and attach a policy set to each web service.

About this task

You have developed a web service that contains all the necessary artifacts and deployed your web services application into your application server instance. Now, you can attach or detach policy sets and manage the associated bindings.

The policy set information is displayed in the Attached Policy Set column. If a policy set is directly attached, then the policy set name appears; for example, `WS-I RSP` is displayed. If there is no policy set attached, and a policy set is attached at a higher level, then the word *inherited* in parentheses is

appended to the policy set name, as the following example demonstrates: `WS-I RSP (inherited)`. If there is no policy set attached directly or at a higher level, then `None` is displayed.

Every attachment of a policy set to a service artifact has an assigned binding. The binding information is displayed in the Binding column. The Binding column can contain the following values:

- Not applicable. There is no policy set attached, either directly or to a higher level service resource.
- *Binding_name* or Default. The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, `MyBindings1`. Default is displayed if a policy set is attached directly but the service resource uses the default bindings.
- *Binding_name* (inherited) or Default (inherited). A service resource inherits the bindings from an attachment to a higher level resource.

In Version 7.0 and later, there are two types of bindings, application specific bindings and general bindings.

Application specific binding

You can create application specific bindings only at a policy set attachment point. These bindings are specific to and constrained to the characteristics of the defined policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have very limited reuse across policy sets.

When you create an application specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding and fully configure the bindings for each policy that you have added. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application specific bindings.

For service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service clients policy sets and bindings collection. Similarly, for service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service client policy set and bindings collection.

General bindings

General bindings were introduced in Version 7.0. These bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust service attachments. Though general bindings are highly reusable, they are however not able to provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings:

- General provider policy set bindings
- General client policy set bindings

You can create general client policy set bindings by accessing **Services > Policy sets > General provider policy set bindings** > **New** in the general provider policy sets panel or by accessing **Services > Policy sets > General client policy set bindings** > **New** in the general client policy set and bindings panel. See defining and managing service client or provider bindings.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Procedure

1. Open the administrative console.
2. In the navigation pane, click **Applications > Application Types > WebSphere enterprise applications** >*Service_client_application_instance* > **Service clients**.
3. Select one or more service, endpoints and operations of interest and view the associated service, endpoints and operations.
4. You can perform any of the following actions:
   - Click **Attach**, to attach a policy set to a selected service, endpoint or operation.
   - Click, **Detach**, to detach a policy set from a list of attached policy sets for a service, endpoint or operation. The service name is the service client reference in the application.
5. Click **Assign Binding** to select from a list of available bindings for the selected policy set attachment. All the bindings are listed along with the following options:

Table 251. Binding descriptions. Use the descriptions of the default bindings for the selected policy set attachment.

Bindings	Description
Default	Specifies the default binding for the selected service client, endpoint, or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application-specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used. For any policy set attachment, the run time checks to see if the attachment includes a binding. If so, it uses that binding. If not, the run time checks in the following order and uses the first available default binding: 1. Default general bindings for the server 2. Default general bindings for the domain in which the server resides 3. Default general bindings for the global security domain
New Application Specific Binding	Select this option to create a new application-specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached.
Client sample	Select this option to use the Client sample binding.
Client sample V2	Select this option to use the Client sample V2 binding when you are using either the Kerberos V5 WSSecurity default or the TrustServiceKerberosDefault policy sets.
Saml Bearer Client sample	Select this option to use the Saml Bearer Client sample. The Saml Bearer Client sample extends the Client sample binding to support SAML Bearer token usage scenarios. You can use this sample with any of the SAML bearer token default policy sets.
Saml HoK Symmetric Client sample	Select this option to use the Saml HoK Symmetric Client sample. The Saml HoK Symmetric Client sample extends the Client sample binding to support SAML holder-of-key (HoK) symmetric key token usage scenarios. You can use this sample with one of the SAML HoK Symmetric key default policy sets: either SAML11 HoK Symmetric WSSecurity default or SAML20 HoK Symmetric WSSecurity default.

6. To close the drop down list for the assign binding action, click **Assign Binding**.

Results

When you finish this task, a policy set is attached, detached or a binding is assigned to the service artifact.

Example

You have configured a service client reference, `EchoService12` in the application instance, WSSampleClientSei. Now you want to attach the WSSecurity default policy to the `EchoService12Port` endpoint of the `EchoService12` service client reference. First locate `EchoService12` in the Services > Service clients collection. Click the **`EchoService12`** service client reference. Select the check box for the `EchoService12Port` resource and click **Attach**. Select the **WSSecurity** default policy from the list. Click **Save**, to save your changes to the master configuration.

What to do next

You can now proceed to manage policy sets and bindings for service clients at the application level using the administrative console.

Service client settings

Use this administrative console page to manage the settings for your service clients. You can attach and detach policy sets to a service, its endpoints, or operations. You can select default bindings, create new application-specific bindings, or use existing bindings for an attached policy set. You can view or change whether the client uses the policy of the service provider.

This service client page displays configuration information for a service client and the associated endpoints and operations. You can view and manage policy set attachments, bindings information, and whether the client uses the policy of the service provider.

The Application and Module links provide access to the application and module settings page.

To view this administrative console page, click **Services** > **Service clients** > ***service_client_instance***.

You can also view this page by clicking **Applications** > **Application Types** > **WebSphere enterprise applications** > ***service_client_application_instance*** > **Service clients** > ***service_client_instance***.

To attach or detach a policy set or binding, do the following:

1. Select a service client, endpoint, or operation from **Service/Endpoint/Operation**. The **Service/Endpoint/Operation** list is nested, indicating parent-child relationships. When you select a parent, the children automatically inherit the settings of the parent.
2. Click the desired button.

Table 252. Button descriptions. Use the buttons to manage policy sets and policy set bindings for service clients.

Button	Resulting action
Attach Client Policy Set	Click this button to view a list of policy sets available for attachment to the selected service, endpoint, or operation. Select a policy set from the list to attach and it is attached to the selected service, endpoint, or operation. To close the menu list, click **Attach Client Policy Set**.
Detach Client Policy Set	Click this button to detach a policy set from a selected service, endpoint, or operation. After the policy set is detached, if there is no policy set attached to an upper level service resource, the Attached Client Policy Set column displays **None** and the Binding column displays **Not Applicable**. If there is a policy set attached to an upper level service resource, the Attached Client Policy Set column displays ***policy_set_name*** **(inherited)** and the binding used for the upper level attachment is applied. The binding name is displayed followed by **(inherited)**.

Table 252. Button descriptions (continued). Use the buttons to manage policy sets and policy set bindings for service clients.

Button	Resulting action
Assign Binding	Click this button to select from a list of available bindings for the selected policy set attachment. The options include the following: **Default** Specifies the default binding for the selected service, endpoint, or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application-specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used. For any policy set attachment, the run time checks to see if the attachment includes a binding. If so, it uses that binding. If not, the run time checks in the following order and uses the first available default binding: 1. Default general bindings for the server 2. Default general bindings for the domain in which the server resides 3. Default general bindings for the global security domain **New Application Specific Binding** Select this option to create a new application-specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached. **Client sample** Select this option to use the Client sample binding. **Client sample V2** Select this option to use the Client sample V2 binding when you are using either the Kerberos V5 WSSecurity default or the TrustServiceKerberosDefault policy sets. **Saml Bearer Client sample** Select this option to use the Saml Bearer Client sample. The Saml Bearer Client sample extends the Client sample binding to support SAML Bearer token usage scenarios. You can use this sample with any of the SAML bearer token default policy sets. **Saml HoK Symmetric Client sample** Select this option to use the Saml HoK Symmetric Client sample. The Saml HoK Symmetric Client sample extends the Client sample binding to support SAML holder-of-key (HoK) symmetric key token usage scenarios. You can use this sample with one of the SAML HoK Symmetric key default policy sets: either SAML11 HoK Symmetric WSSecurity default or SAML20 HoK Symmetric WSSecurity default. To close the menu list, click **Assign Binding**.

Service client:

Specifies the name of the service client that is displayed.

Policy Set Attachments:

Service/Endpoint/Operation:

Specifies the name of the service client, endpoints or operations. The full `QName` (Java class `javax.xml.namespace.QName`) is displayed when you hover the mouse pointer over a service client name.

Attached Client Policy Set:

Specifies the policy set that is attached to the service client, endpoints or operations.

The Attached Client Policy Setcolumn can contain the following values:

- **None**. No policy set is attached, either directly or to a higher level service resource.
- ***policy_set_name***. The name of the policy set that is attached directly to the service resource, for example, `WS-I RSP`.

- ***policy_set_name* (inherited)**. The name of the policy set that is not attached directly to a service resource, but that is attached to a higher level service resource.

When the value in the column is a link, click the link to view or change settings about the attached policy set.

Policies Applied:

Specifies the policies that are applied to the resource.

The Policies Applied column can contain the following values:
- **None**. No policies are applied to the service. This is the default setting if there is no policy set attached to the client.
- **Client only**. The client policy set is applied to the service. This is the default setting if a policy set is attached to the client.
- **Provider only**. The policy configuration of the service provider is applied to the service, as long as the client can support those policies.
- **Client and provider**. A policy that is based on both the client policy set and the policy of the service provider is applied to the service.

When the value in the column is a link, click the link to view or change settings about how the policies are applied.

For a service, if the value in the column is a link followed by the word `inherited` in parentheses, this shows a setting that is inherited from the parent application. You can click the link to change the setting for the service.

For an endpoint or operation, the value is not a link and it is followed by the word `inherited` in parentheses. The setting is inherited from the parent application or service and you cannot change it. If there is no applied policy, the entry in the column is `None`.

Binding:

Specifies the binding information available for a service client, endpoint, or operation.

The Binding column can contain the following values:
- **Not applicable**. There is no policy set attached, either directly or to a higher level service resource.
- ***Binding_name*** or **Default**. The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, `MyBindings1`. Default is displayed if a policy set is attached directly but the service resource uses the default bindings.
- ***Binding_name* (inherited)** or **Default (inherited)**. A service resource inherits the bindings from an attachment to a higher level resource.

When the value in the Binding column is a link, click the link to view or change settings about the binding.

About policy set bindings

In this release, there are two types of bindings: application-specific bindings and general bindings.

Application-specific bindings

You can create application-specific bindings only at a policy set attachment point. These bindings are specific to, and constrained by, the characteristics of the defined policy. Application-specific bindings can

provide configuration for advanced policy requirements such as multiple signatures; however, these bindings are reusable only within an application. Also, application-specific bindings have very limited reuse across policy sets.

When you create an application-specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding, and fully configure the bindings for each policy that you add. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application-specific bindings.

For service providers, you can create application-specific bindings only by selecting **Assign Binding** > **New Application Specific Binding**, on the Service providers policy sets and bindings collection page, for service provider resources that have an attached policy set. Similarly, for service clients, you can create application-specific bindings only by selecting **Assign Binding** > **New Application Specific Binding**, on the Service clients policy sets and bindings collection page, for service client resources that have an attached policy set.

General bindings

You can configure general bindings to be used across a range of policy sets and they can be reused across applications and for trust service attachments. Although general bindings are highly reusable, they cannot provide configuration for advanced policy requirements such as multiple signatures. There are two types of general bindings: general provider policy set bindings and general client policy set bindings.

You can create general provider policy set bindings by clicking **Services** > **Policy sets** > **General provider policy set bindings** > **New** in the general provider policy sets panel, or by clicking **Services** > **Policy sets** > **General client policy set bindings** > **New** in the general client policy set and bindings panel. Read about defining and managing service client or provider bindings for more information. General provider policy set bindings might also be used for trust service attachments.

Managing policy sets and bindings for services references using the administrative console

Use this administrative console task to manage policy sets and bindings for the service reference, its endpoints, and operations.

Before you begin

Before completing this task, you must install one or more Java API for API for XML-based Web Services (JAX-WS) web services, that contain at least one client service reference.

About this task

You have developed a web service that contains all the necessary artifacts and deployed your web services application into your application server instance. Now, you can attach or detach policy sets and manage the associated bindings.

Note: When you configure the policy set attachments for a service reference, you can override the policy set attachments that are inherited from the service client using the administrative console. You can attach a policy set and binding for a service reference that is different from the policy set attachment for the service client. You can also specify to not attach a policy set to a service reference, even if a policy set is attached to the service client.

The default behavior is that a service reference, and its endpoints and operations, inherits the policy set attachment of the corresponding resources of the service. Service references are only valid for service clients.

Using the administrative console, you can configure the service reference to either inherit policy set and bindings configuration from the service client or to specify individual settings for the service reference by attaching policy sets and bindings that are different from the policy sets and bindings attached to the service client.

The policy set information is displayed in the Attached Policy Set column. If a policy set is directly attached, then the policy set name is displayed; for example, `WS-I RSP`. If there is no policy set attached, and a policy set is attached at a higher level or to the service client, then the word *inherited* in parentheses is appended to the policy set name, as the following example demonstrates: `WS-I RSP (inherited)`. If there is no policy set attached directly or at a higher level, then `None` is displayed.

Every attachment of a policy set to a service artifact has an assigned binding. The binding information is displayed in the Binding column. The Binding column can contain the following values:

- Not applicable. There is no policy set attached, either directly, to a service client resource, or to a higher level service reference resource.
- *Binding_name* or Default. The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, `MyBindings1`. Default is displayed if a policy set is attached directly but the service reference resource uses the default bindings.
- *Binding_name* (inherited) or Default (inherited). A service resource inherits the bindings from an attachment to a service client resource or a higher level service reference resource.

There are two types of bindings, application specific bindings and general bindings.

Application specific binding

You can create application specific bindings only at a policy set attachment point. These bindings are specific to and constrained to the characteristics of the defined policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have very limited reuse across policy sets.

When you create an application specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding and fully configure the bindings for each policy that you have added. For WS-Security policy, some high-level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application specific bindings.

For service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service clients policy sets and bindings collection. Similarly, for service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service client policy set and bindings collection.

General bindings

General bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust service attachments. Though general bindings are highly reusable, they are however not able to provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings:

- General provider policy set bindings

- General client policy set bindings

You can create general client policy set bindings by accessing **Services > Policy sets > General provider policy set bindings** > **New** in the general provider policy sets panel or by accessing **Services > Policy sets > General client policy set bindings** > **New** in the general client policy set and bindings panel. See defining and managing service client or provider bindings.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Note: In a mixed cell environment, the following limitations apply to service reference attachments or resource attachments that are specified in name-value pair format:

- You must not create these types of attachments for applications that are deployed on an application server that is prior to WebSphere Application Server Version 8. Service reference attachments are only supported on WebSphere Application Server V8 and later.
- An application that contains these types of attachments must not be deployed on an application server that is prior to WebSphere Application Server Version 8.
- If an application that is deployed in a cluster environment contains these types of attachments, you must not add a member application server that is prior to WebSphere Application Server Version 8 to the cluster.

Procedure

1. Open the administrative console.
2. In the navigation pane, click **Applications > Application Types > WebSphere enterprise applications** >*Service_client_application_instance* > **Service clients**.
3. Select a service references and view the associated service reference, endpoints, and operations.
4. You can perform any of the following actions:
   - Click **Inherit**, to clear existing policy set and binding settings for the service reference and to use policy set attachments that are defined by the service client. By default, a service reference, and its endpoints and operations, inherits the policy set attachment of the corresponding resources of the service.
   - Click **Override**, to override existing policy set and binding settings for the service client and to either define separate policy sets and bindings for the service reference or to specify that a policy set is not attached to the service reference.
   - Click **Attach Client Policy Set**, to attach a policy set to a selected service reference, endpoint, or operation. This button is active only after you have clicked the **Override** button.
   - Click, **Detach Client Policy Set**, to detach a policy set from a list of attached policy sets for a service reference, endpoint, or operation. The service name is the service client reference in the application. This button is active only after you have clicked the **Override** button.
5. Click **Assign Binding** to select from a list of available bindings for the selected policy set attachment. This button is active only after you have clicked the **Override** button. All the bindings are listed along with the following options:

Table 253. Binding descriptions. Use the descriptions of the default bindings to determine which binding to apply to service references.

Bindings	Description
Default	Specifies the default binding for the selected service reference, endpoint, or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application-specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used. For any policy set attachment, the run time checks to see if the attachment includes a binding. If so, it uses that binding. If not, the run time checks in the following order and uses the first available default binding: 1. Default general bindings for the server 2. Default general bindings for the domain in which the server resides 3. Default general bindings for the global security domain
New Application Specific Binding	Select this option to create a new application-specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached.
Client sample	Select this option to use the Client sample binding.
Client sample V2	Select this option to use the Client sample V2 binding when you are using either the Kerberos V5 WSSecurity default or the TrustServiceKerberosDefault policy sets.
Saml Bearer Client sample	Select this option to use the Saml Bearer Client sample. The Saml Bearer Client sample extends the Client sample binding to support SAML Bearer token usage scenarios. You can use this sample with any of the SAML bearer token default policy sets.
Saml HoK Symmetric Client sample	Select this option to use the Saml HoK Symmetric Client sample. The Saml HoK Symmetric Client sample extends the Client sample binding to support SAML holder-of-key (HoK) symmetric key token usage scenarios. You can use this sample with one of the SAML HoK Symmetric key default policy sets: either SAML11 HoK Symmetric WSSecurity default or SAML20 HoK Symmetric WSSecurity default.

6. To close the drop-down list for the assign binding action, click **Assign Binding**.
7. (optional) Display inherit policy set attachments confirmation. Selecting this check box enables the inherit policy set attachments confirmation panel. You must expand the Preferences section to select this check box.

Results

When you finish this task, you have specified policy sets and bindings for a service reference.

Example

Suppose that you have configured a service client reference, `EchoService12` in the application instance, WSSampleClientSei. You want to attach the WSSecurity default policy to the `EchoService12Port` endpoint of the `EchoService12` service client reference. You must override the current service client policy set and bindings. Complete the following steps:

1. Locate `EchoService12` in the **Applications > Application Types > WebSphere enterprise applications** >*WSSampleClientSei* > **Service clients** collection. Alternatively, you can locate `EchoService12` in the **Services > Service clients** collection.
2. Click **Override**, to override the service client attachments.
3. Select the check box for the `EchoService12Port` resource, and click **Attach Client Policy Set**.
4. Select the **WSSecurity default** policy from the list.
5. Click **Save** to save your changes to the master configuration.

Suppose later, you want your service reference, `EchoService12` to not use the WSSecurity default policy. Instead, you want to use the policy sets and attachments from the service client, `WSSampleClientSei`. Complete the following steps:

1. Locate `EchoService12` in the **Applications > Application Types > WebSphere enterprise applications** >*WSSampleClientSei* > **Service clients** collection. Alternatively, you can locate `EchoService12` in the **Services > Service clients** collection.
2. Click **Inherit**, to clear the existing policy set and binding settings for the service reference and to use policy set attachments that are defined by the service client.
3. Click **OK** on the Inherit policy sets page to confirm that you want to inherit the policy set attachments that are defined by the service client. You can optionally select the check box to not show the inherit confirmation page in the future.
4. Click **Save** to save your changes to the master configuration.

What to do next

You can now proceed to manage other service references for the service client or to manage policy sets and bindings for service clients at the application level using the administrative console.

Service reference settings

Use this administrative console page to manage the settings for your service references. Service references can inherit the policy sets and bindings of the service client or you can specify policy sets and bindings that are different from those of the service client.

This service references page displays configuration information for a service reference and the associated endpoints and operations. You can view and configure the service reference to either inherit policy set and binding configurations from the service client or to specify individual settings for the service reference by attaching policy sets and bindings that are different from the policy sets and bindings that are attached to the service client.

The Application, Module, and Service client links provide access to the application, module, and service client settings page.

To view this administrative console page, click **Services** > **Service clients** > ***service_reference_instance***.

You can also view this page by clicking **Applications** > **Application Types** > **WebSphere enterprise applications** > ***service_client_application_instance*** > **Service clients** > ***service_reference_instance***.

You can specify a policy set and binding for a service reference that is different from the policy set attachment for the service. In addition, you can indicate to not attach a policy set to a service reference, even if a policy set is attached to the service. The default behavior is that a service reference, and its endpoints and operations, inherits the policy set attachment of the corresponding resources of the service. Service references are only valid for the client attachment type.

To attach or detach a policy set or binding, complete the following actions:

1. Select a service reference, endpoint, or operation from **Service Reference/Endpoint/Operation**. The **Service Reference/Endpoint/Operation** list is nested, indicating parent-child relationships. When you select a parent, the children automatically inherit the settings of the parent.
2. Click the button for the action that you want to complete.

Table 254. Button descriptions. Use the buttons to manage policy sets and policy set bindings for service references.

Button	Resulting action
Inherit	Click this button to clear the existing policy set and binding settings for the service reference and to use policy set attachments that are defined by the service client. By default, a service reference, as well as its endpoints and operations, inherits the policy set attachment of the corresponding resources of the service.
Override	Click this button to override the existing policy set and binding settings for the service client and to either define separate policy sets and bindings for the service reference or to specify that a policy set is not attached to the service reference.
Attach Client Policy Set	Click this button to view a list of policy sets available for attachment to the selected service reference, endpoint, or operation. Select a policy set from the list to attach; that policy set is attached to the selected service, endpoint, or operation. To close the menu list, click **Attach Client Policy Set**. This button is active only after you have clicked the **Override** button.
Detach Client Policy Set	Click this button to detach a policy set from a selected service reference, endpoint, or operation. After the policy set is detached, if there is no policy set attached to an upper-level service resource, the Attached Client Policy Set column displays **None** and the Binding column displays **Not Applicable**. If there is a policy set attached to an upper-level service reference resource or service client, the Attached Client Policy Set column displays ***policy_set_name*** **(inherited)** and the binding used for the upper-level attachment is applied. The binding name is displayed followed by **(inherited)**. This button is active only after you have clicked the **Override** button.
Assign Binding	Click this button to select from a list of available bindings for the selected policy set attachment. The options include the following: **Default** Specifies the default binding for the selected service reference, endpoint, or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level for a particular server or for a security domain. The default bindings are used when an application-specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the default. If you do not specifically assign a binding to the attachment point using this **Assign Binding** action, the default specified at the nearest scope is used. For any policy set attachment, the runtime environment verifies whether the attachment includes a binding. If so, it uses that binding. If not, the runtime environment checks in the following order and uses the first available default binding: 1. Default general bindings for the server 2. Default general bindings for the domain in which the server resides 3. Default general bindings for the global security domain **New Application Specific Binding** Select this option to create a new application-specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached. **Client sample** Select this option to use the Client sample binding. **Client sample V2** Select this option to use the Client sample V2 binding when you are using either the Kerberos V5 WSSecurity default or the TrustServiceKerberosDefault policy sets. **Saml Bearer Client sample** Select this option to use the Saml Bearer Client sample. The Saml Bearer Client sample extends the Client sample binding to support SAML Bearer token usage scenarios. You can use this sample with any of the SAML bearer token default policy sets. **Saml HoK Symmetric Client sample** Select this option to use the Saml HoK Symmetric Client sample. The Saml HoK Symmetric Client sample extends the Client sample binding to support SAML holder-of-key (HoK) symmetric key token usage scenarios. You can use this sample with one of the SAML HoK Symmetric key default policy sets: either SAML11 HoK Symmetric WSSecurity default or SAML20 HoK Symmetric WSSecurity default. To close the menu list, click **Assign Binding**. This button is active only after you have clicked the **Override** button.

Display inherit policy set attachments confirmation: Selecting this check box specifies that you want to enable the inherit policy set attachments confirmation. You must expand the Preferences section to select this check box.

Service Reference/Endpoint/Operation:

Specifies the name of the service reference, endpoints, or operations. The full resource name is displayed when you hover the mouse pointer over a service reference, endpoint or operation.

Client Policy Set:

Specifies the policy set that is attached to the service reference, endpoints, or operations.

The Attached Client Policy Set column can contain the following values:

- **None**. No policy set is attached, either directly to the service client, or to a higher-level service reference resource.
- ***policy_set_name***. The name of the policy set that is attached directly to the service reference resource, for example, `WS-I RSP`.
- ***policy_set_name*** **(inherited)**. The name of the policy set that is not attached directly to a service reference resource; the policy set is attached to a higher-level service reference resource or to a service client resource.

When the value in the column is a link, click the link to view or change settings about the attached policy set.

Policies Applied:

Specifies the policies that are applied to the service reference.

The Policies Applied service reference link is only enabled after you have clicked the Override button.

The Policies Applied column can contain the following values:

- **None**. No policies are applied to the service. This is the default setting if there is no policy set attached to the client.
- **Client only**. The client policy set is applied to the service. This is the default setting if a policy set is attached to the client.
- **Provider only**. The policy configuration of the service provider is applied to the service, as long as the client can support those policies.
- **Client and provider**. A policy that is based on both the client policy set and the policy of the service provider is applied to the service.

When the value in the column is a link, click the link to view or change settings about how the policies are applied.

For an endpoint or operation, the value is not a link and it is followed by the word `inherited` in parentheses. The setting is inherited from the parent application or service and you cannot change it. If there is no applied policy, the entries in the column are **None** or **None (inherited)**.

Binding:

Specifies the binding information available for a service reference, endpoint, or operation.

The Binding column can contain the following values:

- **Not applicable**. There is no policy set attached, either directly to the service client, or to a higher-level service reference resource.
- ***Binding_name*** or **Default**. The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, `MyBindings1`. Default is displayed if a policy set is attached directly but the service reference resource uses the default bindings.
- ***Binding_name*** **(inherited)** or **Default (inherited)**. A service resource inherits the bindings from an attachment to a higher-level service reference resource or to a service client resource.

About policy set bindings

In this release, there are two types of bindings: application-specific bindings and general bindings.

Application-specific bindings

You can create application-specific bindings only at a policy set attachment point. These bindings are specific to, and constrained by, the characteristics of the defined policy. Application-specific bindings can provide configuration for advanced policy requirements such as multiple signatures; however, these bindings are reusable only within an application. Also, application-specific bindings have very limited reuse across policy sets.

When you create an application-specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding, and fully configure the bindings for each policy that you add. For WS-Security policy, some high-level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application-specific bindings.

For service providers, you can create application-specific bindings only by selecting **Assign Binding** > **New Application Specific Binding**, on the Service providers policy sets and bindings collection page, for service provider resources that have an attached policy set. Similarly, for service clients, you can create application-specific bindings only by selecting **Assign Binding** > **New Application Specific Binding**, on the Service clients policy sets and bindings collection page, for service client resources that have an attached policy set.

General bindings

You can configure general bindings to be used across a range of policy sets and they can be reused across applications and for trust service attachments. Although general bindings are highly reusable, they cannot provide configuration for advanced policy requirements such as multiple signatures. There are two types of general bindings: general provider policy set bindings and general client policy set bindings.

You can create general provider policy set bindings by clicking **Services** > **Policy sets** > **General provider policy set bindings** > **New** in the general provider policy sets panel, or by clicking **Services** > **Policy sets** > **General client policy set bindings** > **New** in the general client policy set and bindings panel. Read about defining and managing service client or provider bindings for more information. General provider policy set bindings might also be used for trust service attachments.

Managing policy sets and bindings for service clients at the application level using the administrative console

Use this administrative console task to manage policy sets for service clients applications or its services, endpoints, or operations.

Before you begin

Before completing this task, you need to install one or more Java API for XML-Based Web Services (JAX-WS) applications.

About this task

You have developed a web service that contains all the necessary artifacts and deployed your web services application into your application server instance. Now, you can attach or detach policy sets and manage the associated bindings.

The policy set information is displayed in the Attached Policy Set column. If a policy set is directly attached, then the policy set name appears; for example, `WS-I RSP` is displayed. If there is no policy set attached, and a policy set is attached at a higher level, then the word *inherited* in parentheses is appended to the policy set name, as the following example demonstrates: `WS-I RSP (inherited)`. If there is no policy set attached directly or at a higher level, then `None` is displayed.

Every attachment of a policy set to a service artifact has an assigned binding. The binding information is displayed in the Binding column. The Binding column can contain the following values:

- Not applicable. There is no policy set attached, either directly or to a higher level service resource.
- *Binding_name* or Default. The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, `MyBindings1`. Default is displayed if a policy set is attached directly but the service resource uses the default bindings.
- *Binding_name* (inherited) or Default (inherited). A service resource inherits the bindings from an attachment to a higher level resource.

In Version 7.0 and later of this product, there are two types of bindings, application specific bindings and general bindings.

Application specific binding

You can create application specific bindings only at a policy set attachment point. These bindings are specific to and constrained to the characteristics of the defined policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have very limited reuse across policy sets.

When you create an application specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding and fully configure the bindings for each policy that you have added. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application specific bindings.

For service clients, you can only create application specific bindings by selecting **Assign Binding** > **New Application Specific Binding** for service client resources that have an attached policy set. See service clients policy sets and bindings collection. Similarly, for service clients, you can only create application specific bindings by selecting **Assign Binding** > **New Application Specific Binding** for service client resources that have an attached policy set. See service client policy set and bindings collection.

General bindings

General bindings were introduced in Version 7.0 of this product. These bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust service

attachments. Though general bindings are highly reusable, they are however not able to provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings:

- General provider policy set bindings
- General client policy set bindings

You can create general client policy set bindings by accessing **Services** > **Policy sets** > **General provider policy set bindings** > **New** in the general provider policy sets panel or by accessing **Services** > **Policy sets** > **General client policy set bindings** > **New** in the general client policy set and bindings panel. See defining and managing service client or provider bindings.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Procedure

1. Open the administrative console.
2. In the navigation pane, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***Service_client_application_instance*** > **Service client policy sets and bindings**.
3. Select the check box next to the **Application/Service/Endpoint/Operation** column. The service name is the service client reference in the application.
4. Click **Attach** to attach a policy set to an application, service, endpoint or operation.
5. [Optional] Click **Detach** to detach a policy set from a list of attached policy sets for an application, service client, endpoint or operation.
6. Click **Assign Binding** to select from a list of available bindings for the selected policy set attachment. All the bindings are listed along with the following options:

Table 255. Binding descriptions. Use the descriptions of the default bindings for the selected policy set attachment.

Bindings	Description
Default	Specifies the default binding for the selected service client, endpoint, or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application-specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used. For any policy set attachment, the run time checks to see if the attachment includes a binding. If so, it uses that binding. If not, the run time checks in the following order and uses the first available default binding: 1. Default general bindings for the server 2. Default general bindings for the domain in which the server resides 3. Default general bindings for the global security domain
New Application Specific Binding	Select this option to create a new application-specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached.
Client sample	Select this option to use the Client sample binding.
Client sample V2	Select this option to use the Client sample V2 binding when you are using either the Kerberos V5 WSSecurity default or the TrustServiceKerberosDefault policy sets.
Saml Bearer Client sample	Select this option to use the Saml Bearer Client sample. The Saml Bearer Client sample extends the Client sample binding to support SAML Bearer token usage scenarios. You can use this sample with any of the SAML bearer token default policy sets.
Saml HoK Symmetric Client sample	Select this option to use the Saml HoK Symmetric Client sample. The Saml HoK Symmetric Client sample extends the Client sample binding to support SAML holder-of-key (HoK) symmetric key token usage scenarios. You can use this sample with one of the SAML HoK Symmetric key default policy sets: either SAML11 HoK Symmetric WSSecurity default or SAML20 HoK Symmetric WSSecurity default.

Results

When you finish this task, a policy set is attached or detached, and a binding is assigned to the service artifact.

Example

If you have configured a service client application instance, `app1` and you want, for example, to attach the Username WSSecurity default policy set to your application, first locate `app1` application in the **Applications** > **Application Types** > **WebSphere enterprise applications**. Click ***app1*** > **Service client policy sets and bindings** under the Web Services Properties section. Select the check box next to the `app1` service application. Click **Attach** and select **Username WSSecurity default** policy set. Click **Save**, to save your changes to the master configuration.

To assign a binding to the attached policy set, click ***app1*** > **Service client policy sets and bindings**. Select the check box next to the `app1` service application and click **Assign Binding**. Select **client sample** binding from the list. Click **Save**, to save your changes to the master configuration.

What to do next

You can proceed to view service clients at the cell level using the administrative console.

Service client policy set and bindings collection

Use this page to attach and detach policy sets to an application, a service client, its endpoints, or operations. You can select the default bindings, create new application-specific bindings, or use existing bindings for an attached policy set. You can view or change whether the client uses the policy of the service provider.

This page displays detail information for an application and its associated web service clients, endpoints, and operations. You can view and manage policy set attachments and bindings information using this page.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***service_client_application_instance*** > **Service client policy sets and bindings**.

This console page can also be viewed for WS-Notification service clients by clicking one of the following paths:

- **Service integration** > **WS-Notification** > **Services** > ***service_name*** > **[Additional properties] Outbound request policy sets and bindings**
- **Service integration** > **Buses** > ***bus_name*** > **[Services] WS-Notification services** > ***service_name*** > **[Additional properties] Outbound request policy sets and bindings**

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Table 256. Button descriptions. Use the buttons to manage policy sets and policy set bindings for a service client, its endpoints, or operations.

Button	Resulting action
Attach Client Policy Set	Click this button to view a list of policy sets available for attachment to the selected service, endpoint, or operation. Select a policy set from the list to attach and it is attached to the selected service, endpoint, or operation. To close the menu list, click **Attach Client Policy Set**. **Note:** Attach policy sets at the highest level, the EAR server level for example, and let the lower levels inherit those bindings. This can significantly improve the processing time needed to attach sets to multiple operations. After you attach sets at the highest level, you can then customize the lower levels by detaching sets or removing bindings from those specific operations.
Detach Client Policy Set	Click this button to detach a policy set from a selected service, endpoint, or operation. After the policy set is detached, if there is no policy set attached to an upper level service resource, the Attached Client Policy Set column displays **None** and the Binding column displays **Not Applicable**. If there is a policy set attached to an upper level service resource, the Attached Client Policy Set column displays ***policy_set_name*** **(inherited)** and the binding used for the upper level attachment is applied. The binding name is displayed followed by **(inherited)**.
Assign Binding	Click this button to select from a list of available bindings for the selected policy set attachment. All the bindings are listed along with the following options: **Default** Specifies the default binding for the selected service, endpoint or operation. You can specify client and provider default bindings to be used at the cell level or global security domain level, for a particular server, or for a security domain. The default bindings are used when an application-specific binding has not been assigned to the attachment. When you attach a policy set to a service resource, the binding is initially set to the default. If you do not specifically assign a binding to the attachment point using this Assign Binding action, the default specified at the nearest scope is used. For any policy set attachment, the run time checks to see if the attachment includes a binding. If so, it uses that binding. If not, the run time checks in the following order and uses the first available default binding: 1. Default general bindings for the server 2. Default general bindings for the domain that the server resides 3. Default general bindings for the global security domain **New Application Specific Binding** Select this option to create a new application-specific binding for the policy set attachments. The new binding you create is used for the selected resources. If you select more than one resource, ensure that all selected resources have the same policy set attached. **Client sample** Select this option to use the Client sample binding. **Client sample V2** Select this option to use the Client sample V2 binding when you are using either the Kerberos V5 WSSecurity default or the TrustServiceKerberosDefault policy sets. **Saml Bearer Client sample** Select this option to use the Saml Bearer Client sample. The Saml Bearer Client sample extends the Client sample binding to support SAML Bearer token usage scenarios. You can use this sample with any of the SAML bearer token default policy sets. **Saml HoK Symmetric Client sample** Select this option to use the Saml HoK Symmetric Client sample. The Saml HoK Symmetric Client sample extends the Client sample binding to support SAML holder-of-key (HoK) symmetric key token usage scenarios. You can use this sample with one of the SAML HoK Symmetric key default policy sets: either SAML11 HoK Symmetric WSSecurity default or SAML20 HoK Symmetric WSSecurity default. To close the menu list, click **Assign Binding**. **Note:** Assign bindings at the highest level, the EAR server level for example, and let the lower levels inherit those bindings. This can significantly improve the processing time needed to attach sets and bindings to multiple operations. After you assign bindings at the highest level, you can then customize the lower levels by detaching sets or removing bindings from those specific operations.

Application/Service/Endpoint/Operation:

Specifies the name of the application and the associated service client, endpoints, or operations. For WS-Notification service clients, the first entry is associated with the WS-Notification service, not an application.

Attached Client Policy Set:

Specifies the policy set that is attached to the application, service clients, endpoints, or operations.

The Attached Client Policy Set column can contain the following values:

- None. No policy set is attached directly, or is attached at an upper level.
- ***policy_set_name***. The name of the policy set that is directly attached, for example, WS-I RSP.
- *policy_set_name* (inherited). A policy set is not directly attached to the resource, but a policy set is attached to a higher-level resource.

When the value in the column is a link, click the link to view or change settings about the attached policy set.

Policies Applied:

Specifies the policies that are applied to the resource. This column is not applicable and is not shown for WS-Notification service clients.

The Policies Applied column can contain the following values:

- **None**. No policies are applied to the application or service. This is the default setting if there is no policy set attached to the client.
- **Client only**. The client policy set is applied to the application or service. This is the default setting if a policy set is attached to the client.
- **Provider only**. The policy configuration of the service provider is applied to the application or service, as long as the client can support those policies.
- **Client and provider**. A policy that is based on both the client policy set and the policy of the service provider is applied to the application or service.

When the value in the column is a link, click the link to view or change settings about how the policies are applied.

For a service, if the value in the column is a link followed by the word `inherited` in parentheses, this shows a setting that is inherited from the parent application. You can click the link to change the setting for the service.

For an endpoint or operation, the value is not a link and it is followed by the word `inherited` in parentheses. The setting is inherited from the parent application or service and you cannot change it.

Binding:

Specifies the name of the binding associated with a policy set.

The Binding column can contain the following values:

- **Not applicable**. There is no policy set attached, either directly or to a higher-level service resource.
- ***Binding_name*** or **Default**. The binding name is displayed if a policy set is attached directly and an application-specific binding or a general binding is assigned, for example, `MyBindings1`. **Default** is displayed if a policy set is attached directly but the service resource uses the default bindings.
- ***Binding_name*** **(inherited)** or **Default (inherited)**. A service resource inherits the bindings from an attachment to a higher-level resource.

When the value in the Binding column is a link, click the link to view or change settings about the binding.

About policy set bindings

In this release, there are two types of bindings: application-specific bindings and general bindings.

Application-specific bindings

You can create application-specific bindings only at a policy set attachment point. These bindings are specific to, and constrained by, the characteristics of the defined policy. Application-specific bindings can provide configuration for advanced policy requirements such as multiple signatures; however, these bindings are reusable only within an application. Also, application-specific bindings have very limited reuse across policy sets.

When you create an application-specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding, and fully configure the bindings for each policy that you add. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application-specific bindings.

For service providers, you can create application-specific bindings only by selecting **Assign Binding > New Application Specific Binding**, on the Service providers policy sets and bindings collection page, for service provider resources that have an attached policy set. Similarly, for service clients, you can create application-specific bindings only by selecting **Assign Binding > New Application Specific Binding**, on the Service clients policy sets and bindings collection page, for service client resources that have an attached policy set.

General bindings

You can configure general bindings to be used across a range of policy sets and they can be reused across applications and for trust service attachments. Although general bindings are highly reusable, they cannot provide configuration for advanced policy requirements such as multiple signatures. There are two types of general bindings: general provider policy set bindings and general client policy set bindings.

You can create general provider policy set bindings by clicking **Services > Policy sets > General provider policy set bindings** > **New** in the general provider policy sets panel, or by clicking **Services > Policy sets > General client policy set bindings** > **New** in the general client policy set and bindings panel. For details about defining and managing service client or provider bindings, see the related links. General provider policy set bindings might also be used for trust service attachments.

Viewing web services deployment descriptors in the administrative console

You can view the web services client and server deployment descriptors for a deployed web services application. You can view the bindings in the deployment descriptors.

Before you begin

Before you can view the deployment descriptors, you need to complete all tasks required to implement a JAX-RPC web service, create the deployment descriptor templates that were generated by the WSDL2Java command-line tool, configure the deployment descriptors and bindings, and deploy the Web service application into WebSphere Application Server. Review the implementing web services application documentation for more information on developing and implementing web services.

About this task

Deployment descriptors contain the information that is needed by a web services client to communicate with the server for which the Web services is installed. This information is added to the deployment descriptor templates after a web service is developed or an existing web service is located. The data that you can view in the deployment descriptor includes the following:

- The web service description including the name, WSDL file, WSDL file location and the mapping file.
- The port description, including the port component name, the WSDL port, the service endpoint interface that indicate the service's bindings, and the EJB that is used to implement the web service.

After you have developed a web service that contains all the necessary artifacts, created the deployment descriptors from the deployment descriptor templates, configured the deployment descriptors, and deployed the web services application into WebSphere Application Server; now you can view the deployment descriptors and bindings in the administrative console.

Similar to Java API for XML-based RPC (JAX-RPC) web services, you can use deployment descriptors to describe JAX-WS web services. For JAX-WS web services, the use of the `webservices.xml` deployment descriptor is optional because you can use annotations to specify all of the information that is contained within the deployment descriptor file. You can use the deployment descriptor file to augment or override existing JAX-WS annotations. Any information that you define in the `webservices.xml` deployment descriptor overrides any corresponding information that is specified by annotations.

Procedure

1. Open the administrative console.
2. Click **Applications > Application Types > WebSphere enterprise applications > *application_name* > Manage Modules**.
   - Click **View web services client deployment descriptor extension**.
   - Click **View web services server deployment descriptor**.
   - Click **View web services server deployment descriptor extension**.
3. Click **Expand All** to view the deployment descriptor contents.
4. Verify deployment descriptor and bindings configurations.

What to do next

You have viewed and verified the deployment descriptors and bindings for the web services application.

Configuring the scope of a JAX-RPC web services port

When a Java API for XML-based RPC (JAX-RPC) web service application is deployed into WebSphere Application Server, an instance is created for each application or module. The instance contains deployment information for the web module or enterprise bean module, including implementation scope, client bindings and deployment descriptor information. There are three levels of scope that can be set: application, session and request.

Before you begin

Deploy a web service into the WebSphere Application Server. To learn more, read about deploying web services applications onto application servers.

About this task

The Web Services for Java Platform, Enterprise Edition (Java EE) specification states that web services implementations must be stateless. Therefore, to maintain specification compliance, the scope can remain at the application level because the state relevant to the individual sessions level or the requests level is

not supposed to be maintained in the implementation. If you want to deviate from the specification and want to access a different JavaBeans instance, because you are looking for information that is located in another JavaBeans implementation, the scope settings need to change.

The setting that you configure for the scope determines how frequently a new instance of a service implementation class is created for the web services ports in a module. Use this task to configure the scope of a web services port.

This task applies only to Java API for XML-based RPC (JAX-RPC) web services.

To change the scope setting in the administrative console:

Procedure

1. Open the administrative console.
2. Click **Applications > Application Types > WebSphere enterprise applications *application_name* > Manage Modules > *module instance* > Web services implementation scope**
3. Set the scope to application, session or request. The application scope causes the same instance of the implementation to be used for all requests on the application. The session scope causes the same instance to be used for all requests in each session. The request scope causes a new instance to be used for every request. For example, with the scope set to application, every message that comes to the server accesses the same JavaBeans instance because that is the way the scope settings are configured.
4. Click **Apply**.
5. Click **OK**.

Results

The scope for a web services port is configured.

What to do next

Now you can finish any other configurations, start or stop the application, and verify the expected behavior of your web service.

Web services implementation scope

Use this page to view and manage the scope of the ports of a Web service application.

To view this administrative console page, click **Applications > Application Types > WebSphere enterprise applications > *application_name* > Manage Modules > *module_instance* > Web services implementation scope**.

This administrative console page applies only to Java API for XML-based RPC (JAX-RPC) applications.

Port:

Specifies a port name for a web service. A module can contain one or more web services, each of which can contain one or more ports.

Web service:

Specifies the name of the web service. A module can contain one or more web services.

URI:

Specifies the Uniform Resource Identifier (URI) of the binding file that defines the scope. The URI is relative to the web module.

Scope:

Specifies the scope of a port. The valid values for scope are request, session and application.

The scope value determines when a new instance of a service implementation is created for the web service ports in a module. When the scope value is set to application, the same instance of the implementation is used for all requests on the application. When the scope value is set to session, the same instance is used for all requests on each session. When the scope value is set to request, a new instance is created for every request.

Suppressing the compensation service

Not all web servers are configured to handle SOAP messages containing CoordinationContext elements. You can use WebSphere Application Server to configure a custom property for the compensation service which processes a predefined list of Enterprise Java Beans for which no CoordinationContext should be sent on web service requests.

About this task

When the compensation service is used, CoordinationContext elements are included in the outgoing SOAP header. For example:

```
<wscoor:CoordinationContext soapenv:mustUnderstand="1"
...
</wscoor:CoordinationContext>
```

If such a SOAP message is received by a web server which is not configured to process CoordinationContext elements, an exception message is produced. See the following example:

```
Header block local name 'CoordinationContext' is not defined.
```

You can construct a file containing a list of all Enterprise Java Beans which should not send the CoordinationContext element in web service requests. This file must be in plain text format and must contain one entry per line, in the following format:

```
application_name#module#bean
application_name#module#bean
application_name#module#bean
```

Here `application_name` is the name of the application as known on the server; `module` is the name of the Enterprise Java Bean jar; and `bean` is the name of the Enterprise Java Bean.

Note: This file must only contain entries for beans not configured to use the compensation service. This custom property will not be effective for any beans listed in the file which have compensation service metadata associated with them.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Container Settings] Container Services** > **Compensation Service** > **[Additional Properties] Custom Properties**
3. Click **New**.
4. Enter SUPPRESS_CSCOPE_ON_WS_CALLS in the Name field.
5. In the Value field, enter a fully qualified file name.
6. Click **Apply** or **OK**.
7. Click **Save** to save your changes to the master configuration.

8. Restart the server.

Results

Web service requests sent from Enterprise Java Beans listed in the custom property file will not contain CoordinationContext metadata in the outgoing SOAP message header.

Managing policy sets using the administrative console

You can use policy sets, or assertions that define services, to simplify your web services configuration because policy sets group security and other web services settings into reusable units. You can use the administrative console to create, modify, and delete custom policy sets.

Before you begin

Before creating policy sets, first identify the security and other requirements of the web service.

Note: You can only use policy sets with JAX-WS applications that run on the Axis2 web service engine. You cannot use policy sets for JAX-RPC applications.

About this task

You can use the administrative console to view and manage policy sets. From the administrative console, click **Services > Policy sets > Application policy sets** or **Services > Policy sets > System policy sets**. The Application policy sets collection displays a listing of the custom (if you have created custom policy sets) and default policy sets. Use the Application or System policy sets collection page to create, copy, delete, export, and import policy sets.

The following policy sets are ready for you to use as is.

- LTPA WSSecurity Default
- Kerberos V5 HTTPS default
- SSL WSTransaction
- Username SecureConversation
- Username WSSecurity default
- WS-Addressing default
- WSHTTPS default
- WS-I RSP ND
- WS-ReliableMessaging persistent

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Procedure

- “Viewing policy sets using the administrative console” on page 2667.
  This topic describes the process of viewing and evaluating policy sets.
- “Creating policy sets using the administrative console” on page 2668.
  This topic describes two ways to create policy sets: creating new policy sets or copying and renaming policy set templates.
- “Modifying policy sets using the administrative console” on page 2678.
  This topic describes how to edit custom policy sets you have created.
- “Importing policy sets using the administrative console” on page 2675.

This topic describes how to import policy sets from the default repository or from a selected location.

- "Exporting policy sets using the administrative console" on page 2759.
  This topic describes how to export policy sets.
- "Deleting policy sets using the administrative console" on page 2679.
  This topic describes how to delete custom policy sets. You can delete policy set templates and re-import them if needed.
- "Managing policies in a policy set using the administrative console" on page 2711
  This topic describes how you can define policies with policy sets to secure messages.
- "Defining and managing policy set bindings" on page 2680
  This topic describes configuring custom binding configurations.

Results

Using these tasks, you can determine how to create a new policy set and verify whether you can reuse an existing policy set. You can configure a policy set, and define policies for that policy set.

What to do next

Depending on how you are using policy sets, you might want to revisit some of the tasks listed in this topic to tweak the configuration for your policy set. You can also proceed to configure bindings for your policy set. See Defining binding information for policy sets.

Viewing policy sets using the administrative console

You can use the administrative console to view lists of policy sets. Policy sets can either be default policy sets that you cannot edit or custom policy sets that you have created and can edit. You can use policy sets, or assertions that define services, to simplify your web services configuration because policy sets group security and other web services settings into reusable units.

Before you begin

If you are creating a custom policy set by copying an existing default policy set, you might want to view the existing policy sets to choose a policy set with properties similar to the one you are planning to create.

About this task

You can view a list of policy sets to decide which policy sets can be reused or copied, modified and reused.

Procedure

1. To view policy sets from the administrative console, click **Services > Policy sets > Application policy sets** or **Services > Policy sets > System policy sets**.
2. Set the number of policy set rows that you want to view at a time using the Preferences settings. The default value is 20. The Editable column on the table in this view shows which policy sets you can edit. You can only edit the custom policy sets that you create. You cannot edit the provided default policy sets.
3. To view the details for any of the policy sets, click the name of the policy set in the Name column of the table. The Policy set settings page displays details about the selected policy set. If the policy set is a custom policy set you can edit the fields on the page. If the policy set is a provided default, then you can copy and reuse the policy set. You cannot edit the fields otherwise.

Results

After you have viewed the available policy sets and their settings, you can then decide if you want to create a new policy set, copy an existing policy set that you can rename, or use one of the existing policy sets that meets your needs.

Creating policy sets using the administrative console

You can use the administrative console to either create a policy set by specifying all the necessary information or by copying an existing policy set that you rename. You can use policy sets, or assertions that define services, to simplify your web services configuration because policy sets group security and other web services settings into reusable units.

Before you begin

To create a new policy set, you can either specify the information to create a new policy set or you can copy and rename an existing policy set. Using either method, you need basic information about the policy set that you want to create, such as the name, description, policies to include, policy details, attachments, and binding configurations. If you are creating a policy set by copying an existing policy set, then you should also view the existing policy sets to choose one with properties that are most similar to the one you plan to create.

About this task

Whether you choose to create a new policy set or copy and rename an existing one, start from the Applications policy sets collection in the administrative console.

Procedure

1. From the administrative console, click **Services > Policy sets > Application policy sets** or **Services > Policy sets > System policy sets**.
2. If the policy set you are creating is:
   - a new policy set, then click **New**.
   - an existing policy set to be copied and renamed, click the **Select** box beside the name of the policy set to be copied in the **Name** column and click **Copy**.

   Using either method, this action opens the Policy set settings view to specify the required information about the policy set being created or copied.
3. Enter the name of the policy set that you want to create or copy in the **Name** field.
4. Enter a brief description of the policy set in the **Description** field. This is the description that displays in the Application policy sets or the System policy set collection, so it must be meaningful to you and other potential users of this policy set.

   Note: If you created a new policy set, it does not contain policies to edit until you add them to the policy set. The policy set is initially empty.

Results

You have provided the basic information to create a policy set.

Example

After you have looked at your web services, you might decide that the WS-I RSP default policy set most closely meets your needs. You would go to the administrative console and click **Services > Policy sets > Application policy sets** to access the Application policy sets collection. Locate the WS-I RSP default in the **Name** column of the table and click the box beside it (in the **Select** column). Click **Copy**. This opens

the Policy set settings window. You might want to name your policy set by your company or division so you could provide a name like `ABC WS-I RSP` in the Name field. Because you know others in your organization might access and use it, you've chosen a name that is meaningful to those people too. You want to be sure everyone knows exactly what this copy of the WS-I RSP policy is used for, so you add a description in the **Description** field describing it. Now you want to customize the policy set so you edit the policy information by clicking the name of a policy to edit it.

When you identify the requirements of your web service, you might decide that none of the default policy sets meet your needs closely enough to use them as a template so you might decide to create your own policy set. You would first create the policy set with the name you choose to give it. As if you were reusing an existing template, you would go to the administrative console and click **Services > Policy sets > Application policy sets** and click **New**. The Policy set settings window opens but note that the Policy set name field is blank and there are not yet any associated policies in the table. Enter the name and add any policies necessary.

When you add policies to a policy set, the policies are set to their default values. You can then edit the policies to modify any attribute values that need to be changed and save the settings.

What to do next

If you are creating a new policy set without copying an existing policy set, you need to specify the policy information. If you are copying an existing policy set, you can either accept the default policies associated with the policy set or you can change the policies.

WS-I RSP default policy sets

The Reliable Asynchronous Message Profile (WS-I RSP) default policy sets are based on the Reliable Asynchronous Message Profile specification. The WS-I RSP default policy sets include the WS-I RSP default policy set, the Lightweight Third-Party Authentication (LTPA) WS-I RSP default policy set and the Username WS-I RSP default policy set. You can use these policy sets to simplify your web services configuration.

The WS-I RSP default policy sets are composed of a set of policies to provide reliable and secure web services. The WS-I RSP default policy sets use the WS-Addressing, WS-ReliableMessaging, and WS-Security specifications. Use the WS-I RSP default policy set, the LTPA WS-I RSP default policy set, or the Username WS-Security WS-I RSP default policy set as provided with the application server. To customize the policy sets, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

The WS-I RSP default policy sets include the following policies:

WS-Addressing policy
: You can use the WS-Addressing policy to enable the addressing capability of the WS-Addressing specification.

WS-ReliableMessaging policy
: You can use the WS-ReliableMessaging policy to specify the quality of service for reliable delivery.

WS-Security policy
: The WS-Security policy in the WS-I RSP default policy set provides the following security:

- Message integrity through digital signature that includes signing the body, time stamp, WS-Addressing headers and WS-ReliableMessaging headers using the WS-SecureConversation and WS-Security specifications.
- Confidentiality through encryption that includes encrypting the body, signature elements, using the WS-SecureConversation and WS-Security specifications.
- Traditional RSA cryptography is used to secure a request to a Trust Server to obtain a Secure Context Token (SCT). Thereafter, the conversation is secured using symmetric keys derived from the SCT.

The application server provides additional policy sets that you can use or customize. To use the following default policy sets, you must import the policy sets from the default repository. Read about importing policy sets using the administrative console for more information.

The following WS-I RSP default policy sets exist:

WS-I RSP default
This policy set provides:

- Reliable message delivery to the intended receiver by enabling WS-ReliableMessaging.
- Message integrity through digital signature that includes signing the body, time stamp, WS-Addressing headers and WS-ReliableMessaging headers using the WS-SecureConversation and WS-Security specifications.
- Confidentiality through encryption that includes encrypting the body, signature elements, using the WS-SecureConversation and WS-Security specifications.

LTPA WS-I RSP default
This policy set provides the WS-I RSP default policy set and adds a Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service.

Username WS-I RSP default
This policy set provides the WS-I RSP default policy set and adds a username token included in the request message to authenticate the client to the service. The username token is encrypted in the request.

SecureConversation default policy sets

The SecureConversation default policy sets are based on the Web Services Secure Conversation Language (SecureConversation) standard that establishes a secure context, based on shared keys for the client and server to use for a series of messages. This standard provides a framework to define how to secure the message exchange across organizations. The SecureConversation default policy sets include the SecureConversation policy set, the Lightweight Third-Party Authentication (LTPA) SecureConversation policy set, and the Username SecureConversation policy set.

The SecureConversation default policy sets are based on the WS-SecureConversation, the WS-Security, and the WS-Addressing specifications. Use the SecureConversation policy set, the LTPA SecureConversation policy set, or the Username SecureConversation policy set as provided with the application server. To customize the policy sets, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

The WS-SecureConversation specification alone does not provide a complete security solution. The WS-SecureConversation is built on the WS-Security and WS-Trust specifications to provide secure communication across one or more messages. Specifically, this specification defines mechanisms for establishing and sharing security contexts, and deriving keys from established security contexts or any shared secret.

WS-Security focuses on the message authentication model but not in a security context. The WS-SecureConversation specification defines mechanisms for establishing and sharing security contexts, and deriving keys from security contexts, to enable a secure conversation. By using the SOAP extensibility model, modular SOAP-based specifications are designed to be composed with each other to provide a rich messaging environment.

The following SecureConversation default policy sets exist:

SecureConversation
This policy set provides:

- Message integrity by digital signature that includes signing the body, timestamp, and WS-Addressing headers using WS-SecureConversation and WS-Security specifications.
- Message confidentiality by encryption that includes encrypting the body, signature and signature confirmation elements, using WS-SecureConversation and WS-Security specifications.

LTPA SecureConversation
This policy set provides the SecureConversation policy set and adds a Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service.

Username SecureConversation
This policy set provides the SecureConversation policy set and adds a username token included in the request message to authenticate the client to the service. The username token is encrypted in the request

WS-ReliableMessaging default policy sets

The WS-ReliableMessaging default policy sets are pre-configured to provide reliable message exchange between web services. Two of these policy sets (WS-I RSP and WS-I RSP ND) are immediately available, and the rest are readily available for import from a default repository.

With WS-ReliableMessaging, you can make your SOAP over HTTP-based web services reliable without writing custom code. You can use the provided non-editable default policy sets without change, or you can create customized copies of them.

All the default policy sets that include the WS-ReliableMessaging policy also include the WS-Addressing policy. The WS-ReliableMessaging policy provides the ability to deliver a message reliably to its intended receiver. The WS-Addressing policy provides a transport-neutral way to uniformly address web services and messages, and WS-ReliableMessaging uses WS-Addressing to provide asynchronous request and reply capabilities.

Note: WS-ReliableMessaging Version 1.1 messaging requires WS-Addressing to be mandatory. If you use a policy set that includes WS-ReliableMessaging and WS-Addressing policies, and the WS-Addressing policy is configured as optional, then WebSphere Application Server overrides the WS-Addressing setting and automatically enables WS-Addressing.

The following default policy sets that include the WS-ReliableMessaging policy are immediately available, as described in “Viewing policy sets using the administrative console” on page 2667:

WS-I RSP
This policy set enables WS-ReliableMessaging Version 1.1 and uses the minimum quality of service, *unmanaged non-persistent*. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages. In-order delivery is set to “false”, so messages are not necessarily delivered in the order in which they were sent. Message integrity is provided by digitally signing the body, the time stamp, and the WS-Addressing headers. Message confidentiality is provided by encrypting the body and the signature. This policy set follows the WS-SecureConversation and WS-Security specifications.

WS-I RSP ND
This is the network deployment version of the WS-I RSP policy set. This policy set provides the WS-I RSP default policy set and adds a *managed non-persistent* quality of service. This in-memory quality of service option uses a messaging engine to manage the sequence state, and messages are written to disk if memory is low. This quality of service allows for the re-sending of messages that are lost in the network, and can also recover from server failure. However, state is discarded after a messaging engine restart so in this case you will lose messages.

The following additional default policy sets that include the WS-ReliableMessaging policy are readily available for import, as described in “Importing policy sets using the administrative console” on page 2675:

LTPA WS-I RSP

This policy set provides the WS-I RSP default policy set and adds a Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service.

Username WS-I RSP

This policy set provides the WS-I RSP default policy set and adds a username token included in the request message to authenticate the client to the service. The username token is encrypted in the request.

WSReliableMessaging 1_0

This policy set enables both WS-ReliableMessaging Version 1.0 and WS-Addressing and uses the minimum quality of service, *unmanaged non-persistent*. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages. In-order delivery is set to “false”, so messages are not necessarily delivered in the order in which they were sent.

You can use this policy set with .NET-based web services.

WSReliableMessaging default

This policy set enables both WS-ReliableMessaging Version 1.1 and WS-Addressing and uses the minimum quality of service, *unmanaged non-persistent*. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages. In-order delivery is set to “false”, so messages are not necessarily delivered in the order in which they were sent.

WSReliableMessaging persistent

This policy set enables both WS-ReliableMessaging and WS-Addressing and uses the maximum quality of service, *managed persistent*. This quality of service supports asynchronous web service invocations and uses a service integration messaging engine and message store to manage the sequence state. Messages are processed within transactions, are persisted at the web service requester server and at the web service provider server, and are recoverable in the event of server failure. In-order delivery is set to “false”, so messages are not necessarily delivered in the order in which they were sent.

Because this policy set specifies managed persistent quality of service, you have to define bindings to the service integration bus and messaging engine that you want to use to manage the WS-ReliableMessaging state. You can attach and bind a WS-ReliableMessaging policy set to a web service application by using the administrative console or the wsadmin tool.

WSAddressing default policy set

The WSAddressing default policy set provides a transport-neutral way to uniformly address web services and messages.

The WSAddressing default policy set is based on the WS-Addressing specification. The WS-Addressing standard uses endpoint references and message addressing properties to facilitate the addressing of web services in a standard and interoperable way.

Use the WSAddressing default policy set as provided with the application server. To customize the policy set, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

To learn more about the WS-Addressing standard, read about Web Services Addressing support.

Web Services Security default policy sets

The Web Services Security default policy sets are based on the WS-Security 1.0 and Web Services Addressing (WS-Addressing) specifications. The Web Services Security default policy sets include the WSSecurity default policy set, the Lightweight Third-Party Authentication (LTPA) WSSecurity policy set, the Username WSSecurity policy set, and the Kerberos V5 HTTPS default policy set. These default policy sets are used to build secure web services.

The Web Services Security default policy sets use the WS-Security 1.0 specification enhancements to SOAP messaging to provide quality of protection through message integrity, message confidentiality, and single message authentication. Providing quality of protection means to prevent the following potential threats to SOAP messages:

- The message being modified or read by antagonists.
- An antagonist sending messages to a service that are formed correctly, but lack the appropriate security claims to be processed.

The WS-Addressing specification defines XML 1.0 and XML Namespaces elements to identify web services endpoints and to secure end-to-end endpoint identification in messages.

You can use the WSSecurity default policy set, the LTPA WSSecurity policy set, the Username WSSecurity policy set, or the Kerberos V5 HTTPS default policy set as provided with the application server. To customize the other Web Services Security policy sets, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

Features and details of the default Web Services Security policy sets are as follows:

Kerberos V5 HTTPS default

This policy set provides message authentication with a Kerberos Version 5 token. Message integrity and confidentiality are provided by Secure Sockets Layer (SSL) transport security. This policy set follows the OASIS Kerberos Token Profile V1.1 and WS-Security specifications.

When you use this policy set, configure the basic authentication data and custom properties such as the com.ibm.wsspi.wssecurity.krbtoken.targetServiceName and com.ibm.wsspi.wssecurity.krbtoken.targetServiceHost custom properties in the client bindings. For more information, see the Authentication generator or consumer token settings and Protection token settings (generator or consumer) topics.

LTPA WSSecurity default

This policy set provides:

- Message integrity through digital signature (using RSA public-key cryptography) to sign the body, time stamp, and WS-Addressing headers using WS-Security specifications.
- Message confidentiality through encryption (using RSA public-key cryptography) to encrypt the body, signature and signature elements using WS-Security specifications.
- A Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service.

Username SecureConversation

This policy set provides:

- Message integrity through digital signature that includes signing the body, time stamp, and WS-Addressing headers using WS-SecureConversation and WS-Security specifications
- Message confidentiality through encryption that includes encrypting the body, signature and signature confirmation elements, using WS-SecureConversation and WS-Security specifications
- A username token included in the request message to authenticate the client to the service. The username token is encrypted in the request

Username WSSecurity default

This policy set provides:

- Message integrity through digital signature (using RSA public-key cryptography) to sign the body, time stamp, and WS-Addressing headers using WS-Security specifications.
- Message confidentiality through encryption (using RSA public-key cryptography) to encrypt the body, signature and signature elements using WS-Security specifications.
- A username token included in the request message to authenticate the client to the service. The username token is encrypted in the request.

WSSecurity default

This policy set provides:

- Message integrity through digital signature (using RSA public-key cryptography) to sign the body, time stamp, and WS-Addressing headers using WS-Security specifications.
- Message confidentiality through encryption (using RSA public-key cryptography) to encrypt the body, signature and signature elements using WS-Security specifications.

WSTransaction default policy sets

The WSTransaction default policy sets are based on the WS-Transaction specification and provide transactional integrity for web services. The WSTransaction default policy sets include the WSTransaction policy set and the SSL WSTransaction policy set.

You can use the WSTransaction default policy sets to make your SOAP over HTTP-based web services interoperable and coordinate atomic transactions or business activities without writing custom code. Use the WSTransaction policy set or the SSL WSTransaction policy set as provided with the application server. To customize the policy sets, you must first copy the policy set, and then configure custom policy settings and bindings to meet your needs.

The WSTransaction default policy sets are:

WSTransaction

Use this policy set to coordinate distributed transactional work atomically and interoperably, by using the WS-AtomicTransaction specification. Also, use this policy set to coordinate loosely coupled business processes that are distributed across the heterogenous web service environment, with the ability to compensate actions if a failure occurs in the business activity, by using the WS-BusinessActivity specification.

SSL WSTransaction

Use this policy set to coordinate distributed transactional work atomically, interoperably and securely, by using the WS-AtomicTransaction specification and SSL Transport security. Also, use this policy set to coordinate loosely coupled business processes, with the ability to compensate actions if a failure occurs in the business activity, securely, by using the WS-BusinessActivity specification and SSL Transport security.

WSHTTPS default policy set

The WSHTTPS default policy set provides SSL transport security for the HTTP protocol with web services applications.

The WSHTTPS default policy set is provided with the application server and it contains the HTTP transport policy, the SSL transport policy and the WS-Addressing policy.

You can use the WSHTTPS default policy set as provided with the application server. You cannot edit the WSHTTPS default policy set. You can create a copy of the default policy set and then configure custom policy settings and bindings to meet your needs. Alternatively, you can create a new policy set and specify the policies for it.

Copy of default policy set and bindings settings

Use this page to copy a policy set that you select from a list of available policy sets.

To view this administrative console page:

1. Click **Services > Policy sets > Application policy sets**.
2. Select the policy set that you want to copy, and click **Copy**.
3. Enter a name for the copy of the policy set in the **Name** field.
4. [Optional] Enter a description for the copy of the policy set in the **Description** field.

Name:

Specifies the name of the policy set. Use this field to enter a name for the copy of the policy set.

Description:

Specifies a description of the policy set that you want to copy.

Transfer attachments:

If the policy set that you want to copy is attached to one or more applications, services, or endpoints, then the check box option for **Attach this policy set in place of the original for all attached applications, services, endpoints, and operations**, is available. The default setting for this check box is cleared. You can perform the following actions:

1. Select the **Attach this policy set in place of the original for all attached applications, services, endpoints, and operations** check box to move the attachments to a new policy set. Selecting the check box detaches the original policy set and attaches the replacement policy set in its place.
2. Select **Copy bindings** if you want to copy the bindings of the policy set that is currently attached.
3. [Optional] Select **Restore default bindings** if you want to restore the default bindings.

Importing policy sets using the administrative console

You can import predefined policy sets or import policy sets from a selected location using the administrative console.

Before you begin

Before you begin this task, review Application policy sets collection.

About this task

The policy sets panel has an Import button to allow the import of policy sets. You can import a policy set from the default repository or from a selected location.

Procedure

1. From the administrative console navigation, click **Services > Policy sets > Application policy sets** or **Services > Policy sets > System policy sets**. The policy sets collection page displays a listing of the custom and default policy sets. Custom policy sets are displayed only if you have created them. If you have not created a custom policy set, then only the default policy sets are displayed.
2. From the Application policy sets panel, click **Import**.
3. Choose the option for importing the policy set. You can choose to import a policy set from the default repository or from a selected location. Selecting **Import from Default Repository** accesses the next panel that displays a set of predefined default policy sets that are available for you to import. Some of the predefined policy sets have already been imported for you from the default repository. You can import additional predefined policy sets that are available in the predefined policy set repository.

   Select **Import from Selected Location** to provide a path or browse your file system for a policy set file to import.

   - To import a policy set from the default repository, select **Import from Default Repository** and perform task step 4.

- To import a policy set from a selected location, select **Import from Selected Location** and perform task step 7.

4. Select **Import from Default Repository** and select either the **Import** or the **Import a Copy** radio button.

   The behavior of **Import** policy set:

   - Available for selection of one or more policy sets.
   - Imports the default, not editable, policy set. You are returned to the Application policy sets panel after the import of the policy set.
   - The imported policy set can be deleted, but it cannot be modified.

   The behavior of **Import a Copy** for a policy set:

   - Not available for multiple selection. If multiple policy sets are selected and the **Import a Copy** radio button is selected, an error message is displayed, indicating that only one policy set can be copied at a time.
   - Prompts you for a name and description for the copy. You are returned to the Application policy sets panel after you import the policy set.
   - The imported policy set can be modified or deleted.

5. If you selected **Import** from the previous step, select one or more policy sets to import in the **Name** column.
   a. Click **OK**. You are returned to the Application policy set panel.
   b. Click **Save**, to save your changes to the configuration.
6. If you selected **Import a Copy** from step 4, select the policy set to import a copy in the **Name** column. You can only select one policy set in the Name column to import its copy.
   a. Provide a different name for the copy.
   b. Click **OK**. You are returned to the Application policy set panel.
   c. Click **Save**, to save your changes to the configuration.
7. Select **Import from Selected Location**.
   a. Specify the full path or browse for the policy set file in your file system.
   b. Select either **Use current policy set name** or **Specify a different name to use for this policy set**.
   c. Click **OK**. You are returned to the Application policy set panel.
   d. Click **Save** to save your changes to the configuration.

Results

When you finish this task, you have been able to import a policy set using either the default repository or from a selected location.

Example

If you have a policy set, `XYZ_ps` and you want to import it from a selected location, perform the following steps:

1. From the Application policy set panel, click **Import**.
2. Select **Import from Selected Location**.
3. Specify the full path or browse to where the `XYZ_ps` policy set file is located in your file system.
4. Select either **Use the current policy set name**, `XYZ_ps`, or **Specify a different name for the policy set**.
5. Click **OK**.
6. Click **Save**, to save your changes to the configuration.

What to do next

You can modify or use the policy set that you just imported.

Import policy sets from default repository settings

Use this page to specify a policy set to import from a default repository. You can import predefined policy sets from the default repository.

To view this administrative console page, complete the following actions:

1. Click **Services** > **Policy sets** > **Application policy sets**.
2. Click **Import**.
3. Select **From Default Repository**.
4. You have the Import and Import a copy options. Select **Import a copy**.
5. In the **Name of copy** field, enter a name for the copy of the policy set that you select to import from the list of policy sets.

The behavior of **Import**:

- Available for selection of one or more policy sets.
- Imports the default, not editable, policy set. You are returned to the Application policy sets panel after the import of the policy set.
- The imported policy set can be deleted, but it cannot be modified.

The behavior of **Import a copy** policy set:

- Not available for multiple selection. If multiple policy sets are selected and the **Import a copy** radio button is selected, an error message is displayed, indicating that only one policy set can be copied at a time.
- Prompts you for a name for the copy. The description of the imported policy set is kept, but you can edit the description after you have imported the policy set. You are returned to the Application policy sets panel after the import of the policy set.
- The imported policy set can be modified or deleted.

Name of copy:

Use this field to enter a name for the copy of the policy set that you select to import from the list.

Before you can edit this field, you must select **Import a copy** option.

Buttons:

Click the appropriate button:

Button	Resulting Action
OK	Imports the specified policy set. You are returned to the Application policy set panel after the import.
Cancel	Returns you to the Application policy set panel without importing a policy set.

Import policy sets from a selected location settings

Use this page to specify a policy set to import from a selected location.

To view this administrative console page, click **Services > Policy sets > Application policy sets > Import policy set from selected location**.

On this page, specify a policy set to import from a selected location.

Path and file name for the policy set file:

Specify a fully qualified path and file name to the policy set file or use the **Browse** to locate the file in your file system.

Select **Use current policy set name** if you are not changing the policy set name and click **OK**.

Select **Specify a different name for this policy set** if you are changing the policy set name. Provide a new name and click **OK**.

Button	Resulting action
OK	Imports the specified policy set file if valid or returns an error if an invalid file is provided. You are returned to the Application policy set panel after the import.
Cancel	Returns you to the Application policy set panel without importing a policy set.

Modifying policy sets using the administrative console

You can use the administrative console to modify existing custom policy sets that you have created. If you have copied an existing default policy set or created a policy set yourself, you can always go back and make changes to them to make them better suit the changing needs of your business.

Before you begin

You can create a copy of a policy set and modify the copy. You must first copy a default policy set before you can modify it. See copy of default policy set and bindings settings.

About this task

To modify a custom policy set, you can use the Policy set settings view to access configuration information for the policy set.

Procedure

1. Create a policy set using the steps in “Creating policy sets using the administrative console” on page 2668
2. From the administrative console, click **Services > Policy sets > Application policy sets** >*policy_set_name* or **Services > Policy sets > System policy sets** >*policy_set_name* where *policy_set_name* is the custom policy set of interest that is displayed in the table. This opens the Policy set settings view. You must specify the required information about the policy set that you want to modify.
3. Change the description of the policy set. Edit the brief description of the policy set in the Description field. This is the description that displays in the Application policy sets collection so it must be meaningful to you and other potential users of this policy set.
4. Edit the policy information. You can include, exclude, add or delete policies from this policy set using the settings in the Policies table. To work more extensively with policies, see “Managing policies in a policy set using the administrative console” on page 2711.
5. This step does not apply to system policy sets. Detach the policy set from an application or replace the policy set attached to the application with another policy set. Click the **Attached applications** link to access applications that are attached to this policy set and applications that contain attached service resources. To detach a policy set from an application, use the following steps:
   a. In the Filter list, click **Name**.
   b. Find the application. In the Search term(s) field, enter all or part of the name of the application you want to detach and click **Go**.
   c. Detach the application. Find and select the application in the listing and click **Detach Policy Set**.

To change the policy set that is attached to an application, use the following steps:

a. In the Filter list, click **Name**.
b. Find the application. In the Search term(s) field, enter all or part of the name of the application and click **Go**.
c. Replace the policy set for this application. Find and select the application in the listing and click **Replace Policy Set**. You then have one of the following options:
   - If there are fewer than 25 policy sets to choose from, the Replace Policy Set button is a drop down list and you can click a policy set to attach to the application.
   - If there are more than 25 policy sets to choose from, the Replace Policy Set button opens a collection of policy sets and you can select the policy set to replace from the listing.

Results

Performing these tasks modifies the application to which the custom policy set is attached.

Example

If you had a custom policy set ABC WS-I RSP, for example, that had a misleading description and you want to change the description so that other users know what the policy set really includes, you would access the Policy Set settings view for that policy set. To do this, from the administrative console, you would click **Services > Policy sets > Application policy sets** > ***ABC WS-I RSP***. Then you would click the description field and edit the text so that it better represents the scope of the policy set.

What to do next

If the policy set you have modified is an attached policy set, restart all affected applications to pick up the changes you made. If the policy set is unattached, then no further action is required.

Deleting policy sets using the administrative console

You can use the administrative console to delete the default policy sets or the application specific policy sets that you have created.

Before you begin

If you are deleting an attached policy set, stop all applications and the associated endpoints or operations, then detach and delete the policy set. If the policy set is unattached, then you do not need to detach the policy set before deleting it.

About this task

If a application specific policy set is no longer needed, you might choose to delete it. To delete a application specific policy set, use the Application policy set collection panel.

Procedure

1. From the administrative console, click **Services > Policy sets > Application policy sets** or **Services > Policy sets > System policy sets**.
2. Click the box in the **Select** column next to the policy set that you want to delete.
3. Click **Delete**.
4. Verify that you want to delete this policy set.

Results

The selected application specific policy set is deleted from the list of policy sets and is no longer available.

Example

You might decide that the *ABC WS-I RSP* policy set that you created did not meet your needs as you had expected and you have already created the *DEF WS-I RSP* policy set to better meet your needs. You have detached all the applications and endpoints from the *ABC WS-I RSP* policy set and you want to delete the policy set. Click **Services > Policy sets > Application policy sets** and find the *ABC WS-I RSP* policy set in the listing. Select the *ABC WS-I RSP* policy set and click **Delete**. Confirm that you want to delete the policy set and it is removed from the listing of policy sets. Restart the applications that you detached the ABC WS-I RSP policy from, and you have successfully deleted the policy set.

Alternatively, and depending on your use case, you might want to reassign the attachment to another resource before deleting the policy set. Make a copy of the policy set that you are about to delete, then attach it later to your application or service artifact. See attaching a policy set to a service artifact. You can now delete the policy set.

What to do next

If you have detached and then deleted a policy set from an application, restart all affected applications to pick up this change.

Defining and managing policy set bindings

Policy set bindings contain platform specific information, like keystore, authentication information or persistent information, required by a policy set attachment. Use this task to create and manage bindings.

About this task

In Version 7.0 and later, there are two types of bindings, application specific bindings and general bindings.

Application specific bindings

You can create application specific bindings only at a policy set attachment point. These bindings are specific to and constrained to the characteristics of the defined policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have very limited reuse across policy sets.

When you create an application specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding and fully configure the bindings for each policy that you have added. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application specific bindings.

For service providers, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service provider resources that have an attached policy set. See service providers policy sets and bindings collection. Similarly, for service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service client policy set and bindings collection.

General bindings

General bindings were introduced in Version 7.0. These bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust service attachments. Though

general bindings are highly reusable, they are however not able to provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings:

- General provider policy set bindings
- General client policy set bindings

You can create general provider policy set bindings by accessing **Services > Policy sets > General provider policy set bindings** > **New** in the general provider policy sets panel or by accessing **Services > Policy sets > General client policy set bindings** > **New** in the general client policy set and bindings panel. See defining and managing service client or provider bindings. General provider policy set bindings might also be used for trust service attachments.

Important: The general bindings that are shipped with the product are provider and client sample bindings. These bindings are initially set as the cell default bindings. Do not use these bindings in their current state in a production environment. To use the sample bindings, modify them to meet your security needs in a production environment. Alternatively, create a copy of the bindings and then modify the copy. For example, change the key and keystore settings to ensure security, and modify other settings to match your environment. You must also configure the username and password for Username or LTPA token authentication. See the topic Configuring the username and password for WS-Security Username or LTPA token authentication for more information.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

To view or work with your current policy sets bindings, perform the following:

Procedure

1. To view your current policy set and application specific bindings from the administrative console, click **Services > Policy sets > Application policy sets** >*policy_set_name* > **Attached applications** and then click an application.

   Depending on the application that you select, you can manage the bindings attached to the following policy sets:

   - Service provider policy sets and bindings
   - Service client policy sets and bindings

   To learn more about managing the bindings attached to policy sets, see the service provider or service client policy sets and bindings information.

   Sort on the **Attached policy set** column on either of the policy sets and bindings pages to select the service resources with the same policy set attached. Likewise, sort on the **Binding** column to select the service resources that share the same custom binding to attach to a different policy set. If you sort on the **Policy Set** or the **Binding** column, the hierarchical relationship of the service resources in the first column is not accurate. You can sort again on the **Application/Service/Endpoint/Operation** column to restore the hierarchical relationship. The entries in the **Application/Service/Endpoint/ Operation** column display in ascending order.
2. To work with an existing bindings from the administrative console, click **Services > Policy sets > Application policy sets** >*policy_set_name* > **Attached applications**. Click an application name, and then click either the **Service provider policy sets and bindings** or the **Service client policy sets and bindings**. Then click a binding name in the Bindings column of the table.

   Note: If no applications appear when you click **Attached applications**, you do not have any applications attached to the selected policy set. To attach a policy set and binding to an application using the administrative console, click **Applications > Enterprise Applications >**

application name. Then, click either **Service provider policy sets and bindings** or **Server client policy sets and bindings** to attach resources to your policy set and to assign bindings.

.

3. [Optional] To work with general bindings, click **Services > Policy sets > General client policy set bindings** or **Services > Policy sets > General provider policy set bindings**.

   You can complete the following actions for general bindings:

   - "Importing policy set bindings using the administrative console"
   - "Export policy sets bindings settings" on page 2689
   - "Defining and managing service client or provider bindings" on page 2685
   - "Creating new or configuring existing general binding settings" on page 2688
   - "Copy policy set binding settings" on page 2689
   - "Deleting policy set bindings" on page 2690

Results

When you finish this task, you would have performed one or more of the following:

- Created an application specific or general policy set binding
- Imported a policy set binding
- Exported a policy set binding
- Deleted a policy set binding
- Modified an application attachment to apply an application specific binding for single security domain
- Modified an application attachment to apply an application specific binding for multiple security domain

Importing policy set bindings using the administrative console

You can import predefined client or provider policy set bindings using the administrative console.

Before you begin

This task only applies to general client or provider bindings. Before you begin this task, review the defining and managing service client or provider bindings.

About this task

The general bindings panel has an Import button to allow the import of client or provider policy set bindings. You can import a policy set binding by specifying the full path and filename of the binding to import.

Procedure

1. Navigate to the General client policy set bindings or the General provider policy set bindings panel using one of the following ways:
   - **Services > Policy sets > General client policy set bindings**
   - **Services > Policy sets > General provider policy set bindings**
2. Click **Import**.
3. Specify the full path and file name of the policy set binding to import.
4. Select either **Use current binding name** or **Specify a different name to use for this binding**. If you are importing a binding and that binding name already exists in the repository, you must specify a different name to use for the binding import.
5. Click **OK**.

Results

When you finish this task, you have been able to import a policy set binding using the administrative console.

Example

If you have a policy set binding, `XYZ_psbind` and you want to import it, perform the following steps:

1. From the General client or provider policy set bindings panel, click **Import**.
2. Specify the full path and file name of the policy set binding to import or use **Browse** to locate the binding in your file system.
3. Select either **Use current binding name** or **Specify a different name to use for this binding**.
4. Click **OK**.
5. Click **Save**, to save your changes to the configuration.

What to do next

You can export a policy set binding to reuse it.

Import policy set bindings settings:

Use this page to specify a service client or provider policy set binding to import for your service.

Navigate to the General client policy set bindings or the General provider policy set bindings panel using one of the following ways:

- **Services > Policy sets > General client policy set bindings**
- **Services > Policy sets > General provider policy set bindings**

Click **Import**. Specify a fully qualified path and binding name that you want to use to import the policy set binding. The policy set binding file must be a compressed file.

Full Path with file name:

Specify a fully qualified path and file name to the policy set file or use the browse button to locate the file in your file system.

Select **Use current binding name** if you are not changing the binding name and click **OK**.

Select **Specify a different name for this binding** if you are changing the binding name. Provide a new name and click **OK**.

Button	Resulting action
OK	Imports the specified binding file if valid or returns an error if an incorrect file is provided. You are returned to the General client or provider policy set binding panel after the import.
Cancel	Returns you to the General client or provider policy set binding panel without importing a binding.

Web services policy set bindings

A set of bindings is a named object that is associated with a specific policy set and service resource that is attached to the policy set.

Bindings contain environment and platform specific information, like the following types of information:

- Keys used for signature and encryption
- Keystore information
- Authentication information
- Persistent information

Typically, bindings are specific to the application or the platform, and they are not shared.

There are two types of bindings, application specific bindings and general bindings.

Application specific binding

You can create application specific bindings only at a policy set attachment point. These bindings are specific to and defined by the characteristics of the policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have limited reuse across policy sets.

When you create an application specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding and fully configure the bindings for each policy that you have added. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application specific bindings.

For service providers, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service provider resources that have an attached policy set. See service providers policy sets and bindings collection. Similarly, for service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service client policy set and bindings collection.

General bindings

General bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust service attachments. Although general bindings are highly reusable, they do not provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings:

- General provider policy set bindings
- General client policy set bindings

You can create general provider policy set bindings by accessing **Services > Policy sets > General provider policy set bindings** > **New** in the general provider policy sets panel or by accessing **Services > Policy sets > General client policy set bindings** > **New** in the general client policy set and bindings panel. See defining and managing service client or provider bindings. General provider policy set bindings might also be used for trust service attachments.

Important:

The sample general bindings that are shipped with the product are provider and client sample. Do not use these sample bindings in their current state in a production environment. However, if they were modified to contain non-sample data, you can use these sample bindings in a production environment.

You cannot assign a binding to a service provider resource that does not have a policy set or has an inherited attachment. To assign a binding to such a service provider resource, you

must first attach a policy set to the resource. Also, you cannot assign a binding to a service client resource that does not have an effective policy configuration or has an inherited policy attachment. To assign a binding to such a service client resource, you must first attach a policy set or specify the use of the provider policy.

Defining and managing service client or provider bindings

Service client or provider bindings are general bindings. You can create, copy, and manage general bindings such as the client or provider policy set bindings. These bindings provide system-specific configuration and can be reused across policy set attachments.

Before you begin

You cannot assign a binding to a service provider resource that does not have a policy set or has an inherited attachment. To assign a binding to such a service provider resource, you must first attach a policy set to the resource. Also, you cannot assign a binding to a service client resource that does not have an effective policy configuration or has an inherited policy attachment. To assign a binding to such a service client resource, you must first attach a policy set or specify the use of the provider policy. For more information, read about attaching a policy set to a service artifact.

About this task

There are two types of bindings, application specific bindings and general bindings.

Application specific binding

You can create application specific bindings only at a policy set attachment point. These bindings are specific to and defined by the characteristics of the policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have limited reuse across policy sets.

When you create an application specific binding for a policy set attachment, the binding begins in an unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding and fully configure the bindings for each policy that you have added. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application specific bindings.

For service providers, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service provider resources that have an attached policy set. Similarly, for service clients, you can only create application specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set.

General bindings

General bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust service attachments. Though general bindings are highly reusable, they do not provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings:

- General provider policy set bindings
- General client policy set bindings

Important: The general bindings that are included with the product are provider and client sample bindings. Do not use these bindings in their current state in a production environment. However, if they were modified to contain non-sample data, they could be used in a production environment.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

You can complete the following tasks to define and manage general client or provider policy set bindings.

Procedure

1. To create a new general client or provider policy set binding or to manage the binding configuration from the administrative console, click **Services > Policy sets > General client policy set bindings** > **New**. You can also access this panel by clicking **Services > Policy sets > General provider policy set bindings** > **New**. Use the resulting detail panel to create a new client or provider policy set binding. For more information, read about creating new or configuring existing general binding settings.
2. To copy a specific policy set binding, select the binding name from the table and click **Copy**. For more information, read about copying a policy set binding settings.
3. To import a client or provider policy set binding, click **Import**. Read about importing policy set bindings using the administrative console to complete the import task.
4. To export a client or provider policy set binding, select the binding name from the table, and click **Export**. For more information, read about export policy set binding settings.
5. To delete a policy set binding, select the binding name from the table, and click **Delete**. For more information, read about deleting policy set bindings.

Results

When you finish this task, you have created, copied, exported, imported or deleted a client or provider policy set binding.

Service client or provider policy set bindings collection:

Use this page to create, copy, and manage general policy set bindings, such as the service client or provider bindings. These bindings provide system-specific configuration, and can be reused across policy set attachments. You can select the general default bindings, create new general bindings, or use existing bindings for an attached policy set.

To view this administrative console page, click **Services** > **Policy Sets** > **General client policy set bindings**. You can also view this page by clicking **Services** > **Policy Sets** > **General provider policy set bindings**.

About policy set bindings

There are two types of bindings, application specific bindings and general bindings.

Application specific binding

You can create application specific bindings only at a policy set attachment point. These bindings are specific to and defined by the characteristics of the defined policy. Application specific bindings can provide configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have limited reuse across policy sets.

When you create an application specific binding for a policy set attachment, the binding begins in an unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding and fully configure the bindings for each policy that you have added. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application specific bindings.

For service providers, you can only create application specific bindings by selecting **Assign Binding** > **New Application Specific Binding** for service provider resources that have an attached policy set. See service providers policy sets and bindings collection. Similarly, for service clients, you can only create application specific bindings by selecting **Assign Binding** > **New Application Specific Binding** for service client resources that have an attached policy set. See service client policy set and bindings collection.

General bindings

General bindings were introduced in WebSphere Application Server Version 7.0. These bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust service attachments. Though general bindings are highly reusable, they are however not able to provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings:

- General provider policy set bindings
- General client policy set bindings

You can create general provider policy set bindings by accessing **Services** > **Policy sets** > **General provider policy set bindings** > **New** in the general provider policy sets panel. Or, you can create general client policy set bindings by accessing **Services** > **Policy sets** > **General client policy set bindings** > **New** in the general client policy sets panel. See defining and managing service client or provider bindings. General provider policy set bindings might also be used for trust service attachments.

Important:

The sample general bindings that are shipped with the product are provider and client sample. Do not use these sample bindings in their current state in a production environment. However, if they were modified to contain non-sample data, you can use these sample bindings in a production environment.

You cannot assign a binding to a service provider resource that does not have a policy set or has an inherited attachment. To assign a binding to such a service provider resource, you must first attach a policy set to the resource. Also, you cannot assign a binding to a service client resource that does not have an effective policy configuration or has an inherited policy attachment. To assign a binding to such a service client resource, you must first attach a policy set or specify the use of the provider policy.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Name:

Specifies the name of the service client or provider policy set binding.

The following list of buttons are available to create and manage service client or provider policy set bindings:

Button	Resulting Action
New	Creates a new client or provider policy set binding. This option accesses the New binding panel. The binding is empty initially; you must enter a name and an optional description for a new client or provider policy set binding.

Button	Resulting Action
Delete	Removes the selected client or provider general policy set binding. The default general bindings are being used as the default for a server or a security domain, including the global security domain. You cannot delete default bindings for global security or other security domains. An attempt to delete such default general binding generates an error message that the selected binding cannot be deleted because it is currently the default binding for a security domain.
Copy	Creates a modifiable copy of the selected client or provider policy set binding using a new name that you provide.
Import	Imports a client or provider policy set binding. This is a menu item with the option of importing a binding with the same name or providing a different name for the import.
Export	Exports the selected client or provider policy set binding to an archive file.

Security Domain:

Indicates which security domain uses the general policy set binding. The default domain is global security. This column in the collection table appears only when there are multiple security domains to which the binding can be scoped.

Description:

Specifies the user-defined description for the client or provider policy set bindings.

Creating new or configuring existing general binding settings:

Use this page to create a new client or provider policy set binding. You can also use this page to configure an existing general binding. Empty bindings will be deleted. Scoping a binding to a security domain constrains the configuration options to those applicable to that domain and limits use of the binding to the specified domain.

To view this administrative console page, click **Services > Policy sets > General client policy set bindings** > **New**. You can also view this page by clicking **Services > Policy sets > General provider policy set bindings** > **New**.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Bindings configuration name:

Specifies the name of the new binding configuration.

You must enter a binding configuration name to proceed. The name of the binding is automatically applied when you add a policy type and provide additional configuration information. At that time, the initial **Cancel** button is replaced with an **OK** button. Each binding that you add is initially empty, and you are directed to the binding configuration panel to provide additional information for the binding.

Button	Resulting Action
Add	Adds a policy type, such as WS-Security, to a new binding that you create or to an existing binding. You can access the configuration of each policy type binding through the policy type name link. If you click **Cancel** without providing any configuration information for the policy type, that policy type is not saved or included in the list of policy types. You might receive an attention message that the policy type was not saved as part of the binding configuration.

Button	Resulting Action
Delete	Deletes a policy type from the list.
OK	Associates the name of the binding to the policy type information after you add a policy type and provide additional configuration information.
Cancel	Returns you to the General client or provider policy set bindings panel without creating a new binding configuration.

Security domain:

This field is only available in a multiple security domain environment and specifies a valid security domain. You can scope the binding to that particular security domain, which is scoped to the global security domain by default.

Description:

Specifies a brief description of the new client or provider policy set binding.

Export policy sets bindings settings

This task only applies to general client or provider bindings. Use this page to export either a client or provider policy set binding for reuse.

Navigate to the General client policy set bindings or the General provider policy set bindings panel using one of the following paths:

- **Services** > **Policy sets** > **General client policy set bindings**
- **Services** > **Policy sets** > **General provider policy set bindings**

1. Select a binding from the list and click **Export**.
2. Click the binding to download the archive file.
3. Use the file dialog box to select a location for the exported binding. The policy set binding file is exported as a compressed file.
4. Click **Done**.

Copy policy set binding settings

Use this page to view and copy general policy set bindings for either a single security or a multiple security domain environment.

To access this administrative console page, perform the following steps:

1. Click **Services** > **Policy sets** > **General client policy set bindings**. You can also access this page by clicking **Services** > **Policy sets** > **General provider policy set bindings**.
2. Select an existing binding from the list, and click **Copy**.
3. Provide a name and description for the copy.
4. Click **OK**.
5. Click **Save**, to save your changes.

Name:

Specifies the name of copy. You must provide a different name for the copy of the binding configuration.

Security domain:

Specifies a valid security domain. This field is only available in a multiple security domain environment. You can scope the binding to a particular security domain; it is scoped to the global security domain by default.

Description:

Specifies a brief description of the copy of the policy set binding.

Deleting policy set bindings

Use this task to delete general policy set bindings using the administrative console.

About this task

You cannot delete general bindings specified as the default for any server or domain. You also cannot delete general bindings that are assigned to a policy set attachment. To delete other bindings, perform the following steps:

Procedure

1. Click **Services > Policy sets > General client policy set bindings**. You can also access this page by clicking **Services > Policy sets > General provider policy set bindings**.
2. Select an existing binding from the list, and click **Delete**.
3. Click **Save**, to save your changes.

Results

When you finish this task, you have deleted a general policy set binding.

Creating application specific bindings for policy set attachment

After you attach a policy set to a service artifact such as an application, service, or endpoint, you can define application specific bindings for the attached policy set.

Before you begin

Before you can start this task, you must deploy an application containing web services, and attach a policy set. See attaching a policy set to a service artifact.

About this task

The application specific binding panels display options based on the definitions in the attached policy set. For example, if the policy set does not have WS-ReliableMessaging configured, then the application specific binding panels do not display an option to configure WS-ReliableMessaging bindings. To create application specific bindings for an attached policy set, perform the following steps:

Procedure

1. Open the administrative console.
2. To create application specific bindings for a service provider policy attachment, click **Applications > Application Types > WebSphere enterprise applications** >*Service_provider_application_instance* > **Service provider policy sets and bindings**.

   To create application specific bindings for a service client policy attachment, click **Applications > Enterprise applications** > ***application_name*** > **Service client policy sets and bindings**.
3. Select the check box for the service artifact with an attached policy set.
4. Click **Assign Binding** to see a list of available bindings to assign.
5. [Optional] Select a previously defined application specific attachment binding from the list.

   If you decide to create a new application specific binding, complete steps 6 through 9.
6. Click **New**.
7. Specify a name for the binding and select which policies that you want to include in this application specific binding. Click **Add**, and select the policies to add.

8. Complete the information for the specified policies to define associated configuration data.
9. Click **Save**, to save your changes to the master configuration.

Results

When you finish this task, a application specific binding is created for the service artifact with the attached policy set.

Example

You have the application, `app1` with the attached policy set `Username WSSecurity default`, and you want to define application specific bindings. First locate the application in the **Applications > Application Types > WebSphere enterprise applications** collection. Click the **app1** application. You can then click the **Service provider policy sets and bindings** link or the **Service client policy sets and bindings** link. Select the check box for the `app1` application where the policy set is attached. Click **Assign Binding** and click **New**. Specify a name for the binding, such as `myBinding`. Click **Add** and select **WS-Security** from the list. Next, click the link for **WS-Security** policy and complete the panels with the appropriate information. Click **Save**, to save your changes to the master configuration.

What to do next

Restart the application that contains the service artifact with the application specific bindings you created.

Setting server default bindings for policy sets

You can set server default bindings if you want the policy set attachments for service providers and clients that are deployed to the server to use bindings that are different than those that are specified for the cell. If you use multiple security domains, your default server bindings will also override the security domain default bindings.

Before you begin

Before you can set server default bindings for your Java API for XML-Based Web Services (JAX-WS) application, you must first configure at least one general provider policy set binding or general client policy set binding. To define and manage these general bindings, use the administrative console and select **Services > Policy sets > General provider policy set bindings** or **Services > Policy sets > General client policy set bindings** .

About this task

Note: In WebSphere Application Server Version 7.0 and later, the security model was enhanced to a domain-centric security model instead of a server-based security model. The configuration of the default global security (cell) level and default server level bindings has also changed in this version of the product. In the WebSphere Application Server Version 6.1 Feature Pack for Web Services, you can configure one set of default bindings for the cell and optionally configure one set of default bindings for each server. In Version 7.0 and later, you can configure one or more general service provider bindings and one or more general service client bindings. After you have configured general bindings, you can specify which of these bindings is the global default binding. You can also optionally specify general binding that are used as the default for an application server or a security domain.

General service provider and client bindings are not linked to a particular policy set, and they provide configuration information that you can reuse across multiple applications. You can create and manage general provider and client policy set bindings, and then select one of each binding type to use as the default for an application server. Setting the server default bindings is useful if you want the services that are deployed to a server to share binding configuration. You can also accomplish this sharing of binding

configuration by assigning the binding to each application deployed to the server or by setting default bindings for a security domain and assigning the security domain to one or more servers.

You can specify default bindings for your service provider or client that are used at the global security (cell) level, for a security domain, for a particular server. The default bindings are used in the absence of an overriding binding specified at a lower scope. The following list is the order of precedence from lowest to highest that the application server uses to determine which default bindings to use:

1. Server level default
2. Security domain level default
3. Global security (cell) default

The sample general bindings that are provided with the product are initially set as the global security (cell) default bindings. The default service provider binding and the default service client bindings are used when no application specific bindings or trust service bindings are assigned to a policy set attachment. For trust service attachments, the default bindings are used when no trust specific bindings are assigned. If you do not want to use the provided **Provider sample** as the default service provider binding, you can select an existing general provider binding or create a new general provider binding to meet your business needs. Likewise, if you do not want to use the provided **Client sample** as the default service client binding, you can select an existing general client binding or create a new general client binding. To specify your global security (cell) default bindings, use the administrative console, and click **Services > Policy sets > Default policy set bindings**. For environments with multiple security domains, you can optionally choose the general provider and general client bindings that you want to use as the default bindings for a domain.

In addition to choosing default bindings for the global security (cell), you can also choose the general provider and general client bindings that you want to use as the default bindings for a server. This is only necessary if you want to use different default bindings for a particular server than those used by the other servers in the security domain or cell.

To choose the default bindings for a server from the administrative console, click **Servers > Server Types > WebSphere application servers > *server_name*** and then under Security, click **Default policy set bindings**. If you do not choose a general binding as the default for a server, the default bindings for the domain in which the server resides is used. If you do not choose a binding as the default for a domain, the default bindings for the global security (cell) are used. You must choose a default service provider and default service client bindings for the cell. The general bindings that are included with the product are initially set as the global security (cell) default bindings. You cannot delete a binding that is used as part of any policy set attachment or specified as the default binding for server, a domain, or the cell. To learn more about defining default bindings for a server, see the server default bindings documentation.

Note:

> If you have an application that contains one or more application specific bindings that are configured at the WebSphere Application Server Version 6.1 level, this application is a V6.1 application. If you have applications that are deployed to V6.1 servers within the Version 7.0 or later application server environment, or you have V6.1 applications that are deployed to V7.0 or later versions of the application server, you can specify Version 6.1 default policy set bindings for the cell. These bindings are used for both client and provider policy set attachments within V6.1 applications and attachments to service applications that are deployed to a V6.1 server. Additionally, these default bindings are used for V6.1 attachments unless they are overridden at the attachment point by an application specific binding or a V6.1 server default binding. You can upgrade V6.1 bindings to the bindings that are used by WebSphere Application Server V7.0 and later versions. Use the upgradeBindings command using the wsadmin tool to upgrade the bindings level, if the V6.1 application is not installed on WebSphere Application Server V6.1.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation

to learn more about the valid roles for the application server.

Procedure

1. Open the administrative console.
2. To set default policy set bindings for your server, select**Servers > Server Types > WebSphere application servers > *server_name* > Default policy set bindings**.
3. Select the server default provider binding.

   If you specify a server default provider binding, the selected binding overrides the default provider bindings that are specified for the cell or the security domain to which the server is deployed. The default setting is **None**.

   If multiple security domains are in use, the name of the security domain to which each binding is scoped displays beside the name of each available provider binding. Only the bindings that are scoped to the global security level or to the security domain to which the server is deployed are displayed.
4. Select the server default client binding.

   If you specify a server default client binding, the selected binding overrides the default client bindings that are specified for the cell or the security domain to which the server is deployed. The default setting is **None**.

   If multiple security domains are in use, the name of the security domain to which each binding is scoped displays beside the name of each available provider binding. Only the bindings that are scoped to the global security level or to the security domain to which the server is deployed are displayed.
5. Click **Apply** or **OK** to submit your changes.
6. Click **Save** to save your changes to the master configuration.
7. (optional) If you are using a Version 6.1 application, you can specify server V6.1 default policy set bindings. To set these bindings, select **Servers > Server Types > WebSphere application servers > *server_name* > Default policy set bindings > Version 6.1 default policy set bindings**.

   Note: Select the V6.1 default bindings for this server. If your application contains one or more application specific bindings that are configured at the WebSphere Application Server V6.1 level, this application is a V6.1 application. These default bindings are used for client and provider policy set attachments for applications that are deployed to V6.1 servers, and for V6.1 applications that are deployed to V7.0 and later servers. These bindings are used for both client and provider policy set attachments within V6.1 applications and attachments to service applications that are deployed to a V6.1 server. Additionally, these default bindings are used for V6.1 attachments unless they are overridden at the attachment point by an application specific binding or a V6.1 server default binding.

Results

When you complete these steps, the server default bindings are defined and all policy set attachments that specify use of the default binding for your web service applications that are deployed to the server will use server level default bindings.

Example

Suppose you have configured an application server, `server1`, and you have deployed several web service applications to the `server1` application server. Because these applications have similar security and quality of service requirements and you plan for them to share security configuration, you want to define the default bindings for policy set attachments to service providers and clients using the `server1`.

Suppose also that you want to modify the provided general provider binding, **Provider sample**. You can copy and modify this provided sample to take advantage of existing bindings.

1. Copy and modify the provided **Provider sample** and **Client sample** to meet your security and quality of service requirements. Include binding configuration for all policy types.

- Click **Services > Policy sets > General provider policy set bindings**. Select **Provider sample > copy**. Name the new general provider binding, MyServiceProviderbinding , and provide a description for the new binding.
- Click **Services > Policy sets > General client policy set bindings**. Select **Client sample > copy**. Name the new general client binding, MyServiceClientbinding, and provide a description for the new binding.

2. Locate *server1* in the Application servers collection and click the instance. From the administrative console, select **Servers > Server Types > WebSphere application servers** , and click the *server1* instance.
3. Click **Default policy set bindings**.
4. Select the bindings that you want to use for your provider and client policy set attachments. In this example, select your customized general bindings, MyServiceProviderbinding and MyServiceClientbinding.
5. Click **Apply** or **OK** to submit your changes.
6. Click **Save** to save your changes to the master configuration.

Each time you attach a policy set to a service or client deployed to the *server1* application server, it is initially set to use the specified bindings.

.

What to do next

After setting server default bindings, you can start deploying services to the server and start attaching policy sets. Alternatively, you might already have services deployed to the server, and the server is using the global default bindings because there is no server default binding. Now that you have set server default bindings, ensure that the server default bindings are used for the service messages as specified.

Server default binding settings:

Use this page to specify the server default bindings if you want to override the default bindings that are specified for the cell (global security) or the security domain to which the server is deployed.

To view this administrative console page, complete the following actions:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. From Security, click **Default policy set bindings**.

This administrative console page applies only to Java API for XML Web Services (JAX-WS) applications.

Policy set bindings for servers

To understand default policy set bindings, it is important to first understand policy set bindings.

Policy set bindings contain platform-specific information, such as keystore, authentication information or persistent information that is required by a policy set attachment. A policy set attachment is a policy set that is attached to an application resource. In WebSphere Application Server Version 7.0 and later, there are two types of bindings, general bindings and application specific bindings.

There are two types of general bindings, general service provider bindings and general service client bindings. You can configure one or more general service provider bindings and one or more general service client bindings across a range of policy sets. Additionally, you can re-use these general bindings across applications and for trust service attachments. To define and manage general bindings, in the administrative console click **Services** > **Policy sets** > **General provider policy set bindings** or **Services** > **Policy sets** > **General client policy set bindings**. The general service provider and client bindings

have independent settings that you can customize to meet the needs of your environment. To learn more about general bindings, read about defining and managing policy set bindings.

You can create application specific bindings when you attach a policy set to an application resource. These bindings are specific to and defined to the characteristics of the policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have limited reuse across policy sets. To assign application specific bindings to an application for service providers, in the administrative console click **Applications** > **Applications Types** > **WebSphere enterprise applications** > ***application_name*** > **Service provider policy sets and bindings** > **Assign Binding** > **New Application Specific Binding**. To assign application specific bindings to an application for service clients, in the administrative console click **Applications** > **Applications Types** > **WebSphere enterprise applications** > ***application_name*** > **Service client policy sets and bindings** > **Assign Binding** > **New Application Specific Binding**.

Default policy set bindings for servers

Note: In WebSphere Application Server Version 7.0 and later, the security model was enhanced to a domain-centric security model instead of a server-based security model. The configuration of the default global security (cell) level and default server level bindings has also changed in this version of the product. In the WebSphere Application Server Version 6.1 Feature Pack for Web Services, you can configure one set of default bindings for the cell and optionally configure one set of default bindings for each server. In Version 7.0 and later, you can configure one or more general service provider bindings and one or more general service client bindings. After you have configured general bindings, you can specify which of these bindings is the global default binding. You can also optionally specify general binding that are used as the default for an application server or a security domain.

General service provider and client bindings are not linked to a particular policy set, and they provide configuration information that you can reuse across multiple applications. You can create and manage general provider and client policy set bindings and then select one of each binding to use as the default for an application server. Setting the server default bindings is useful if you want the services that are deployed to a server to share binding configuration. You can also accomplish this sharing of binding configuration by assigning the binding to each application deployed to the server or by assigning a security domain with a default binding to your server.

You can specify default bindings for your service provider or client that are used at the cell (global security) level, for a security domain, or for a particular server. The default bindings are used in the absence of an overriding binding specified at a lower scope. The application server uses the following order of precedence, from lowest to highest, when determining which default bindings to use:

1. Server level default
2. Security domain level default
3. Cell (global security) default

The general bindings that are provided with the product are initially set as the cell (global security) default bindings. The default service provider binding and the default service client bindings are used when no application specific bindings or trust service bindings are assigned to a policy set attachment. If you do not want to use the provided **Provider sample** as the default service provider binding, you can select an existing general provider binding or create a new general provider binding to meet your business needs. Likewise, if you do not want to use the provided **Client sample** as the default service client binding, you can select an existing general client binding or create a new general client binding. To specify a cell (global security) default bindings, in the administrative console click **Services** > **Policy sets** > **Default policy set bindings**. For environments with multiple security domains, you can optionally choose the

general provider and general client bindings that you want to use as the default bindings for a domain. To learn more about default policy set bindings for the cell (global security), see the default policy set bindings documentation.

In addition to choosing default bindings for the cell (global security), you can also choose the general provider and general client bindings that you want to use as the default bindings for a server. Use this page to choose the default bindings for a server from the administrative console. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** and then from Security, click **Default policy set bindings**. If you do not choose a general binding as the default for a server, the default bindings for the domain in which the server resides is used. If you do not choose a binding as the default for a domain, the default bindings for the cell (global security) is used. You must choose a default service provider and default service client bindings for the cell. The general bindings that are included with the product are initially set as the cell (global security) default bindings. You cannot delete a binding that has been selected as the default binding for server, a domain, or the cell. Before you delete the binding, you must select a different binding as the default or choose to use the defaults for the cell (global security).

Note:

If you have an application that contains one or more application specific bindings that are configured at the WebSphere Application Server Version 6.1 level, this application is a V6.1 application. If you have applications that are deployed to V6.1 servers within the Version 7.0 or later application server environment, or you have V6.1 applications that are deployed to V7.0 or later versions of the application server, you can specify Version 6.1 default policy set bindings for the cell. These bindings are used for both client and provider policy set attachments within V6.1 applications and attachments to service applications that are deployed to a V6.1 server. Additionally, these default bindings are used for V6.1 attachments unless they are overridden at the attachment point by an application specific binding or a V6.1 server default binding. You can upgrade V6.1 bindings to the bindings that are used by WebSphere Application Server V7.0 and later versions. Use the upgradeBindings command using the wsadmin tool to upgrade the bindings level, if the V6.1 application is not installed on WebSphere Application Server V6.1.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Server default provider binding:

Specifies the default server binding. Select the name of the binding you want to use as the default for service providers deployed to this server.

If you are using multiple security domains, the name of the security domain to which the binding is scoped is specified with the name of the server default provider binding. Only bindings that are scoped to global security or to the security domain to which the server is assigned are available in the list.

Note: It is a best practice to specify a default binding that includes all of the policy types. This practice ensures that your default service provider binding has the necessary configuration for all policy types that you want to use.

Server default client binding:

Specifies the default client binding. Select the name of the binding you want to use as the default for service clients deployed to this server.

If you are using multiple security domains, the name of the security domain to which the binding is scoped is specified with the name of the server default client binding. Only bindings that are scoped to global security or to the security domain to which the server is assigned are available in the list.

Note: It is a best practice to specify a default binding that includes all of the policy types. This practice ensures that your default service client binding has the necessary configuration for all policy types that you want to use.

Version 6.1 default bindings:

If you have a Version 6.1 application that you want to use in the Version 7.0 and later application server environment and you want to specify Version 6.1 default bindings for this server, you can click this link to specify Version 6.1 default bindings.

Server Version 6.1 default policy set bindings:

Use this page to specify the server Version 6.1 default policy set bindings for this server. These default bindings are used for client and provider policy set attachments for applications that are deployed to Version 6.1 servers, and for Version 6.1 applications that are deployed to Version 7.0 servers. The default bindings are used for Version 6.1 attachments unless overridden at the attachment point.

To view this administrative console page, complete the following actions:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***
2. Under Security, click **Default policy set bindings**
3. Click **Version 6.1 default policy set bindings**

This administrative console page applies only to Java API for XML Web Services (JAX-WS) applications.

Version 6.1 default policy set bindings

You can install a WebSphere Application Server Version 6.1 Feature Pack for Web Services application within the WebSphere Application Server Version 7.0 and later environment. If your application contains Version 6.1 custom bindings, the application is defined as a Version 6.1 application to the application server. Additionally, if your application is installed on a WebSphere Application Server Version 6.1 Feature Pack for Web Services server within the WebSphere Application Server Version 7.0 and later environment, the custom binding is created as a Version 6.1 custom binding.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Bindings configuration name:

Specifies the name of the policy set bindings configuration. This field is read-only for default policy set bindings.

Button	Resulting action
Add	Adds a policy to the collection.
Delete	Removes a policy from the collection.

Setting default policy set bindings

You can set provider and client default policy set bindings that are used as the global security default policy set bindings. The specified global security default bindings apply to all web services unless the bindings are overridden at the attachment point, at the server, or at a security domain.

Before you begin

You must first install and configure an application server. After the application server is installed, you must install a Java API for XML-Based Web Services (JAX-WS) application onto your server. Now, you are

ready to attach a policy set to the web service application. You can define and manage general service provider and client policy set bindings for your web service resource by using the administrative console.

About this task

Policy set bindings for servers

After you understand policy set bindings, then it is easier to understand how the default bindings are used.

Policy set bindings contain platform-specific information, such as keystore, authentication information or persistent information that is required by a policy set attachment. A policy set attachment is a policy set that is attached to an application resource. Starting with WebSphere Application Server Version 7.0 and later, there are two types of bindings, general bindings and application specific bindings.

There are two types of general bindings, *general service provider bindings* and *general service client bindings*. You can configure one or more general service provider bindings and one or more general service client bindings and then use them across a range of policy sets. Additionally, you can re-use these general bindings across applications and for trust service attachments. To define and manage general bindings, in the administrative console click **Services > Policy sets > General provider policy set bindings** or **Services > Policy sets > General client policy set bindings**. The general service provider and client bindings have independent settings that you can customize to meet the needs of your environment.

You can create *application specific bindings* when you attach a policy set to a web service application resource. These bindings are specific to and defined by to the characteristics of the defined policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have limited reuse across policy sets. To assign application specific bindings to an application for service providers, in the administrative console click **Applications > Applications Types > WebSphere enterprise applications > *application_name* > Service provider policy sets and bindings**. Select a web service resource with an attached policy and click **Assign Binding > New Application Specific Binding**. To assign application specific bindings to an application for service clients, in the administrative console click **Applications > Applications Types > WebSphere enterprise applications > *application_name* > Service client policy sets and bindings** . Select a web services resource with an attached policy and click **Assign Binding > New Application Specific Binding**. You can additionally assign application specific bindings for service providers or service clients using the administrative console and click **Services > Service providers > *application_name*** or **Services > Service clients > *application_name*** and then select a web services resource with an attached policy and assign your bindings.

To learn more about general bindings or application specific bindings, read about defining and managing policy set bindings.

Default policy set bindings

Note: In WebSphere Application Server Version 7.0 and later, the security model was enhanced to a domain-centric security model instead of a server-based security model. The configuration of the default global security (cell) level and default server level bindings has also changed in this version of the product. In the WebSphere Application Server Version 6.1 Feature Pack for Web Services, you can configure one set of default bindings for the cell and optionally configure one set of default bindings for each server. In Version 7.0 and later, you can configure one or more general service provider bindings and one or more general service client bindings. After you have configured general bindings, you can specify which of these bindings is the global default binding. You can also optionally specify general binding that are used as the default for an application server or a security domain.

General service provider and client bindings are not linked to a particular policy set, and they provide configuration information that you can reuse across multiple applications. You can create and manage general provider and client policy set bindings and then select one of each binding type to use as the default for an application server. Setting the server default bindings is useful if you want the services that are deployed to a server to share binding configuration. You can also share binding configuration by either assigning the binding to each application that is deployed to the server or by setting default bindings for a security domain and assigning the security domain to one or more servers.

You can specify default bindings for your service provider or client that are used at the global security (cell) level, for a security domain, for a particular server. The default bindings are used in the absence of an overriding binding specified at a lower scope. The following list is the order of precedence from lowest to highest that the application server uses to determine which default bindings to use:

1. Server level default
2. Security domain level default
3. Global security (cell) default

The sample general bindings that are provided with the product are initially set as the global security (cell) default bindings. The default service provider binding and the default service client bindings are used when no application specific bindings or trust service bindings are assigned to a policy set attachment. For trust service attachments, the default bindings are used when no trust specific bindings are assigned. If you do not want to use the provided **Provider sample** as the default service provider binding, you can select an existing general provider binding or create a new general provider binding to meet your business needs. Likewise, if you do not want to use the provided **Client sample** as the default service client binding, you can select an existing general client binding or create a new general client binding. To specify your global security (cell) default bindings, in the administrative console click **Services > Policy sets > Default policy set bindings**. For environments with multiple security domains, you can optionally choose the general provider and general client bindings that you want to use as the default bindings for a domain.

In addition to choosing default bindings for the global security (cell), you can also choose the general provider and general client bindings that you want to use as the default bindings for a server. This is only necessary if you want to use different default bindings for a particular server than those used by the other servers in the security domain or cell. To choose the default bindings for a server from the administrative console, click **Servers > Server Types > WebSphere application servers >** *server_name* and then from Security, click **Default policy set bindings**. If you do not choose a general binding as the default for a server, the default bindings for the domain in which the server resides is used. If you do not choose a binding as the default for a domain, the default bindings for the global security (cell) are used. You must choose a default service provider and default service client bindings for the cell. The general bindings that are included with the product are initially set as the global security (cell) default bindings. You cannot delete a binding that is used as part of any policy set attachment or specified as the default binding for the server, a domain, or the cell. To learn more about defining default bindings for a server, see the server default bindings documentation.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Procedure

1. Open the administrative console.
2. To set global security default policy set bindings, select **Services > Policy sets > Default policy set bindings**.
3. Select the default service provider binding. The default service provider binding is used as the default for policy set attachments unless the provider or client binding is overridden at the attachment point, at the server, or at a security domain. The default setting is **Provider sample**.

4. Select the default service client binding. If you specify a default service client binding, the selected binding overrides the default bindings that are specified for the cell or the security domain to which the server is deployed. The default setting is **Client sample**.
5. If multiple security domains are enabled, you can view the default provider bindings and the default client bindings for each security domain that is defined in the security domain default bindings collection. You can select the security domain name link if you want to access the domain and select different default bindings. Additionally, you can select the default provider binding links or the default client binding links to access the default bindings and select different default binding settings.
6. Click **Apply** to apply selected bindings as the global default bindings.
7. Click **Save** to save your changes to the master configuration.
8. (optional) If you are using a Version 6.1 application, you can specify server V6.1 default policy set bindings. To set these bindings, select **Services > Policy sets > Default policy set bindings > Version 6.1 default policy set bindings**.

   Note:

   If you have an application that contains one or more application specific bindings that are configured at the WebSphere Application Server Version 6.1 level, this application is a V6.1 application. If you have applications that are deployed to V6.1 servers within the Version 7.0 or later application server environment, or you have V6.1 applications that are deployed to V7.0 or later versions of the application server, you can specify Version 6.1 default policy set bindings for the cell. These bindings are used for both client and provider policy set attachments within V6.1 applications and attachments to service applications that are deployed to a V6.1 server. Additionally, these default bindings are used for V6.1 attachments unless they are overridden at the attachment point by an application specific binding or a V6.1 server default binding. You can upgrade V6.1 bindings to the bindings that are used by WebSphere Application Server V7.0 and later versions. Use the upgradeBindings command using the wsadmin tool to upgrade the bindings level, if the V6.1 application is not installed on WebSphere Application Server V6.1.

Results

When you complete these steps, you have defined your global security (cell) default policy set bindings and domain default policy set bindings, if applicable.

Example

Suppose that you do not want to use the provided general provider binding, **Provider sample**, as your default service provider binding. To take advantage of existing bindings, you can copy and modify the **Provider sample** to meet your business needs. This example assumes that your server environment has SecurityDomain1 and SecurityDomain2 defined.

1. Copy and modify the provided **Provider sample** general service provider binding. Click **Services > Policy sets > General provider policy set bindings**. Select **Provider sample > copy**. Name the new general provider binding, MyServiceProviderbinding, and provide a description for the new binding.
2. Copy and modify the provided **Client sample** general service client binding. Click **Services > Policy sets > General client policy set bindings**. Select **Client sample > copy**. Name the new general client binding, MyServiceClientbinding, and provide a description for the new binding.
3. To specify the default policy set bindings for your global security (cell) and for your domains, click **Services > Policy sets > Default policy set bindings**. From this page, select MyServiceProviderbinding as the default service provider binding, and select MyClientProviderbinding as the default service client binding.
4. Click **Apply** and **Save** to save your changes to the master configuration.

Assigning a domain default binding is optional. Generally, you assign domain default policy set bindings only when you want the servers in the domain to use different default bindings than the rest of the cell. In this example, suppose you have defined another general provider binding, MyServiceProviderbinding2, and you want to specify this binding as the domain default binding for your SecurityDomain1 domain.

1. From the security domain default bindings collection click **SecurityDomain1 > Default policy set bindings**. From this page, you can select MyServiceProviderbinding2 as the service provider domain default binding.
2. Click **Apply** and **Save** to save your changes to the master configuration.

Default policy set bindings collection:

Use this page to specify the service provider and client default bindings. The specified service provider and client bindings are used at the cell (global security) level unless these specified bindings are overridden at the attachment point, at the server, or at a security domain.

To view this administrative console page, click **Services** > **Policy sets** > **Default policy set bindings**.

This administrative console page applies only to Java API for XML Web Services (JAX-WS) applications.

Policy set bindings for servers

To understand default policy set bindings, it is important to first understand policy set bindings.

Policy set bindings contain platform-specific information, such as keystore, authentication information or persistent information that is required by a policy set attachment. A policy set attachment is a policy set that is attached to an application resource. There are two types of bindings, general bindings and application specific bindings.

There are two types of general bindings, general service provider bindings and general service client bindings. You can configure one or more general service provider bindings and one or more general service client bindings across a range of policy sets. Additionally, you can re-use these general bindings across applications and for trust service attachments. To define and manage general bindings, in the administrative console click **Services > Policy sets > General provider policy set bindings** or **Services** > **Policy sets** > **General client policy set bindings**. The general service provider and client bindings have independent settings that you can customize to meet the needs of your environment. To learn more about general bindings, read about defining and managing policy set bindings.

You can create application specific bindings when you attach a policy set to an application resource. These bindings are specific to and defined to the characteristics of the policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application specific bindings have limited reuse across policy sets. To assign application specific bindings to an application for service providers, in the administrative console click **Applications** > **Applications Types** > **WebSphere enterprise applications** > ***application_name*** > **Service provider policy sets and bindings** > **Assign Binding** > **New Application Specific Binding**. To assign application specific bindings to an application for service clients, in the administrative console click **Applications** > **Applications Types** > **WebSphere enterprise applications** > ***application_name*** > **Service client policy sets and bindings** > **Assign Binding** > **New Application Specific Binding**.

Default policy set bindings for servers

Note: In WebSphere Application Server Version 7.0 and later, the security model was enhanced to a domain-centric security model instead of a server-based security model. The configuration of the default global security (cell) level and default server level bindings has also changed in this version of the product. In the WebSphere Application Server Version 6.1 Feature Pack for Web Services, you can configure one set of default bindings for the cell and optionally configure one set of default

bindings for each server. In Version 7.0 and later, you can configure one or more general service provider bindings and one or more general service client bindings. After you have configured general bindings, you can specify which of these bindings is the global default binding. You can also optionally specify general binding that are used as the default for an application server or a security domain.

General service provider and client bindings are not linked to a particular policy set, and they provide configuration information that you can reuse across multiple applications. You can create and manage general provider and client policy set bindings and then select one of each binding to use as the default for an application server. Setting the server default bindings is useful if you want the services that are deployed to a server to share binding configuration. You can also accomplish this sharing of binding configuration by assigning the binding to each application deployed to the server or by assigning a security domain with a default binding to your server.

You can specify default bindings for your service provider or client that are used at the cell (global security) level, for a security domain, or for a particular server. The default bindings are used in the absence of an overriding binding specified at a lower scope. The application server uses the following order of precedence, from lowest to highest, when determining which default bindings to use:

1. Server level default
2. Security domain level default
3. Cell (global security) default

The general bindings that are provided with the product are initially set as the cell (global security) default bindings. The default service provider binding and the default service client bindings are used when no application specific bindings or trust service bindings are assigned to a policy set attachment. If you do not want to use the provided **Provider sample** as the default service provider binding, you can select an existing general provider binding or create a new general provider binding to meet your business needs. Likewise, if you do not want to use the provided **Client sample** as the default service client binding, you can select an existing general client binding or create a new general client binding. To specify a cell (global security) default bindings, in the administrative console click **Services** > **Policy sets** > **Default policy set bindings**. For environments with multiple security domains, you can optionally choose the general provider and general client bindings that you want to use as the default bindings for a domain. To learn more about default policy set bindings for the cell (global security), see the default policy set bindings documentation.

In addition to choosing default bindings for the cell (global security), you can also choose the general provider and general client bindings that you want to use as the default bindings for a server. Use this page to choose the default bindings for a server from the administrative console. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** and then from Security, click **Default policy set bindings**. If you do not choose a general binding as the default for a server, the default bindings for the domain in which the server resides is used. If you do not choose a binding as the default for a domain, the default bindings for the cell (global security) is used. You must choose a default service provider and default service client bindings for the cell. The general bindings that are included with the product are initially set as the cell (global security) default bindings. You cannot delete a binding that has been selected as the default binding for server, a domain, or the cell. Before you delete the binding, you must select a different binding as the default or choose to use the defaults for the cell (global security).

Note:

If you have an application that contains one or more application specific bindings that are configured at the WebSphere Application Server Version 6.1 level, this application is a V6.1 application. If you have applications that are deployed to V6.1 servers within the Version 7.0 or later application server environment, or you have V6.1 applications that are deployed to V7.0 or later versions of the application server, you can specify Version 6.1 default policy set bindings for the cell. These bindings are used for both client and provider policy set attachments within V6.1

applications and attachments to service applications that are deployed to a V6.1 server. Additionally, these default bindings are used for V6.1 attachments unless they are overridden at the attachment point by an application specific binding or a V6.1 server default binding. You can upgrade V6.1 bindings to the bindings that are used by WebSphere Application Server V7.0 and later versions. Use the upgradeBindings command using the wsadmin tool to upgrade the bindings level, if the V6.1 application is not installed on WebSphere Application Server V6.1.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Default service provider binding:

Specifies the default service provider binding that is used as the default for policy set attachments. You can override this default at the attachment point or by a lower level default.

Note: It is a best practice to specify a default binding that includes all of the policy types. This practice ensures that your default service provider binding has the necessary configuration for all policy types that you want to use..

Default service client binding:

Specifies the default service client binding that is used as the default for policy set attachments. You can override this default at the attachment point or by a lower level default.

Note: It is a best practice to specify a default binding that includes all of the policy types. This practice ensures that your default service client binding has the necessary configuration for all policy types that you want to use.

Security domain default bindings:

Specifies a collection of security domain default bindings. This collection only displays if you are using multiple security domains.

If you are using multiple security domains, this collection displays the default client and provider bindings for each security domain. You can select the security domain name link if you want to access the domain and select different default bindings.

Security domain:

Specifies the name of a security domain.

Default provider binding:

Specifies the default service provider binding for the security domain. You can view the default provider binding settings by clicking on the name of default provider binding.

Default client Binding:

Specifies the default client binding for the security domain. You can view the default client binding settings by clicking on the name of default client binding.

Version 6.1 default bindings:

If you have a Version 6.1 application that you want to use in the Version 7.0 application server environment and you want to specify Version 6.1 default bindings for this server, you can click this link to specify Version 6.1 default bindings.

Version 6.1 default policy set bindings:

Use this page to specify Version 6.1 default policy set bindings for the cell (global security). These bindings are used for both client and provider policy set attachments within Version 6.1 applications and attachments to service applications that are deployed to a Version 6.1 server. These default bindings are used for Version 6.1 attachments unless they are overridden at the attachment point or by a Version 6.1 server default binding.

To view this administrative console page when you are specifying Version 6.1 cell level default policy set bindings, complete the following actions:

1. Click **Services** > **Policy sets** > **Default policy set bindings**
2. Click **Version 6.1 default policy set bindings**

This administrative console page applies only to Java API for XML Web Services (JAX-WS) applications.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Version 6.1 default policy set bindings

You can install a WebSphere Application Server Version 6.1 Feature Pack for Web Services application within the WebSphere Application Server Version 7.0 and later environments. If your application contains Version 6.1 custom bindings, the application is defined as a V6.1 application to the application server. Additionally, if your application is installed on a WebSphere Application Server Version 6.1 Feature Pack for Web Services server within the WebSphere Application Server Version 7.0 and later environments, the custom binding is created as a V6.1 custom binding.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Bindings configuration name:

Specifies the name of the policy set bindings configuration. This field is read-only for default policy set bindings.

Policies – HTTP transport:

Links to the HTTP transport policy settings page where you define the HTTP transport settings. The HTTP features and HTTP connection polices are applied to outbound messages. The response listener policy is enforced on inbound messages.

Policies – SSL transport:

Links to the SSL transport policy configuration settings page where you define the SSL transport settings.

Policies – WS-Addressing:

Links to the configuration settings page for the WS-Addressing policy. In a network deployment environment, use this page to enable or disable workload management. Otherwise, you can attach the WS-Addressing policy set to service resources. No additional configuration is required.

Policies – WS-ReliableMessaging:

Links to the page where you configure the WS-ReliableMessaging bindings.

Policies – WS-Security:

Links to the WS-Security policy set bindings settings page where the WS-Security binding are configured.

Domain default bindings settings:

Use this page to specify the default policy set bindings for this security domain.

To view this administrative console page, complete the following actions:
1. Click **Security domains >** *domain_name*
2. From Web Services Bindings, click **Default policy set bindings**

Alternatively, you can view this administrative console page when multiple security domains are defined:
1. Click **Services > Policy sets > Default policy set bindings>*domain_name***
2. In the Security Domain Default Bindings collection, click *domain_name*
3. From Web Services Bindings, click **Default policy set bindings**

This administrative console page applies only to Java API for XML Web Services (JAX-WS) applications.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Domain default provider binding:

Specifies the default provider binding for a specific security domain. You can specify `None` if you want to use the server or global default bindings for services deployed to this server. If you specify a server default binding, this binding takes precedence over the default bindings that are specified for the security domain to which the server is deployed. The name of the security domain to which each binding is scoped is displayed to the right of the name of the binding.

Note: It is a best practice to specify a binding that includes all of the policy types. This practice ensures that your default service provider binding has the necessary configuration for all policy types that you want to use.

Domain default client binding:

Specifies the default client binding for a specific security domain. You can specify `None` if you want to use the server or global default bindings for services deployed to this server. If you specify a server default binding, this binding will take precedence over the default bindings specified for the security domain to which the server is deployed. The name of the security domain to which each binding is scoped is displayed to the right of the name of the binding.

Note: It is a best practice to specify a binding that includes all of the policy types. This practice will ensure that your default client binding has the necessary configuration for all policy types that you want to use.

Modifying default bindings at the server level for policy sets

You can define default bindings for HTTP transport, JMS transport, Secure Sockets Layer (SSL) transport, WS-Addressing, WS-ReliableMessaging, and WS-Security policies.

Before you begin

To create or modify server default bindings, you must first install and configure an application server.

About this task

You can modify default cell bindings that are delivered with the product. Default bindings are not linked to a particular policy set and they provide default settings that might be used for sharing configuration information across multiple applications.

You can create default bindings for individual application servers and customize those bindings to meet your requirements. The policy set bindings are optional. If a policy set binding is not defined at the server level, then the default cell level bindings are used. To modify these default bindings, complete the following steps:

Procedure

1. Open the administrative console.
2. To see which bindings are defined as the defaults for the cell or server, click **Services > Policy sets > Default policy sets bindings**.

   After seeing which bindings are defaults, you can select and edit them from the General provider or General client policy set bindings pages.
3. To edit the default bindings, see “Setting default policy set bindings” on page 2697.

Results

When you finish these steps, the default policy set bindings are modified. If you created default bindings at the server level, those default bindings are used instead of the default bindings at the cell level.

What to do next

You can create application specific bindings for your policy sets. Read about creating application specific bindings for policy set attachments.

Reassigning bindings to policy sets attachments

After you create a custom attachment binding, you can reassign that binding to another service artifact if necessary. You can reset a service artifact, such as an application, service, or endpoint to use the inherited bindings or default bindings.

Before you begin

To reassign an application specific binding or a default binding, there must be an assigned binding for the service artifact.

About this task

You can assign bindings to policy sets and other service artifacts. If you created a policy set and attached it to a service artifact, you can reassign the binding that was initially assigned to that policy set.

Procedure

1. Open the administrative console.
2. To reassign a binding for your service provider, click **Applications > Application Types > WebSphere enterprise applications > *application_name* > Service provider policy sets and bindings**.

   To reassign a binding for your service client, click **Applications > Application Types > WebSphere enterprise applications > *application_name* > Service client policy sets and bindings**.
3. Select the check box for the service artifact with an attachment binding.
4. Select **Assign Binding**.
5. Select the binding that you want to assign.

6. Click **Save**, to save your changes to the master configuration.

Results

The service artifact now inherits the policy set bindings that are indicated in either the **Service provider policy sets and bindings** or **Service client policy sets and bindings** panel.

Restriction: Reassigning the binding for a service artifact only reassigns it for that service artifact and any inherited artifacts. It does not reassign the binding for other non-related and non-inherited attachments to the same policy set or to a different policy set.

Example

If you have the application, `app1` with an attached policy set `Username WSSecurity default`, and you want to define custom bindings, then perform the following steps:

1. Locate the application in the **Applications > Application Types > WebSphere enterprise applications >** ***application_name*** collection.
2. Click the **app1** application.
3. Click the **Service provider policy sets and bindings** link or the **Service client policy sets and bindings** link.
4. Select the check box for the**app1** application where the custom attachment binding is defined.
5. Click **Assign Binding** and select **New**.
6. Provide a name for the application specific bindings.
7. Add required policies to the new application specific bindings.
8. Configure the bindings.
9. Click **Save**, to save your changes to the master configuration.

What to do next

Restart the application that contains the policy set where you reassigned the bindings.

Policy set bindings settings

Use this page to view or define general, application specific, or trust service specific bindings configuration information for policies that you can associate with the selected policy set. This bindings configuration information is specific to a system. Use the links on this page to work with bindings for each specific policy.

To view this administrative console page when you are creating or editing a trust service specific binding, click **Services** > **Trust service** > **Trust service attachments**. Select a binding by clicking the binding name in the table if the binding has been assigned to an attachment. To create a new trust service specific binding, click **Assign binding** > **New Trust Service Specific Binding**.

To view this administrative console page when you are editing a general binding, click **Services** > **Policy sets** > **General provider policy set bindings** or **Services** > **Policy sets** > **General client policy set bindings**.

To view this administrative console page when you are creating or editing an application specific binding, complete the following actions:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications**.
2. Select an application that contains web services. The application must contain a service provider or a service client.
3. Click **Service provider policy sets and bindings** or **Service client policy sets and bindings** in the Web Services Properties section.

4. Select a binding by clicking the binding name in the table if the binding has been assigned to an attachment. You must have previously attached a policy set and assigned an application specific binding.
5. [Optional] To edit a default cell binding or default server binding, click either**Services** > **Policy sets** > **General provider policy set bindings** or **Services** > **Policy sets** > **General client policy set bindings**.

This administrative console page applies only to Java API for XML Web Services (JAX-WS) applications.

About Policy set bindings

Policy set bindings contain platform-specific information, like keystore, authentication information or persistent information, required by a policy set attachment. Each policy set attachment to a service provider or service client must have exactly one binding. When you create a policy set attachment, the general default bindings are used initially. When general bindings are used in association with a policy set attachment, the cell-level general bindings are applied at run time. If application server level bindings exist, the server-level general bindings override the cell-level definition. General bindings specify configuration for both service client and service provider attachments and the general bindings are not tailored to a specific policy set or application. When you define server-level general bindings, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP Transport, that you want to override the general binding and you must fully configure the bindings for each policy that you have added.

An application specific binding is a named binding that you create. Application specific bindings enable you to provide platform-specific configuration information for specific policy set attachments. When you create an application specific binding, the available binding configuration options are tailored to the definitions in the attached policy set. You can reuse application specific bindings for multiple service resources within an application. For example, if you create a trust service specific binding, that binding can be reused only for trust service attachments. When you create an application specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP Transport, that you want to override the general binding and you must fully configure the bindings for each policy that you have added.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Bindings configuration name:

Specifies the name of the policy set bindings configuration. The binding name is not editable when you are editing a binding. When you are creating a new binding, you must specify the binding name.

Note: If you are running a Version 6.1 application, the Binding configuration name is displayed as Version 6.1 default policy set bindings.

Use the following actions to create, edit, or delete policy set bindings.

Button	Resulting action
Add	Adds the selected policy set binding to the application.
Delete	Removes the selected policy set binding from the application.

Policies – HTTP transport:

Links to the HTTP transport policy configuration settings page where you define the HTTP transport settings. The HTTP features and HTTP connection polices are applied to outbound messages. The response listener policy is enforced on inbound messages.

Policies – SSL transport:

Links to the SSL transport policy configuration settings page where you define the SSL transport settings.

Policies – JMS transport:

Links to the JMS transport policy configuration settings page where you define the JMS transport settings.

Policies – WS-Addressing:

Links to the configuration settings page for the WS-Addressing policy. In a WebSphere Application Server, Network Deployment environment, use this page enable or disable workload management. Otherwise, you can attach the WS-Addressing policy set to service resources. No additional configuration is required.

Policies – WS-ReliableMessaging:

Links to the panel where the WS-ReliableMessaging bindings are configured.

Policies – WS-Security:

Links to the WS-Security policy set bindings settings page where the WS-Security bindings are configured.

Policies – Custom properties:

Links to the Custom properties policy set bindings settings page where the Custom properties bindings are configured. The CustomProperties binding is only supported for service clients.

Web Services Addressing policy set binding

Use this page to modify the endpoint reference binding for Web Services Addressing (WS-Addressing). The product enforces this binding on JAX-WS web service applications that use WS-Addressing. This panel applies only to the WebSphere Application Server, Network Deployment version of the product.

To view this administrative console page, click **Services** > **Policy Sets** > **Default policy set bindings** > **WS-Addressing**.

Prevent workload management of referenced endpoints in clusters:

By default, when an application uses the WS-Addressing API createEndpointReference(service, port) method to create an endpoint reference in a cluster environment, that endpoint reference is workload managed. Select this option to prevent the workload management of such endpoint references.

If you select this option, messages that are targeted at such an endpoint reference are always sent to the node on which the endpoint reference was created. This behavior is useful when the endpoint contains in-memory state that is held on a single node, for example, in Web Services Resource Framework (WS-RF) applications.

Note: Although the endpoint reference always represents the same endpoint, the state that is held at that endpoint is not reliable. If the node that is hosting the endpoint fails, the state might be lost. Note also that if the node fails, the endpoint reference is no longer valid.

Data type	Check box
Default	Cleared

Range

Cleared
Endpoint references that are created by the application in a cluster environment are workload managed.

Selected
Endpoint references that are created by the application in a cluster environment are not workload managed.

Attaching a policy set to a service artifact

Attach a policy set to a service artifact, such as an application, service, endpoint or operation, to define the quality of services that are supported. Policy sets can define the policies for WS-Addressing, WS-Security, WS-ReliableMessaging, WS-Transaction, HTTP transport, Java Messaging Service (JMS) transport, and Secure Sockets Layer (SSL) transport.

Before you begin

Before you can start this task, you must deploy an application containing web services. Also, if none of the default policy sets contain the necessary policy definitions, then you must create a custom policy set with the necessary definitions.

About this task

Develop a web service that contains each of the necessary artifacts, and deploy your web services application into your application server instance. Now you can attach policy sets to your service artifacts, such as an application, service, or endpoint.

To attach a policy set to a service artifact, perform the following steps:

Procedure

1. Open the administrative console.
2. To attach a policy set to a service provider, click **Applications > Enterprise applications** > ***application_name*** > **Service provider policy sets and bindings**.

   To attach a policy set to a service client, click **Applications > Enterprise applications** > ***application_name*** > **Service client policy sets and bindings**.
3. Select the check box for the service artifact.
4. Select **Attach** to display a list of available policy sets to attach. Select a policy set from the list.
5. Click **Save**, to save your changes to the master configuration.
6. [Optional] To see what attachments are defined for a given policy set, select **Services** > **Policy sets** > **Application policy sets** > ***policy_set_name*** > **Attached applications**.

Results

When you finish these steps, a policy set is attached to the service artifact.

Example

If you have the application, `app1` and you want to attach the policy set, `WSSecurity default`, then perform the following steps:

1. Locate the `app1` application in the **Applications** > **Enterprise applications** collection.
2. Click the **app1** application.

3. Click the **Service provider policy sets and bindings** link or the **Service client policy sets and bindings** link.
4. Select the check box for the service artifact where the policy set is to be attached.
5. Click **Attach**. Select **WSSecurity default** policy set.
6. Click **Save**, to save your changes to the master configuration.

What to do next

You can create custom bindings for policy set attachments. Read about creating custom bindings for policy set attachments.

You can configure the service client or service provider to share their policies. Read about using WS-Policy to exchange policies in a standard format.

Managing policies in a policy set using the administrative console

When working with policy sets in the administrative console, you can customize the included policies to ensure message security. You can enable, disable, customize, add, or delete policies from a policy set. With your policy sets, you can define policies for WS-Addressing, WS-Security, WS-ReliableMessaging, WS-Transaction, HTTP transport, Java Messaging Service (JMS) transport, and Secure Sockets Layer (SSL) transport. The policies for all but WS-Security are relatively straightforward to define.

Before you begin

You can customize the policies for custom policy sets. The provided default policy sets cannot be edited. Make sure that you have created a copy of the default policy set or created a completely new policy set to specify the policies for this policy set.

About this task

Customize policies associated with a policy set using the administrative console.

Procedure

1. Click one of the following:
   - **Services > Policy sets > Application policy sets** >*policy_set_name*
   - **Services > Policy sets > System policy sets** >*policy_set_name*

   You can also click **Services > Policy sets > Application policy sets** > **New** or **Services > Policy sets > System policy sets** > **New**. Follow this path when you want to create a new policy set and the associated policy or policies.
2. Add a policy to a custom policy set. To do this, see “Adding policies to policy sets using the administrative console” on page 2712.
3. Enable a policy for a custom policy set. To do this, see “Enabling policies for policy sets using the administrative console” on page 2757.
4. Optional: You can also disable a policy from a custom policy set. To do this, see “Disabling policies from policy sets using the administrative console” on page 2757.
5. Optional: You can also delete a policy from a custom policy set. To do this, see “Deleting policies from policy sets using the administrative console” on page 2712.

Results

After you have customized your policies, the associated policy set can protect messages according to the policy or policies defined.

What to do next

If the policy set you have modified is an attached policy set, restart all affected applications to pick up the changes you made. If the policy set is unattached, then no further action is required.

Adding policies to policy sets using the administrative console

You can use the administrative console to add policies to policy sets. Adding and configuring policies to a policy set further defines the rules governing the policy set.

Before you begin

Before adding a policy to a policy set, check that it is not listed as disabled in the **Policies** table. A disabled policy can be listed for the policy set and only need to be enabled to be included in the policy set. If this is the case, the policy does not need to be added and it is not available to be added.

About this task

All policies are initially set to their default values. These values can be edited and the attributes changed using the administrative console.

Procedure

1. Click **Services > Policy sets > Application policy sets** > ***policy_set_name*** or **Services > Policy sets > System policy sets > *policy_set_name***. This displays a listing of available policies in the **Policies** table for the policy set selected. If you created a new policy set and did not copy and rename an existing policy set, this table might contain no policies and you must add them.
2. Add a policy. To add a policy not listed in the **Policies** table of the Policy set settings page, click the **Add** drop down button. This button displays a list of available policies that are not already listed in the **Policies** table and therefore not included in the policy set.
3. Click the policy to be added. The selected policy is added to the **Policies** table. Each policy you add has default settings that can be modified.

Results

After you have added a policy, it is then included in the policy set.

Example

If you were working on policy set ABC_ps (that you created and it therefore has no policies associated with it) you would click the ABC_ps name in the **Policy Sets** collection and then click the **Add** button in the **Policies** table on the **Policy set** settings window. The drop down list displays all available policies for you to choose from. You might decide you want to include the WS-Addressing and WS-Security policies for this policy set. You would select each of those from the list. Then, click the policy name in the table to edit the properties of these policies.

What to do next

If the modified policy set is an attached policy set, restart all affected applications to apply the changes. If the policy set is unattached, then no further action is required.

Deleting policies from policy sets using the administrative console

You can use the administrative console to delete policies from policy sets. Deleting the policy removes the policy that further defined the rules governing the policy set.

Before you begin

Before deleting a policy from a policy set, be sure that you no longer want the policy to be available to the policy set. Otherwise, consider disabling it so that it is still available to the policy set but not currently associated with the policy set. You can disable the policy and leave it available for the policy set by clicking the **Select** button by the policy to be disabled and then clicking the **Disable** button. That policy (and any configuration changes you have made to it) is still available to the policy set but is not currently included in the policy set.

About this task

To delete a policy from a policy set, use the administrative console.

Procedure

1. Click **Services > Policy sets > Application policy sets** > ***policy_set_name*** or **Services > Policy sets > System policy sets > *policy_set_name***. The Policy set settings page displays a listing of available policies in the **Policies** table of the Policy set settings page for the policy set selected. If you created a new policy set and did not copy and rename an existing policy set, this table might contain no policies to delete.
2. Delete the policy from the policy set.
   a. Click the **Select** box beside the policy that you want to delete in the **Policies** table of the Policy set settings page.
   b. Click the **Delete** button.
3. Verify that you want to delete the selected policy from the policy set.

Results

You have deleted the policy from the policy set.

Example

If you have a policy set containing a policy that you no longer want included in that policy set, you have two options: disable it or delete it. In some cases, you might want to disable the policy if you have configured attributes for it that you might want to enable at a later time. You can disable the policy and leave it available for the policy set by clicking the **Select** button by the policy to be disabled and then clicking the **Disable** button. But for this example, you have decided that the policy WS-Addressing is no longer valid for your custom policy set ABC_ps and you and you want to delete it. To delete it, click the **Select** button beside the WS-Addressing policy and then click **Delete**. Confirm that you want to delete the policy.

What to do next

You can now add other policies to the policy set or enable or disable existing policies.

Modifying policies using the administrative console

With your policy sets, you can define policies for WS-Addressing, WS-Security, WS-ReliableMessaging, WS-Transaction, HTTP transport, Java Messaging Service (JMS) transport, and Secure Sockets Layer (SSL) transport. The policies for all but WS-Security are relatively straightforward to define.

Before you begin

The provided default policy sets cannot be edited. You can create a copy of the default policy set or create a completely new policy set in order to specify the policies for it.

About this task

Polices are associated with policy sets, so you can change an instance of a policy for a particular policy set.

Procedure

1. Select the policy set containing the policy you want to modify. To customize the policies associated with a policy set, from the administrative console, click:
   - **Services > Policy sets > Application policy sets** >*policy_set_name*. Click a policy name in the Policies table.
   - Or **Services > Policy sets > System policy sets** >*policy_set_name*. Click a policy name in the Policies table.
2. Modify the settings. Depending on which Policy you choose, different settings can be modified.
3. [Optional] If the policy to be modified is not already in the Policies table, click **Add** and select a policy from the list to modify.
4. Save the changes you have made. Once you change the settings on a policy, you need to save the changes to return to the policy set.

Results

The policy set configuration is saved with the selected modifications.

Example

You have created a copy of the WSReliableMessaging persistent policy set and named it `WSRM_p1`. You want to change the settings on the WSReliableMessaging policy that is included, by default, in the copy of this policy set. So you click your `WSRM_p1` policy set from the Application policy sets window and then click the WSReliableMessaging policy from the Policies table. You can then alter the following settings:

Standard
The default setting is WSReliableMessaging 1.1.

Deliver messages in the order that they were sent
The default setting is false. Valid values are true or false.

Quality of service
The default is Unmanaged non-persistent

Save your changes and return to the Application policy sets window for the WSRM_p1 policy set.

What to do next

You can use the policy set as you have configured or you can change the bindings, attach or detach the policy set from applications.

Note: Because this policy set specifies managed persistent quality of service, you have to define bindings to the service integration bus and messaging engine that you want to use to manage the WS-ReliableMessaging state. You can attach and bind a WS-ReliableMessaging policy set to a web service application by using the administrative console or the wsadmin tool.

Configuring the WS-ReliableMessaging policy:

When working with policy sets in the administrative console, you can customize some policies.

Before you begin

This task assumes that you are working with a policy set to which the WS-ReliableMessaging policy has been added.

Do not edit the policies associated with the provided default policy sets. If you have to modify the reliable messaging policy settings, use a copy of a default policy set or create a new policy set.

At any stage - that is, before or after you have built your reliable web service application, or configured your policy sets - you can set a property that configures endpoints to only support clients that use reliable messaging. This setting is reflected by WS-Policy if engaged.

About this task

To configure the WS-ReliableMessaging policy for a given policy set, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Services** > **Policy sets** > **Application policy sets** > ***policy_set_name*** > **WS-ReliableMessaging**. The "WS-ReliableMessaging settings" on page 2716 form is displayed.
2. Modify one or more of the following properties:

   Standard

   Select the WS-ReliableMessaging specification to use for reliable transmission of your messages. WS-ReliableMessaging Version 1.1 is the default value. Select the WS-ReliableMessaging specification to use for reliable transmission of your messages. WS-ReliableMessaging Version 1.1 is the default value. Details of the supported WS-ReliableMessaging specifications are available at the following web addresses:

   - The WS-ReliableMessaging specification Version 1.0, February 2005.
   - The OASIS WS-ReliableMessaging specification Version 1.1, February 2007.

   Note: If you plan to invoke a .NET-based web service, you must select WS-ReliableMessaging Version 1.0.

   Deliver messages in the order that they were sent

   Select this option if the sender of a request has to receive a response before it sends the next request, or if you want to enable transaction support for inbound (provider) message exchanges as described in "Providing transactional recoverable messaging through WS-ReliableMessaging" on page 3126, or if you want to marginally increase reliability as described in A message is not recovered after a server becomes unavailable, even with the managed persistent quality of service.

   Tip: When you enable this option, WS-ReliableMessaging ensures that the messages are made available to the requester application in the order that they were sent. That is, if WS-ReliableMessaging cannot make a given message available, it will not make any subsequent messages available. However, the requester application must also poll for the messages in the order in which it is to receive them. For example:

   a. WS-ReliableMessaging makes message 1 available, then message 2, then message 3.
   b. The requester application uses asynchronous polling to deliberately poll for message 2, then message 3, then message 1. All three messages are available, so this polling out of order is successful.

   Even though WS-ReliableMessaging is delivering the messages in the order that they were sent, the requester application is choosing to receive them out of order.

Quality of service

Select the radio button for your required quality of service. The three choices are:

Unmanaged non-persistent

You can configure web service applications to use WS-ReliableMessaging with a default in-memory store. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages.

Managed non-persistent

This in-memory quality of service option uses a messaging engine to manage the sequence state, and messages are written to disk if memory is low. This quality of service allows for the re-sending of messages that are lost in the network, and can also recover from server failure. However, state is discarded after a messaging engine restart so in this case you will lose messages.

Managed persistent

This quality of service for asynchronous web service invocations is recoverable. This option also uses a messaging engine and message store to manage the sequence state. Messages are persisted at the web service requester server and at the web service provider server, and are recoverable if the server becomes unavailable. Messages that have not been successfully transmitted when a server becomes unavailable can continue to be transmitted after the server restarts.

The default is unmanaged non-persistent.

Note: All three qualities of service are supported when applications are deployed to the application server. Thin client and client container applications use the first option only.

Note: In WebSphere Application Server Version 6.1, you could also configure whether to use the WS-MakeConnection protocol. This configuration option has now been removed from the administrative console panel, because the product now automatically determines whether WS-MakeConnection is used, based on the following criteria:

- Whether you are using WS-ReliableMessaging Version 1.0 or Version 1.1.
- Whether the requester supports WS-MakeConnection.
- Whether the message exchange protocol is synchronous or asynchronous.

3. Click **OK**.
4. Save your changes to the master configuration.

Results

After you have customized the reliable messaging policy, the associated policy set uses this policy to help ensure reliable delivery of messages.

WS-ReliableMessaging settings:

For the WS-ReliableMessaging policy you can configure the version of the WS-ReliableMessaging standard that you want to use, the order in which messages are delivered, and the required quality of service (the reliability level) for message delivery. The product can enforce these policies on inbound messages and applies them to outbound messages.

To view this page in the console, click the following path: **Services** > **Policy sets** > **Application policy sets** > ***policy_set_name*** > **WS-ReliableMessaging**.

With WebSphere Application Server, you can use WS-ReliableMessaging with Java API for XML-Based Web Services (JAX-WS) web services applications that use a SOAP over HTTP binding. Select the

WS-ReliableMessaging specification to use for reliable transmission of your messages. WS-ReliableMessaging Version 1.1 is the default value. Select the WS-ReliableMessaging specification to use for reliable transmission of your messages. WS-ReliableMessaging Version 1.1 is the default value. Details of the supported WS-ReliableMessaging specifications are available at the following web addresses:

- The WS-ReliableMessaging specification Version 1.0, February 2005.
- The OASIS WS-ReliableMessaging specification Version 1.1, February 2007.

Note: If you plan to invoke a .NET-based web service, you must select WS-ReliableMessaging Version 1.0.

Do not edit the policies associated with the provided default policy sets. If you have to modify the reliable messaging policy settings, use a copy of a default policy set or create a new policy set.

At any stage - that is, before or after you have built your reliable web service application, or configured your policy sets - you can set a property that configures endpoints to only support clients that use reliable messaging. This setting is reflected by WS-Policy if engaged.

Standard:

Deliver messages in the order that they were sent:

Select this option if the sender of a request has to receive a response before it sends the next request.

If you enable in-order delivery, you must also ensure that the requester application polls for the messages in the order in which it is to receive them. For more information, see “Configuring the WS-ReliableMessaging policy” on page 2714.

Specifying in-order delivery also marginally increases reliability if you are using the managed persistent quality of service.

Quality of Service: Select one of the following qualities of service:

Unmanaged non-persistent - Tolerates network and remote system failures
You can configure web service applications to use WS-ReliableMessaging with a default in-memory store. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages. The default is Unmanaged Non-Persistent.

Managed non-persistent - Tolerates system, network, and remote system failures, but state is discarded after messaging engine restart
This in-memory quality of service option uses a messaging engine to manage the sequence state, and messages are written to disk if memory is low. This quality of service allows for the re-sending of messages that are lost in the network, and can also recover from server failure. However, state is discarded after a messaging engine restart so in this case you will lose messages.

Managed persistent - Tolerates system, network, and remote system failures
This quality of service for asynchronous web service invocations is recoverable. This option also uses a messaging engine and message store to manage the sequence state. Messages are persisted at the web service requester server and at the web service provider server, and are recoverable if the server becomes unavailable. Messages that have not been successfully transmitted when a server becomes unavailable can continue to be transmitted after the server restarts.

Note:

- All three qualities of service are supported when applications are deployed to the application server. Thin client and client container applications use the first option only.
- For the unmanaged non-persistent quality of service, the messages are stored only in memory. For both of the managed qualities of service, the messages are managed by a messaging engine and stored in a message store. You specify a binding to a bus and messaging engine on the “WS-ReliableMessaging policy binding” form. If your chosen quality of service is Unmanaged Non-Persistent, which does not use a binding to a messaging engine, then any binding that you specify is ignored.

WS-ReliableMessaging policy binding:

To configure a web service application to use WS-ReliableMessaging, you attach a policy set that contains a WS-ReliableMessaging policy type. This policy type offers a range of qualities of service: managed persistent, managed non-persistent, or unmanaged non-persistent. The managed qualities of service, managed persistent and managed non-persistent, are supported by the service integration bus. Use this page to select the bus and messaging engine to use for the reliable messaging protocol state.

To view this page in the console, click one of the following paths:

- **Services** > **Policy sets** > **Default policy set bindings** > **Version 6.1 default policy set bindings** > **WS-ReliableMessaging** (This is the default binding for client and provider policy set attachments within WebSphere Application Server Version 6.1 applications, and attachments to service applications that are deployed to a Version 6.1 server.)
- **Services** > **Policy sets** > **General provider policy set bindings** > ***provider_policy_set_binding_name*** > **WS-ReliableMessaging** (This binding is used for the specified provider policy set.)
- **Services** > **Policy sets** > **General client policy set bindings** > ***client_policy_set_binding_name*** > **WS-ReliableMessaging** (This binding is used for the specified client policy set.)

Note:

- You only have to specify a binding to a bus and messaging engine if you are using a managed quality of service. If your chosen quality of service is Unmanaged Non-Persistent, any binding that you specify is ignored. The quality of service is defined on the “WS-ReliableMessaging settings” on page 2716 form for your chosen policy set. For more information, see “Configuring the WS-ReliableMessaging policy” on page 2714.
- When many applications use the same messaging engine, it can impact performance. Factors to consider include the number of applications that are already binding to the messaging engine, the CPU utilization, and the message throughput. To improve performance for a single server configuration, create a new messaging engine to bind to your application.

Bus name:

Specifies a list of available service integration buses in the cell. Use the list to select a bus, or click **Manage buses, bus members, and messaging engines** to add a new bus. The bus that you add is selected for this binding configuration when you return to this panel.

Messaging engine:

Specifies a list of each bus member for the selected bus. Use the list to select a bus member, or click **Manage buses, bus members, and messaging engines** to add a new bus member. The bus member that you add is selected for this binding configuration when you return to this panel.

Configuring the WS-Addressing policy:

When working with policy sets in the administrative console, you can add and configure policies to enable standard addressing of web services.

Before you begin

You can specify policies for custom policy sets. The provided default policy sets cannot be edited. You must create a copy of the default policy set or create a completely new policy set in order to specify the policies for it.

About this task

Adding a WS-Addressing policy enables the support for WS-Addressing. This support provides a standard way to address Web services and include addressing information in messages. Adding a WS-Addressing policy is equivalent to configuring the WSDL file for the web service to specify that WS-Addressing should be used.

To specify or configure the policies associated with a policy set, use the administrative console.

Procedure

1. In the navigation pane of the administrative console, click **Services** > **Policy sets** > **Application policy sets** > ***policy_set_name*** > **[Policies] WS-Addressing**. The WS-Addressing settings pane is displayed.
2. Select **WS-Addressing is mandatory** to specify that WS-Addressing information must be included in SOAP message headers. For servers, this setting means that the server returns a fault if it receives a message that does not contain a WS-Addressing header. For clients, this setting means that WS-Addressing headers are always added to SOAP messages. If you have enabled WS-Policy, this requirement is communicated between servers and clients that support WS-Policy.
3. In the **Messaging style** box, select the message exchange pattern to use:
   - **Synchronous and asynchronous**. The targeting of response messages is not restricted.
   - **Synchronous only**. Response messages must be targeted at the WS-Addressing anonymous URI.
   - **Asynchronous only**. Response messages must not be targeted at the WS-Addressing anonymous URI.
4. Click **OK**.
5. Save your changes to the master configuration.

Results

After you have included the WS-Addressing policy in a policy set, the associated policy set uses this policy to address web services.

WS-Addressing policy settings:

Use this page to define the appropriate WS-Addressing policy assertions for this policy set.

To view this administrative console page, click **Services** > **Policy sets** > **Application policy sets** > ***policy_set_name*** > **[Policy] WS-Addressing**, when the policy set includes the WS-Addressing policy type.

You can configure the WS-Addressing policy type for both client-side and provider-side policy sets. If you enable WS-Policy, this configuration is communicated between servers and clients that support WS-Policy.

WS-Addressing is mandatory:

Specifies whether a WS-Addressing SOAP header is included on messages.

Data type	Check box
Default	Cleared

Range

Cleared
WS-Addressing is not mandatory. Servers will not generate a fault if they receive a message that does not contain a WS-Addressing header. Clients might not include WS-Addressing headers in SOAP messages, for example, if WS-Policy is enabled and the server does not specify that WS-Addressing is mandatory.

Selected
WS-Addressing is mandatory. Servers return a fault if they receive a message that does not contain a WS-Addressing header. Clients always include WS-Addressing headers in SOAP messages.

Messaging style:

Specifies the messaging style supported by this policy set.

Use the radio buttons to configure the messaging style.

- Select **Synchronous and asynchronous** to specify that there is no restriction on the targeting of response messages.
- Select **Synchronous only** to specify that response messages must be targeted at the WS-Addressing anonymous URI. You might want to use this messaging style in the following situations:
  - The SOAP headers are not signed, and WS-Security is not enabled. Specifying the synchronous message exchange pattern prevents the server sending messages to a third party, thereby preventing the server from potentially taking part in a Denial of Service attack.
  - Clients with a NAT device between themselves and the endpoint. In this configuration, non-anonymous URIs cannot be routed. Use this setting to prevent the client from sending a message containing a ReplyTo endpoint reference with a non-anonymous URI.
- Select **Asynchronous only** to specify that response messages must not be targeted at the WS-Addressing anonymous URI. This setting does not mean that all non-anonymous URIs are supported, therefore a server can return a fault if it receives a response endpoint reference that it cannot process. You might want to use this messaging style if the endpoint has a very long-running invocation time, and you do not want to hold the connection open while waiting for a response.

The following table shows how the messaging style options correspond to WS-Policy assertions.

Table 257. WS-Addressing messaging style and WS-Policy. This table provides a mapping between messaging style options and WS-Policy assertions.

Messaging style	WS-Policy mapping
Synchronous and asynchronous	wsam:AnonymousResponses or wsam:NonAnonymousResponses
Synchronous only	wsam:AnonymousResponses
Asynchronous only	wsam:NonAnonymousResponses

Required No
Data type Radio button

Configuring the HTTP transport policy:

When working with policy sets in the administrative console, you can customize policies to ensure message security. You can customize the Hypertext Transfer Protocol (HTTP) transport policy configuration or use the policy as it is provided with the default settings.

Before you begin

You can configure some settings for default policies for custom policy sets. The provided default policy sets cannot be edited. To customize a policy set, you must create a copy of the default policy set or create a new policy set and specify the policies for the custom policy set.

About this task

You can configure HTTP transport with the HTTP transport policy. HTTP is an application-level protocol for distributed, collaborative, hypermedia information systems. It is a generic, stateless, protocol that can be used for many tasks beyond its use for hypertext, such as name servers and distributed object management systems, through extension of request methods, error codes and headers. A feature of HTTP is the typing and negotiation of data representation, allowing systems to be built independently of the data being transferred. HTTP features and HTTP connections properties are applied to outbound messages for both the service client and service provider.

You can only configure a policy through a policy set. Therefore, before you can configure the HTTP transport policy, a policy set must exist that contains the HTTP transport policy. The provided default WSHTTPS policy set is read only and it cannot be edited. To customize a policy set that contains the HTTP transport policy, you must first create a copy of the WSHTTPS default policy set or create a new policy set and add the HTTP transport policy to the new policy set.

Note: The WSHTTPS default policy set contains the HTTP transport policy, the SSL transport policy and WS-Addressing policy. If you do not require the SSL transport policy or the WS-Addressing policy, you can customize your copy of the WSHTTPS default policy set to delete the policies that you do not require.

After you have created a copy of the WSHTTPS default policy set or created a new policy set with the HTTP transport policy added, you can customize the HTTP transport policy. Use the HTTP transport policy settings panel to customize the values of the HTTP transport policy properties such as read or write timeout values. Your customized values for the HTTP transport policy now apply for your policy set that contains that custom HTTP transport policy. You can attach this policy set containing your customized HTTP transport policy to your Java API for XML-Based Web Services (JAX-WS) application, its services, endpoints, or operations. This change affects all JAX-WS applications to which that policy set is attached. To learn more about attaching policy sets to applications, see the documentation for managing policy sets for service providers and service clients at the application level.

For example, if you have multiple policy sets, *mypolicyset1* and *mypolicyset2*, containing the HTTP transport policy, you can customize the HTTP transport policy for each policy set to reflect different properties, such as timeout values. Now, you can attach these customized policy sets to one or more applications and these applications will use the HTTP property values associated with the HTTP transport policy that is contained within the attached policy set.

Procedure

1. Create a policy set that contains the HTTP transport policy.
   a. Create a custom policy set.

      From the administrative console, click **Services > Policy Sets > Application policy sets** . From this panel you can create a new policy set, copy an existing default policy set such as WSHTTPS, import a copy of a policy set from the default repository or you can import an existing policy set from your specified location.
   b. Add the HTTP transport policy to the policy set. From the administrative console, click **Services > Policy Sets > Application policy sets > *policy_set_name***. In the policy collection, click **HTTP transport**. The HTTP transport window displays options for configuring the HTTP settings for the transport policy.

c. In the **Protocol Version** drop down list, click the HTTP version to use. HTTP 1.1 is the default setting but HTTP 1.0 is also available. Selecting HTTP 1.1 enables more of the function on the rest of the HTTP transport window as some of the options are not available for HTTP version 1.0.

d. Complete the HTTP Features section. The following check boxes determine which HTTP features are enabled for this transport:

Session Enabled
Whether the HTTP session is enabled when a message is sent.

Enable chunked transfer encoding
Whether chunked transfer encoding is enabled when a message is sent. This option is only available if HTTP 1.1 is selected in the **Protocol version** field (it is greyed out and disabled if HTTP 1.0 is selected).

Send expect "100-request" header
Displays whether the expect "100-request" header is enabled when a message is sent. This option is only available if HTTP 1.1 is selected in the **Protocol version** field (it is greyed out and disabled if HTTP 1.0 is selected).

Accept URL redirection automatically
Displays whether the URL is automatically redirected when a message is sent.

Compress request content
Displays whether the request content is compressed when a message is sent.

Compress response content
Displays whether the response content is compressed when a message is sent.

e. Complete the HTTP Connections section. The following fields determine how HTTP connections are configured for this transport:

Read timeout
Displays the length of time, in seconds, for the read to time out when a message is sent.

Write timeout
Displays the length of time, in seconds, for the write to time out when a message is sent.

Connection timeout
Displays the length of time, in seconds, for the connection to time out when a message is sent.

Use persistent connection
Displays whether a persistent connection is to be used when a message is sent. This option is only available if HTTP 1.1 is selected in the **Protocol version** field.

Resend enabled
Displays whether or not a message can be resent. Click this check box to enable a message to be sent again.

2. Customize the HTTP transport provider bindings.

a. Navigate to the HTTP transport provider bindings. From the administrative console, click **Services > Policy Sets > General provider policy set bindings > *provider_policy_set_binding_name* > HTTP transport**.

The HTTP transport (bindings) window displays options for configuring the HTTP transport bindings.

b. Specify the properties for the Proxy for outbound asynchronous service responses.

The following fields determine proxy specifications for outbound asynchronous service responses:

Host Displays the host name for the outbound asynchronous service responses proxy.

Port Displays the port number for the outbound asynchronous service responses proxy. You can enter or edit the port number.

User name
Displays the user name for the outbound asynchronous service responses proxy.

Password
Displays a placeholder for the password for the outbound asynchronous service responses proxy. You can enter or edit the password. The actual password is masked.

Confirm password
Displays a placeholder for the password for the outbound asynchronous service responses proxy that must match the one in the **Password** field. The actual password is masked.

c. Specify the properties for the Basic authentication for outbound asynchronous responses.

The following fields determine authentication specifications for outbound asynchronous responses:

User name
Displays the user name for basic authentication of outbound asynchronous responses.

Password
Displays a placeholder for the password for basic authentication of outbound asynchronous responses. The actual password is masked.

Confirm password
Displays a placeholder for the password for basic authentication of outbound asynchronous responses that must match the one in the **Password** field. The actual password is masked.

3. Customize the HTTP transport client bindings.

a. Navigate to the HTTP transport client bindings. From the administrative console, click **Services > Policy Sets > General client policy set bindings > *provider_policy_set_binding_name* > HTTP transport**.

The HTTP transport (bindings) window displays options for configuring the HTTP transport bindings.

b. Specify the properties for the Proxy for outbound service requests. The following fields determine proxy specifications for outbound service requests:

Host Displays the host name for the outbound service request proxy.

Port Displays the port number for the outbound service request proxy.

User name
Displays the user name for the outbound service request proxy.

Password
Displays a placeholder for the password for the outbound service request proxy. The actual password is masked.

Confirm password
Displays a placeholder for the password for the outbound service request proxy that must match the one in the **Password** field. The actual password is masked.

c. Specify the properties for Basic authentication for outbound service requests. The following fields determine authentication specifications for outbound service requests:

User name
Displays the user name for basic authentication of outbound service requests.

Password
Displays a placeholder for the password for basic authentication of outbound service requests. The actual password is masked.

Confirm password
Displays a placeholder for the password for basic authentication of outbound service requests that must match the one in the **Password** field. The actual password is masked.

Results

After you have customized the HTTP transport policy, the associated policy set uses this policy to protect message transmission.

Example

You can attach policy sets to an application, its services, endpoints, or operations. In this example scenario, suppose you have two different JAX-WS service clients for your application, but you want to use different HTTP transport property values for each service client. Specifically, you want to configure a different read or write timeout value for each service client. To modify the HTTP timeout values, you can edit the values of the HTTP transport policy that is contained within the policy set that is attached to your application or in this case, your service client. This change affects all applications to which the policy set containing the custom HTTP transport policy is attached.

This example describes the steps for configuring different read, write, and connection timeout values for service clients deployed in the same application server. This example makes the following assumptions:

- There are two JAX-WS service clients, ServiceClient1 and ServiceClient2, that are deployed in the application server.
- The HTTP transport policy has not been previously attached to these applications.

1. Create two new policy sets and add the HTTP transport policy to them. For example: *HTTPServiceClient1Policy* and *HTTPServiceClient2Policy*
   a. Click **Services > Policy sets > Application policy sets > New** .
   b. Enter the name of the new application policy set, *HTTPServiceClient1Policy*.
   c. From the Policies collection, click **Add > HTTP transport**.
   d. Click **Apply** and **Save** to save your changes to the master configuration.
   e. Repeat these steps to create the HTTPServiceClient2Policy.
2. Customize the HTTP transport policy settings for the newly created HTTPServiceClient1Policy and HTTPServiceClient2Policy policy sets. For example, customize the read and write timeout values for the HTTP transport policy contained in the HTTPServiceClient1Policy policy set and the connection timeout value for the HTTP transport policy contained in the HTTPServiceClient2Policy policy set.
   a. Click **Services > Policy sets > Application policy sets >***HTTPServiceClient1Policy* .
   b. From the Policies collection, click **HTTP transport**.
   c. From the HTTP transport policy configuration panel, change the HTTP connection read and write timeout values to 500 seconds.
   d. Click **Apply** and **Save** to save your changes to the master configuration.
   e. Click **Services > Policy sets > Application policy sets >***HTTPServiceClient2Policy* .
   f. From the Policies collection, click **HTTP transport**.
   g. From the HTTP transport policy configuration panel, change the HTTP connection timeout value to 360 seconds.
   h. Click **Apply** and **Save** to save your changes to the master configuration.
3. Attach the custom HTTP transport policy, HTTPServiceClient1Policy, to your application, ServiceClient1. Similarly, attach the custom HTTP transport policy, HTTPServiceClient2Policy, to ServiceClient2.
   a. Click **Services > Service clients >** *ServiceClient1*.
   b. From the Policy set attachments collection, select the service, *ServiceClient1*.
   c. Click **Attach Client Policy Set** and click on *HTTPServiceClient1Policy*.
   d. Click **Save** to save your changes to the master configuration.
   e. Click **Services > Service clients >** *ServiceClient2*.
   f. From the Policy set attachments collection, select the service, *ServiceClient2*.

g. Click **Attach Client Policy Set** and click on *HTTPServiceClient2Policy*.
h. Click **Save** to save your changes to the master configuration.

As a result, the ServiceClient1 application now has the HTTPServiceClient1Policy attached and the HTTP sessions will use a read and write timeout value of 500 seconds. The ServiceClient2 application has the HTTPServiceClient2Policy attached and the HTTP sessions will use a connection timeout value of 360 seconds.

What to do next

You can customize policies to ensure message security by configuring the SSL transport policy.

HTTP transport policy settings:

Use this page to define HTTP transport policy configuration. HTTP features and HTTP connection policies are applied to outbound messages. Any changes to the HTTP transport policy from this console page affects all Java API for XML-Based Web Services (JAX-WS) applications to which this custom HTTP transport policy is attached.

To view this administrative console page, click **Services > Policy sets > Application policy sets** >*policy_set_name* > **HTTP transport**, where *policy_set_name*, applies to any policy set that contains HTTP transport policy.

This administrative console page applies only to Java API for XML Web Services (JAX-WS) applications.

You can only configure a policy through a policy set. Therefore, before you can configure the HTTP transport policy, a policy set must exist that contains the HTTP transport policy.

The WSHTTPS default policy set is provided with the application server and it contains the HTTP transport policy, the SSL transport policy and the WS-Addressing policy. The provided default WSHTTPS policy set is read only and it cannot be edited. To customize a policy set that contains the HTTP transport policy, you must first create a copy of the WSHTTPS default policy set or create a new policy set and add the HTTP transport policy to the new policy set.

After you customize values for the HTTP transport policy, these values now apply for your policy set that contains that custom HTTP transport policy. You can attach this policy set that contains your customized HTTP transport policy to your application, its services, endpoints, or operations. This change affects all JAX-WS applications to which that policy set is attached. To learn more about attaching policy sets to applications, see the documentation for managing policy sets for service providers and service clients at the application level.

Protocol version:

Specifies the version of HTTP protocol to use. Use this list to specify the version of HTTP protocol. The default value is `HTTP 1.1`. The `HTTP 1.0` value is also a valid option.

Some of the remaining options on the HTTP Transport panel only work with HTTP Version 1.1. The following brief descriptions compare these options:

HTTP 1.0
Allows messages to be in MIME-like format, containing meta information about the data transferred and modifiers on the request, response, or both. However, HTTP 1.0 does not sufficiently address the effects of hierarchical proxies, caching, the need for persistent connections, or virtual hosts.

HTTP 1.1
Enables each of two communicating applications to determine the true capabilities or the other. This protocol includes more stringent requirements than HTTP 1.0 to ensure reliable implementation of features.

Session enabled:

Specifies whether the HTTP session is enabled when a message is sent. Select this check box to enable an HTTP session.

If this property is used within a policy set that is attached to a service client, then it indicates whether HTTP session information is propagated to subsequent requests invoked by the same client application. If the property is enabled, the HTTP session information is returned to the service client in a response message is sent in subsequent requests invoked using the same RequestContext object.

If this property is used within a policy set that is attached to a service provider, then it indicates whether or not a new HTTP session is created when a request is being processed. If the property is enabled, then as a request is being processed, a new HTTP session is created if one does not already exist. This HTTP session information is then returned to the service client in the response message.

Enable chunked transfer encoding:

Specifies whether chunked transfer encoding is enabled when a message is sent. Select this check box to enable a chunked transfer encoding. This option is only available if you select HTTP 1.1 in the **Protocol version** field. This option is disabled if you selected the HTTP 1.0 protocol.

The default for this property is `true`.

Send expect "100-request" header:

Specifies whether the `expect "100-request"` header is enabled when a message is sent. Select this check box to enable the `expect "100-request"` header. This option is only available if you selected HTTP 1.1 in the **Protocol version** field. This option is disabled if you selected the HTTP 1.0 protocol.

The purpose of the 100 status is to allow a client that is sending a request message with a request body to determine if the origin server accepts the request, based on the request headers, before the client sends the request body. In some cases, you might not want the client to send the body if the server rejects the message without looking at the body.

The Expect request-header field is used to indicate that particular server behaviors are required by the client. A server that cannot comply with any of the expectation values in the Expect field if a request responds with an appropriate error status.

Accept URL redirection automatically:

Specifies whether the automatic URL redirection is accepted when a message is sent. Select this check box to enable a URL that has been automatically redirected to be accepted.

Compress request content:

Specifies whether the request content is compressed when a message is sent. Content coding is used to allow a document to be compressed without losing the identity of its underlying media type and without loss of information. Select this check box to enable request content that you want to compress. Clicking the Compress request content button enables the **Compression format** option to select the compression method. The default value for the compression format is `gzip`.

Compress response content:

Specifies whether the response content is compressed when a message is sent. Content coding is used to allow a document to be compressed without losing the identity of its underlying media type and without loss of information. Select this check box to enable response content that you want to compress. Clicking the Compress response content button enables the **Compression format** option as he compression method. The default value for the compression format is `gzip`.

Read timeout:

Specifies the length of time, in seconds, for the Web services client to completely read the SOAP response. If the read process does not complete within the specified time, a SOAP fault error is generated on the client machine.

Write timeout:

Specifies the length of time, in seconds, for the write action to time out when a message is sent. Specify the time, in seconds, to enable the write to time out length of time.

Connection timeout:

Specifies the length of time, in seconds, for the connection to time out when a message is sent. Specify the time, in seconds, to enable the connection to time out length of time.

Use persistent connection:

Specifies whether a persistent connection is used when a message is sent. Select this check box to enable use of a persistent connection. This option is only available if you selected HTTP 1.1 in the **Protocol version** field. This option is disabled if you selected the HTTP 1.0 protocol.

Resend enabled:

Specifies whether a message can be resent. Select this check box to resend a message.

HTTP transport bindings settings:

Use this page to define the HTTP transport bindings for the HTTP transport policy.

To configure the HTTP transport bindings for the HTTP transport policy, perform the following:

1. Navigate to the general bindings collection panel using either the **Services > Policy sets > General client policy set bindings** or **Services > Policy sets > General provider policy set bindings** path.
2. Click a general binding in the Name column.
3. Click the **HTTP transport** policy in the Policies table.

This administrative console page applies only to Java API for XML Web Services (JAX-WS) applications.

Important: You can also configure HTTP transport properties such as read or write timeout values for JAX-WS applications that are deployed in the same application server. If you want to customize these HTTP properties, you must edit the HTTP transport policy. To customize the HTTP transport policy settings, click **Services > Policy sets > Application policy sets >*policy_set_name*>HTTP transport policy** where *policy_set_name* applies to any policy set that contains the HTTP transport policy. Your customized values for the HTTP transport policy now apply for your policy set that contains that custom HTTP transport policy. You can attach this policy set that contains your customized HTTP transport policy to your application, its services, endpoints, or operations. This change affects all JAX-WS applications to which that

policy set is attached. To learn more about attaching policy sets to applications, see the documentation for managing policy sets for service providers and service clients at the application level.

Proxy for outbound service requests – Host:

Specifies the host name for the outbound service request proxy. In this field, you can change the name of the host if you are editing an existing set of application specific bindings or you can enter the host name for the outbound service request proxy.

Proxy for outbound service requests – Port:

Specifies the port number for the outbound service request proxy. You can edit an existing port number, or enter a new port number for the outbound service request proxy in this field.

Proxy for outbound service requests – User name:

Specifies the user name for the outbound service request proxy. Enter a user name in this field.

Proxy for outbound service requests – Password:

Specifies a placeholder for the outbound service request proxy password. The actual password is masked.

Proxy for outbound service requests – Confirm password:

Specifies a placeholder for the outbound service request proxy password. Re-enter the password you entered in the **Password** field. The actual password is masked.

Basic authentication for outbound service requests – User name:

Specifies the user name for basic authentication of outbound service requests. Enter or edit the user name.

Basic authentication for outbound service requests – Password:

Specifies a placeholder for basic authentication of outbound service requests password. The actual password is masked.

Basic authentication for outbound service requests – Confirm password:

Specifies a placeholder for basic authentication of outbound service requests password. Re-enter the same password as in the **Password** field. The actual password is masked.

Proxy for outbound asynchronous service responses – Host:

Specifies the host name for the outbound asynchronous service responses proxy. You can enter or edit the host name.

Proxy for outbound asynchronous service responses – Port:

Specifies the port number for the outbound asynchronous service responses proxy. You can enter or edit the port number.

Proxy for outbound asynchronous service responses – User name:

Specifies the user name for the outbound asynchronous service responses proxy. You can enter or edit the user name.

Proxy for outbound asynchronous service responses – Password:

Specifies a placeholder for the outbound asynchronous service responses proxy password. You can enter or edit the password. The actual password is masked.

Proxy for outbound asynchronous service responses – Confirm password:

Specifies a placeholder for the outbound asynchronous service responses proxy password. You can re-enter or edit the password. The actual password is masked.

Basic authentication for outbound asynchronous service responses – User name:

Specifies the user name for basic authentication of outbound asynchronous responses. You can enter or edit the user name.

Basic authentication for outbound asynchronous service responses – Password:

Specifies a placeholder for basic authentication of outbound asynchronous responses password. You can enter or edit the password in this field. The actual password is masked.

Basic authentication for outbound asynchronous service responses – Confirm password:

Specifies a placeholder for basic authentication of outbound asynchronous responses password. Re-enter the password in this field. The actual password is masked.

Custom Properties – Name:

Specifies the name of custom property. Custom properties are not initially displayed in this column until you define them.

Custom Properties – Value:

Specifies the value of the custom property. With the **Value** entry field, you can enter, edit, or delete the value for a custom property.

Click one of the following buttons to enable the action described:

Button	Resulting Action
New	Creates a new custom property entry. To add a custom property, enter the name and value.
Delete	Removes the selected custom property.
Edit	You can edit a selected custom property. It is only displayed when one or more properties exist.

Configuring the Java Message Service (JMS) transport policy:

You can define a Java Message Service (JMS) transport policy configuration if you are using SOAP over JMS with your Java API for XML-Based Web Services (JAX-WS) applications.

Before you begin

You can configure some settings for policies for custom policy sets. The provided default policy sets cannot be edited. You must create a copy of the default policy set or create a new policy set in order to specify the policies for it.

About this task

When using the SOAP over JMS transport with JAX-WS applications, you can customize the transport by configuring the JMS transport policy. The SOAP over JMS transport provides an alternative to HTTPS for transporting SOAP requests and response messages between clients and servers. See the documentation on using SOAP over JMS to transport web services to learn more about this transport protocol.

You can only configure a policy through a policy set. Therefore, before you can configure the JMS transport policy, a policy set must exist that contains the JMS transport policy. To customize a policy set that contains the JMS transport policy, you must first create a policy set and add the JMS transport policy to the new policy set.

Use the JMS transport policy settings panel to customize the values of the JMS transport policy properties, such as the request timeout value. Your customized values for the JMS transport policy now apply for your policy set that contains that custom JMS transport policy. You can attach this policy set containing your customized JMS transport policy to your JAX-WS application, its services, endpoints, or operations. This change affects all JAX-WS applications to which that policy set is attached. To learn more about attaching policy sets to applications, see the documentation for managing policy sets for service providers and service clients at the application level.

Procedure

1. Create a policy set that contains the JMS transport policy.
   a. Create a custom policy set. From the administrative console, click **Services > Policy Sets > Application policy sets**. From this panel you can create a new policy set, import a copy of a policy set from the default repository, or you can import an existing policy set from your specified location.
   b. Add the JMS transport policy to the policy set. From the administrative console, click **Services > Policy Sets > Application policy sets > *policy_set_name***. In the policy collection, click **JMS transport**. The JMS transport window displays options for configuring the JMS settings for the transport policy.
   c. Specify the JMS connection properties for the JMS transport requests. The following fields configure the JMS features for this transport:

      Request timeout
      Specifies whether to enable a request timeout value. The request timeout value is the amount of time that the client waits for a response after sending the request to the server. The range is from 0 to 2147483647.

      Allow transactional messaging for one-way and asynchronous operations
      Specifies to enable a client to use transactions in one-way or asynchronous two-way requests. Select this check box to enable transactional messaging.

      When this option is selected, the client runtime environment exchanges SOAP request and response messages with the server over the JMS transport in a transactional manner if the client is operating under a transaction. This process indicates that the clients transaction is used to send the SOAP request message to the destination queue or topic, and the server receives the request message only after the client commits the transaction. Similarly, the server receives the request message under the control of a container-managed transaction and sends the reply message, if applicable, back to the client using that same transaction. The client then receives the reply message only after the server transaction has been committed.

      If this option is not selected, then the client and server runtime environments perform messaging operations in a non-transactional manner as transactions are temporarily suspended for the JMS request. The transactions are enabled again after the request has completed.

Note: Transactional messaging operations are not supported for two-way synchronous operations as this leads to a deadlock condition.

2. Customize the JMS transport provider bindings.
   a. Navigate to the JMS transport provider bindings. From the administrative console, click **Services > Policy Sets > General provider policy set bindings > *provider_policy_set_binding_name* > JMS transport**.

      The JMS transport provider bindings window displays options for defining basic authentication for asynchronous service responses and custom properties for the JMS service provider binding configuration.

   b. Specify the properties for basic authentication for asynchronous service responses.

      You can use the JMS transport provider policy bindings to configure a service that uses the JMS transport to send asynchronous response messages back to the client. The application server runtime environment uses the user name and password that you configure when connecting to the JMS messaging provider and this configuration enables the service to send an asynchronous response message to the client in a secure manner.

      The following fields determine the authentication requirements for responses from the server:

      User name
      Specifies the user name for the asynchronous service responses for the service provider.

      Password
      Specifies a placeholder for the password for the asynchronous service responses from the service provider. You can enter or edit the password in this field. The actual password is masked.

      Confirm password
      Specifies a placeholder for the password for the asynchronous service responses from the service provider that must match the one in the **Password** field. The actual password is masked.

3. Customize the JMS transport client bindings.
   a. Navigate to the JMS transport client bindings. From the administrative console, click **Services > Policy Sets > General client policy set bindings > *client_policy_set_binding_name* > JMS transport**.

      The JMS transport provider bindings window displays options for defining basic authentication for outbound service requests and custom properties for the JMS client binding configuration.

   b. Specify the Basic Authentication for Outbound Service Requests properties.

      You can use the JMS transport client policy bindings to configure a client that uses the JMS transport to send a request message to the server. The client runtime environment uses the user name and password that you configure when connecting to the JMS messaging provide. This configuration enables the client to send the request message to the server in a secure manner.

      The following fields determine the authentication requirements for requests sent to the server:

      User name
      Specifies the user name that is used by the client runtime when connecting to the JMS messaging provider to send an outbound request to the destination queue or topic. Enter a user name in this field.

      Password
      Specifies a placeholder for the password that is used by the client runtime when connecting to the JMS messaging provider to send an outbound request to the destination queue or topic. You can enter or edit the password in this field. The actual password is masked.

      Confirm password
      Specifies a placeholder for the password that is used by the client runtime when connecting to the JMS messaging provider to send an outbound request to the destination

queue or topic. Re-enter the password in this field. This password must match the one in the **Password** field. The actual password is masked.

Results

After you have customized the JMS transport policy, the associated policy set uses this policy to configure the runtime behavior of the SOAP over JMS transport.

Example

You can attach policy sets to an application, its services, endpoints, or operations. In this example scenario, suppose you have two different JAX-WS service clients for your application, but you want to use different JMS transport request timeout values for each service client. To modify the JMS request timeout values, you can edit the values of the JMS transport policy that is contained within the policy set that is attached to your application or in this case, your service client. This change affects all applications to which the policy set containing the custom JMS transport policy is attached.

This example describes the steps for configuring different request timeout values for service clients deployed in the same application server. This example includes the following assumptions:

- Two JAX-WS service clients exist, ServiceClient1 and ServiceClient2, that are deployed in the application server.
- The JMS transport policy has not been previously attached to these applications.

1. Create two new policy sets and add the JMS transport policy to them. For example: *JMSServiceClient1Policy* and *JMSServiceClient2Policy*
   a. Click **Services > Policy sets > Application policy sets > New** .
   b. Enter the name of the new application policy set, `JMSServiceClient1Policy`.
   c. From the Policies collection, click **Add > JMS transport**.
   d. Click **Apply** and **Save** to save your changes to the master configuration.
   e. Repeat these steps to create the JMSServiceClient2Policy.
2. Customize the JMS transport policy settings for the newly created JMSServiceClient1Policy and JMSServiceClient2Policy policy sets. For example, set the request timeout value to `180` seconds for the JMS transport policy contained in the JMSServiceClient1Policy. The JMS transport policy contained in the JMSServiceClient2Policy specifies `300` seconds as the request timeout value.
   a. Click **Services > Policy sets > Application policy sets > *JMSServiceClient1Policy*** .
   b. From the Policies collection, click **JMS transport**.
   c. From the JMS transport policy configuration panel, specify `180` seconds for the request timeout value.
   d. Click **Apply** and **Save** to save your changes to the master configuration.
   e. Click **Services > Policy sets > Application policy sets > *JMSServiceClient2Policy*** .
   f. From the Policies collection, click **JMS transport**.
   g. From the JMS transport policy configuration panel, specify 300 seconds for the request timeout value.
   h. Click **Apply** and **Save** to save your changes to the master configuration.
3. Attach the custom JMS transport policy, JMSServiceClient1Policy, to your application, ServiceClient1. Similarly, attach the custom JMS transport policy, JMSServiceClient2Policy, to ServiceClient2.
   a. Click **Services > Service clients >** *ServiceClient1*.
   b. From the Policy set attachments collection, select the service, *ServiceClient1*.
   c. Click **Attach Client Policy Set**, and click *JMSServiceClient1Policy*.
   d. Click **Save** to save your changes to the master configuration.
   e. Click **Services > Service clients >** *ServiceClient2*.

f. From the Policy set attachments collection, select the service, *ServiceClient1*.
g. Click **Attach Client Policy Set**, and click *JMSServiceClient2Policy*.
h. Click **Save** to save your changes to the master configuration.

As a result, the ServiceClient1 application now has the JMSServiceClient1Policy attached, and the JMS sessions use a request timeout of 180 seconds. The ServiceClient2 application has the policy, JMSServiceClient2Policy, attached and the JMS sessions use a request timeout of 300 seconds.

What to do next

You can customize other policies that you might need for your application.

JMS transport policy settings:

Use this page to configure settings for the Java Message Service (JMS) transport policy. You can configure a client that is using the JMS transport policy to exchange request and response messages with the server.

To view this administrative console page:
1. Click **Services**, expand **Policy sets**, and click **Application policy sets**.
2. Click **New** to create a new application policy set and provide a name for it in the **Name** field.
3. Under the **Policy** heading, click **Add** and select **JMS transport**.
4. Click **OK** or **Apply**.
5. Click **JMS transport** to view the JMS transport policy settings panel.

This administrative console page applies only to Java API for XML Web Services (JAX-WS) applications.

You can only configure a policy through a policy set. Therefore, before you can configure the JMS transport policy, a policy set must exist that contains the JMS transport policy.

To customize a policy set that contains the JMS transport policy, you must create a new policy set, import a copy of a policy set from the default repository, or you can import an existing policy set from your specified location. After you have an editable policy set, you can add the JMS transport policy to your policy set.

After you customize values for the JMS transport policy, these values now apply for your policy set that contains that customized JMS transport policy. You can attach this policy set that contains your customized JMS transport policy to your application, its services, endpoints, or operations. This change affects all JAX-WS applications to which that policy set is attached. To learn more about attaching policy sets to applications, read about managing policy sets for service providers and service clients at the application level.

Client JMS connection properties - Request timeout:

Specifies the request timeout value. The request timeout value is the amount of time that the client waits for a response after sending the request to the server. The default value is 300 seconds.

Client JMS connection properties - Allow transactional messaging for one-way and asynchronous operations:

Specifies to enable a client to use transactions in one-way or asynchronous two-way requests. Select this check box to enable transactional messaging.

If this option is selected, the client runtime exchanges SOAP request and response messages with the server over the JMS transport in a transactional manner if the client is operating under a transaction. Therefore, the client transaction is used to send the SOAP request message to the destination queue or topic, and the server receives the request message only after the client commits the transaction. Similarly, the server receives the request message under the control of a container-managed transaction and sends the reply message, if applicable, back to the client using that same transaction. The client then receives the reply message only after the server transaction is committed.

If this option is not selected, the client and server runtimes perform messaging operations in a non-transactional manner.

Note: Transactional messaging operations are not supported for two-way synchronous operations as this leads to a deadlock condition.

.

JMS transport bindings:

Use this page to define the Java Message Service (JMS) transport provider or client bindings configuration.

If you are using JMS transport provider bindings, to view this administrative console page, complete the following actions:

1. Click **Services > Policy Sets > General provider policy set bindings**.
2. Click ***provider_policy_set_binding_name***.
3. In the policy collection, click **JMS transport**.

If the JMS transport policy has not been added to the selected general provider policy set, then use the create general provider bindings panel to add the JMS transport policy to the selected general provider policy set.

You can use the JMS transport provider policy bindings to configure a service that uses the JMS transport to send asynchronous response messages back to the client. The application server run time uses the user name and password that you configure when connecting to the JMS messaging provider and this configuration enables the service to send an asynchronous response message to the client in a secure manner.

If you are using JMS transport client bindings, to view this administrative console page, complete the following actions:

1. Click **Services > Policy Sets > General client policy set bindings**.
2. Click ***client_policy_set_binding_name***.
3. In the policy collection, click **JMS transport**.

If the JMS transport policy has not been added to the selected general client policy set, then use the create general client bindings panel to add the JMS transport policy to the selected general client policy set.

You can use the JMS transport client policy bindings to configure a client that uses the JMS transport to send a request message to the server. The client run time uses the user name and password that you specify when connecting to the JMS messaging provider, and this configuration enables the client to send the request message to the server in a secure manner.

This administrative console page applies only to Java API for XML Web Services (JAX-WS) applications.

Important: You can also configure JMS transport properties, such as request timeout values or whether to enable transactional messaging for one-way asynchronous operations for JAX-WS

applications that are deployed in the same application server. If you want to customize these JMS properties, you must edit the JMS transport policy. To customize the JMS transport policy settings, click **Services > Policy sets > Application policy sets > *policy_set_name* >JMS transport policy**, where *policy_set_name* applies to any policy set that contains the JMS transport policy. Your customized values for the JMS transport policy now apply for your policy set that contains that custom JMS transport policy. You can attach this policy set that contains your customized JMS transport policy to your application, its services, endpoints, or operations. This change affects all JAX-WS applications to which that policy set is attached. To learn more about attaching policy sets to applications, see the documentation for managing policy sets for service providers and service clients at the application level.

Basic Authentication – User name:

For the service provider, this field specifies the user name for the asynchronous service responses. For the client, this field specifies the user name that is used by the client runtime when connecting to the JMS messaging provider to send an outbound request to the destination queue or topic. Enter a user name in this field.

Basic Authentication – Password:

For the service provider, this field specifies a placeholder for the password of the asynchronous service responses. For the client, this field specifies the password that is used by the client runtime when connecting to the JMS messaging provider to send an outbound request to the destination queue or topic. You can enter or edit the password in this field. The actual password is masked.

Basic Authentication – Confirm password:

For the service provider, this field specifies a placeholder for the password for the asynchronous service responses. For the client, this field specifies the password that is used by the client runtime when connecting to the JMS messaging provider to send an outbound request to the destination queue or topic. Re-enter the password in this field. The actual password is masked.

Custom Properties – Name:

Specifies the name of custom property. Custom properties are not initially displayed in this column until you define them.

Click one of the following buttons to enable the described action:

Button	Resulting Action
New	Creates a new custom property entry. To add a custom property, enter the name and value.
Delete	Removes the selected custom property.
Edit	Edit a selected custom property. This button is only displayed when one or more properties exist.

Custom Properties – Value:

Specifies the value of the custom property. With the **Value** entry field, you can enter, edit, or delete the value for a custom property.

Configuring the WS-Transaction policy:

When you work with policy sets in the administrative console, you can configure the WS-Transaction policy type for the WS-AtomicTransaction (WS-AT) and the WS-BusinessActivity (WS-BA) protocols. You can configure whether a client propagates, and a server receives, a WS-AT context, and whether a client propagates, and a server receives, a WS-BA context.

Before you begin

You must be working with a policy set that includes the WS-Transaction policy type.

Do not edit the policies associated with the provided default policy sets. To modify the WS-Transaction policy settings, use a copy of a default policy set or create a new policy set.

About this task

You can configure the policies for the WS-AtomicTransaction and WS-BusinessActivity protocols. The WS-AT protocol supports coordination of activities so that either all the activities occur, or none of them occur. The WS-BA protocol supports coordination of activities that are more loosely coupled than atomic transactions and that therefore require a compensation process if a failure occurs in the business activity.

When you add a WS-Transaction policy, it is equivalent to setting the following deployment descriptors that are associated with an EJB or web module:

- Use Web Services Atomic Transaction
- Send Web Services Atomic Transaction on requests
- Execute using Web Services Atomic Transaction on incoming requests

A WS-BA context is sent if the client is running in a BusinessActivity scope (BAScope). A provider runs in a BAScope if it receives a message that contains a WS-BA context, as long as the provider is set to run Enterprise JavaBeans (EJB) methods in a Business Activity scope.

Procedure

1. In the navigation pane of the administrative console, click **Services** > **Policy sets** > **Application policy sets** > ***policy_set_name*** > **[Policies] WS-Transaction**. The WS-Transactions settings pane is displayed.
2. In the WS-AtomicTransaction section, select the option you require:
   - **Mandatory**. For a client, the client always propagates a WS-AT context on an outbound request. For a server, any request that is received must include a WS-AT context, otherwise the request is rejected.
   - **Supports**. For a client, the client can propagate a WS-AT context on an outbound request when that context is available. For a server, if a request includes a WS-AT context, the context is imported and established on the thread before the request is processed.
   - **Never**. For a client, the client never propagates a WS-AT context on an outbound request. For a server, any request that is received must not include a WS-AT context, otherwise the request is rejected.
3. In the WS-BusinessActivity section, select the option you require:
   - **Mandatory**. For a client, the client always propagates a WS-BA context on an outbound request. For a server, any request that is received must include a WS-BA context, otherwise the request is rejected.
   - **Supports**. For a client, the client can propagate a WS-BA context on an outbound request when that context is available. For a server, if a request includes a WS-BA context, the context is imported and established on the thread before the request is processed.
   - **Never**. For a client, the client never propagates a WS-BA context on an outbound request. For a server, any request that is received must not include a WS-BA context, otherwise the request is rejected.

4. Click **OK**.
5. Save your changes to the master configuration.

Results

After you configure the WS-Transaction policy, the associated policy set uses this policy to support WS-AtomicTransaction and WS-BusinessActivity.

WS-Transaction policy settings:

Use this page to specify the policies for the WS-AtomicTransaction (WS-AT) and WS-BusinessActivity (WS-BA) protocols. WS-AT supports coordination of activities so that either all the activities occur, or none of them occur. WS-BA supports coordination of activities that are more loosely coupled than atomic transactions, and that therefore, require a compensation process if an error occurs.

To view this page in the console, click the following path: **Services** > **Policy sets** > **Application policy sets** > ***policy_set_name*** > **[Policy] WS-Transaction**, when the policy set includes the WS-Transaction policy type.

You can configure the WS-Transaction policy type for both client and provider policy sets.

WS-AtomicTransaction: Specifies behavior with the WS-AT policy. The options are:

Mandatory
For a client, the client always propagates a WS-AT context on an outbound request. If there is no transaction on the thread when the request is made, the attempt to make the request fails.

For a server, any request that is received must include a WS-AT context, otherwise the request is rejected. If any Web Services Description Language (WSDL) is generated for the web service with which the policy type is associated, a policy assertion is included that indicates that an operation must be invoked with an atomic transaction context.

Supports
For a client, the client can propagate a WS-AT context on an outbound request when it is available. For example, a transaction is associated with the thread that makes the request, and the policy of the provider requires WS-AT context.

For a server, if a request includes a WS-AT context, the context is imported and established on the thread before the request is processed. If a request does not include a WS-AT context, the request is processed as usual. If any WSDL is generated for the web service with which the policy type is associated, a policy assertion is included that indicates that an operation supports invocation with an atomic transaction context when that context is available.

Never For a client, the client never propagates a WS-AT context on an outbound request.

For a server, any request that is received must not include a WS-AT context, otherwise the request is rejected with a MustUnderstand error. If any WSDL is generated for the web service with which the policy type is associated, that WSDL does not include a policy assertion for an atomic transaction context.

WS-BusinessActivity: Specifies behavior with the WS-BA policy. The options are:

Mandatory
For a client, the client always propagates a WS-BA context on an outbound request. If there is no business activity scope on the thread when the request is made, the attempt to make the request fails.

For a server, any request that is received must include a WS-BA context, otherwise the request is rejected. If any WSDL is generated for the web service with which the policy type is associated, a policy assertion is included that indicates that an operation must be invoked with a business activity context.

Supports
For a client, the client can propagate a WS-BA context on an outbound request when it is available. For example, a business activity scope is associated with the thread that makes the request, and the policy of the provider requires a WS-BA context.

For a server, if a request includes a WS-BA context, the context is imported and established on the thread before the request is processed. If a request does not include a WS-BA context, the request is processed as usual. If any WSDL is generated for the web service with which the policy type is associated, a policy assertion is included that indicates that an operation supports invocation with a business activity context when that context is available.

Never For a client, the client never propagates a WS-BA context on an outbound request.

For a server, any request that is received must not include a WS-BA context, otherwise the request is rejected with a MustUnderstand error. If any WSDL is generated for the web service with which the policy type is associated, that WSDL does not include a policy assertion for a business activity context.

Configuring the WS-Security policy:

When working with policy sets in the administrative console, you can customize policies to ensure message security. The WS-Security policy can be configured to apply a message security (WS-Security) profile to requests. Message security policies are applied to requests and enforced on responses to support interoperability.

Before you begin

You can configure some settings for default policies for custom policy sets. The provided default policy sets cannot be edited. You must create a copy of the default policy set or create a completely new policy set in order to specify the policies for it.

About this task

Message security policies are applied to requests and enforced on responses to support interoperability.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Procedure

1. Use the WS-Security policy panel to begin configuring the WS-Security policy. To access the WS-Security policy panel, from the administrative console, click **Services > Policy sets > Application policy sets > *policy_set_name* > WS-Security policy**.
2. Choose which type of message security to configure.
   - Click the Main policy link to specify how message security policies are applied to requests and enforced on responses to support interoperability.
   - Click the Bootstrap policy link to configure how secure conversations are established. A bootstrap policy might already be configured. If no bootstrap policy is currently configured, first ensure that you have enabled message security with symmetric signature and encryption policies and secure conversation tokens for both integrity and confidentiality protection.
3. Use the Main policy settings panel or the Bootstrap policy settings panel to specify how message security policies are applied to requests and enforced on responses. Assertions for WS-Security

versions are already generated based on assertions in the policy set. If the policy set includes a WS-S 1.1 assertion, then WS-S 1.1 itself is asserted. Configure the settings on this panel to configure main or bootstrap policy settings:

a. Select whether Message level protection is required. Select this check box if any of the message parts should be digitally signed or encrypted or if a timestamp should be inserted in the message. It this box is unchecked, the Signature confirmation, Key symmetry, and Timestamp and Security header layout options are disabled.

b. Specify whether signature confirmation is required. Click this check box to require signature confirmation.

c. Configure the settings in the Key Symmetry section. The following fields can be configured in the Key symmetry section:

   Use symmetric tokens
   Click this radio button to use symmetric tokens. You can then configure symmetric tokens with the **Symmetric signature and encryption policies** link. Click this link to access the Symmetric Signature and Encryption Policies panel where you can create the trust context in which to use symmetric tokens. Using the same token for signing and validating messages and encrypting and decrypting messages provides better performance than can be achieved with asymmetric tokens. Symmetric tokens should be used within a trust context.

   Use asymmetric tokens
   Click this link to access the Asymmetric Signature and Encryption Policies panel where you can create the trust context (message integrity and confidentiality) in which to use asymmetric tokens. You can do this by specifying which token type to use for the initiator and recipient signature as well as the initiator and recipient encryption.

   Include timestamp in header
   Click this check box to include a timestamp in the header. You can then specify if the timestamp is positioned first or last in the header by using the Security header layout radio button options:
   - **Strict: Declarations must precede use**
   - **Layout (Lax): Order of contents can vary**
   - **Lax but timestamp required first in header**
   - **Lax but timestamp required last in header**

d. Optional: Click the **Algorithms** link under the **Policy Details** section if you want to access the Algorithms panel to view and select from available algorithms. The available algorithms include cryptographic algorithms and their key lengths, as well as canonicalization algorithms for reconciling XML differences. Click this link to view the cryptographic and cannonicalization algorithms that are supported.

e. Optional: Configure the request settings. Click either of the following links to configure request settings:

   Request message part protection
   Links to configuration for request message part protection. Click this link to define which message parts are to be protected and how that protection is provided.

   Request token policies
   Links to configuration for request token policies. Click this link to define policies that specify which types of security tokens are supported and the properties of those token types.

f. Optional: Configure the response settings. Click either of the following links to configure response settings:

   Response message part protection
   Links to configuration for response message part protection. Click this link to define which message parts are to be protected and how that protection is provided.

Response token policies

Links to configuration for response token policies. Click this link to define policies that specify which types of security tokens are supported and the properties of those token types.

Results

Once you have customized the WS-Security policy, the associated policy set uses this policy to protect messages.

WS-Security policy settings:

Use this page to configure the WS-Security policy and apply a message security WS-Security profile to requests. WS-Security policies are applied to requests and enforced on responses to support inter-operability.

To view this administrative console page, click **Services > Policy sets > Application policy sets > *policy_set_name* > WS-Security policy**.

Main policy:

Links to configuration settings for a main policy. Use the Main policy link if you want to configure how WS-Security policies are applied to requests and enforced on responses to support interoperability.

Secure conversation bootstrap policy:

Links to configuration settings for a secure conversation bootstrap policy. Use the bootstrap policy link if you want to configure how secure conversations are established. To configure a secure conversation bootstrap policy, first ensure that you have enabled message security in the main policy with symmetric signature and encryption policies and secure conversation tokens for both integrity and confidentiality protection.

Click **Remove bootstrap policy** to discontinue using secure conversation policy settings.

Configuring the request or response token policies:

You can configure the request and response token policies that are part of the WS-Security policy using the administrative console. Message requests token policies are applied to requests and enforced on responses to support both quality and interoperability.

Before you begin

You can configure some settings for the policies within your policy sets. The default policy sets provided in the product cannot be edited. You must create a copy of the default policy set or create a completely new policy set in order to specify the policies for it.

About this task

Use this administrative console task to define policies that specifically support security tokens and properties.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Procedure

1. Click **Services > Policy sets > Application policy sets > *policy_set_name* > WS-Security policy**.
2. Click one of the following links:
   - **Main policy** or
   - **Bootstrap policy**
   - Click the Main policy link to specify how message security policies are applied to requests and enforced on responses to support interoperability.
   - Click the Bootstrap policy link to configure how secure conversations are established. A bootstrap policy might already be configured. If no bootstrap policy is currently configured, first ensure that you have enabled message security with symmetric signature and encryption policies and secure conversation tokens for both integrity and confidentiality protection. See Configuring the WS-Security policy.
3. Click **Request token policies** under Request Policies or **Response token policies** under Response Policies. Use this to panel to define policies that specify which types of security tokens are supported for the properties of each token type.

Results

Once you have customized the WS-Security policy with the associated properties, including the request and response token policies, you can then send and receive protect messages.

Request or Response token policies collection:

Use this page to define policies that specify supporting security tokens and properties.

To view this administrative console page, complete the following:

1. Click **Services** > **Policy sets** > **Application policy sets** > ***policy_set_name***.
2. Click the **WS-Security** policy in the policies table.
3. Click the **Main policy** link or the **Bootstrap policy** link.
4. Click **Request token policies** or **Response token policies** from the Policy Details section.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Add:

Add a token from a list of supported token types. You can only add a token to a custom policy set.

This option provides the following supported token types:

- Username
- X.509
- LTPA
- Custom

To change the settings for a token after adding it, click on the token identifer name in the table.

Delete:

Removes the selected token name. This action is only available for a custom policy set.

Token Identifier:

Specifies the name of the token.

Type:

Specifies the token type in the Supported token types table. This list displays a token type for each token name in the list.

Version:

Specifies the version of the token in the Supported token types table. This list displays the version of each token in the list.

Token type settings:

Use the administrative console to define the details about the token types. This panel is displayed differently for each different token type. Policies can be defined that specify which types of security tokens are supported as well as properties for the token type.

To view token types for a policy set, complete the following steps:

1. Click **Services > Policy sets > Application policy sets > *policy_set_name***.
2. Click the **WS-Security** policy in the Policies table.
3. Click the **Main policy** link or the **Bootstrap policy** link.
4. Click one of the following:
   - **Request token policies** from the Policy detail section.
   - **Response token policies** from the Policy detail section.
   - **Symmetric signature and encryption policies** from the Key symmetry section.
   - **Asymmetric signature and encryption policies** from the Key symmetry section.
5. For a Request token policy or a Response token policy, click a token from the Supported Token Types table or click the **Add Token Type** button to select the type of token to add.
6. For a symmetric signature and encryption policy or an asymmetric signature and encryption policy, click **Edit Selected Type Policy**.

This panel is displayed for each token type you are configuring or adding. It displays fields for some token types and not for others. This help topic contains all of the fields for each of the token types and describes which token is being configured for each field.

Custom token name:

For a custom token, specify the name of the token being configured. Enter or edit the name for the custom token in this entry field.

Local name:

For a custom token, specify the local name.

If the custom token type is used to generate a Kerberos token as defined in the OASIS Web Services Security Specification for Kerberos Token Profile v1.1, use one of the values in the following table for the local name. The value you choose depends on the specification level of the Kerberos token generated by the Key Distribution Center (KDC). The table lists the values and the specification level associated with each value. For purposes of interoperability, the Basic Security Profile V1.1 standard requires the use of the local name, http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ.

Local Name Value for Kerberos Token	Associated Specification Level
http://docs.oasis-open.org/wss/oasiswss-kerberos-token-profile-1.1#Kerb erosv5_AP_REQ	Kerberos V5 AP-REQ as defined in the Kerberos specification. This value is used when the Kerberos ticket is an AP Request.
http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ	GSS-API Kerberos V5 mechanism token containing a KRB_AP_REQ message as defined in RFC-1964 [1964], Sec. 1.1 and its successor RFC-4121, Sec. 4.1. This value is used when the Kerberos ticket is an AP Request (ST + Authenticator).
http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ1510	Kerberos V5 AP-REQ as defined in RFC1510. This value is used when the Kerberos ticket is an AP Request per RFC1510.
http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ1510	GSS-API Kerberos V5 mechanism token containing a KRB_AP_REQ message as defined in RFC-1964, Sec. 1.1 and its successor RFC-4121, Sec. 4.1. This value is used when the Kerberos ticket is an AP Request (ST + Authenticator) per RFC1510.
http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ4120	Kerberos V5 AP-REQ as defined in RFC4120. This value is used when the Kerberos ticket is an AP Request per RFC4120.
http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ4120	GSS-API Kerberos V5 mechanism token containing an KRB_AP_REQ message as defined in RFC-1964, Sec. 1.1 and its successor RFC-4121, Sec. 4.1. This value is used when the Kerberos ticket is an AP Request (ST + Authenticator) per RFC4120.

URI:

For a custom token, specify the uniform resource identifier (URI).

Leave this field empty, if the custom token type is used to generate a Kerberos token as defined in the OASIS Web Services Security Specification for Kerberos Token Profile v1.1.

LTPA token name:

For an LTPA token, specify the name of the token being configured. Enter or edit the name for the LTPA token in this entry field.

Propagate the JAAS subject:

For an LTPA token, specify whether the associated Java Authentication and Authorization Service (JAAS) subject is propagated. Select this check box to propagate the JAAS subject. The default value is not selected. Therefore, the JAAS subject is not propagated by default.

Username token name: Specify the name of the token being configured. Enter or edit the name for the username token in this entry field.

WS-Security version:

For a Username token, specify the version of Web Services Security, the WS-Security specification, that is used to secure the message transmission.

The following versions are available:

- WS-Security V1.0

- WS-Security V1.1

X.509 token name:

For a X.509 token, specify the name of the token being configured. Enter or edit the name for the X.509 token in this entry field.

WS-Security version:

For a X.509 token, specify the version of Web Services Security that is used to secure the message transmission.

The following versions are available:
- WS-Security V1.0
- WS-Security V1.1

X.509 type:

For a X.509 token, specify the type of X.509 token being configured.

The following types are available for the X.509 token:
- X.509 Version 1. This option is available with WS-Security Version 1.1 only.
- X.509, Version 3
- X.509 PKCX7
- PKI Path Version 1

Secure conversation token: The secure conversation token is available only when using symmetric signature and encryption policies.

Require reference to secure context token issuer:

For a secure conversation token, select this option to specify a reference to the issuer of the security context token.

After selecting the **Require reference to secure context token issuer** option, specify the URI of the security context token issuer.

Transform algorithms settings:

Use this administrative console page to select the uniform resource locator (URL) for the transform algorithms that are needed to protect the message part.

To view this administrative console page, complete the following:
1. Click **Services > Policy sets > General provider policy set bindings** or **General client policy set bindings**.
2. Click the name of the binding you want to edit.
3. Click **WS-Security** policy in the Policies table
4. Click the **Authentication and Protection** link in the Main message security policy bindings section.
5. Select a signature protection in the Request message and encryption protection section or the Response message signature and encryption protection section.
6. Click the **Additional bindings > Signed part reference default** at the end of the panel.
7. Click a URL in the Transform algorithms table.

You can also get to this administrative console page by completing the following actions:

1. Click **Applications > Application Types > WebSphere enterprise applications**.
2. Select an application that contains web services.
3. Select **Service provider policy sets and bindings** or **Service client policy sets and bindings**.
4. Select a binding.

   Important: You must have previously attached a policy set and assigned an application specific binding before you can do this step.
5. Select **WS-Security**.

   Important: You must have previously added WS-Security to the bindings.
6. Click the **Authentication and Protection** link in the Main message security policy bindings section.
7. Select a signature protection in the Request message and encryption protection section or the Response message signature and encryption protection section.
8. Click the **Additional bindings > Signed part reference default** at the bottom of the panel.
9. Click **New** to add a transform.
10. [Optional] Click a URL in the Transform algorithms table. This step assumes that a transform algorithm has previously been configured.

URL:

Specifies the URL for the transform algorithms that are used to protect the message part.

The URLs of the supported transform algorithms are listed in the table. The recommended transform is *http://www.w3.org/2001/10/xml-exc-c14n#* and it is the Exclusive XML Canonicalization, as well as the default value provided in the URL field when a transform is added.

List of URLs for the transform algorithms
http://www.w3.org/2001/10/xml-exc-c14n#
http://www.w3.org/TR/1999/REC-xpath-19991116
http://www.w3.org/2002/06/xmldsig-filter2
http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform
http://www.w3.org/2002/07/decrypt#XML
http://www.w3.org/2000/09/xmldsig#enveloped-signature

Custom properties:

Specifies the custom properties name and value pair for the transform algorithms. Click **New** to add a new custom property. Click **Delete** to delete a custom property.

Name Specifies the name of a custom property that you choose to set to protect the message part.

Value Specifies the value of a custom property that you choose to set to protect the message part.

Signed part reference default bindings settings:

Use this administrative console page to configure the signed part reference general bindings and the uniform resource locator (URL) for the transform algorithms that are needed to protect the message part.

You can view and configure bindings for WS-Security using this administrative console page:

1. Click **Applications > Application Types > WebSphere enterprise applications**.
2. Select an application that contains web services

3. Select **Service provider policy sets and bindings** or **Service client policy sets and bindings**
4. Select a binding.

   Note: You must have previously attached a policy set and assigned an application specific binding before you can do this step.
5. Select **WS-Security**.

   Note: You must have previously added WS-Security to the bindings.
6. Click the **Authentication and Protection** link in the Main message security policy bindings section.
7. Select a signature protection in the Request message and encryption protection section or the Response message signature and encryption protection section.
8. Click the **Additional bindings - Signed part reference default** at the bottom of the panel. For the custom, select an assigned message part and click **Edit**. In the custom version, there is also a reference field, **Specifies the name of the signature protection in the policy set**. Use this field to specify the name of the signature protection in the policy set.
9. Check the **Include timestamp** check box to include the timestamp when the message part is signed.
10. Check the **Include nonce** check box to include the nonce when the message part is signed.

Part reference properties:

Specifies the name of the part reference properties that include the transform algorithms used to protect the message part.

1. Check the **Include timestamp** check box to include the timestamp for the message part.
2. Check the **Include nonce** check box to include the nonce when the message part is signed.

Transform algorithms:

Specifies the uniform resource locator (URL) description for the transform algorithms. Click the URL to view the transform algorithms.

Main policy and bootstrap policy settings:

Use this page to specify how message security policies are applied to requests and enforced on responses, as defined by the main policy settings and the bootstrap policy settings. Assertions for Web Services Security (WS-Security) versions are already generated based on assertions in the policy set. If the policy set includes a Web Services Security Version 1.1 assertion, then Web Services Security Version 1.1, itself, is asserted.

To view this administrative console page, use one of the following steps:

1. Click **Services** > **Policy sets** > **Application policy sets** > ***policy_set_name*** .
2. Click the **WS-Security** policy in the Policies table.
3. Click the **Main policy** link or the **Bootstrap policy** link.

Message level protection:

Specifies whether message level protection, using digital signatures and encryption, is required.

Require signature confirmation
Specifies whether the signature confirmation is required. Select this check box to require a signature confirmation.

Message part protection:

Specifies whether message part protection, using digital signatures and encryption, is required.

Request message part protection
Click this link to define which request message parts you want protected and how that protection is provided.

Response message part protection
Click this link to define policies that specify which response message parts you want protected and how that protection is provided.

When the Message level protection check box is cleared, the link to Request message part protection is disabled, because the configuration information associated with message level security is removed when message level protection is cleared.

Key symmetry – Use symmetric tokens:

Specifies whether to use symmetric tokens. Select this radio button to use symmetric tokens. You can then configure symmetric tokens using the **Symmetric signature and encryption policies** link. Click this link to access the Symmetric signature and encryption policies panel where you can create the trust context in which to use symmetric tokens. Using the same token for signing and validating messages and encrypting and decrypting messages provides higher performance than can be achieved with asymmetric tokens. Use symmetric tokens within a trust context. If a custom Kerberos token type is used, you must select the Use symmetric tokens option.

Key symmetry – Use asymmetric tokens:

Specifies whether to use asymmetric tokens. Select this button to use asymmetric tokens. You can then configure asymmetric tokens using the **Asymmetric signature and encryption policies** link. Click this link to access the Asymmetric signature and encryption policies panel where you can create the trust context (message integrity and confidentiality) in which to use asymmetric tokens. Specify which token type to use for the initiator and recipient signature as well as the initiator and recipient encryption.

Include time stamp in security header:

Specifies whether to use a time stamp in the header. Select this check box to include a time stamp in the header. You can then specify where in the header to place the time stamp by using the **Security header layout** radio buttons.

Security header layout:

Specifies the layout rules for the security header.

You can use the following radio buttons for the security header layout:

Strict: declarations must precede use
The declarations in the header must precede the use.

Layout (Lax): order of contents can vary
The order of contents in the header can vary.

Lax but timestamp required first in header
The timestamp must be first in the header, but the order of the remaining elements can vary.

Lax but timestamp required last in header
The timestamp must be last in the header, but the order of the remaining elements can vary.

Policy details:

Specifies links for accessing the request token policies, response token policies, and algorithms for asymmetric tokens. Click these links to view token policies and cannonicalization algorithms that are supported. Algorithms are used to reconcile XML differences.

Request token policies:

Click this link to define policies that specify which types of supporting authentication tokens are used in the request and the properties of those token types.

Response token policies:

Click this link to define policies that specify which types of supporting authentication tokens are used in the response and the properties of those token types.

Algorithms for symmetric or asymmetric tokens:

Links to a view of available algorithms. Click this link to view the cryptographic and cannonicalization algorithms that are supported. Algorithms are used to reconcile XML differences.

Asymmetric signature and encryption policies settings:

Use this page to create the trust context, message integrity and confidentiality, to use asymmetric tokens. You can create the trust context by specifying which token type to use for the initiator and recipient signature as well as the initiator and recipient encryption.

To view this administrative console page complete the following actions:

1. Click **Services > Policy sets > Application policy sets > *policy_set_name* > WS-Security policy type**.
2. Click **Main policy** or **Bootstrap policy**.
3. Click the **Asymmetric signature and encryption policies** link.

This administrative console page applies only to Java API for XML Web Services (JAX-WS) applications.

Message integrity policies – Initiator signature token:

Specifies the token type of the initiator signature token. To add a token type or change the current token type that is displayed in the **Initiator signature token** field, or to edit the displayed token type, click **Action**.

Message integrity policies – Recipient signature token:

Specifies the token type of the recipient signature token. To add a token type or change the current token type that is displayed in the **Recipient signature token** field, or to edit the displayed token type, click **Action**.

Message confidentiality policies – Use the same token types that are used for integrity protection:

Specifies whether the token type set for initiator signature token and recipient signature token are used for the initiator encryption token and the recipient encryption token. When the box is checked the fields are empty and are cleared of data when **Ok** or **Apply** is selected.

Message confidentiality policies – Initiator encryption token:

Specifies the initiator encryption token type. To add a token type or change the current token type that is displayed in the **Initiator encryption token** field, or to edit the displayed token type, click **Action**.

Message confidentiality policies – Recipient encryption token:

Specifies recipient encryption token type. To add a token type or change the current token type that is displayed in the **Recipient encryption token** field, or to edit the displayed token type, click **Action**.

Action:

Specifies an option for each of the signature and encryption token fields. Use the **Action** button to change, delete, add, or edit the listed token type.

The Action button lists supported token types and provides the following options:

Edit selected type policy
Opens a page to edit the token type shown in the signature or encryption token fields.

Delete selected type policy
Removes the token type from the signature or encryption token fields.

Change to custom type
Opens the Custom type page to specify the uniform resource identifier (URI) for a custom token type.

Add custom type
Adds the custom type entry in the signature or encryption token fields.

Change to X.509
Changes the listed token type to X.509.

Add X.509
Adds the X.509 token type.

When you change the token type, any values you specified for the former token type are lost and the default values for the newly assigned token type are used.

Symmetric signature and encryption policies settings:

Use this page to create the trust context to use symmetric tokens. Using the same token for signing and validating messages and encrypting and decrypting messages increases performance. Use symmetric tokens within a trust context.

To view this administrative console page, complete the following options:
1. Click **Services > Policy sets > Application policy sets**.
2. Select a ***policy_set_name*** in the policy sets table that contains WS-Security content.
3. Click **WS-Security** in the policies table.
4. Click the **Main policy** link or the **Bootstrap policy** link.
5. Click the **Symmetric signature and encryption policies** link.

Message Integrity – Token type for signing and validating messages:

Specifies the current token type used for signing and validating messages.

To change the current token type that is displayed in the **Token type for signing and validating messages** field or to edit the displayed token type, click **Action**.

Message Confidentiality – Use same token type for confidentiality that is used for integrity:

Specifies whether the token type set for signing and validating messages is also used for encrypting and decrypting messages. For a Kerberos token, message confidentiality uses the same token that is used for the message integrity.

If you select this check box, then the **Token type for encrypting and decrypting messages** field is blank. If you clear this check box, then a different token can be used for message confidentiality.

Message Confidentiality – Token type for encrypting and decrypting messages:

Specifies the current token type that is used for encrypting and decrypting messages.

To change the current token type that is displayed in the **Token type for encrypting and decrypting messages** field or to edit the displayed token type, verify that the **Use the same token type for confidentiality that is used for integrity protection** check box is cleared, and click **Action**.

Action:

Enables the token type selected to be changed or edited.

The **Action** button lists supported token types and provides the following options:

Edit selected type policy
Opens a page to edit the token type for signing or encrypting fields.

Change to Secure Conversation
Changes the token type to Secure Conversation.

Change to custom type
Opens the custom type page to specify the Uniform Resource Identifier (URI) for a custom token type.

When you change the token type, any values that you specified for the former token type are lost, and the default values for the newly assigned token type are used.

Algorithms settings:

Use this page to view the supported cryptographic and cannonicalization algorithms. Algorithms are used to reconcile XML differences.

To view this administrative console page:
1. Click **Services** > **Policy sets** > **Application policy sets** > ***policy_set_name***.
2. Click the **WS-Security** policy in the Policies table.
3. Click the **Main policy** link or the **Bootstrap policy** link.
4. Click the **Algorithms for symmetric tokens** link or the **Algorithms for asymmetric tokens** link.

This administrative console page applies only to Java API for XML Web Services (JAX-WS) applications.

Algorithm suite:

Specifies the supported algorithms that are required for performing cryptographic operations with symmetric or asymmetric key-based security tokens.

All of the algorithm values in this field specify an algorithm suite. Algorithm suites and the values they each represent are detailed in the *Web Services Security Policy Language (WS-SecurityPolicy) July 2005 Version 1.1* specification. Select a supported algorithm from the following list:
- Basic256
- Basic192
- Basic128
- TripleDes
- Basic256Rsa15
- Basic192Rsa15
- Basic128Rsa15

- TripleDesRsa15
- Basic256Sha256
- Basic192Sha256
- Basic128Sha256
- TripleDesSha256
- Basic256Sha256Rsa15
- Basic192Sha256Rsa15
- Basic128Sha256Rsa15
- TripleDesSha256Rsa15

This table defines values for the components for each algorithm suite.

Table 258. Algorithm suite components. The algorithms are used to perform cryptographic operations on tokens.

Algorithm Suite	Digest	Encryption	Symmetric Key Wrap	Asymmetric Key Wrap	Encryption key Derivation	Signature key Derivation	Minimum Symmetric Key Length
Basic256	Sha1	Aes256	KwAes256	KwRsaOaep	PSha1L256	PSha1L192	256
Basic192	Sha1	Aes192	KwAes192	KwRsaOaep	PSha1L192	PSha1L192	192
Basic128	Sha1	Aes128	KwAes128	KwRsaOaep	PSha1L128	PSha1L128	128
TripleDes	Sha1	TripleDes	KwTripleDes	KwRsaOaep	PSha1L192	PSha1L192	192
Basic256Rsa15	Sha1	Aes256	KwAes256	KwRsa15	PSha1L256	PSha1L192	256
Basic192Rsa15	Sha1	Aes192	KwAes192	KwRsa15	PSha1L192	PSha1L192	192
Basic128Rsa15	Sha1	Aes128	KwAes128	KwRsa15	PSha1L128	PSha1L128	128
TripleDesRsa15	Sha1	TripleDes	KwTripleDes	KwRsa15	PSha1L192	PSha1L192	192
Basic256Sha256	Sha256	Aes256	KwAes256	KwRsaOaep	PSha1L256	PSha1L192	256
Basic192Sha256	Sha256	Aes192	KwAes192	KwRsaOaep	PSha1L192	PSha1L192	192
Basic128Sha256	Sha256	Aes128	KwAes128	KwRsaOaep	PSha1L128	PSha1L128	128
TripleDesSha256	Sha256	TripleDes	KwTripleDes	KwRsaOaep	PSha1L192	PSha1L192	192
Basic256Sha256Rsa15	Sha256	Aes256	KwAes256	KwRsa15	PSha1L256	PSha1L192	256
Basic192Sha256Rsa15	Sha256	Aes192	KwAes192	KwRsa15	PSha1L192	PSha1L192	192
Basic128Sha256Rsa15	Sha256	Aes128	KwAes128	KwRsa15	PSha1L128	PSha1L128	128
TripleDesSha256Rsa15	Sha256	TripleDes	KwTripleDes	KwRsa15	PSha1L192	PSha1L192	192

When using a Kerberos custom token based on the OASIS Web Services Security Specification for Kerberos Token Profile V1.1, only Aes128, Aes256, and TripleDes encryption-based algorithm suites are supported.

Cannonicalization algorithm:

Specifies whether to use inclusive or exclusive cannonicalization.

The following supported cannonicalization algorithms are available in this list:

- Exclusive cannonicalization
- Inclusive cannonicalization

The default value is `Exclusive cannonicalization`.

XPath version:

Specifies the version of the XPath filter to use.

The following supported XPath versions are available:

- XPath 1.0
- XPathfilter 2.0

The `XPathfilter 2.0` version is the default value.

Use security token reference transformation:

Specifies whether the security token reference is transformed. Indicate whether the security token reference transform is either `True` or `False`.

Message part protection settings:

Use this page to define the message parts that you want protected and how that protection is provided.

To view this administrative console page, complete the following actions:
1. Click **Services > Policy sets > Application policy sets** >*policy_set_name*.
2. Click the **WS-Security** policy in the Policies table.
3. Click the **Main policy** link or the **Bootstrap policy** link.
4. Click the **Request message part protection** link or the **Response message part protection** link from the Message Part Protection section.

Integrity protection – Signed parts:

Specifies the signed parts that you have added for message integrity protection. You can select parts to edit or delete, or add new signed parts.

Button	Resulting Action
Add	Specifies each element of a new signed part and to add those elements to the Signed parts listing.
Edit	Loads the specific part you selected for editing.
Delete	Removes the selected signed part from the list.

Confidentiality protection – Encrypted parts:

Specifies the encrypted parts that have been added for message confidentiality protection. You can select parts to edit or delete, or add new encrypted parts.

Button	Resulting Action
Add	Enables you to specify each of the elements of a new encrypted part and to add those elements to the Encrypted parts listing.
Edit	Loads the specific part you selected for editing.
Delete	Removes the selected encrypted part from the list.

Signed part settings:

Use this page to define the elements of a signed part. Signed parts are used to protect message integrity and, in this case, the signed parts are being defined as part of the policy set process.

To view this administrative console page, complete the following actions:
1. Click **Services > Policy sets > Application policy sets > *policy_set_name***.
2. Click the **WS-Security** policy in the Policies table.
3. Click either the **Main policy** link or the **Bootstrap policy** link.
4. Click the **Request message part protection** link or the **Response message part protection** link in the Message Part Protection section.
5. In the Integrity protection section, complete one of the following actions:

- Click **Add** to add a new signed part.
- Select an existing signed part and click **Edit**.

Name of part to be signed:

Specifies the name of this set of one of more message parts that you have selected to sign. The name you choose is a label and must be unique within the Response message part protection or Request message part protection collections for this WS-Security policy.

Elements in part:

Specifies a list of the message elements included in the signed part. The **Elements in part** field contains a listing of message elements that are included in this signed part to provide message integrity.

Click **Add** to add an element to the signed part of the message. To remove a message element from a signed part of a message, first click the selection box next to the element to be removed, then click **Remove**. Use the **OK**, **Apply**, **Reset** or **Cancel** buttons for the text entry fields. The QName or the Xpath expression value is required and can be edited at any time, such as when adding a new element, or after the element is added.

Protect message body:

Specifies if the message body is protected in this part. To protect the message body in this part, click **Protect message body**.

XPath expression:

Specifies if the displayed XPath expression is used as the method for specifying that a specific element is included in this part.

Select **XPath** from the **Add** menu list and provide an expression in the new XPath entry that is displayed in the table. Any Xpath expression row on the table that has no corresponding value is removed when you click **OK** or **Apply**.

QName for SOAP header elements only:

Specifies the Qname type for a namespace value for the SOAP header element that you want to encrypt. To encrypt a SOAP header element, select **Qname** and provide the **namespace** and optionally the **localname** of the SOAP header element in the **Value** field. When specifying the Qname, if using the optional localname, a comma must be inserted between the namespace and the localname, for example **<namespace>,<localname>**. If the **localname** is omitted, all SOAP header elements with the specified **namespace** are encrypted. To use the **Qname** selection method, the SOAP header elements must be the immediate children of the SOAP header. Any Qname row in the table that has no corresponding value is removed when you click **OK** or **Apply**.

Restriction:
You cannot select header elements that are sub-elements of other elements in the SOAP header using **Qname**. In this case, you must use an **Xpath expression** to select these header elements.

Encrypted message part settings:

Use this page to define the elements of an encrypted part of a message. Encrypted parts are used to protect message confidentiality, and in this case, the encrypted parts are being defined as part of the policy set process. A message part is a named set of one or more message elements.

To view this administrative console page, complete the following actions:

1. Click **Services > Policy sets > Application policy sets > *policy_set_name***.
2. Click the **WS-Security** policy in the Policies table.
3. Click the **Main policy** link or the **Bootstrap policy** link.
4. Click the **Request message part protection** link or the **Response message part protection** link in the Message Part Protection section.
5. In the Confidentiality protection section, you can perform any of the following:
   - Click **Add** to add a new encrypted part.
   - Select an existing encrypted part, and click **Edit**.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Name of part to encrypt:

Specifies the name of the set of one or more message parts that you have selected to encrypt. The name you choose is a label and must be unique within the Response message part protection or Request message part protection collections for this WS-Security policy.

Elements in part:

Specifies a list of the message elements that are included in the encrypted part. The **Elements in part** field contains a listing of message elements that are included in this encrypted part to provide message confidentiality.

Click **Add** to add an element to the encrypted part of the message. To remove a message element from an encrypted part of a message, first click the selection box next to the element to be removed, then click **Remove**. The value of the Qname namespace, or the Xpath expression, is required and can be edited at any time, while adding a new element or after the element is added.

Body Specifies the body of the message part.

Qname for SOAP header elements only
Specifies the Qname type for a namespace value for the SOAP header element that you want to encrypt. To encrypt a SOAP header element, select **Qname** and provide the **namespace** and optionally the **localname** of the SOAP header element in the **Value** field. When specifying the Qname, if using the optional localname, a comma must be inserted between the namespace and the localname, for example **<namespace>,<localname>**. If the **localname** is omitted, all SOAP header elements with the specified **namespace** are encrypted. To use the **Qname** selection method, the SOAP header elements must be the immediate children of the SOAP header. Any Qname row in the table that has no corresponding value is removed when you click **OK** or **Apply**.

Restriction: You cannot select header elements that are sub-elements of other elements in the SOAP header using Qname. In this case, you must use an Xpath expression to select these header elements.

Xpath expression
Specifies if the displayed Xpath expression is used as the method for specifying that a specific element is included in this part. Select **XPath** from the **Add** menu list, and provide an expression in the new XPath entry that is displayed in the table. Any Xpath expression row on the table that has no corresponding value is removed when you click **OK** or **Apply**.

Configuring the Custom properties policy:

When working with policy sets in the administrative console, you can customize policies to set generic properties that are not supported in other policy types. You must customize the Custom properties policy configuration because all properties within the policy are user-defined.

About this task

This administrative console page applies only to Java API for XML Web Services (JAX-WS) applications.

You can configure generic properties that are not supported in other policy types with the Custom properties policy. These additional properties are set in the binding. The Custom properties policy provides an alternative way to set a binding property instead of using the JAX-WS programming model to set the property on the BindingProvider object. The CustomProperties binding is only supported for service clients.

After you have created a new policy set with the Custom properties policy added, you must create a Custom properties binding and add at least one custom property to configure the binding. A Custom properties binding type can be added to a general client binding or an application specific client binding. You cannot create an empty Custom properties binding. You must define at least one name and value pair within the binding.

Note: In a mixed cell environment, the following limitations apply to attachments to policy sets containing CustomProperties policy:

- You must not create attachments to policy sets containing CustomProperties policy for applications that are deployed on an application server that is prior to WebSphere Application Server Version 8. The CustomProperties policy is only supported on WebSphere Application Server V8 and later.
- An application that contains an attachment to a policy set containing CustomProperties policy must not be deployed on an application server that is prior to WebSphere Application Server Version 8.
- If an application that is deployed in a cluster environment contains an attachment to a policy set containing CustomProperties policy, you must not add a member application server that is prior to WebSphere Application Server Version 8 to the cluster.

Procedure

1. Create the Custom properties policy.
   a. Navigate to the Application policy sets or the System policy sets From the administrative console, click **Services** > **Policy Sets** > **Application policy sets** or **Services** > **Policy Sets** > **System policy sets**.
   b. Click the **New...** button.
   c. Enter a unique policy set name.
   d. Click the **Add** button and choose the **Custom properties** policy in the Policies table.
   e. Click the **Apply** button.
   f. Click the **Save** link.

   You cannot configure the Custom properties policy from this panel. You must configure your Custom properties with a Custom properties binding.
2. Customize the Custom properties bindings.
   a. Navigate to the Custom properties bindings. From the administrative console, click **Services** > **Policy Sets** > **General client policy set bindings** > ***client_policy_set_binding_name***.
   b. Click **Add** > **Custom properties**.

      The Custom properties (bindings) window displays options for adding Custom properties bindings.
   c. Specify the properties for each custom property you want to add. The following fields are required:

      Name Displays the name of the custom property.

Value Displays the value of the custom property.

The application specific bindings can be customized similarly, from the application policy set and bindings attachments panel.

Results

After you have customized the Custom properties policy, the associated policy set uses this policy to set generic properties that are not supported in other policy types.

Policy set bindings settings for Custom properties:

Use this page to view, define, or configure general bindings or application specific bindings, for the Custom properties policy.

This administrative console page applies only to Java API for XML Web Services (JAX-WS) applications.

To view this administrative console panel, click **Services** > **Policy sets** > **General client policy set bindings**.

To edit or configure the general bindings, complete the following steps:

1. Click **New**.
2. For **Bindings configuration name**, specify a unique binding name.
3. Optionally, specify a description.
4. Click **Add** and select the **Custom properties** policy in the Policies table.
5. Specify a unique name and value pair.
6. Optionally, to add additional properties, click **New**.
7. Optionally, to edit a property, select a property and click **Edit**.
8. Optionally, to delete a property, select a property and click **Delete**.
9. Click **Apply**.
10. Click **Save**.

Note: This product supports using the Custom properties policy and binding to set generic properties that are not supported in other policy types. The additional properties are set in the binding. The Custom properties policy provides an alternative way to set a binding property instead of using the JAX-WS programming model to set the property on the BindingProvider object. You cannot create an empty Custom properties binding. You must define at least one name and value pair within the binding. Additionally, there are no predefined properties in the binding because all properties are user-defined. The CustomProperties binding is only supported for service clients.

Note: In a mixed cell environment, the following limitations apply to attachments to policy sets containing CustomProperties policy:

- You must not create attachments to policy sets containing CustomProperties policy for applications that are deployed on an application server that is prior to WebSphere Application Server Version 8. The CustomProperties policy is only supported on WebSphere Application Server V8 and later.
- An application that contains an attachment to a policy set containing CustomProperties policy must not be deployed on an application server that is prior to WebSphere Application Server Version 8.
- If an application that is deployed in a cluster environment contains an attachment to a policy set containing CustomProperties policy, you must not add a member application server that is prior to WebSphere Application Server Version 8 to the cluster.

Name:

Specifies the name associated with this property.

Data type String

Value:

Specifies the value associated with this property.

Data type String

Enabling policies for policy sets using the administrative console

Policies can be listed in a policy set in the disabled state so that they are not currently included in the policy set. You can enable a policy to be included in a policy set using the administrative console.

Before you begin

To enable a policy for a policy set, be sure the policy is listed in the policy set and shown in the **Disabled** state in the **State** column of the **Policies** table on the Policy set settings page.

About this task

To enable a policy in a policy set, use the administrative console.

Procedure

1. Click **Services > Policy sets > Application policy sets** > ***policy_set_name*** or **Services > Policy sets > System policy sets** > ***policy_set_name***. The Policy Set Settings page displays a listing of available policies in the **Policies** table for the policy set selected. If this table contains no policies to enable, no policies exist for the policy set of interest. In this case, you must add the policies to the policy set.
2. Click the **Select** box beside the disabled policy that you want to enable. You can select multiple policies if you want to enable more than one.
3. Click the **Enable** button. The **State** column of the **Policies** table is updated to display the selected policy as enabled.

Results

You have enabled a policy for the selected policy set.

What to do next

If the policy is not listed in the Policies table, it cannot be enabled and must be added. You can modify the policy after it is enabled.

Disabling policies from policy sets using the administrative console

You can have policies listed in a policy set that are in the enabled state so that they are currently included in the policy set. You can disable a policy from being included in a policy set without deleting it from the policy set. You might want to do this if you want the policy included in the policy set in the future. You can use the administrative console to change this setting.

Before you begin

To disable a policy for a policy set, be sure the policy is listed in the policy set and shown in the **Enabled** state in the **State** column of the **Policies** table on the Policy set settings page. If the policy is not listed, it might have been deleted and you must add it again and then disable it.

About this task

You can disable a policy in a policy set, from the menu of the administrative console.

Procedure

1. Click **Services > Policy sets > Application policy sets** >***policy_set_name*** or **Services > Policy sets > System policy sets** >***policy_set_name***. Clicking a policy set name from the listing in the policy sets collection opens the Policy set settings panel for that policy set. This panel displays a listing of available and enabled policies in the **Policies** table for the policy set you selected. If this table contains no policies, there are no existing policies to disable.
2. Click the**Select** box beside the enabled policy to be disabled. You can select multiple policies if you want to disable more than one.
3. Click **Disable**. The **State** column of the **Policies** table is updated to display the selected policy as disabled. The policy was not deleted from the policy set and is still available to be enabled.

Results

You have disabled a policy for the selected policy set.

What to do next

You could now enable other policies or add or modify existing policies for this policy set.

Web services policies

Policies define the type of web service policy based on the quality of service type. Policies are initially set with default settings but the attributes can be edited and changed.

Provided policies include:

WS-Addressing
: Based on the World Wide Web Consortium (W3C) WS-Addressing specifications for web services. This family of specifications provide transport-neutral mechanisms to address web services and to facilitate end-to-end addressing. This specification provides asynchronous support.

WS-Security
: Based on the WS-Secure Conversation (WS-SC) and WS-Security specifications along with the associated token profiles. The WS-Security specification and its associated token profiles define a way to send security tokens and provide message integrity and confidentiality. The WS-Secure Conversation specification establishes a secure context, based on shared keys, for the client and server to use for a series of messages. This standard provides a framework across organizations that defines how to secure the entire conversation. Use the WS-Security policy to define how the SOAP messages are secured. It has options such as:

  - which message parts are signed and encrypted
  - the tokens types to be included
  - whether to use symmetric or asymmetric cryptography

  You can also use WS-Security policies to define the bootstrap policy that is used to acquire security context tokens. Security context tokens are used by secure conversation.

WS-Reliable Messaging (WS-RM)
: This specification enables the sender and receiver to assure the quality of services in a set of messages. It helps the application developer deal with latency issues, maintenance interruption, and other problems that prevent messages from being completed. This quality assurance is critical for stateful applications.

WS-Transaction
: This specification provides support for coordination of atomic transactions or business activities for

web services applications. You can enable WS-Transaction on both the client (outbound) and server (inbound) side by attaching a policy set that enables the WS-Transaction policy as part of the policy set. This policy is based on the WS-AtomicTransaction specification and the WS-BusinessActivity specification, together with the WS-Coordination specification.

HTTP Transport
The HTTP transport policy applies the HTTP features and HTTP connections polices to outbound messages. The response listener policy is enforced on inbound messages.

SSL Transport
Provides SSL transport security for the HTTP protocol with web services applications.

JMS Transport
When using the SOAP over JMS transport with JAX-WS applications, you can customize the transport by configuring the JMS transport policy. The SOAP over JMS transport provides an alternative to HTTPS for transporting SOAP requests and response messages between clients and servers. Use the JMS transport policy to configure a service that uses the JMS transport to send asynchronous response messages back to the client.

Custom Properties
Provides the ability to specify generic binding properties for web service applications. The CustomProperties binding is only supported for service clients.

Exporting policy sets using the administrative console

You can export policy sets between a client and a provider or between servers using the administrative console.

Before you begin

Before you begin this task, select the policy set to be exported. Read about the application policy sets collection and exporting policy sets to client or server environments using the wsadmin tool.

About this task

Static export is used in development environment to exchange a policy sets between a client and a provider. You can also export between servers. The exported format is a .zip file.

Procedure

1. From the administrative console navigation, click **Services** > **Policy sets** > **Application policy sets** or **Services** > **Policy sets** > **System policy sets**. The Application policy sets collection page displays a listing of the custom and default policy sets. Custom policy sets are displayed only if you have created them. If you have not created a custom policy set, then only the default policy sets are displayed.
2. From the Application policy sets panel, select a policy set and click **Export**.
3. Locate the export archive file. From the Export policy set archive file settings panel, click the archive file to export.
4. Choose a location to export the file. Do not export the file to a browser.

Results

When you finish this task, the policy set archive file has been exported to the location you specified.

Example

If you have a policy set, `ABC_ps` and you want to move it from `ServerA` to `ClientA`, you can use the export function. The export policy set can be used by importing it into another application server. Read about the command task for importing an exported policy set compression file.

What to do next

You can import the policy set to reuse it.

Application policy sets collection

Use this page to manage policy sets. You can create, copy, export, and import policy sets. You can also view or delete existing policy sets. You can use policy sets, or assertions that define services, to simplify your web services configuration because policy sets group security and other web services settings into reusable units.

To view this administrative console page, click **Services** > **Policy sets** > **Application policy sets**.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Name

Specifies a list of available policy sets. Click a policy set name to access the details panel for that policy set. Use the buttons on the page to create a new policy set or manage the existing policy sets. You can also import a policy set to display in the list of available policy sets.

The following list of buttons are available to you for creating and managing policy sets:

Button	Resulting action
New	Creates a new policy set. This option opens an empty policy set and allows you to provide additional details, such as the name, description, and policy configuration options.
Delete	Removes the selected policy set.
Copy	Creates a copy of the policy set that is selected from a list. After you create a copy, you can provide a name and a description for the copy. You must also specify whether to transfer attachments and binding information, where these options are available, from the original to the copy.
Import	Imports a policy set. This is a menu item with the option of importing a policy set from a default repository or a selected location. You can select and import the default policy sets from the default repository. The default repository for the import function in the administrative console is the directory that contains the default policy sets. Initially, a subset of pre-configured policy sets are exposed. However, there are other default policy sets that are available to import when you select **Import** > **From Default Repository**. The administrative console also displays the default policy sets in a list that includes descriptions, that you can use to select the policy set that you want to import.
Export	Exports the selected policy set to an archive file.

Editable

This column shows whether the policy set is a user-defined, custom policy set that can be edited or whether the policy set is a default policy set that is not editable.

Values displayed in this field are `Editable` or `Not editable`. Even though a policy set is identified as not editable, it is deletable. For example, you cannot edit information for the default system policy set, but you can delete the policy set. You can change the properties for a default, not editable policy set by copying it, and then modifying the properties of the copy. For more information on modifying a default policy set, see copy of default policy set and bindings settings document.

Data type: String

Default: Not editable

Description
Provides a brief description of the application policy sets that currently exist. You cannot edit information for the default application policy sets; however, you can delete the policy sets. The list of contained policies for each policy set that it relates to are displayed in the Name column. The contained policies that are displayed are only those that are enabled. From this panel, the field is not editable.

For custom policy sets that you create or modify, you can edit this description when you create or customize policy sets on the details panel. The description is the same one that you entered in the **Description** field when you created that policy set. The included and enabled policies appear at the top followed by a bulleted list of the key attributes of the policy set.

Application policy set settings
Use this page to view, create, enable or disable your policy sets. You can use policies, or assertions that define services, to simplify your web services configuration.

To view this administrative console page, click one of the following paths:
- **Services** > **Policy sets** > **Application policy sets** > ***policy_set_name***.
- **Services** > **Policy sets** > **Application policy sets** > **New**.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Important: You can only edit the fields on this page if you open this page for a custom policy set. You cannot edit default policies.

Policy set name
Specifies the name of a selected policy set. This field is empty if you are creating a new policy set and you can enter a policy set name. If you select an existing policy set from the Policy set page, then this field displays the name of that policy set. This field is also not editable for existing custom policy sets and default policy sets.

Description
Specifies a brief description of the policy set being viewed, modified or created. This field displays a brief description of the policy set displayed in the Policy set name field or is empty if a new policy set is being created. You can edit this field for custom policy sets only.

Policies
The Policies table displays a list of policies that are contained in the policy set. This table initially contains no policies when you are creating a new custom policy set. If this is a default policy set, then you cannot add, delete, enable or disable the policy. The configuration of a policy in a default policy set cannot be altered but you can view a policy by clicking on the policy name link. If the policy is a custom policy, you can modify the configuration of the policy by clicking the policy name link. You can alter the policies contained in a custom policy set using the following buttons:

Button	Resulting Action
Add	Provides a list of valid policies, instances of which are not already included in the collection, that can be added to the policy set collection. The following policies are available: • Custom properties • HTTP transport • JMS transport • SSL transport • WS-Addressing • WS-ReliableMessaging • WS-Security • WS-Transaction
Delete	Removes the selected policy from the policy set and from the listing in the Description column of the table.
Enable	The policy is enabled for the policy set and displayed as enabled in the State column.
Disable	The policy is disabled for the policy set. The policy remains in the list but the State field shows the policy as Disabled.

Policies - Policy
Specifies the name of a policy. This field is empty if you are creating a new policy set. If you select an existing policy, then this field displays the name of that policy. If the policy settings are viewable, then you can click on the policy name to view the settings. For custom policy sets, you can click on the policy name to configure the policy settings.

Policies - State
Specifies an Enabled or Disabled status for each policy in the policy set. You cannot change the state for default policy sets. To change the state of the policy, select the policy and click **Enable** or **Disable**. The state is refreshed in this column to reflect your change.

If you disable a policy, you are temporarily removing the policy from the policy set without losing the configuration details for that policy. When a policy is disabled, you can easily enable the policy again by selecting **Enable**. If the policy is deleted, the configuration for that policy no longer exists. After you delete a policy, to enable that policy in a policy set, you must add the policy to the policy set and enter the configuration details for that policy.

Policies - Description
Specifies a brief description of each policy in the policies table. The product does not support custom policies; therefore, this field is not editable. You cannot create a new policy.

Additional properties – Attached deployed assets
Click this link to search for applications to which this policy set is attached. You can also find applications that contain service resources to which the policy set is attached.

Search attached applications collection
Use this page to search for applications and other resources that are attached to a specific policy set or to search for applications and other resources that have attached service resources.

To view this administrative console page, complete the following actions:

1. Click **Services > Policy sets > Application policy sets** >*policy_set_name*.
2. Click **Attached applications** link in the Additional Properties section.

Name
Specifies a list of applications that match the search text. The application names that are displayed in the Name column are either attached explicitly to the specified policy set or have service resources attached to this policy set.

To alter the policy set that is attached to an application, select an application, and click a button to enable the following options:

Button	Resulting Action
Detach Policy Set	Detaches the current policy set from the selected application or applications. This action also detaches any attached application service resources. This action does not detach other policy sets from the application or application service resources.
Replace Policy Set	Displays a list of policy sets that can be attached to the selected application or applications and any contained attached service resources. The policy set is replaced with the one selected. This action does not replace other policy sets that are attached to resources in the application that you select.

Click the application name to complete actions such as attaching policy sets to the application, its services, or its endpoints.

Web services policy sets
Policy sets are assertions about how services are defined. They are used to simplify your quality of service configuration for web services.

Note: You can use policy sets only with Java API for XML-Based Web Services (JAX-WS) applications. You cannot use policy sets with Java API for XML-based RPC (JAX-RPC) applications.

Policy sets combine configuration settings, including those for transport and message level configuration, such as WS-Addressing, WS-ReliableMessaging, and WS-Security.

There are two main types of policy sets; application policy sets and system policy sets. Application policy sets are used for business-related assertions. These assertions are related to the business operations that are defined in the Web Services Description Language (WSDL) file. System policy sets, on the other hand, are used for non-business-related system messages. These messages are not related to the business operations that are defined in the WSDL, but instead refer to messages that are defined in other specifications which apply qualities of service (QoS). Such QoS are the request security token (RST) messages that are defined in WS-Trust, or create sequence messages that are defined in WS-Reliable Messaging metadata exchange messages of the WS-MetadataExchange.

Policies are defined based on a quality of service. Policy definition is typically based on WS-Policy standard language, for example, the WS-Security policy is based on the current WS-SecurityPolicy from the Organization for the Advancement of Structured Information Standards (OASIS) standards.

An instance of a policy set consists of a collection of policies. For example, the WS-I RSP default policy set consists of instances of the WS-Security, WS-Addressing, and WS-ReliableMessaging policy types. A policy set is identified by a unique name that is unique across the cell. An empty policy set is a policy set with no policies defined.

You can use a default policy set after it is imported. If you want to change the properties for a default, not editable policy set, you need to copy the policy set to create an editable version to modify. See copy of default policy set and bindings settings. You can perform the following actions on policy sets:

- create
- copy
- edit
- delete
- attach to service resources like applications
- detach from service resources like applications
- export
- import

Note which functions you can configure using policy sets and the relationship of the security information that is configured. A set of default policy sets are included that you can import; then copy and rename for reuse. You can use a default policy set after it is imported, but if you want to change any of the settings, you need to copy the policy set to create an editable version. The configuration can then be altered and customized on the copy.

Important: You can only copy and customize policy sets using the administrative console or administrative commands. Policy sets do not function correctly if they are copied manually.

On the application server, policy sets are stored at the cell level. Policy sets are centrally located so that they are available to all applications on the server.

The following application policy sets are installed on the base or network deployment (ND) profile by default: WS-I RSP or WS-I RSP (ND), Username WSSecurity default, and WSHTTPS default. The WS-I RSP (ND) is installed in a network deployment environment.

The following policy sets are ready for you to use as is.
- LTPA WSSecurity Default
- Kerberos V5 HTTPS default
- SSL WSTransaction
- Username SecureConversation
- Username WSSecurity default
- WS-Addressing default
- WSHTTPS default
- WS-I RSP ND
- WS-ReliableMessaging persistent

The application server also provides other default policy sets that you can use or customize. To use the additional policy sets, you must import them from the default repository. Read about importing policy sets from the administrative console for more information.

The following default policy sets are provided:

WS-I RSP default

This policy set provides:
- Reliable message delivery to the intended receiver by enabling WS-ReliableMessaging
- Message integrity through digital signature that includes signing the body, time stamp, WS-Addressing headers and WS-ReliableMessaging headers using the WS-SecureConversation and WS-Security specifications
- Confidentiality through encryption that includes encrypting the body, signature elements, using the WS-SecureConversation and WS-Security specifications

LTPA WS-I RSP default

This policy set provides:

- Reliable message delivery to the intended receiver by enabling WS-ReliableMessaging
- Message integrity through digital signature that includes signing the body, time stamp, WS-Addressing headers and WS-ReliableMessaging headers using the WS-SecureConversation and WS-Security specifications
- Confidentiality through encryption that includes encrypting the body, signature elements, using the WS-SecureConversation and WS-Security specifications
- A Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service

Username WS-I RSP default

This policy set provides:

- Reliable message delivery to the intended receiver by enabling WS-ReliableMessaging
- Message integrity through digital signature that includes signing the body, time stamp, WS-Addressing headers and WS-ReliableMessaging headers using the WS-SecureConversation and WS-Security specifications
- Confidentiality through encryption that includes encrypting the body, signature elements, using the WS-SecureConversation and WS-Security specifications
- A username token included in the request message to authenticate the client to the service. The username token is encrypted in the request

SecureConversation

This policy set provides:

- Message integrity through digital signature that includes signing the body, time stamp, and WS-Addressing headers using WS-SecureConversation and WS-Security specifications
- Message confidentiality through encryption that includes encrypting the body, signature and signature confirmation elements, using WS-SecureConversation and WS-Security specifications

LTPA SecureConversation

This policy set provides:

- Message integrity through digital signature that includes signing the body, time stamp, and WS-Addressing headers using WS-SecureConversation and WS-Security specifications
- Message confidentiality through encryption that includes encrypting the body, signature and signature confirmation elements, using WS-SecureConversation and WS-Security specifications
- A Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service

Username SecureConversation

This policy set provides:

- Message integrity through digital signature that includes signing the body, time stamp, and WS-Addressing headers using WS-SecureConversation and WS-Security specifications
- Message confidentiality through encryption that includes encrypting the body, signature and signature confirmation elements, using WS-SecureConversation and WS-Security specifications
- A username token included in the request message to authenticate the client to the service. The username token is encrypted in the request

WSAddressing default

Enables WS-Addressing support, which uses endpoint references and message addressing properties to facilitate the addressing of web services in a standard and interoperable way.

WSHTTPS default

Provides SSL transport security for the HTTP protocol with Web services applications.

Kerberos V5 HTTPS default

This policy set provides message authentication with a Kerberos Version 5 token. Message integrity and confidentiality are provided by Secure Sockets Layer (SSL) transport security. This policy set follows the OASIS Kerberos Token Profile V1.1 and WS-Security specifications.

When you use this policy set, configure the basic authentication data and custom properties such as the com.ibm.wsspi.wssecurity.krbtoken.targetServiceName and com.ibm.wsspi.wssecurity.krbtoken.targetServiceHost custom properties in the client bindings. For more information, see the Authentication generator or consumer token settings and Protection token settings (generator or consumer) topics.

Kerberos V5 SecureConversation

This policy set provides message integrity by digitally signing the body, time stamp, and WS-Addressing headers. Message confidentiality is provided by encrypting the body and the signature. The bootstrap policy is configured with the Kerberos V5 token. This policy set follows the WS-SecureConversation, OASIS specification for the Kerberos Token Profile, in addition to the WS-Security specification.

To use this policy set, you must also use the Client sample V2 and Provider sample V2 general sample bindings for your applications. For more information, refer to the topic General sample bindings for JAX-WS applications. To use this new policy set, create a new profile after installing the product.

To update existing profiles with this new policy set and the general bindings, Client sample V2 and Provider sample V2 general sample bindings, you must complete some manual steps. You only need to update the deployment manager profile and stand-alone application server profiles. To complete the manual steps for an existing profile, refer to the topic Configuring Kerberos policy sets and V2 general sample bindings.

Kerberos V5 WSSecurity default

This policy set provides message integrity by digitally signing the body, time stamp, and WS-Addressing headers. Message confidentiality is provided by encrypting the body and the signature using Advanced Encryption Standard (AES) encryption. The derived key from the Kerberos V5 token is used. This policy set follows the OASIS specification for the Kerberos Token Profile, in addition to the WS-Security specification.

To use this policy set, you must also use the Client sample V2 and Provider sample V2 general sample bindings for your applications. For more information, refer to the topic General sample bindings for JAX-WS applications. To use this new policy set, create a new profile after installing the product.

To update existing profiles with this new policy set and the general bindings, Client sample V2 and Provider sample V2 general sample bindings, you must complete some manual steps. You only need to update the deployment manager profile and stand-alone application server profiles. To complete the manual steps for an existing profile, refer to the topic Configuring Kerberos policy sets and V2 general sample bindings.

TrustServiceKerberosDefault

This policy set specifies the symmetric algorithm and the derived keys to provide message security. Message integrity is provided by digitally signing the body, time stamp, and WS-Addressing headers using the HMAC-SHA1 algorithm. Message confidentiality is provided by encrypting the body and signature using the Advanced Encryption Standard (AES). This policy set follows the WS-Security and Secure Conversation specifications for issuing and renewing trust operation requests.

To use this policy set, you must also use the Client sample V2 and Provider sample V2 general sample bindings for your applications. For more information, refer to the topic General sample bindings for JAX-WS applications. To use this new policy set, create a new profile after installing the product.

To update existing profiles with this new policy set and the general bindings, Client sample V2 and Provider sample V2 general sample bindings, you must complete some manual steps. You only need to update the deployment manager profile and stand-alone application server profiles. To complete the manual steps for an existing profile, refer to the topic Configuring Kerberos policy sets and V2 general sample bindings.

WSReliableMessaging default

This policy set enables both WS-ReliableMessaging Version 1.1 and WS-Addressing and uses the minimum quality of service, *unmanaged non-persistent*. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages. In-order delivery is set to “false”, so messages are not necessarily delivered in the order in which they were sent.

WSReliableMessaging persistent

This policy set enables both WS-ReliableMessaging and WS-Addressing and uses the maximum quality of service, *managed persistent*. This quality of service supports asynchronous web service invocations and uses a service integration messaging engine and message store to manage the sequence state. Messages are processed within transactions, are persisted at the web service requester server and at the web service provider server, and are recoverable in the event of server failure. In-order delivery is set to “false”, so messages are not necessarily delivered in the order in which they were sent.

Because this policy set specifies managed persistent quality of service, you have to define bindings to the service integration bus and messaging engine that you want to use to manage the WS-ReliableMessaging state. You can attach and bind a WS-ReliableMessaging policy set to a web service application by using the administrative console or the wsadmin tool.

WSReliableMessaging 1_0

This policy set enables both WS-ReliableMessaging Version 1.0 and WS-Addressing and uses the minimum quality of service, *unmanaged non-persistent*. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages. In-order delivery is set to “false”, so messages are not necessarily delivered in the order in which they were sent.

You can use this policy set with .NET-based web services.

WSSecurity default

This policy set provides:

- Message integrity through digital signature (using RSA public-key cryptography) to sign the body, time stamp, and WS-Addressing headers using WS-Security specifications.
- Message confidentiality through encryption (using RSA public-key cryptography) to encrypt the body, signature and signature elements using WS-Security specifications.

LTPA WSSecurity default

This policy set provides:

- Message integrity through digital signature (using RSA public-key cryptography) to sign the body, time stamp, and WS-Addressing headers using WS-Security specifications.
- Message confidentiality through encryption (using RSA public-key cryptography) to encrypt the body, signature and signature elements using WS-Security specifications.
- A Lightweight Third Party Authentication (LTPA) token included in the request message to authenticate the client to the service.

Username WSSecurity default

This policy set provides:

- Message integrity through digital signature (using RSA public-key cryptography) to sign the body, time stamp, and WS-Addressing headers using WS-Security specifications.

- Message confidentiality through encryption (using RSA public-key cryptography) to encrypt the body, signature and signature elements using WS-Security specifications.
- A username token included in the request message to authenticate the client to the service. The username token is encrypted in the request.

WSTransaction

This policy set enables WS-Transaction, which provides:

- The ability to coordinate distributed transactional work atomically and interoperably using the WS-AtomicTransaction specification.
- The ability to coordinate loosely coupled business processes that are distributed across the heterogenous web service environment, with the ability to compensate actions if a failure occurs in the business activity, using the WS-BusinessActivity specification.

SSL WSTransaction

This policy set enables WS-Transaction, which provides:

- The ability to coordinate distributed transactional work atomically, interoperably, and securely, using the WS-AtomicTransaction specification and SSL Transport security.
- The ability to coordinate loosely coupled business processes, with the ability to compensate actions if a failure occurs in the business activity, securely, using the WS-BusinessActivity specification and SSL Transport security.

Policy sets do not include environment or platform-specific information, such as keys for signing, keystore information, or persistent store information. This type of information is defined in the binding. A policy set attachment defines how a policy set is attached to service resources and bindings. The attachment definition is outside the policy set definition and is defined as meta-data associated with application data.

Bindings are made up of environment and platform-specific information. General bindings such as the service client or provider bindings for the global security domain can be shared across applications.

To enable policy sets to work with applications, bindings are needed. Use the administrative console to configure general bindings and application specific bindings. Read about defining binding information for policy sets for more information about working with attachments and bindings.

Overview of migrating policy sets and bindings

Policy sets are migrated during the product migration from Version 6.1 Feature Pack for Web Services or Version 7.0 to Version 8.0. This topic describes the different rules that apply to migrating policy sets and bindings. For information about migrating the version of the product that you are running, see migrating and coexisting.

Migration from Version 6.1 Feature Pack for Web Services

Migration rules for policy sets

For the following policy sets, the migration code first checks for any application attachment for a policy set. If there is an application attachment, the migration code upgrades and renames the policy set to *oldPolicySet_wsfep*; then updates the policy set attachments from *oldPolicySet* to *oldPolicySet_wsfep* in Version 7.0 and later. If there is no attachment for the policy set, then the policy set is not migrated or renamed.

- LTPA RAMP default
- LTPA SecureConversation
- LTPA WSSecurity default
- Username RAMP default
- Username SecureConversation
- Username WSSecurity default

Other policy sets are migrated to Version 7.0 and later only if there is no other policy set in Version 7.0 and later with the same name.

Migration rules for bindings

In Version 7.0 and later, custom bindings are called application specific bindings. Read web services policy set bindings.

The following migration rules apply to application specific bindings, cell level default bindings, server level default bindings, and trust service bindings:

Application specific bindings

During migration, the Version 6.1 application specific bindings in the applications are not upgraded. They are copied with the applications to the Version 7.0 and later system. After migration, you can upgrade the Version 6.1 application specific bindings in an application using the administrative command, `upgradeBindings`.

Cell level default bindings

During migration, the cell level default bindings from the Version 6.1 Feature Pack for Web Services are copied to the Version 7.0 and later system, and they replace any existing Version 6.1 cell default bindings in the Version 7.0 and later system. The Version 6.1 cell default bindings are migrated to general bindings in Version 7.0 and later.

Attention:
There is a security fix for the Version 6.1 cell level default WSSecurity bindings. Run the script, *updateBindings.py* that is located in `WAS_HOME/bin` to fix issues with the Version 6.1 cell level default WSSecurity bindings.

You can install a WebSphere Application Server Version 6.1 Feature Pack for Web Services application within the WebSphere Application Server Version 7.0 and later environment. If your application contains Version 6.1 application specific bindings, the application is defined as a Version 6.1 application to the application server. Additionally, if your application is installed on a WebSphere Application Server Version 6.1 Feature Pack for Web Services server within the WebSphere Application Server Version 7.0 and later environment, the application specific binding is created as a Version 6.1 application specific binding.

When you create an application specific binding, the system checks to see if the application is installed on a Version 6.1 server or if the application contains any Version 6.1 application specific bindings. If either of these conditions is true, the system creates Version 6.1 application specific bindings. In addition, you are not allowed to assign a general binding to a policy set attachment for that application because general bindings are for Version 7.0 and later level of the product.

Server level default bindings

During migration, the server default bindings in the Version 6.1 Feature Pack for Web Services are copied over to the Version 7.0 and later server. The server default bindings are also migrated to general bindings. You can decide whether or not to use these general bindings as the Version 7.0 and later server default bindings. The Version 6.1 applications and other applications that are installed on a Version 6.1 server use the Version 6.1 default bindings.

Trust service bindings

Trust service bindings are migrated during the product migration. The migrated trust service bindings replace the trust service bindings in Version 7.0 and later.

Migrating general bindings from Version 7.0 and later to Version 8.0

A general binding is migrated from Version 7.0 to Version 8.0 only if there is no other general binding in Version 8.0 with the same name. If a general binding is not migrated because it has the same name as a Version 8.0 binding, then you can export the binding from the Version 7.0 system and import it into Version 8.0 with a different name.

The default binding settings which specify which provider and client bindings are used as defaults are not migrated from Version 7.0 to Version 8.0. You must modify your default binding settings in Version 8.0 if you want to use the same defaults that were specified in Version 7.0.

Chapter 30. Administering web services - bus-enabled web services

You can associate your web services with the service integration bus, to achieve the following goals: make internal services available as web services; make external web services available internally at bus destinations. Bus-enabled web services also provide a choice of quality of service and message distribution options for web services, along with intelligence in the form of mediations that allow for the rerouting of messages.

Enabling web services through the service integration bus

Web services can use the service integration bus to provide a single point of control, access, and validation of web service requests and allow control of web services that are available to different groups of web service users.

About this task

With bus-enabled web services you can achieve the following goals:

- Create an *inbound service*: Take an internally-hosted service that is available at a bus destination, and make it available as a web service.
- Create an *outbound service*: Take an externally-hosted web service, and make it available internally at a bus destination.

Bus-enabled web services provide a choice of quality of service and message distribution options, along with intelligence in the form of mediations that allow for the rerouting of messages.

To enable web services through service integration technologies, complete the following steps:

Procedure

1. Optional: Learn about bus-enabled web services. Explore the concepts that underly service integration bus-enabled web services.
2. Plan your bus-enabled web services installation. Determine the bus-enabled web services roles that each server is to perform.
3. Ensure that every server that is to play a bus-enabled web services role is a member of a service integration bus. For more information, see “Configuring the members of a bus” on page 1889.
4. For every server that is to play a bus-enabled web services role, install and configure a Service Data Objects (SDO) repository on the server.

   Note: For WebSphere Application Server Version 6.0, you also had to manually install a selection of the following applications:
   - The service integration technologies resource adapter (used to invoke web services at outbound ports).
   - The bus-enabled web services application.
   - One or more endpoint listener applications.

   For later versions of WebSphere Application Server, these applications are installed automatically as and when needed. For example, the endpoint listener application is installed automatically when you configure an endpoint listener.
5. Create a new endpoint listener configuration for each endpoint listener application that you plan to use to receive inbound service requests.
6. Optional: Create an inbound service. An inbound service is a web interface to a service that is provided internally (that is, a service provided by your own organization and hosted in a location that is

directly available through a service integration bus destination). To configure a locally-hosted service as an inbound service, you associate it with a service destination, and with one or more endpoint listeners through which service requests and responses are passed to the service. You can also choose to have the local service made available through one or more UDDI registries.

7. Optional: Create an outbound service. An outbound service is a web service that is hosted externally, and is made available through a service integration bus. To make an externally-hosted service available through a bus, you first associate it with a service destination, then you configure one or more port destinations (one for each type of binding, for example SOAP over HTTP or SOAP over JMS) through which service requests and responses are passed to the external service. You get the port definitions from the WSDL, but you can choose which ones you want to create.
8. Optional: Apply additional security to your bus-enabled web services. By default, the bus-enabled web services configuration works when WebSphere Application Server security is enabled and your service integration buses are secured. However this level of security does not impose any security restrictions on the users of your bus-enabled web services configuration. To control how your bus-enabled web services configuration is used by each group of your colleagues or customers, use the bus-enabled web services additional security features to enable working with password-protected components and servers, with WS-Security and with HTTPS.

What to do next

For more information about specific aspects of bus-enabled web services, see the following topics:

- Bus-enabled web services
- "Installing and configuring the SDO repository"
- "Configuring web services for a service integration bus" on page 2777
- "Administering the bus-enabled web services resources" on page 2789
- Securing bus-enabled web services
- "Passing SOAP messages with attachments through the service integration bus" on page 2824
- "SIBWebServices command group for the AdminTask object" on page 2933
- Bus-enabled web services troubleshooting tips
- Tuning bus-enabled web services

Installing and configuring the SDO repository

Service Data Objects (SDO) is an open standard for enabling applications to handle data from different data sources in a uniform way, as data graphs. Service integration bus-enabled web services use an SDO repository for storing and serving WSDL definitions. Use this task to create and configure your preferred database to store SDO data, and to install and configure an SDO repository on each server that you plan to use for bus-enabled web services.

Before you begin

Determine the servers on which to install and configure an SDO repository as described in Planning your bus-enabled web services installation, then add each server as a member of a bus as described in "Configuring the members of a bus" on page 1889.

An SDO repository can work with most database products. For specific information about choosing and configuring your preferred database, consult your database administrator or database product documentation, and read the notes in this topic on database usage.

About this task

To install and configure an SDO repository, complete the following steps:

- Install your preferred database product.

- Create a JDBC provider and a data source for your database.
- Run the `installSdoRepository.jacl` script one or more times, to install the SDO application on each server and to set the database type that the SDO repository is to use.

For more information about how to do this, first read the following notes on database usage and on the `installSdoRepository.jacl` script, and then complete the steps for one of these configurations:

- "Configure the SDO repository for a single server, and to use the embedded Derby database" on page 2774.
- "Configure the SDO repository for a single server, and to use a database other than embedded Derby" on page 2775.

Notes on database usage:

- For a single server configuration, you can use either your preferred database or the embedded Apache Derby database that is supplied with WebSphere Application Server.
- The SDO repository dictates the schema and table names that it uses, so different repositories must use different databases to ensure that they do not access the same data.
- Create the database for your preferred database supplier by using the `Table.ddl` file from the relevant *app_server_root*`/util/SdoRepository/`*database_type* directory. The `Table.ddl` file describes the database table that is needed by the SDO repository.
- The **-editBackendId** flag on the `installSdoRepository.jacl` script determines the database type that the repository is to use. The back end ID determines what database-specific rules the application follows when talking to the database. See the associated note on the `installSdoRepository.jacl` script.
- Some databases require a user ID that has been granted permissions to access the SDO repository database. Create a user ID for user name `SDOREP` before you create the tables for Oracle, Sybase, and SQL Server databases. Because of the way these databases handle user names and table names, the user name must be `SDOREP` to enable the SDO repository to access its table with the fully qualified name `SDOREP.BYTESTORE`. Make sure that you grant permission for the `SDOREP` user to read from, and write to, the database.
- If you use an Informix database, do not disable logging.
- The SDO repository does not require *XA* support. In most cases you can use either an XA or a non-XA data source. However, if your database is Oracle 8 or 9, you must use the Oracle JDBC driver (non-XA) for the SDO repository data source.
- You might also choose to complete other steps such as creating an index of the primary key to improve database performance. Do not change the schema, table and column names.

Notes on the installSdoRepository.jacl script:

- Use the wsadmin scripting client to run the script.
- Run the script from within QShell.
- The script is provided in the *app_server_root*`/bin` directory, where *app_server_root* is the root directory for the installation of WebSphere Application Server. If you choose to run the wsadmin scripting client from another directory, specify the full path to the script on

the command option. For example to work with a profile other than the default profile, change to the *app_server_root*/profiles/*profile_name*/bin directory then specify the following path to the script:

```
wsadmin -f app_server_root/bin/installSdoRepository.jacl
```

- The **-editBackendId** flag on the installSdoRepository.jacl script determines the database type that the repository is to use. The back end ID determines what database-specific rules the application follows when talking to the database. To see the full list of available back end ID values, use the -listBackendIds flag:

  ```
  wsadmin -f installSdoRepository.jacl -listBackendIds
  ```

  All the back end ID values in the list can be used when the SDO repository is installed on one or more WebSphere Application Server Version 7.0 or later application servers. Values marked with (*) cannot be used when the SDO repository is installed on Version 6.0 servers. Values marked with (**) cannot be used when the SDO repository is installed on Version 6.0 or Version 6.1 servers.
- If the data source already exists, or there has been a previous broken or partial installation of the SDO repository application, the installSdoRepository.jacl script fails to complete and configuration changes are not saved. In these cases, run the SDO repository uninstall script, fix the problem, then rerun the installSdoRepository.jacl script.

Configure the SDO repository for a single server, and to use the embedded Derby database

About this task

If you are creating a single server configuration and you want to use embedded Derby, you run the installSdoRepository.jacl script with the -createDb switch. This action creates the Derby database and installs the SDO repository.

To configure the SDO repository for a single server and to use the embedded Derby database, complete the following steps:

Procedure

1. Open a command prompt, then change to the *app_server_root*/bin directory.
2. Enter the following command:

   ```
   wsadmin -f installSdoRepository.jacl -createDb
   ```

   Note: The -createDb flag tells the command to create a default Derby database. If you omit this flag, the command still installs an SDO repository that is configured to use Derby, but the command does not also create the database.

Configure the SDO repository for a single server, and to use a database other than embedded Derby

About this task

If you are creating a single server configuration that uses a database other than embedded Derby, you install your preferred database product, then create a JDBC provider and a data source, then run the `installSdoRepository.jacl` script twice:

1. One time to install the SDO application on the application server.
2. One time to set the database type that the SDO repository is to use.

To configure the SDO repository for a single server and to use a database other than embedded Derby, complete the following steps:

Procedure

1. Create the database for your preferred database supplier by using the `Table.ddl` file from the relevant *app_server_root*`/util/SdoRepository/`*database_type* directory.

   For an illustration of the process for creating tables in DB2, see Recreating database tables from the exported table data definition language . For more information, see “Deploying data access applications” on page 171.
2. Create a J2C authentication alias.

   This is for use with the data source that you create in the next step. Check that the authentication alias matches the login details for your database instance, otherwise a connection will not be made.
3. Create and configure a JDBC provider and data source.

   Set the following data source properties:
   - Set the **authentication** property to use the authentication alias you created in the previous step.
   - Select the **Use this Data Source in container managed persistence (CMP)** check box.
   - Set the **Name** property to a name of your own choosing. For example, SDO Repository DataSource.
   - Set the **JNDI name** property to the following exact value: jdbc/com.ibm.ws.sdo.config/SdoRepository.
   - Set any other properties that are required settings for your chosen database.
4. Optional: Test the data source connection:

   Note: This option does not work in all configurations. The availability of this option depends on the scope at which the data source is defined, and the scope of any WebSphere Application Server variables that are used in the JDBC provider and data source configurations. For more information about testing connections to data sources, see Test connection service.

   a. In the administrative console, navigate to **Resources -> JDBC -> Data sources**.
   b. Select the SDO repository data source.
   c. Click **Test connection**.
5. Configure the SDO repository:
   a. Open a command prompt, then change to the *app_server_root*`/bin` directory.
   b. Install the SDO repository application on the server:

      ```
      wsadmin -f installSdoRepository.jacl
      ```
   c. Set the database type that the SDO repository is to use:

```
wsadmin -f installSdoRepository.jacl -editBackendId database_type
```

      for example:

```
wsadmin -f installSdoRepository.jacl -editBackendId DB2UDB_V82
```

The SDO repository uninstall script

Use this script to uninstall a Service Data Objects (SDO) repository that was previously installed, or failed to install correctly.

You install the SDO repository application on every server that you plan to use for one or more of the service integration bus-enabled web services roles as described in “Installing and configuring the SDO repository” on page 2772.

If the data source already exists, or there has been a previous broken or partial installation of the SDO repository application, the `installSdoRepository.jacl` script fails to complete and configuration changes are not saved. In these cases, you have to run the `uninstallSdoRepository.jacl` script. This script continues when it finds unexpected results, so it can clean up a broken or partial installation.

Note: Run the script from within QShell.

The script is provided in the *app_server_root*`/bin` directory, where *app_server_root* is the root directory for the installation of WebSphere Application Server. If you choose to run the wsadmin scripting client from another directory, specify the full path to the script on the command option. For example to work with a profile other than the default profile, change to the *app_server_root*`/profiles/`*profile_name*`/bin` directory then specify the following path to the script:

```
wsadmin -f app_server_root/bin/uninstallSdoRepository.jacl
```

The SDO repository script install and uninstall pairs

The following are the install and uninstall command pairs, where each uninstall command undoes the action of the related install command. If you attempt to uninstall with a different set of arguments to those previously used with the `installSdoRepository.jacl` script, you might find that the uninstall does not remove everything or that it displays warnings when it tries to remove non-existent settings.

For configuration of the SDO repository on a server, the `-createDb` flag tells the install command to create a default (Apache Derby) database and configure it for use with this application server. The `-removeDb` flag tells the uninstall command to remove the database configuration from the application server, but not to delete the Apache Derby database:

```
wsadmin -f installSdoRepository.jacl -createDb
wsadmin -f uninstallSdoRepository.jacl -removeDb
```

Note:

- If you did not use `-createDb` on the installer, because you had already configured an Apache Derby database for some other purpose, then you should not use the `-removeDb` flag on the uninstaller.
- To avoid deleting data that you might want to keep, the `-removeDb` flag does not delete the Apache Derby database. If you are certain that you want to delete the database, you can do so manually. An Apache Derby database is a directory on the file system. The one created by the installer with the `-createDb` flag is in the *profile_root*`/databases/SdoRepDb` directory, where *profile_root* is the directory in which profile-specific information is stored. If you do not delete the database, and you try to install again with the `-createDb` flag, the installation process fails stating that the `SdoRepDb` directory already exists.

For installation or removal of the SDO repository application from a server:

```
wsadmin -f installSdoRepository.jacl
wsadmin -f uninstallSdoRepository.jacl
```

Bus-enabled web services installation files and locations

When you install WebSphere Application Server, the files that are required for running service integration bus-enabled web services are copied into your file system under *app_server_root*, where *app_server_root* is the root directory for the installation of WebSphere Application Server.

The following table lists the main bus-enabled web services files that you might have to access, and the locations into which they are placed.

Table 259. Bus-enabled web services files and their locations. The first column of this table lists the main bus-enabled web services files, the second column describes the purpose of the files, the third column lists the locations of the files.

File name	Purpose	Location
`installSdoRepository.jacl`	The script used to configure the SDO repository. Bus-enabled web services use an SDO repository for storing and serving their WSDL definitions.	*app_server_root*`/bin`
`uninstallSdoRepository.jacl`	The script used to uninstall the SDO repository.	*app_server_root*`/bin`
SDO repository resources	The resource files used to configure the SDO repository to work with a range of different databases.	*app_server_root*`/util/SdoRepository`
`sibwsauthbean.ear`	The application for Password-protecting a web service operation.	*app_server_root*`/installableApps`
`sibwsAuthGen`	The command file used to generate authorization beans for password-protecting a web service operation.	*app_server_root*`/util`
`soaphttpchannel1.ear`	The SOAP over HTTP endpoint listener 1 application. This application is installed automatically when you create an associated endpoint listener configuration.	*app_server_root*`/installableApps`
`soaphttpchannel2.ear`	The SOAP over HTTP endpoint listener 2 application. This application is installed automatically when you create an associated endpoint listener configuration.	*app_server_root*`/installableApps`
`soapjmschannel1.ear`	The synchronous SOAP over Java Messaging Service (JMS) endpoint listener 1 application. This application is installed automatically when you create an associated endpoint listener configuration.	*app_server_root*`/installableApps`
`soapjmschannel2.ear`	The synchronous SOAP over JMS endpoint listener 2 application. This application is installed automatically when you create an associated endpoint listener configuration.	*app_server_root*`/installableApps`

Configuring web services for a service integration bus

Take an internally-hosted service that is available at a bus destination, and make it available as a web service; Take an externally-hosted web service, and make it available internally at a bus destination; Use the web services gateway to map an existing service - either an inbound or an outbound service - to a new Web service that appears to be provided by the gateway.

About this task

In figure 1, a client request is received by an endpoint listener then passed through an inbound port to an inbound service destination. An outbound service destination passes a request through an outbound port to an external service.

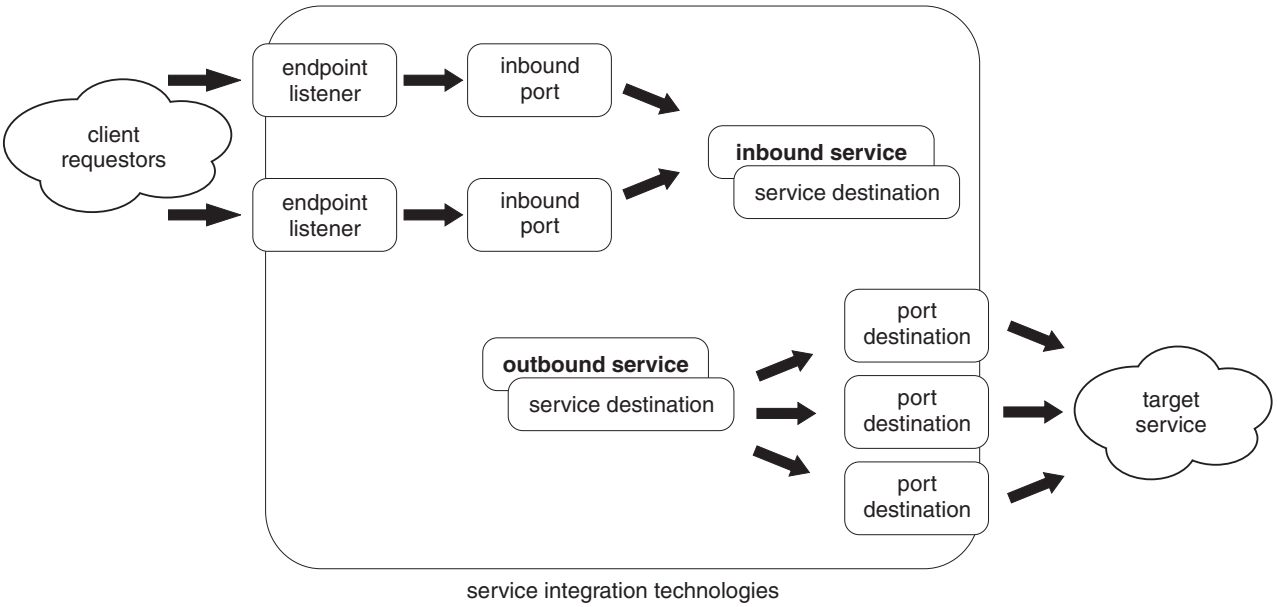

Figure 42. Inbound and outbound services

In figure 2, a client request is received by an endpoint listener, then passed through an inbound port to an inbound service destination. An outbound service destination passes a request through an outbound port to an external service, and a gateway service resembles an inbound service and maps to an outbound service.

Through service integration bus-enabled web services you can achieve the following goals:

Procedure

- Create an *inbound service*: Take an internally-hosted service that is available at a bus destination, and make it available as a web service.
- Create an *outbound service*: Take an externally-hosted web service, and make it available internally at a bus destination.

Making an internally-hosted service available as a web service

Create an inbound service. An inbound service is a Web interface to a service that is provided internally (that is, a service provided by your own organization and hosted in a location that is directly available through a service integration bus destination). To configure a locally-hosted service as an inbound service, you associate it with a service destination, and with one or more endpoint listeners through which service requests and responses are passed to the service. You can also choose to have the local service made available through one or more UDDI registries.

Before you begin

This topic assumes that:

- You have created and installed a Service Data Objects (SDO) repository (used for storing and serving WSDL definitions) on every server that is to play a service integration bus-enabled web services role.
- You have created a new endpoint listener configuration for each endpoint listener that you plan to use to receive inbound service requests.
- You already have an internally-hosted service that you want to configure as an inbound service, and you have made the service available at a service integration bus destination.
- You have created references to any UDDI registries in which you want to register this service.

You must also create a template WSDL file that describes the service, and make the WSDL available at a URL or through a UDDI registry. For information on how to create a WSDL file, see Developing a WSDL file for JAX-RPC applications.

You can create an inbound service by using the administrative console as described in this task, or by using the “createSIBWSInboundService command” on page 2940.

Note: If the bus needs to pass messages through an authenticating proxy server to retrieve WSDL documents, then you cannot use the administrative console for this task and you must create your new inbound service by using the wsadmin tool. For more information see the corresponding troubleshooting tip.

About this task

In the following figure, a client request is received by an endpoint listener, then passed through an inbound port to an inbound service destination. JAX-RPC handlers and WS-Security bindings can be applied at the ports.

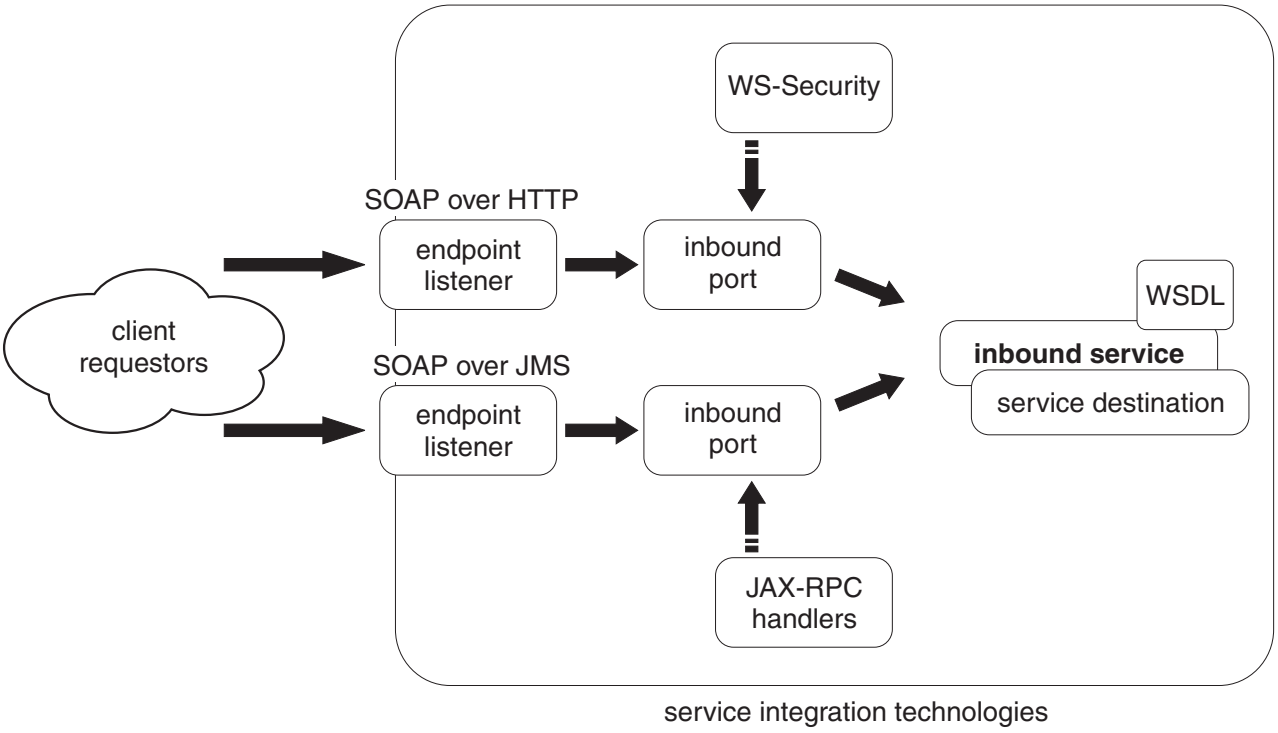

Figure 43. Inbound service

Web service requests and responses to an inbound service can be sent across any binding (for example SOAP over HTTP or SOAP over JMS) that is available to the bus. Each available binding type is represented by an inbound port, and each inbound port is associated with a binding-specific endpoint listener.

You can control and monitor access to your inbound services in the following ways:

- You can control which groups of users can access a particular inbound web service by making the service available only through specific endpoint listeners.
- You can associate JAX-RPC handler lists with ports, so that the handlers can monitor activity at the port, and take appropriate action depending upon the sender and content of each message that passes through the port.

- You can set the level of security to be applied to messages (the WS-Security configuration and bindings). The security level can be set independently for request and response messages.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Buses -> *bus_name* -> [Services] Inbound Services**. The inbound services collection form is displayed.
3. Click **New**. The New inbound service wizard is displayed.
4. Use the wizard to create the new inbound service configuration by completing the following steps. For more information about the properties that you set with the wizard, see Inbound services settings.
   a. Select the service destination and template WSDL location.

      Note: The template WSDL is the service-specific WSDL file that you have created to describe this inbound service.

   b. Select the service from the template WSDL.

      Note:

      - This option is needed in case there is more than one service in the template WSDL. The field is filled in for you by default. If there is only one service in the WSDL, accept the default.

   c. Specify the name of the inbound service and select the endpoint listeners.

      Note:

      - You need not supply a name for the inbound service. If you choose not to supply a name, a default name is created. The default name is derived from the service destination name, with characters that are not valid for names filtered out.
      - An inbound port is automatically created for each endpoint listener that you select. Each inbound port is created without a template port, JAX-RPC handler list or security settings and is given a default name that relates to the endpoint listener selected. For an overview of the relationship between endpoint listeners and inbound ports, see Endpoint listeners and inbound ports: Entry points to the service integration bus.

   d. Define any UDDI publication properties.

      Note: You can use the wizard to specify the UDDI publication properties that are used to publish this inbound service to an initial UDDI registry. After you create an inbound service through the wizard, you can use the modify an existing inbound service configuration option to publish the service to more UDDI registries. For information about the UDDI publication properties, see UDDI Publication settings and UDDI registries: Web service directories that can be referenced by bus-enabled web services.
5. Click **Finish**.

Results

If the processing completes successfully, the list of inbound services for this service integration bus is updated to include the new inbound service. Otherwise, an error message is displayed.

What to do next

If you want to secure your new inbound service, or apply any JAX-RPC handler lists to the ports for the service, or publish the service to more UDDI registries, use the administrative console to modify your inbound service configuration.

Modifying an existing inbound service configuration:

Modify the configuration details for an existing inbound service. For example: secure the service; apply JAX-RPC handler lists to the ports for the service; publish the service to more than one UDDI registry.

About this task

An inbound service is a web interface to a service that is provided internally (that is, a service provided by your own organization and hosted in a location that is directly available through a service integration bus destination).

When you first create an inbound service, you connect the service to one or more endpoint listeners and (optionally) specify the UDDI publication properties that are used to publish the inbound service to an initial UDDI registry. An inbound port is automatically created for each endpoint listener that you select, but each inbound port is created without a template port, JAX-RPC handler list or security settings. Modify your inbound service configuration if you want to control and monitor access to your inbound services in any of the following ways:

- Associate JAX-RPC handler lists with ports, so that the handlers can monitor activity at the port, and take appropriate action depending upon the sender and content of each message that passes through the port.
- Password-protect a web service operation.
- Set the level of security to be applied to messages (the WS-Security configuration and bindings). The security level can be set independently for request and response messages.
- Publish the service to more than one UDDI registry.

To list the existing inbound services, and to view and modify their configuration details, complete the following steps:

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Buses -> *bus_name* -> [Services] Inbound Services**. A list of all the inbound services is displayed in an inbound services collection form.
3. Click the name of an inbound service in the list. The current settings for this inbound service are displayed.
4. Optional: Click **Reload template WSDL** to reload the template WSDL file for this inbound service.

   Note:

   - When you create a new inbound service, a copy of the template WSDL file for the service is loaded into a locally-maintained repository. If you change the template WSDL file, you must update the local copy.
   - When you click **Reload template WSDL**, you run the command that is described in Refreshing the inbound service WSDL file by using the wsadmin tool. For the command to complete successfully, the conditions must be met that are described in that topic.
   - If the bus needs to pass messages through an authenticating proxy server to retrieve WSDL documents, then you cannot use the **Reload template WSDL** option and you must run the refresh WSDL command by using the wsadmin tool. For more information, see the corresponding troubleshooting tip.
5. Modify the general properties. For information about each of these properties, see Inbound services settings.

   Note:

   - When you change an inbound service name, the system looks up all objects that refer to it and updates the name.

- The template WSDL is the service-specific WSDL file that you create to describe this inbound service. For information about how to create a WSDL file, see Developing a WSDL file for JAX-RPC applications.
- Although logically the template WSDL name and namespace are only required if there is more than one service in the WSDL, the fields that you use to set them are coded within the administrative console as compulsory fields. They are filled in for you by default, so if they are not logically required for your service you should leave the default values. If you remove the value from either field, the administrative console treats the empty field as an error.
- If you select the option to **Enable operation-level security** then you must also complete, for this inbound service, the steps described in Password-protecting a web service operation.

6. Modify the additional properties.
   a. Modify the inbound ports that are associated with this inbound service.

      An inbound port describes the web service enablement of a service destination on a specific endpoint listener, with associated configuration. Each inbound port is associated with an endpoint listener, and you can control which groups of users can access a particular inbound service by making the service available only through specific endpoint listeners. For more information, see Endpoint listeners and inbound ports: Entry points to the service integration bus.

      You can use a JAX-RPC handler list to monitor activity at the port, and take appropriate action (for example logging, or rerouting) depending upon the sender and content of each message that passes through the port. For more information, see Bus-enabled web services and JAX-RPC handlers.

      You can use WS-Security to set the levels of security to be applied to messages. The security level can be set independently for request and response messages. For more information, see Service integration technologies and WS-Security.

      See also Inbound ports settings.

   b. Modify the UDDI publication properties that are used to publish this inbound service to one or more UDDI registries. For information about the UDDI publication properties, see UDDI Publication settings and UDDI registries: Web service directories that can be referenced by bus-enabled web services.

   c. Modify the custom properties, if any, that you have set for this inbound service. These custom properties are name and value pairs that you can use to set internal system configuration properties. In each pair, the name is a property key and the value is a string value.

   d. Use the publish WSDL files property to export the template WSDL for this inbound service to a compressed file.

      As a technology preview, the exported compressed file includes a version of the WSDL file that has no ports (bindings) defined. This non-bound WSDL is intended for use by your colleagues preparing to deploy an inbound service. It gives you a convenient way of sharing information about the planned deployment details for the service among your team. When you finally deploy the inbound service, the associated WSDL must be complete (that is, it must include the binding information).

      The non-bound WSDL file is always published in the exported compressed file for the inbound service, along with the bound WSDL file if the inbound service has any ports defined. The compressed file, named *inbound_service_name*.zip, therefore always contains the following files:

      - *bus_name*.*inbound_service_name*NonBound.wsdl (this file contains the non-bound service, port and binding for the inbound service).
      - *bus_name*.*inbound_service_name*PortTypes.wsdl (this file contains the port type definition for the inbound service).

      If the inbound service has one or more ports, then the compressed file additionally contains the following files:

      - *bus_name*.*inbound_service_name*Service.wsdl (this file contains the service and port elements for the inbound service).

- *bus_name*.*inbound_service_name*Bindings.wsdl (this file contains the binding elements that correspond to the ports for the inbound service).

If there is an error generating the WSDL then an error page is returned.

7. Save your changes to the master configuration.

Results

If the processing completes successfully, the list of inbound services for this service integration bus is redisplayed. Otherwise, an error message is displayed.

Deleting inbound services configurations:

Use this task to delete inbound services configurations using the administrative console.

Before you begin

Decide which method to use to configure these resources. You can delete an inbound service by using the administrative console as described in this task, or by using the “deleteSIBWSInboundService command” on page 2941.

About this task

To delete one or more inbound services by using the administrative console, complete the following steps:

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Buses -> *bus_name* -> [Services] Inbound Services**. A list of all the inbound services is displayed in an inbound services collection form.
3. Select the check box for every inbound service that you want to remove.
4. Click **Delete**.

Results

If the processing completes successfully, the list of inbound services for this service integration bus is updated. Otherwise, an error message is displayed.

Making an externally-hosted web service available internally

Create an outbound service. An outbound service provides access, through one or more outbound ports, to a web service that is hosted externally. An outbound service can be used by any of your internal systems that can access the service integration bus on which it is hosted. To make an externally-hosted service available through a bus, you first associate it with a service destination, then you configure one or more port destinations (one for each type of binding, for example SOAP over HTTP or SOAP over JMS) through which service requests and responses are passed to the external service. You get the port definitions from the WSDL, but you can choose which ones you want to create.

Before you begin

This topic assumes that you have created and installed a Service Data Objects (SDO) repository (used for storing and serving WSDL definitions) on every server that is to play a service integration bus web services role.

To create an outbound service, you must know the location of the externally-published WSDL file that describes the service. This WSDL file is either available at a web address or through a UDDI registry.

If the WSDL file for your outbound service is stored in a UDDI registry, you associate the outbound service with a UDDI reference to the registry. You select the UDDI reference from a drop-down list, so you must configure the UDDI reference before you configure a new outbound service that uses it.

Decide which method to use to configure these resources. You can create an outbound service by using the administrative console as described in this task, or by using the “createSIBWSOutboundService command” on page 2934.

Note: If the bus needs to pass messages through an authenticating proxy server to retrieve WSDL documents, then you cannot use the administrative console for this task and you must create your new outbound service by using the wsadmin tool. For more information see the corresponding troubleshooting tip.

About this task

In the following figure, each message is passed from the outbound service to the target service through an outbound port. A separate outbound port is created for each available binding. JAX-RPC handlers and WS-Security settings can be applied at the ports.

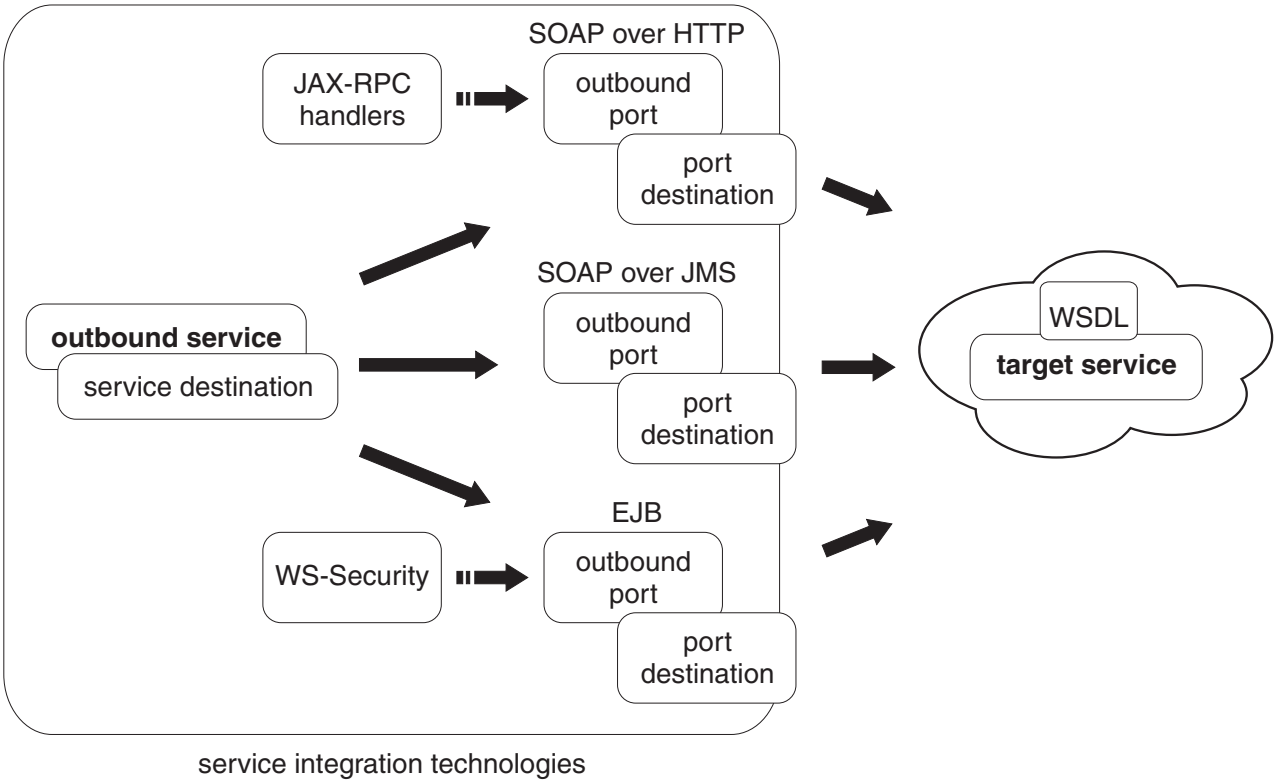

Figure 44. Outbound service

Requests and responses to an outbound service are sent across any transport binding (for example SOAP over HTTP, SOAP over JMS, EJB binding) that is available to both the target service and the service integration bus. Each available binding type is represented by an outbound port configured at a port destination. For more information, see Outbound ports and port destinations.

You can control and monitor access to the target service in the following ways:

- You can associate JAX-RPC handler lists with ports, so that the handlers can monitor activity at the port, and take appropriate action depending upon the sender and content of each message that passes through the port.

- You can set the level of security to be applied to messages (the WS-Security binding). The security level can be set independently for request and response messages.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Buses -> *bus_name* -> [Services] Outbound Services**. The outbound services collection form is displayed.
3. Click **New**. The New outbound service wizard is displayed.
4. Use the wizard to create the new outbound service configuration by completing the following steps. For more information about the properties that you set with the wizard, see Outbound services settings and Outbound ports settings.
   a. Locate the target service WSDL.
   b. Select the service from the WSDL.

      Note:
      - This option is needed in case there is more than one service in the WSDL. The field is filled in for you by default. If there is only one service in the WSDL, accept the default.
      - There needs to be at least one port defined in the service you select.

   c. Select the ports that are to be enabled for this service.

      Note: Select at least one port.

   d. Name the outbound service, the service destination and all of the port destinations.

      Note:
      - Default names are generated, but you can rename them. The default names are unique within the current service integration bus. Any replacement names that you choose must be similarly unique. If you enter a name that is not unique, an error message is displayed.
      - If you have created a port selection mediation and deployed it to the service integration bus, then it is available for selection in the list of mediations. If you do not want to use a port selection mediation with this outbound service, select `none` from the drop-down list. This list contains all mediations, including port selection mediations, that are currently deployed to this service integration bus.
      - The list of available ports is a subset of the ports that are described in the WSDL file. You chose this subset in the previous step. If you selected more than one port in the previous step, you should also set the default port to be used unless otherwise specified by a port selection mediation.

   e. Assign each port destination and (optionally) the port selection mediation to a bus member.

      Note:
      - Bus members are application servers or clusters that are added to this bus.
      - The option to assign a port selection mediation to a bus member is only displayed if you selected a mediation in the previous step.
5. Click **Finish**.

Results

If the processing completes successfully, the list of outbound services for this service integration bus is updated to include the new outbound service. Otherwise, an error message is displayed.

What to do next

Because the service is hosted externally, you might also need to enable proxy server authentication for each port to get permission to access the Internet.

If you want to secure your new outbound service, or apply any JAX-RPC handler lists to the ports, or enable proxy server authentication for any of the ports, use the administrative console to modify your outbound service configuration.

Modifying an existing outbound service configuration:

Modify the configuration details for an outbound service. For example: secure the service; apply JAX-RPC handler lists to the ports for the service; publish the service to more than one UDDI registry.

About this task

An outbound service provides access, through one or more outbound ports, to a web service that is hosted externally. An outbound service can be used by any of your internal systems that can access the service integration bus on which it is hosted.

When you first create an outbound service you select the ports that are to be enabled for the service, but you do not associate the ports with JAX-RPC handler lists or security settings. You need to modify your outbound service configuration if you want to control and monitor access to the target service in any of the following ways:

- Associate JAX-RPC handler lists with ports, so that the handlers can monitor activity at the port, and take appropriate action depending upon the sender and content of each message that passes through the port.
- Password-protect a web service operation.
- Set the level of security to be applied to messages (the WS-Security binding). The security level can be set independently for request and response messages.
- Enable proxy server authentication for any of the ports.

To list the existing outbound services, and to view and modify their configuration details, complete the following steps:

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Buses -> *bus_name* -> [Services] Outbound Services**. A list of outbound services is displayed in an outbound services collection form.
3. Click the name of an outbound service in the list. The current settings for this outbound service are displayed.
4. Optional: Click **Reload WSDL** to reload the external WSDL file for this outbound service.

   Note:

   - When you create a new outbound service, a copy of the external WSDL file for the service is loaded into a locally-maintained repository. If the external service provider changes the WSDL file, you must update the local copy.
   - When you click **Reload WSDL**, you run the command that is described in Refreshing the outbound service WSDL file by using the wsadmin tool. For the command to complete successfully, the conditions must be met that are described in that topic.

- If the bus needs to pass messages through an authenticating proxy server to retrieve WSDL documents, then you cannot use the **Reload WSDL** option and you must run the refresh WSDL command by using the wsadmin tool. For more information see the corresponding troubleshooting tip.

5. Modify the general properties. For information about each of these properties, see Outbound services settings.

   Note:

   - When you change an outbound service name, the system looks up all objects that refer to it and updates the name. Any replacement name that you choose must be unique within the current service integration bus. If you enter a name that is not unique, an error message is displayed.
   - You cannot change the **Service destination name**. However, if you click **View** alongside the name, you can view and modify the configuration information for the service destination.
   - If you change the WSDL location information (that is the fields **WSDL location type**, **WSDL location** and **WSDL UDDI Registry**), then click **Apply**, the outbound service WSDL file is reloaded. Therefore you should click **Apply** after you make any changes to the WSDL location information and before you change any of the WSDL-derived fields (for example WSDL service name, and list of available ports).
   - Although logically the WSDL service name and namespace are only required if there is more than one service in the WSDL, the fields that you use to set them are coded within the administrative console as compulsory fields. They are filled in for you by default, so if they are not logically required for your service you should leave the default values. If you remove the value from either field, the administrative console treats the empty field as an error.
   - The list of available ports from which you choose the **Default port name** is a subset of the ports that are described in the WSDL file. You chose this subset when you created or last modified this outbound service. To add or remove available ports, use the additional properties option **Outbound Ports**.
   - If you have created a port selection mediation and deployed it to the service integration bus, then it is available for selection in the list of mediations. If you do not want to use a port selection mediation with this outbound service, select `none` from the drop-down list. This list contains all mediations, including port selection mediations, that are currently deployed to this service integration bus.
   - Bus members are application servers or clusters that are added to this bus. The **Bus member** property defines the bus member to which the port selection mediation is assigned. If you change the **Port selection mediation** property value to (`none`), you should also change the **Bus member** property value to (`none`). If you want to use a port selection mediation, assign it to a bus member. If you do not do this, the administrative console displays an error message.
   - If you select the option to **Enable operation-level security** then you must also complete, for this outbound service, the steps described in Password-protecting a web service operation.
   -

6. Modify the additional properties.
   a. Modify the ports that are associated with this outbound service. For information about the properties of outbound service ports, see Outbound ports settings.

      Note:

      - Requests and responses to an outbound service can be sent across any binding (for example SOAP over HTTP or SOAP over JMS) that is available to both the service integration bus and the external web service. Each available binding is represented by a port.

- You can use a JAX-RPC handler list to monitor activity at the port, and take appropriate action (for example logging or re-routing) depending upon the sender and content of each message that passes through the port. If the external web service requires HTTP basic authentication, you can use a JAX-RPC handler list to provide an HTTP basic authentication header as described in Invoking a password-protected outbound service.
- You can use WS-Security to set the levels of security to be applied to messages. The security level can be set independently for request and response messages. For more information, see Service integration technologies and WS-Security.
- You can set the levels of security to be applied to messages. The security level can be set independently for request and response messages.
- The service integration technologies require access to the Internet to invoke an outbound service or to retrieve a target service WSDL file. If you use a proxy server in support of Internet routing, and if your proxy server requires authentication before it grants access to the Internet, then you must enable proxy server authentication.

b. Modify the custom properties, if any, that you have set for this outbound service. These custom properties are name and value pairs that you can use to set internal system configuration properties. In each pair, the name is a property key and the value is a string value.

7. Save your changes to the master configuration.

Results

If the processing completes successfully, the list of outbound services for this service integration bus is redisplayed. Otherwise, an error message is displayed.

Deleting outbound service configurations:

Use this task to delete outbound services configurations using the administrative console.

Before you begin

Decide which method to use to configure these resources. You can delete an outbound service by using the administrative console as described in this task, or by using the “deleteSIBWSOutboundService command” on page 2935.

About this task

To delete one or more outbound services by using the administrative console, complete the following steps:

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Buses -> *bus_name* -> [Services] Outbound Services**. A list of outbound services is displayed in an outbound services collection form.
3. Select the check box for every outbound service that you want to remove.
4. Click **Delete**.

Results

If the processing completes successfully, the list of outbound services for this service integration bus is updated. Otherwise, an error message is displayed.

Administering the bus-enabled web services resources

Use the administrative console to configure the main service integration bus-enabled web services resources: endpoint listeners; JAX-RPC handler lists; WS-Security bindings and configurations; references to UDDI registries.

About this task

When you configure a bus-enabled web service you associate it with one or more of the following resources:

- The endpoint listeners on which you want the service to be available.
- Any JAX-RPC handler lists that apply to the service.
- Any WS-Security bindings and configurations that apply to the service.
- Any references to UDDI registries in which entries for the service are created.

You choose each of these resources from a list of resources that you have previously configured.

Use the administrative console to administer the bus-enabled web services resources as described in the following topics:

Procedure

1. “Creating a new endpoint listener configuration.”
2. “Working with JAX-RPC handlers and clients” on page 2799.
3. “Working with mediations” on page 2810.
4. “Creating a new UDDI reference” on page 2811.

Creating a new endpoint listener configuration

An endpoint listener is the point (address) at which messages for an inbound service are received. The endpoint listeners that are supplied with WebSphere Application Server support SOAP over HTTP and SOAP over JMS bindings.

Before you begin

For every server that is to host an endpoint listener, you must install and configure a Service Data Objects (SDO) repository on the server.

If you want to change the default HTTP endpoint listener security role, do so before you configure the SOAP over HTTP endpoint listener.

Before you configure a SOAP over JMS endpoint listener, configure the associated JMS resources.

You can set up separate endpoint listeners for inbound and outbound requests. For more information, see Endpoint listeners and inbound ports: Entry points to the service integration bus.

Decide which method to use to configure these resources. You can create a new endpoint listener configuration by using the administrative console as described in this task, or by using the “createSIBWSEndpointListener command” on page 2949.

Note: If you want to create an endpoint listener configuration for your own endpoint listener application, rather than for one of the listeners that is supplied with WebSphere Application Server, you must use the wsadmin tool.

About this task

Endpoint listeners are a physical endpoint for receiving inbound service requests. An inbound service describes a bus destination as a logical web service. An inbound port associates a (logical) inbound

service with an endpoint listener to provide a (physical) endpoint where the service can be invoked. Therefore you must have defined an endpoint listener before you can create an inbound port.

A request arrives at an endpoint listener. It is passed to an inbound port, at which point security and JAX-RPC handler lists can be applied, then sent on to the service destination. Responses follow the same path in reverse.

To configure a new endpoint listener for use with an inbound service is a two-stage process:

1. Configure the listener for a specific application server or cluster (as described in this task).
2. Configure an inbound service on the same bus to use the listener (as described in the task “Making an internally-hosted service available as a web service” on page 2778).

To use the administrative console to configure an endpoint listener, complete the following steps:

Procedure

1. Start the administrative console.
2. In the navigation pane, click one of the following paths:
   - **Servers -> Server Types -> WebSphere application servers -> *server_name* -> Endpoint listeners**
   - **Servers -> Clusters -> WebSphere application server clusters -> *cluster_name* -> Endpoint listeners**

   The endpoint listeners collection form is displayed.
3. Click **New**. The New endpoint listener wizard is displayed.
4. Use the wizard to create the new endpoint listener configuration by completing the following steps. For more information about the properties that you set with the wizard, see “Endpoint listeners [Settings]” on page 2830. You might want to use the values given in “Example values for endpoint listener configuration” on page 2792.
   a. Select listener name and binding type.
      Endpoint listener name
      Type the name of your choice by which the endpoint listener is known. For example: `wsgwsoaphttp`; `wsgwsoaphttp2`; `SOAPJMSChannel1`; `SOAPJMSChannel2`.
      Binding type
      Select the type of binding that this endpoint listener supports. For a SOAP over HTTP or SOAP over HTTPS endpoint listener, select `SOAP/HTTP` or `SOAP/HTTPS`. For a SOAP over JMS endpoint listener select `SOAP/JMS`.
   b. Optional: Configure JMS settings.
      This panel is only displayed if you selected `SOAP/JMS` in the previous panel.
      You can choose to deploy your endpoint listener application to use an activation specification or a listener port. Listener ports are stabilized. For more information, read the article on stabilized features. Wherever possible, you should deploy your endpoint listener application to use an activation specification. You can use only activation specifications with the default messaging provider; you can use either activation specifications or listener ports with the WebSphere MQ messaging provider.
      Select from the drop-down lists the **listener port**, or the **activation specification** and **queue connection factory** that you have previously configured as described in “Configuring JMS resources for the synchronous SOAP over JMS endpoint listener” on page 2795.
   c. Configure required URLs. Configure web addresses for the application root and the WSDL serving root. You can either select pre-configured addresses based on the known virtual hosts, or create new values.
      URL root
      Select or type the address at which external clients access the endpoint listener endpoint.

The URL root is the context root of the endpoint listener application, and provides the root of the web address that is used to build the endpoint addresses within WSDL files to direct requesters to this endpoint listener.

An HTTP server can be used with a stand-alone application sever. Alternatively, if your endpoint listener is used by external clients to access a cluster providing high availability or workload management, your cluster usually employs a suitably configured HTTP server (or WebSphere proxy server) operating as an IP-sprayer. In either case, if external clients access the endpoint listener through an HTTP server or server cluster, using default port 80, then specify the HTTP server name and no port number. For example (for SOAP over HTTP endpoint listener 1):
`http://www.yourcompany.com/wsgwsoaphttp1`
For a stand-alone application server, your endpoint listener is typically configured for clients to connect directly to an individual application server. If your endpoint listener is used by external clients to access a cluster, you can configure the listener so that clients connect directly to an individual application server within the cluster as shown in the following example, but this might restrict the high availability or workload management capabilities of your cluster. However, if you allow external clients to connect direct to your application server (for example because it is a stand-alone server or in a development or test environment) then specify the application server host name and port number. For example (for SOAP over HTTP endpoint listener 1):
`http://your.server.name:9080/wsgwsoaphttp1`
where the port number (specified as 9080 in this example) matches the **WC_defaultHost** port value for the application server concerned.

WSDL serving HTTP URL root

Type the root of the web address for the WSDL files of the inbound services that are available at this endpoint listener. This address comprises the root of the HTTP address at which external clients access your endpoint listener application, followed by `/sibws`. This represents the URL that is used when publishing the WSDL URL to a UDDI registry. The host and port name you specify for the **WSDL serving HTTP URL root** typically match those you specify for the **URL root**.

If external clients access the endpoint listener through an HTTP server or server cluster, typically by using default port 80, then this URL root includes the HTTP server name and no port number. For example:

`http://www.yourcompany.com/sibws`

However, if you allow external clients to connect direct to your application server (for example in a development or test environment) then this URL root includes the application server host name and port number. For example:

`http://your.server.name:9080/sibws`

Note: The WSDL serving HTTP URL root is only used internally by other components of WebSphere Application Server (notably the IBM UDDI registry). For all other uses, you access the WSDL file through the endpoint listener endpoint for the inbound service. To get the location details for a given inbound service WSDL file, publish the WSDL file to a compressed file as described in “Modifying an existing inbound service configuration” on page 2780, then look up the location within the exported WSDL file.

d. Select the service integration buses to which the new endpoint listener should be connected. Only buses of which the application server or cluster is a member are available for selection.

5. Click **Finish**.

Results

If the processing completes successfully, the list of endpoint listeners is updated to include the new endpoint listener. Otherwise, an error message is displayed.

What to do next

You are now ready to select this endpoint listener for use with an inbound service as described in “Making an internally-hosted service available as a web service” on page 2778.

Example values for endpoint listener configuration:

You can configure any number of endpoint listeners with values of your own choosing, including the example values given in this topic.

When you create an endpoint listener configuration, you provide the following configuration details:

Endpoint listener name
The name by which the endpoint listener is known.

URL root
The address at which external clients access the endpoint listener endpoint. The URL root is the context root of the endpoint listener application, and provides the root of the web address that is used to build the endpoint addresses within WSDL files to direct requesters to this endpoint listener.

WSDL serving HTTP URL root
The root of the web address for the WSDL files of the inbound services that are available at this endpoint listener. This address comprises the root of the HTTP address at which external clients access your endpoint listener application, followed by `/sibws`.

Note: The WSDL serving HTTP URL root is only used internally by other components of WebSphere Application Server (notably the IBM UDDI registry). For all other uses, you access the WSDL file through the endpoint listener endpoint for the inbound service. To get the location details for a given inbound service WSDL file, publish the WSDL file to a compressed file as described in “Modifying an existing inbound service configuration” on page 2780, then look up the location within the exported WSDL file.

The rest of this topic gives example configuration details (endpoint listener name, endpoint listener URL root and WSDL serving URL root) for four endpoint listeners that you might want to create:

- “SOAP over HTTP endpoint listener 1”
- “SOAP over HTTP endpoint listener 2” on page 2793
- “Synchronous SOAP over Java Message Service (JMS) endpoint listener 1” on page 2793
- “Synchronous SOAP over JMS endpoint listener 2” on page 2794

SOAP over HTTP endpoint listener 1

Endpoint listener name
`SOAPHTTPChannel1`.

URL root
The address at which external clients access the endpoint listener endpoint. If external clients access the endpoint listener through an HTTP server or server cluster, by using default port 80, then specify the HTTP server name and no port number. For example (for this endpoint listener):

http://*www.yourcompany.com*/wsgwsoaphttp1However, if you allow external clients to connect direct to your application server (for example because it is a stand-alone server or in a development or test environment) then specify the application server host name and port number. For example (for this endpoint listener):

http://*your.server.name:9080*/wsgwsoaphttp1

WSDL serving HTTP URL root

The root of the HTTP address at which external clients access your endpoint listener application, followed by /sibws. For example:

http://*www.yourcompany.com*/sibws

or

http://*your.server.name:9080*/sibws

Note: The WSDL serving HTTP URL root is only used internally by other components of WebSphere Application Server (notably the IBM UDDI registry). For all other uses, you access the WSDL file through the endpoint listener endpoint for the inbound service.

SOAP over HTTP endpoint listener 2

Endpoint listener name

SOAPHTTPChannel2.

URL root

The address at which external clients access the endpoint listener endpoint. If external clients access the endpoint listener through an HTTP server or server cluster, by using default port 80, then specify the HTTP server name and no port number. For example (for this endpoint listener):

http://*www.yourcompany.com*/wsgwsoaphttp2However, if you allow external clients to connect direct to your application server (for example because it is a stand-alone server or in a development or test environment) then specify the application server host name and port number. For example (for this endpoint listener):

http://*your.server.name:9080*/wsgwsoaphttp2

WSDL serving HTTP URL root

The root of the HTTP address at which external clients access your endpoint listener application, followed by /sibws. For example:

http://*www.yourcompany.com*/sibws

or

http://*your.server.name:9080*/sibws

Note: The WSDL serving HTTP URL root is only used internally by other components of WebSphere Application Server (notably the IBM UDDI registry). For all other uses, you access the WSDL file through the endpoint listener endpoint for the inbound service.

Synchronous SOAP over Java Message Service (JMS) endpoint listener 1

Endpoint listener name

SOAPJMSChannel1.

URL root

You specify the properties of the synchronous SOAP over JMS endpoint listener 1 endpoint by using the following syntax:

jms:/*queue_or_topic_indicator*?*property_name=property_value* and so on, separating each property using the "&" character.

For example, if you use the default values for queue destination and queue connection factory when you install the synchronous SOAP over JMS endpoint listeners, then the first part of the end point address is:

```
jms:/queue?destination=jms/SOAPJMSQueue1&connectionFactory=jms/SOAPJMSFactory1
```

For each of the synchronous SOAP over JMS endpoint listeners, here is the full list of properties that you can specify in the endpoint address:

Table 260. Property descriptions. The first column of this table lists the property names, and the second column lists the property description.

Property name	Property description
Destination-related Properties (required)	
connectionFactory	The JNDI name of the queue or topic connection factory.
destination	The JNDI name of the destination queue or topic.
JNDI-related Properties (optional)	
initialContextFactory	The name of the initial context factory to use (this is mapped to the java.naming.factory.initial property).
jndiProviderURL	The JNDI provider web address (this is mapped to the java.naming.provider.url property).
JMS-related Properties (optional)	
deliveryMode	Indicates whether the request message is persistent. The valid values are 1 (non persistent) and 2 (persistent). The default value is 1.
timeToLive	The lifetime (in milliseconds) of the request message. A value of 0 indicates an infinite lifetime.
priority	The JMS priority associated with the request message. Valid values are 0 - 9. The default value is 4.
userid	The user ID that is used to gain access to the connection factory.
password	The password that is used to gain access to the connection factory.

WSDL serving HTTP URL root

The root of the HTTP address at which external clients access your endpoint listener application, followed by /SIBWS.

If external clients access the endpoint listener through an HTTP server or server cluster, typically by using default port 80, then this URL root includes the HTTP server name and no port number. For example:

```
http://www.yourcompany.com/sibws
```

However, if you allow external clients to connect direct to your application server (for example in a development or test environment) then this URL root includes the application server host name and port number. For example:

```
http://your.server.name:9080/sibws
```

Note: The WSDL serving HTTP URL root is only used internally by other components of WebSphere Application Server (notably the IBM UDDI registry). For all other uses, you access the WSDL file through the endpoint listener endpoint for the inbound service.

Synchronous SOAP over JMS endpoint listener 2

Endpoint listener name

SOAPJMSChannel2.

URL root

You specify the properties of the synchronous SOAP over JMS endpoint listener 2 endpoint by using the following syntax:

jms:/*queue_or_topic_indicator*?*property_name=property_value* and so on, separating each property using the "&" character.

For example, if you use the default values for queue destination and queue connection factory when you install the synchronous SOAP over JMS endpoint listeners, then the first part of the end point address is:

```
jms:/queue?destination=jms/SOAPJMSQueue2&connectionFactory=jms/SOAPJMSFactory2
```

For the full list of properties that can be specified in the endpoint address for synchronous SOAP over JMS endpoint listener 2, see the list of properties detailed above for Synchronous SOAP over JMS endpoint listener 1.

WSDL serving HTTP URL root

The root of the HTTP address at which external clients access your endpoint listener application, followed by `/SIBWS`.

If external clients access the endpoint listener through an HTTP server or server cluster, typically by using default port 80, then this URL root includes the HTTP server name and no port number. For example:

```
http://www.yourcompany.com/sibws
```

However, if you allow external clients to connect direct to your application server (for example in a development or test environment) then this URL root includes the application server host name and port number. For example:

```
http://your.server.name:9080/sibws
```

Note: The WSDL serving HTTP URL root is only used internally by other components of WebSphere Application Server (notably the IBM UDDI registry). For all other uses, you access the WSDL file through the endpoint listener endpoint for the inbound service.

Configuring JMS resources for the synchronous SOAP over JMS endpoint listener:

Configure the synchronous SOAP over Java Message Service (JMS) endpoint listeners to use a JMS provider - either the default messaging provider, or another provider such as the WebSphere MQ messaging provider - to pass SOAP messages over JMS.

Before you begin

If you have not already done so, choose a JMS messaging provider.

About this task

If you are defining a SOAP over JMS endpoint listener, you must first configure the following JMS resources for your JMS provider:

- Service integration bus queue destination (for the default messaging provider)
- JMS queue connection factory
- JMS queue destination
- JMS activation specification or listener port

Note:

Listener ports are stabilized. For more information, read the article on stabilized features. Wherever possible, you should deploy your endpoint listener application to use an activation specification. You can use only activation specifications with the default messaging provider; you can use either activation specifications or listener ports with the WebSphere MQ messaging provider.

Procedure

1. Use the administrative console to create and configure queue connection factories and queue destinations.

For more information about how to do this for your messaging provider, see the related links.

Create a queue connection factory and a queue destination for each endpoint listener that you plan to configure. For example, if you plan to configure both of the SOAP over JMS endpoint listeners that are supplied with WebSphere Application Server, create two connection factories (one for each endpoint listener) and two queues. The JMS resources and JNDI names that the supplied SOAP over JMS endpoint listeners expect by default are provided in the following table. If you use different resources and names in this step, then change the defaults when you subsequently configure the endpoint listener.

Table 261. JMS resources and expected JNDI names. The first column of this table lists the JMS resources, the second column shows the expected default JNDI names for endpoint listener 1, the third column shows the expected default JNDI name for endpoint listener 2, the fourth column shows the expected queue name for endpoint listener 1, and the fifth column shows the expected queue name for endpoint listener 2.

JMS resource	default JNDI name (endpoint listener 1)	default JNDI name (endpoint listener 2)	queue name (endpoint listener 1)	queue name (endpoint listener 2)
JMS queue connection factory	jms/SOAPJMSFactory1	jms/SOAPJMSFactory2	Not required	Not required
JMS queue destination	jms/SOAPJMSQueue1	jms/SOAPJMSQueue2	User defined (for example: SOAPJMSDestQueue1)	User defined (for example: SOAPJMSDestQueue2)

2. Configure the underlying destination for each JMS queue.

   Configure these destinations as described in the documentation for your JMS provider. If you are using the default messaging provider, use the administrative console to add the two new queue names specified in the previous table as destinations for your application server as described in Creating a queue for point-to-point messaging. The identifier for the destination should match that defined by the user as the queue name in the previous table.

3. Configure the deployment details for the application.

   If you are using activation specifications, use the administrative console to create and configure the activation specifications as described in “Configuring an activation specification for the default messaging provider” on page 524 or Creating an activation specification for the WebSphere MQ messaging provider. Create two activation specifications, one for each endpoint listener. The default JMS resources and associated names that the synchronous SOAP over JMS endpoint listeners expect are provided in the following table. However, you can use any JNDI name for the activation specification, provided that the EAR file has the same JNDI reference in the administrative console “Binding enterprise beans to listener port names or activation specification JNDI names” panel. If you use different resources and names in this step, change the defaults when you subsequently configure the endpoint listener. You must also stop then restart the application server.

Table 262. Default JMS resource and associated name expected. The first column of this table lists the JMS resources, the second column shows the expected default JNDI names for endpoint listener 1, the third column shows the expected default JNDI name for endpoint listener 2, the fourth column shows the expected queue name for endpoint listener 1, and the fifth column shows the expected queue name for endpoint listener 2.

JMS resource	default JNDI name (endpoint listener 1)	default JNDI name (endpoint listener 2)	destination JNDI name (endpoint listener 1)	destination JNDI name (endpoint listener 2)
activation specification	eis/SOAPJMSChannel1	eis/SOAPJMSChannel2	jms/SOAPJMSQueue1	jms/SOAPJMSQueue2

If you are using listener ports with any supported JMS provider, use the administrative console to create and configure the listener ports in the message listener service as described in Adding a new listener port. Create two listener ports (one for each endpoint listener). The default JMS resources and associated names that the supplied SOAP over JMS endpoint listeners expect are provided in the following table. If you use different resources and names in this step, then change the defaults when you subsequently configure the endpoint listener.

Table 263. Default JMS resources and expected names. The first column of this table lists the JMS resources, the second column shows the expected default JNDI names for endpoint listener 1, the third column shows the expected default JNDI name for endpoint listener 2, the fourth column shows the expected queue name for endpoint listener 1, and the fifth column shows the expected queue name for endpoint listener 2.

JMS resource	default name (for use with SOAP over JMS endpoint listener 1)	default name (for use with SOAP over JMS endpoint listener 2)
listener port	SOAPJMSPort1	SOAPJMSPort2
connection factory	jms/SOAPJMSFactory1	jms/SOAPJMSFactory2
destination	jms/SOAPJMSQueue1	jms/SOAPJMSQueue2

4. Save your changes to the master configuration.
5. Bind the JMS resources by stopping then restarting the application server.

What to do next

You are now ready to create a new SOAP over JMS endpoint listener configuration.

Modifying an existing endpoint listener configuration:

Modify the additional properties for an endpoint listener that has been configured for use with inbound services.

Before you begin

You cannot use this task to modify the general properties of an existing endpoint listener. The reason for this is that, when you create a new endpoint listener, an associated endpoint listener application is automatically installed that uses the same general property values. Therefore if you subsequently change the general properties, you break the link between the configuration and the underlying application. If you have to change the general properties, you must delete and recreate the endpoint listener configuration.

About this task

To list the endpoint listeners, and to view and modify their configuration details, complete the following steps.

Procedure

1. Start the administrative console.
2. In the navigation pane, click one of the following paths:
   - **Servers -> Server Types -> WebSphere application servers -> *server_name* -> Endpoint listeners**
   - **Servers -> Clusters -> WebSphere application server clusters -> *cluster_name* -> Endpoint listeners**

   A list of endpoint listeners is displayed in an endpoint listener collection form.
3. Click the name of an endpoint listener in the list. The current endpoint listener settings for this endpoint listener are displayed.
4. View the following general properties. If you are modifying an endpoint listener that is supplied with WebSphere Application Server, you might want to use the values given in “Example values for endpoint listener configuration” on page 2792.
   Name View the name by which the endpoint listener is known. If this is your own endpoint listener, rather than one that is supplied with WebSphere Application Server, then this name must match the name given in the endpoint listener application that you have installed (that is, the *display name* of the endpoint module within the endpoint application EAR file).

DescriptionDescription
View the (optional) description of the endpoint listener.

URL root
View the address at which external clients access the endpoint listener endpoint. The URL root is the context root of the endpoint listener application, and provides the root of the web address that is used to build the endpoint addresses within WSDL files to direct requesters to this endpoint listener.

If external clients access the endpoint listener through an HTTP server or server cluster, by using default port 80, then specify the HTTP server name and no port number. For example (for SOAP over HTTP endpoint listener 1):
`http://www.yourcompany.com/wsgwsoaphttp1`
However, if you allow external clients to connect direct to your application server (for example because it is a stand-alone server or in a development or test environment) then specify the application server host name and port number. For example (for SOAP over HTTP endpoint listener 1):
`http://your.server.name:9080/wsgwsoaphttp1`

WSDL serving HTTP URL root
View the root of the web address for the WSDL files of the inbound services that are available at this endpoint listener. This address comprises the root of the HTTP address at which external clients access your endpoint listener application, followed by `/sibws`.

If external clients access the endpoint listener through an HTTP server or server cluster, typically by using default port 80, then this URL root includes the HTTP server name and no port number. For example:

`http://www.yourcompany.com/sibws`

However, if you allow external clients to connect direct to your application server (for example in a development or test environment) then this URL root includes the application server host name and port number. For example:

`http://your.server.name:9080/sibws`

Note: The WSDL serving HTTP URL root is only used internally by other components of WebSphere Application Server (notably the IBM UDDI registry). For all other uses, you access the WSDL file through the endpoint listener endpoint for the inbound service. To get the location details for a given inbound service WSDL file, publish the WSDL file to a compressed file as described in “Modifying an existing inbound service configuration” on page 2780, then look up the location within the exported WSDL file.

5. Under the additional properties heading, click **Connection properties**. A list of all the service integration buses that are currently connected to this endpoint listener is displayed in a service integration bus connection properties collection form. Add, amend or delete buses in the list of currently-connected buses. To add a new bus, complete the following steps:
   a. Click **New**. The service integration bus connection properties settings form is displayed.
   b. Under the general properties heading, select an available service integration bus from the drop-down list. The bus is selected and the additional properties for the bus are displayed.

      Note: Under the connection properties for the bus there are **Custom properties**. These custom properties are name and value pairs that you can use to set internal system configuration properties. In each pair, the name is a property key and the value is a string value. You use custom properties to define the manner in which the endpoint listener connects to this bus. Included in this set is property name `com.ibm.ws.sib.webservices.replyDestination`, which defines the reply destination name used by the endpoint listener. Do not modify or remove this property, which is set automatically when the service integration bus is associated with the endpoint listener.
6. Under the additional properties heading, click **Associated application**. Details for the application that handles the requests for this endpoint listener are displayed in an enterprise application settings form.

7. Save your changes to the master configuration.

Results

If the processing completes successfully, the list of service integration buses that are connected to this endpoint listener is updated, and the list of endpoint listeners is redisplayed. Otherwise, an error message is displayed.

What to do next

You are now ready to select this endpoint listener for use with an inbound service as described in “Making an internally-hosted service available as a web service” on page 2778.

Deleting endpoint listener configurations:

Use this task to delete endpoint listener configurations using the administrative console.

Before you begin

You cannot delete an endpoint listener that has inbound ports associated with it. If you try to do this, an error is generated. Before you can delete an endpoint listener, you must either delete each associated inbound service or remove each associated port from the port list for the inbound service.

Decide which method to use to configure these resources. You can delete an endpoint listener configuration by using the administrative console as described in this task, or by using the “deleteSIBWSEndpointListener command” on page 2951.

About this task

To remove one or more endpoint listener configurations, complete the following steps:

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Servers -> Server Types -> WebSphere application servers -> *server_name* -> Endpoint listeners**. A list of endpoint listeners is displayed in an endpoint listener collection form.
3. Select the check box for every endpoint listener configuration that you want to remove.
4. Click **Delete**.

Results

If the processing completes successfully, the list of endpoint listeners is updated. Otherwise, an error message is displayed.

Working with JAX-RPC handlers and clients

The Java API for XML-based remote procedure calls (JAX-RPC) provides you with a standard way of developing interoperable and portable web services. You can use JAX-RPC handlers, handler lists and client applications with your service integration bus-enabled web services.

About this task

There are two main elements of JAX-RPC that you can use directly with the service integration bus:

- JAX-RPC handlers and handler lists.
- JAX-RPC client applications.

A JAX-RPC handler is a Java class that performs a range of handling tasks.For example: logging messages, or transforming their contents, or terminating an incoming request. To create a JAX-RPC handler, you can use a tool such as IBM Rational Application Developer. To enable handlers to undertake more complex operations, you chain them together into handler lists. You associate each handler list with one or more ports, so that the handler list can monitor activity at the port, and take appropriate action depending upon the sender and content of each message that passes through the port.

JAX-RPC client applications send and receive web service request and response messages. JAX-RPC client applications that use the IBM JAX-RPC run-time environment can do this in a number of different ways, depending on the bindings in the WSDL document that they are developed against, and the configuration data that is used at run time.

Detailed instructions on how to configure JAX-RPC handlers, handler lists and client applications for use with the service integration bus are provided in the following topics:

Procedure

- "Creating a new JAX-RPC handler configuration."
- "Creating a new JAX-RPC handler list" on page 2804.
- "Sending web service messages directly over the bus from a JAX-RPC client" on page 2807.
- "Implementing JAX-RPC handlers to access SDO messages" on page 2809.

Creating a new JAX-RPC handler configuration:

Create a JAX-RPC handler configuration for use, as part of a handler list, with service integration bus-deployed web services. Handlers monitor messages at ports, and take appropriate action depending upon the sender and content of each message.

Before you begin

This task assumes that you have already created your handler. You can do this by using IBM Rational Application Developer or a similar tool. For more information, see the IBM developerWorks article Support for J2EE Web Services in WebSphere Studio Application Developer V5.1 -- Part 3: JAX-RPC Handlers.

You must also make the handler class available to the server that hosts the port for the service that you want to monitor, as detailed in "Loading JAX-RPC handler classes" on page 2801.

About this task

A Java API for XML-based remote procedure calls (JAX-RPC) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. To make WebSphere Application Server aware of your handler, and to make the handler available for inclusion in one or more handler lists, you use the administrative console to create a new handler configuration.

Procedure

1. In the navigation pane, click **Service integration -> Web services -> JAX-RPC Handlers**. The JAX-RPC handlers collection form is displayed.
2. Click **New**. The JAX-RPC handlers settings form is displayed.
3. Type the following general properties:
   Name Type the name by which the handler is known.

   This name must be unique, and it must obey the following syntax rules:
   - It must not start with "." (a period).
   - It must not start or end with a space.
   - It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

For example `TestHandler`.

Description
Type the (optional) description of the handler.

Class name
Type the name of the class that is to be instantiated. For example `com.ibm.jaxrpc.handler.TestHandler`.

Note: You can configure multiple instances of a handler by creating each instance with a different handler name, and pointing to the same handler class.

4. Click **OK**. The general properties for this item are saved, and the additional properties options are made available.
5. Type the following additional properties:

SOAP roles
Add SOAP actor definitions to the list of SOAP roles in which this handler acts. For more information, see the SOAP specification.

JAX-RPC headers
Add JAX-RPC header definitions (Namespace URI and Local part) to the list of JAX-RPC headers against which this handler operates. JAX-RPC headers are SOAP headers that are processed by a JAX-RPC handler.

Custom properties
Add custom properties (name/value pairs, where the name is a property key and the value is a string value that can be used to set internal system configuration properties).

6. Save your changes to the master configuration.

Results

If the processing completes successfully, the list of handlers is updated to include the new handler. Otherwise, an error message is displayed.

What to do next

To use this handler, add it to a handler list as described in Creating a new JAX-RPC handler list or Modifying an existing JAX-RPC handler list.

Loading JAX-RPC handler classes:

A JAX-RPC handler interacts with messages as they pass into and out of the service integration bus, therefore you make the handler class available to the server or cluster that hosts the inbound or outbound port for the service that you want to monitor.

Before you begin

This task assumes that you have already created your handler. You can do this by using IBM Rational Application Developer or a similar tool. For more information, see the IBM developerWorks article Support for J2EE Web Services in WebSphere Studio Application Developer V5.1 -- Part 3: JAX-RPC Handlers.

About this task

Before you can configure your JAX-RPC handler for use with service integration bus-deployed web services, you must make the handler class available. If you want to monitor an inbound port, make the handler class available to the server on which the endpoint listener for that port is located. If you want to monitor an outbound port, make the handler class available to the server on which the outbound port destination is localized.

To make the handler class available to the server that hosts the port that you want to monitor, you create a shared library for the class then add the shared library to the class loader for the server.

Procedure

1. Package the class file for your handler as a JAR file, then copy the JAR file into a convenient directory.

   Make the handler class available to the application server in one of the following ways:

   - Copy the individual class file into a directory structure under *app_server_root*/classes that matches the package name of the class, where *app_server_root* is the root directory for the installation of WebSphere Application Server. For example a handler class com.ibm.jaxrpc.handler.TestHandler is copied into the *app_server_root*/classes/com/ibm/jaxrpc/handler directory.
   - Package the class files for all your handlers as a JAR file, then copy it into the *app_server_root*/lib/app directory.

2. Start the administrative console.
3. Create a shared library for the JAR file.
   a. Navigate to **Environment -> Shared libraries**.
   b. Set the scope at which you want the new library to be visible, then click **New**.
   c. Give the new library a name.
   d. Set the class path to the directory and file name for your handler JAR file.
   e. Save your changes to the master configuration.

   For more information, see Creating shared libraries.
4. Create a class loader for the server on which you want to make the JAR file available.
   a. Navigate to **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server Infrastructure] Java and Process Management -> Class loader**.
   b. Click **New**.
   c. Click **OK**.
   d. Save your changes to the master configuration.

   For more information, see Configuring class loaders of a server.
5. Add the shared library to the class loader for the server.
   a. Navigate to **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server Infrastructure] Java and Process Management -> Class loader -> *class_loader_name* > [Additional Properties] Shared library references**.
   b. Click **Add**.
   c. Click on the name of your new library, then click **OK**.
   d. Save your changes to the master configuration.

   For more information, see Associating shared libraries with servers.

What to do next

You are now ready to configure your handler for use (as part of a handler list) with service integration bus-enabled web services.

Modifying an existing JAX-RPC handler configuration:

A Java API for XML-based remote procedure calls (JAX-RPC) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. Handlers monitor messages at ports, and take appropriate action depending upon the sender and content of each message. Modify the configuration details for a JAX-RPC handler that has been configured for use, as part of a handler list, with service integration bus-deployed Web services.

Before you begin

If you modify a handler class but do not change the class name, you do not have to modify the handler configuration as described in this topic. You just have to stop then restart the servers that host the ports that this handler monitors.

About this task

To list the handlers, and to view and modify their configuration details, complete the following steps.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Web services -> JAX-RPC Handlers**. A list of handlers is displayed in a JAX-RPC handlers collection form.
3. Click the name of a handler in the list. The current JAX-RPC handlers settings for this handler are displayed.
4. Modify the following general properties:
   Name Modify the name of the handler.

   This name must be unique, and it must obey the following syntax rules:
   - It must not start with "." (a period).
   - It must not start or end with a space.
   - It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

   Note: When you change a handler name, the system looks up all objects that refer to it and updates the name.

   Description
   Modify the (optional) description of the handler.

   Class name
   Change the name of the class that is to be instantiated. If you change the class name, you must also make the new class available to the servers that host the ports that this handler monitors, as detailed in "Loading JAX-RPC handler classes" on page 2801.
5. Modify the following additional properties:
   SOAP roles
   Add, modify or remove SOAP actor definitions from the list of SOAP roles in which this handler acts. For more information, see the SOAP specification.

   JAX-RPC headers
   Add, modify or remove JAX-RPC header definitions (Namespace URI and Local part) from the list of JAX-RPC headers against which this handler operates. JAX-RPC headers are SOAP headers that are processed by a JAX-RPC handler.

   Custom properties
   Add, modify or remove custom properties (name/value pairs, where the name is a property key and the value is a string value that can be used to set internal system configuration properties).
6. Save your changes to the master configuration.

Results

If the processing completes successfully, the list of handlers is redisplayed. Otherwise, an error message is displayed.

Deleting JAX-RPC handler configurations:

A Java API for XML-based remote procedure calls (JAX-RPC) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. Delete JAX-RPC handlers that are configured for use (as part of a handler list) with service integration bus-deployed web services.

About this task

When you remove a handler that is currently used by one or more web services on a service integration bus, the system removes the handler from the handler lists for each associated web service.

To remove one or more handlers that are currently configured for a service integration bus, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Service integration -> Web services -> JAX-RPC Handlers**. A list of handlers is displayed in a JAX-RPC handlers collection form.
2. Select the check box for every handler that you want to remove.
3. Click **Delete**.

Results

If the processing completes successfully, the list of handlers is updated. Otherwise, an error message is displayed.

Creating a new JAX-RPC handler list:

A Java API for XML-based remote procedure calls (JAX-RPC) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. Create a JAX-RPC handler list for use with service integration bus-enabled web services.

Before you begin

You can only add previously-configured handlers to a handler list. To configure a handler, see Creating a new JAX-RPC handler configuration.

About this task

Handlers monitor messages at ports, and take appropriate action depending upon the sender and content of each message. To enable handlers to undertake more complex operations, you chain them together into handler lists. The approach taken in WebSphere Application Server is to apply handler lists (rather than individual handlers) at the ports, where each handler list contains one or more handlers.

To create a new JAX-RPC handler list, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Service integration -> Web services -> JAX-RPC Handler Lists**. The JAX-RPC handler lists collection form is displayed.
2. Click **New**. The JAX-RPC handler lists settings form is displayed.
3. Type the following general properties:
   Name Type the name by which the handler list is known.

   This name must be unique, and it must obey the following syntax rules:
   - It must not start with "." (a period).
   - It must not start or end with a space.

- It must not contain any of the following characters: \ / , # $ @ : ; " * ? < > | = + & % '

For example TestList.

Description

Type the (optional) description of the handler list.

JAX-RPC handlers

In the JAX-RPC handlers pane, complete the following steps:

a. Select one or more handlers from the list of available JAX-RPC handlers, then click **Add** to move the selected handlers into the list of handlers for this JAX-RPC handler list.
b. Select a handler in the list of handlers for this JAX-RPC handler list, then click **Up** or **Down** to change the position of the handler within the list.

Handlers are applied in the sequence in which they appear in the handler list.

Note: If you click **Reset**, only the **Name** and **Description** fields are reset to their state when the form was first loaded. The two lists of available and assigned handlers are not reset.

4. Click **OK**. The general properties for this item are saved.
5. Save your changes to the master configuration.

Results

If the processing completes successfully, the list of handler lists is updated to include the new handler list. Otherwise, an error message is displayed.

What to do next

To use this handler list, select it for use with a web service as described in “Modifying an existing inbound service configuration” on page 2780 or “Modifying an existing outbound service configuration” on page 2786.

Modifying an existing JAX-RPC handler list:

A Java API for XML-based remote procedure calls (JAX-RPC) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. Modify the configuration details for a JAX-RPC handler list that has been configured for use with service integration bus-deployed web services.

Before you begin

You can only add previously-configured handlers to a handler list. To configure a handler, see Creating a new JAX-RPC handler configuration.

About this task

Handlers monitor messages at ports, and take appropriate action depending upon the sender and content of each message. To enable handlers to undertake more complex operations, you chain them together into handler lists. The approach taken in WebSphere Application Server is to apply handler lists (rather than individual handlers) at the ports, where each handler list contains one or more handlers.

To list the existing handler lists, and to view and modify their configuration details, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Service integration -> Web services -> JAX-RPC Handler Lists**. A list of all the handler lists is displayed in a JAX-RPC handler lists collection form.

2. Click the name of a handler list in the list. The current JAX-RPC handler lists settings for this handler are displayed.
3. Modify the following general properties:
   Name Modify the name of the handler list.

   This name must be unique, and it must obey the following syntax rules:
   - It must not start with "." (a period).
   - It must not start or end with a space.
   - It must not contain any of the following characters: \ / , # $ @ : ; " * ? < > | = + & % '

   When you change a handler list name, the system looks up all objects that refer to it and updates the name.

   Description
   Modify the (optional) description of the handler list.

   JAX-RPC handlers
   In the JAX-RPC handlers pane, complete the following steps:
   a. Select one or more previously-configured handlers from either the list of available JAX-RPC handlers or the list of handlers for this JAX-RPC handler list, then click **Add** or **Remove** to modify the list of handlers for this JAX-RPC handler list.
   b. Select a handler in the list of handlers for this JAX-RPC handler list, then click **Up** or **Down** to change the position of the handler within the list.

   Handlers are applied in the sequence in which they appear in the handler list.

   Note: If you click **Reset**, only the **Name** and **Description** fields are reset to their state when the form was first loaded. The two lists of available and assigned handlers are not reset.
4. Save your changes to the master configuration.

Results

If the processing completes successfully, the list of handler lists is redisplayed. Otherwise, an error message is displayed.

What to do next

To use this handler list, select it for use with a web service as described in "Modifying an existing inbound service configuration" on page 2780 or "Modifying an existing outbound service configuration" on page 2786.

Deleting JAX-RPC handler lists:

A Java API for XML-based remote procedure calls (JAX-RPC) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. Delete JAX-RPC handler lists that are configured for use with service integration bus-deployed Web services.

About this task

When you remove a handler list that is currently used by one or more web services on a service integration bus, the system removes the handler list for each associated web service.

To remove one or more handler lists, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Service integration -> Web services -> JAX-RPC Handler Lists**. A list of handler lists is displayed in a JAX-RPC handler lists collection form.
2. Select the check box for every handler list that you want to remove.

3. Click **Delete**.

Results

If the processing completes successfully, the list of handler lists is updated. Otherwise, an error message is displayed.

Sending web service messages directly over the bus from a JAX-RPC client:

Use this task to send web service messages over a bus by retargeting the JAX-RPC client.

About this task

Java API for XML-based remote procedure calls (JAX-RPC) client applications send and receive web service request and response messages. JAX-RPC client applications that use the IBM JAX-RPC run-time environment can do this in a number of different ways, depending on the bindings in the WSDL document that they are developed against, and the configuration data that is used at run time.

For an introduction to basic JAX-RPC programming concepts, including the JAX-RPC client and server programming models, see Getting Started with JAX-RPC.

If you want to use a JAX-RPC client to send messages over the service integration bus, you have two choices:

- Use a SOAP binding (SOAP over HTTP or SOAP over JMS), and pass messages indirectly through an endpoint listener to an inbound service. You would do this if you had SOAP-specific JAX-RPC handlers that must run in the client application context.
- Pass messages directly into the service integration bus at a destination by “retargeting” the JAX-RPC client application as described in this topic.

  Note: There are currently limitations regarding the Java types used by services that are retargeted through a JAX-RPC client application.

Retargeting involves setting the following two values into the client application deployment descriptor, or specifying them dynamically at run time from within the client application:

- The *binding namespace* is set to indicate that the client uses the messaging bus directly.
- The *endpoint address* is set to include the particular destination and (optionally) the format of messages that the client uses.

The destination also needs to be configured so that it knows the port type of messages that the JAX-RPC client is using. There are two ways to achieve this:

- Create an outbound service. An outbound service represents an externally-provided web service. In this case, requests from the JAX-RPC client pass through the service destination and are then sent on to the service provider defined by the outbound service configuration.
- Create an inbound service. An inbound service represents a service provided somewhere within or beyond the messaging bus. You can create an inbound service on any existing destination. The creation of an inbound service associates a WSDL port type with the destination. When retargeting to a destination with an inbound service, the client application needs to specify both the destination name and inbound service name, because it is possible to configure more than one inbound service against a single destination. In this case, requests from the JAX-RPC client pass through the destination and then onwards through the service integration bus depending on routing that is done at the initial destination.

To have web service messages sent directly to a destination using a JAX-RPC client, complete the following steps:

Procedure

1. Create the JAX-RPC client application.
2. Create the outbound service or inbound service with which you want the JAX-RPC client application to exchange messages.
3. Use the administrative console to access the port information for your JAX-RPC client application, as described in “Configuring web services client bindings” on page 2605 and Web services client port information.
4. Override the default SOAP binding for your JAX-RPC client application. Change the binding namespace to `http://www.ibm.com/ns/2004/02/wsdl/mp/sib`
5. Override the endpoint that your JAX-RPC client application uses to send web service requests. The new endpoint should use the sib: URL syntax and include either the outbound service destination name, or both the inbound service name and its corresponding destination name.

What to do next

After you change the *binding namespace*, any JAX-RPC handler lists that were configured for the retargeted port are ignored. For clients that are developed against WSDL with a SOAP binding, retargeting directly to the bus causes the handlers to be ignored. However if the client is developed against the non-bound WSDL for the service, retargeting to the bus is not considered to be changing the binding namespace, and so the handler information is retained. In this case the JAX-RPC handlers are called with the SDOMessageContext subclass.

Associated reference information:

- “sib: URL syntax”

sib: URL syntax:

The `sib:` URL has the following syntax:

`sib:/[destination|path]?`*`property_1=value_1`*`&`*`property_2=value_2`*`&...`

where:

- Square brackets (“[ ]”) indicate that a parameter is optional.
- Transport type is `sib:`, followed by either `/destination` to specify destination type or `/path` to specify a forward routing path, followed by a “query string” that contains one or more properties. The permitted properties are described in the subsequent sections of this topic.

Required properties

The following properties are required. They are used to specify the destination for the request.

Note: All destination names must be fully-qualified. That is, they must include the name of the service integration bus as well as the destination name itself. Use the syntax *`bus:destination`*. If a bus or destination name contains a colon or comma, wrap the name in double quotation marks (“”). If it contains a double quotation mark, repeat the quotation mark.

destinationName
The destination name.

path The forward routing path, in the form of a sequence of destination names separated by commas.

replyDestinationName
The name of the destination to be used for the reply.

inboundService
The name of the inbound service that identifies the specific attachment that the requester

application uses. You can omit this value if the destination is a service destination with an associated outbound service configuration, because in that case the requester is attaching to the outbound service through the service destination.

timeout
The time the requester waits for a response. The default value is 60 seconds. A zero value indicates an unlimited wait.

Service integration technologies-related properties

The following properties are optional. If you do not specify a value for a property, then the default value is used. For more information regarding the permitted values for these properties, see the generated API information for the SIMessage interface.

reliability
The reliability of the request message.

timeToLive
The amount of time (in milliseconds) before the request times out. A zero value indicates that the request never times out.

Note: The **timeout** property (see the required properties) is the time delay after which the requester application blocks the application thread that is waiting for a response to a request and response operation. The **time to live** and **replyTimeToLive** optional properties indicate how long the request and reply messages should be processed by the messaging engines. This does not include the processing time at the service implementation. You would therefore usually set the timeout to be the sum of the request and response times to live, plus some amount for the service processing time.

priority
The priority of the request message.

user
The user ID required to access the request destination.

password
The password required to access the request destination.

replyReliability
The reliability of the reply message.

replyTimeToLive
The amount of time (in milliseconds) before the reply times out. A zero value indicates that the reply never times out.

replyPriority
The priority of the reply message.

Other properties

You can also include user-defined properties in the URL. These properties must be named with a `user.` prefix. For example:

```
sib:/destination?destinationName=myBus:myDestination & reliability=assured & user.customData=XYZ
```

After the request is sent, the URL itself is available within the message properties, named `inbound.url`.

Implementing JAX-RPC handlers to access SDO messages:

JAX-RPC handlers are invoked during the processing of request and response messages. For messages that are exchanged by using the SOAP protocol, each JAX-RPC handler is passed a SOAP-specific

MessageContext object. For other protocols, the IBM web services runtime environment passes a MessageContext object that provides a Service Data Objects view of the message. Service Data Objects (SDO) is an open standard for enabling applications to handle data from different data sources in a uniform way, as data graphs.

If the JAX-RPC handler only deals with message context properties, it does not have to be aware of the particular subclass of MessageContext that it is given, because the context property methods are defined by the MessageContext interface itself. If the handler needs to process information contained within the message, it must be coded to work with the required subclasses. Your JAX-RPC handlers should test whether the MessageContext is an instance of the required subclass.

A JAX-RPC handler is given an SDO-specific MessageContext object (an instance of the com.ibm.websphere.webservices.handler.sdo.SDOMessageContext class) rather than the SOAP-specific MessageContext object in the following cases:

- A JAX-RPC client or outbound invocation from the service integration bus invokes a service by using the EJB binding.
- A JAX-RPC client is developed against a non-bound WSDL and is retargeted to a destination in the service integration bus.

The SDOMessageContext class provides methods to get and set the com.ibm.websphere.sdo.SDOMessage instance that represents the message that is being processed. The SDOMessage has a method to access the SDO DataGraph object that holds the message content as SDO DataObjects.

A JAX-RPC handler can modify the SDO DataGraph contents, but it cannot change the format or schema of the message.

The following example shows code that can be used to access the SDO DataGraph from the MessageContext object in a JAX-RPC handler handleRequest method:

```
public boolean handleRequest(MessageContext messageContext) {

  // Convert the MessageContext into an SDOMessageContext
  if( messageContext instanceof SDOMessageContext) {
   SDOMessageContext smc = (SDOMessageContext)messageContext;

   // Retrieve the message
   SDOMessage message = smc.getSDOMessage();

   // Get the root object in the SDO DataGraph
   DataGraph graph = message.getDataGraph();
   DataObject content = graph.getRootObject();

   // Now do something with the message content.....
  }
  return true;
 }
```

Working with mediations

Use a mediation to change the content of a message, or the way in which a message is handled.

Before you begin

For an introduction to using mediations with the service integration bus, see Learning about mediations.

About this task

A mediation is an application that contains a mediation handler. You associate a mediation with a service integration bus destination, and the mediation acts on messages that pass through the destination. The

action taken by a mediation depends upon the specific instructions you give in the mediation handler. For example, you can use a mediation to change the contents of a message, or to choose a particular forward route for a message.

To write a mediation application that contains a mediation handler, install it into WebSphere Application Server and associate it with a bus destination, complete the following steps:

Procedure

1. Create the mediation application. For examples of how to do this, see:
   - Writing a routing mediation
   - Writing a mediation that maps between attachment encoding styles
2. Install the mediation application into WebSphere Application Server.
3. Create the associated mediation object in the bus.

   Note: The **handler list name** is the name you gave to your handler when you defined the handler class as a mediation handler.
4. Mediate the destination. Use the administrative console to access the destination that you want to mediate, then select your mediation from the list of available mediations.

Creating a new UDDI reference

Create a reference (a pointer) to a UDDI registry for use with service integration bus-enabled web services.

Before you begin

This topic assumes that you have already created a J2C authentication alias for each *Authorized Name* that you want to associate with this UDDI reference. For more information about *Authorized Names*, see UDDI registries: Web service directories that can be referenced by bus-enabled web services.

About this task

A UDDI reference is a pointer to a UDDI registry. This registry can be a private UDDI registry such as the IBM WebSphere UDDI Registry, or a public UDDI registry. The service integration technologies interact with UDDI registries in two ways:

- When you configure an inbound service, you can create entries for the web service in one or more UDDI registries.
- When you configure an outbound service, you specify the location of the target WSDL file that describes the web service. This WSDL file can be located at a URL or through a UDDI registry.

In the UDDI model, web services are owned by businesses, and businesses are owned by Authorized Names. Each UDDI reference gives access to the Web services that are owned by a single Authorized Name in a single UDDI registry. For more information about how the service integration technologies work with UDDI registries, see UDDI registries: Web service directories that can be referenced by bus-enabled web services and Publishing a web service to a UDDI registry. For more general information about UDDI and UDDI registries, see the UDDI community at uddi.org.

To create a new UDDI reference, complete the following steps:

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Web services -> UDDI References**. The UDDI references collection form is displayed.
3. Click **New**. The UDDI references settings form is displayed.
4. Type the following general properties:

Name Type the name by which the UDDI reference is known. This name must be unique, and it must follow the following syntax rules:
- It must not start with "." (a period).
- It must not start or end with a space.
- It must not contain any of the following characters: \ / , # $ @ : ; " * ? < > | = + & % '

You might need more than one UDDI reference for a given UDDI registry. For more information, see UDDI registries: Web service directories that can be referenced by bus-enabled web services.

Description
Type the (optional) description of the UDDI reference.

Inquiry URL
Type the web address that provides access to this registry for the SOAP inquiry API.

Publish URL
Type the web address that provides access to this registry for the SOAP publish API.

Authentication alias

Type the J2C authentication alias for the user ID and password of an "Authorized Name" that has update access to this registry.

The alias you enter here must match the user ID of the owner of the corresponding business in the UDDI registry. You can see the owning user ID in UDDI by looking at the business details under the "Authorized Name" field. If the alias you enter here does not match the "Authorized Name" value for the business that owns the service, then the service is not published or found.

If the business has more than one "Authorized Name", you might want to set up multiple UDDI references (each with a different authentication alias) to the same UDDI registry.

5. Click **OK**.

Results

If the processing completes successfully, the list of UDDI references is updated to include the new UDDI reference. Otherwise, an error message is displayed.

What to do next

To use this UDDI reference, select it when "Making an internally-hosted service available as a web service" on page 2778 or "Making an externally-hosted web service available internally" on page 2783.

Modifying an existing UDDI reference:

Modify the configuration details for a UDDI reference that has been configured for use with service integration bus-enabled web services.

About this task

A UDDI reference is a pointer to a UDDI registry. This registry can be a private UDDI registry such as the IBM WebSphere UDDI Registry, or a public UDDI registry. The service integration technologies interact with UDDI registries in two ways:
- When you configure an inbound service, you can create entries for the web service in one or more UDDI registries.
- When you configure an outbound service, you specify the location of the target WSDL file that describes the web service. This WSDL file can be located at a URL or through a UDDI registry.

To list the UDDI references, and to view and modify their configuration details, complete the following steps:

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Web services -> UDDI References**. A list of UDDI references is displayed in a UDDI references collection form.
3. Click the name of a UDDI reference in the list. The current UDDI reference settings for this UDDI reference are displayed.
4. Modify the following general properties:

   Name Modify the name of the UDDI reference.

   This name must be unique, and it must obey the following syntax rules:
   - It must not start with "." (a period).
   - It must not start or end with a space.
   - It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

   Note: When you change a UDDI reference name, the system looks up all objects that refer to it and updates the name.

   Description
   Modify the (optional) description of the UDDI reference.

   Inquiry URL
   Type the new web address that provides access to this registry for the SOAP inquiry API.

   Publish URL
   Type the new web address that provides access to this registry for the SOAP publish API.

   Authentication alias

   Type the new J2C authentication alias for the user ID and password of an "Authorized Name" that has update access to this registry.

   The alias you enter here must match the user ID of the owner of the corresponding business in the UDDI registry. You can see the owning user ID in UDDI by looking at the business details under the "Authorized Name" field. If the alias you enter here does not match the "Authorized Name" value for the business that owns the service, then the service is not published or found.

   If the business has more than one "Authorized Name", you might want to set up multiple UDDI references (each with a different authentication alias) to the same UDDI registry.
5. Save your changes to the master configuration.

Results

If the processing completes successfully, the list of UDDI references is redisplayed. Otherwise, an error message is displayed.

What to do next

To use this UDDI reference, select it when "Making an internally-hosted service available as a web service" on page 2778 or "Making an externally-hosted web service available internally" on page 2783.

Deleting UDDI references:

delete UDDI references that are configured for use with service integration bus-deployed web services.

About this task

When you remove a UDDI reference that is currently used by one or more web services on a service integration bus, the system removes the UDDI reference for each associated web service and makes any necessary updates in the associated UDDI registry.

To remove UDDI references, complete the following steps:

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Web services -> UDDI References**. A list of UDDI references is displayed in a UDDI references collection form.
3. Select the check box for every UDDI reference that you want to remove.
4. Click **Delete**.

Results

If the processing completes successfully, the list of UDDI references is updated. Otherwise, an error message is displayed.

Publishing a web service to a UDDI registry:

When you configure an inbound or outbound service, you enable UDDI interaction by associating the service with a UDDI reference, and (depending upon what you are trying to do) either or both of the following pieces of information: The *business key* that identifies the UDDI business category under which you want your service to appear in the UDDI registry, and the service-specific part of the *service key* that the UDDI registry assigns to your service. To help you understand what UDDI business keys and service keys are, and where you find them in a UDDI registry, here is a description of how to publish a web service to a UDDI registry.

About this task

Service integration technologies interact with UDDI registries as described in UDDI registries: Web service directories that can be referenced by bus-enabled web services. When you publish a web service to a UDDI registry, you:

- Specify the type of business that your web service supports. This usually means choosing an existing business type from a list, but you can also create a new business type. For each type of business there is an associated business key. Service integration bus-enabled web services use this key, in combination with the service key, to find the web service in the registry.
- Add a Technical model. Technical models are generic categories. Using these models, a UDDI registry user can search for a type of service, rather than needing to know the access details for a specific service. Bus-enabled web services interact with UDDI registries at the level of individual Web services, and therefore do not use Technical models.
- Add the web service. The UDDI registry assigns a service key to your service, and publishes the service. Bus-enabled web services use this key, in combination with the business key, to find the web service in the registry.

The following steps describe how you publish a web service to the IBM WebSphere UDDI Registry. If you are working with a different UDDI registry, then the specific navigation is different but the underlying principles are the same.

Procedure

1. Specify a business:
   a. To get a list of valid business keys, look up `businesses` in the UDDI registry. Here is an example of a UDDI business key:

      ```
      08A536DC-3482-4E18-BFEC-2E2A23630526
      ```

      .

b. If you do not find an appropriate existing business in the UDDI registry, then use the **Add a business** option on the **Advanced Publish** section of the Publish pane to add a new one.

2. Add a technical model:
   a. Select **Add a technical model** on the **Advanced Publish** section of the Publish pane.
   b. Enter the name as specified for the target namespace of your binding (or interface) WSDL file, then add a description (if required).
   c. Add a category of Type `unspsc` and value `wsdlSpec` (the Key name field can be left blank).
   d. Add an overview URL specifying the web address for your binding WSDL file, then add a description (if required).

      Note: The binding and the service definition for your web service might be held in separate WSDL files, therefore be careful to type the web address of the WSDL file that defines the *binding*.
   e. Click **Publish Technical Model**.
3. Add a service:
   a. Select **Show owned entities** on the **Advanced Publish** section of the Publish pane.
   b. Select **Add a Service** for your business.
   c. Enter the name as specified for the target service in your WSDL file, then add a description (if required).
   d. For the **Access point** verify that the correct web address type is selected (for example `http` for an HTTP access point), then enter the value of the `soap:address` location (or its equivalent) from your service definition WSDL file (for example `http://yourhost:80/SimpleTest/servlet/rpcrouter`).
   e. For the **Technical model** select **Add**, then find the required Technical model by entering a suitable prefix and selecting **Find technical models**, then select the check box for the required Technical model and click **Update**.
   f. Click **Publish Service**.

Results

The UDDI registry assigns a service key to your service, and publishes the service.

What to do next

After the service has been published you can get the service key from the target UDDI registry.

Here is an example of a full UDDI service key:

```
uddi:blade108node01cell:blade108node01:server1:default:6e3d106e-5394-44e3-be17-aca728ac1791
```

The service-specific part of this key is the final part:

```
6e3d106e-5394-44e3-be17-aca728ac1791
```

Creating a new WS-Security binding

Create a new WS-Security binding for use with service integration bus-enabled web services. You use WS-Security bindings to secure the SOAP messages that pass between service requesters (clients) and inbound services, and between outbound services and target web services.

Before you begin

Use this option to create WS-Security bindings that comply with either the Web Services Security (WS-Security) 1.0 specification, or the previous WS-Security specification, WS-Security Draft 13 (also known as the Web Services Security Core Specification).

Note: Use of WS-Security Draft 13 was deprecated in WebSphere Application Server Version 6.0. Use of WS-Security Draft 13 is deprecated, and you should only use it to allow continued use of an existing web services client application that has been written to the WS-Security Draft 13 specification.

This topic assumes that you have got, from the owning parties, the WS-Security bindings for the client (for an inbound service) and the target web service (for an outbound service).

You can only use WS-Security with web service applications that comply with the *Web Services for Java Platform, Enterprise Edition (Java EE)* or *Java Specification Requirements (JSR) 109* specification. For more information, see Web Services Security and Java Platform, Enterprise Edition security relationship. For information about how to make your web service applications JSR-109 compliant, see Implementing JAX-RPC web services clients or Implementing static JAX-WS web services clients .

About this task

WS-Security bindings provide the information that the run-time environment needs to implement the WS-Security configuration (for example “To sign the body, use this key”), You receive this security binding information direct from the service requester or target service provider, in the form of an `ibm-webservicesclient-bnd.xmi` file for the client, and an `ibm-webservices-bnd.xmi` file for the target web service. You extract the information from these `.xmi` files, then manually enter it into the WS-Security bindings forms.

Bindings are administered independently from any web service that uses them, so you can create a binding then apply it to many web services.

WebSphere Application Server also includes a set of default WS-Security binding objects, as described in Default bindings and runtime properties for Web Services Security. However, if you are using either of the single server products WebSphere Application Server or WebSphere Application Server Express, then these default bindings are configured within the application server, and are not available for use with bus-enabled web services.

Unlike most other configuration objects, when you create a WS-Security binding you can only define its basic aspects. To define the binding details you save the new binding, then reopen it for modification as described in Modifying an existing WS-Security binding.

To create a new WS-Security binding, complete the following steps:

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Web services -> WS-Security bindings**. The WS-Security bindings collection form is displayed.
3. Click **New**. The New WS-Security binding wizard is displayed.
4. Use the wizard to assign the following general properties:
   a. Select the version of the WS-Security specification. Set this option to either Draft 13 (for a binding that complies with the WS-Security Draft 13 specification) or 1.0 (for a binding that complies with the Web Services Security (WS-Security) 1.0 specification.

      Note: Use of WS-Security Draft 13 was deprecated in WebSphere Application Server Version 6.0. Use of WS-Security Draft 13 is deprecated, and you should only use it to allow continued use of an existing web services client application that has been written to the WS-Security Draft 13 specification.

   b. Specify the binding type.

      Set this option to one of the following binding types:

For WS-Security Version 1.0:

- *request consumer*, for use when consuming requests from a client to an inbound service.
- *request generator*, for use when generating requests from an outbound service to a target web service.
- *response consumer*, for use when consuming responses from a target web service to an outbound service.
- *response generator*, for use when generating responses from an inbound service to a client.

For WS-Security Draft 13:

- *request receiver*, for use when receiving requests from a client to an inbound service.
- *request sender*, for use when sending requests from an outbound service to a target web service.
- *response receiver*, for use when receiving responses from a target web service to an outbound service.
- *response sender*, for use when sending responses from an inbound service to a client.

c. Specify the WS-Security binding.

Give a name to this binding. This name must be unique and it must follow the following syntax rules:

- It must not start with "." (a period).
- It must not start or end with a space.
- It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

(WS-Security 1.0 bindings only. Optional.) Select the **Use defaults** check box to create a convenient default binding for use in a development and test environment. If you select this option, the binding uses the WebSphere Application Server default set of binding information rather than any custom information that you might subsequently add. Note however that this default binding is by definition insecure, and is not for production use. You can also select or clear this check box when you modify an existing WS-Security binding.

Note: If you are creating a WS-Security 1.0 request generator binding, the web address for the WS-Security 1.0 namespace is displayed in a drop-down list. This is the namespace used by WS-Security 1.0 to send a request, and you should not have to change this value. The other values included in the drop-down list refer to namespaces used by earlier versions of the WS-Security draft specification, and are included for backwards compatibility.

5. Click **Finish**. The general properties for this item are saved.

Results

If the processing completes successfully, the list of WS-Security bindings is updated to include the new binding. Otherwise, an error message is displayed.

What to do next

You are now ready to define the binding details as described in "Modifying an existing WS-Security binding."

Modifying an existing WS-Security binding

You can add or modify the configuration details for a WS-Security binding that is configured for use with service integration bus-enabled web services. You use WS-Security bindings to secure the SOAP messages that pass between service requesters (clients) and inbound services, and between outbound services and target web services.

About this task

WS-Security bindings provide the information that the run-time environment needs to implement the WS-Security configuration (for example “To sign the body, use this key”). You receive this security binding information direct from the service requester or target service provider, in the form of an `ibm-webservicesclient-bnd.xmi` file for the client, and an `ibm-webservices-bnd.xmi` file for the target web service. You extract the information from these `.xmi` files, then manually enter it into the WS-Security bindings forms.

Bindings are administered independently from any web service that uses them, so you can create a binding then apply it to many web services.

To list the WS-Security bindings, and to view and modify their configuration details, complete the following steps:

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Web services -> WS-Security bindings**. A list of WS-Security bindings is displayed in a WS-Security bindings collection form.

   Each available binding is flagged as one of the following binding types:

   For WS-Security Version 1.0:

   - *request consumer*, for use when consuming requests from a client to an inbound service.
   - *request generator*, for use when generating requests from an outbound service to a target web service.
   - *response consumer*, for use when consuming responses from a target web service to an outbound service.
   - *response generator*, for use when generating responses from an inbound service to a client.

   For WS-Security Draft 13:

   - *request receiver*, for use when receiving requests from a client to an inbound service.
   - *request sender*, for use when sending requests from an outbound service to a target web service.
   - *response receiver*, for use when receiving responses from a target web service to an outbound service.
   - *response sender*, for use when sending responses from an inbound service to a client.

   Each available binding is also flagged as complying with either the Web Services Security (WS-Security) 1.0 specification or the WS-Security Draft 13 specification.

   Note: Use of WS-Security Draft 13 was deprecated in WebSphere Application Server Version 6.0. Use of WS-Security Draft 13 is deprecated, and you should only use it to allow continued use of an existing web services client application that has been written to the WS-Security Draft 13 specification.
3. Click the name of a WS-Security binding in the list. The current settings for this WS-Security binding are displayed.
4. Modify the configuration details for this WS-Security binding. For detailed reference information about each value that you can set, click on the associated link in the following tables:

Table 264. Value references for WS-Security 1.0 bindings. The left hand column of this table lists the value references for theWS-Security 1.0 request consumer, and the right hand column lists the value references for the WS-Security 1.0 request generator.

WS-Security 1.0 request consumer	WS-Security 1.0 request generator
• "Signing information collection" on page 3298 • "Encryption information collection" on page 3357 • "Token consumer collection" on page 3397 • "Key information collection" on page 3317 • "Key locator collection" on page 3407 • "Collection certificate store collection" on page 3425 • "Trust anchor collection" on page 3417 • "Web Services Security property collection" on page 3411	• "Signing information collection" on page 3298 • "Encryption information collection" on page 3357 • "Token generator collection" on page 3386 • "Key information collection" on page 3317 • "Key locator collection" on page 3407 • "Collection certificate store collection" on page 3425 • Properties

Table 265. Value references for WS-Security 1.0 bindings. The left hand column of this table lists the value references for the WS-Security 1.0 response generator, and the right hand column lists the value references for the WS-Security 1.0 response consumer.

WS-Security 1.0 response generator	WS-Security 1.0 response consumer
• "Signing information collection" on page 3298 • "Encryption information collection" on page 3357 • "Token generator collection" on page 3386 • "Key information collection" on page 3317 • "Key locator collection" on page 3407 • "Collection certificate store collection" on page 3425 • "Web Services Security property collection" on page 3411	• "Signing information collection" on page 3298 • "Encryption information collection" on page 3357 • "Token consumer collection" on page 3397 • "Key information collection" on page 3317 • "Key locator collection" on page 3407 • "Collection certificate store collection" on page 3425 • "Trust anchor collection" on page 3417 • "Web Services Security property collection" on page 3411

Table 266. Value references for Draft 13 WS-Security bindings. The left hand column of this table lists the value references for the WS-Security Draft 13 request receiver, and the right hand column lists the value references for the WS-Security Draft 13 request receiver.

WS-Security Draft 13 request receiver	WS-Security Draft 13 request sender
• "Signing information collection" on page 3298 • "Encryption information collection" on page 3357 • "Trust anchor collection" on page 3417 • "Collection certificate store collection" on page 3425 • "Key locator collection" on page 3407 • "Trusted ID evaluator collection" on page 3436 • "Login mappings collection" on page 3441	• "Signing information collection" on page 3298 • "Encryption information collection" on page 3357 • "Key locator collection" on page 3407 • "Login bindings configuration settings" on page 3458

Table 267. Value references for Draft 13 WS-Security bindings. The left hand column of the table lists the value references for the WS-Security Draft 13 response sender, and the right hand column lists the value references for the WS-Security Draft 13 response receiver.

WS-Security Draft 13 response sender	WS-Security Draft 13 response receiver
• "Signing information collection" on page 3298 • "Encryption information collection" on page 3357 • "Key locator collection" on page 3407	• "Signing information collection" on page 3298 • "Encryption information collection" on page 3357 • "Trust anchor collection" on page 3417 • "Collection certificate store collection" on page 3425 • "Key locator collection" on page 3407

5. Save your changes to the master configuration.

Results

If the processing completes successfully, the list of WS-Security bindings is redisplayed. Otherwise, an error message is displayed.

Deleting WS-Security bindings

Delete WS-Security bindings that are configured for use with service integration bus-deployed web services.

About this task

When you remove a WS-Security binding that is currently used by one or more web services on a service integration bus, the system removes the WS-Security binding for each associated web service. To remove WS-Security bindings, complete the following steps:

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Web services -> WS-Security bindings**. A list of WS-Security bindings is displayed in a WS-Security bindings collection form.
3. Select the check box for every WS-Security binding that you want to remove.
4. Click **Delete**.

Results

If the processing completes successfully, the list of WS-Security bindings is updated. Otherwise, an error message is displayed.

Creating a new WS-Security configuration

Create a new WS-Security configuration for use with service integration bus-deployed web services. You use WS-Security configurations to secure the SOAP messages that pass between service requesters (clients) and inbound services, and between outbound services and target web services.

Before you begin

Use this option to work with WS-Security configurations that comply with either the Web Services Security (WS-Security) 1.0 specification, or the previous WS-Security specification, WS-Security Draft 13 (also known as the Web Services Security Core Specification).

Note: Use of WS-Security Draft 13 was deprecated in WebSphere Application Server Version 6.0. Use of WS-Security Draft 13 is deprecated, and you should only use it to allow continued use of an existing web services client application that has been written to the WS-Security Draft 13 specification.

This topic assumes that you have got, from the owning parties, the WS-Security configurations for the client (for an inbound service) and the target web service (for an outbound service).

You can only use WS-Security with web service applications that comply with the *Web Services for Java Platform, Enterprise Edition (Java EE)* or *Java Specification Requirements (JSR) 109* specification. For more information, see Web Services Security and Java Platform, Enterprise Edition security relationship. For information about how to make your web service applications JSR-109 compliant, see Implementing JAX-RPC web services clients or Implementing static JAX-WS web services clients .

About this task

WS-Security configurations specify the level of security that you require (for example “The body must be signed”). This level of security is then implemented through the run-time information contained in a WS-Security binding. You receive the security configuration information direct from the service requester or target service provider, in the form of an `ibm-webservicesclient-ext.xmi` file for the client, and an `ibm-webservices-ext.xmi` file for the target web service, which contain the information about the levels of

security (integrity, confidentiality and identification) that are required. You extract the information from these `.xmi` files, then manually enter it into the WS-Security configuration forms.

Configurations are administered independently from any web service that uses them, so you can create a configuration then apply it to many web services. However, the security requirements for an inbound service (which acts as a target web service) are significantly different to those required for an outbound service (which acts as a client). Consequently, configurations are further divided by service type (inbound or outbound).

Unlike most other configuration objects, when you create a WS-Security configuration you can only define its basic aspects. To define the details you save the new WS-Security configuration, then reopen it for modification as described in “Modifying an existing WS-Security configuration” on page 2822.

To create a new WS-Security configuration, complete the following steps:

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Web services -> WS-Security configurations**. The WS-Security service configurations collection form is displayed.
3. Click **New**. The New WS-Security Service Configuration wizard is displayed.
4. Use the wizard to assign the following general properties:
   a. Select the version of the WS-Security specification. Set this option to either Draft 13 (for a configuration that complies with the WS-Security Draft 13 specification) or 1.0 (for a configuration that complies with the Web Services Security (WS-Security) 1.0 specification.

      Note: Use of WS-Security Draft 13 was deprecated in WebSphere Application Server Version 6.0. Use of WS-Security Draft 13 is deprecated, and you should only use it to allow continued use of an existing web services client application that has been written to the WS-Security Draft 13 specification.

   b. Specify the service type. If you are creating a configuration to secure the SOAP messages that pass between a service requester (client) and an inbound service (which acts as a target web service), select Inbound Service. If you are creating a configuration to secure the SOAP messages that pass between an outbound service (which acts as a client) and a target Web service, select Outbound Service.
   c. Specify the WS-Security configuration type.

      Give a name to this configuration. This name must be unique across both WS-Security Version 1.0 and Draft 13 configurations, and it must follow the following syntax rules:

      - It must not start with “.” (a period).
      - It must not start or end with a space.
      - It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

      (Optionally) Specify an Actor URI for this configuration. WS-Security headers within the consumed request message are only processed if they have the specified Actor URI.
5. Click **Finish**. The general properties for this item are saved.

Results

If the processing completes successfully, the list of WS-Security configurations is updated to include the new configuration. Otherwise, an error message is displayed.

What to do next

You are now ready to define the configuration details as described in “Modifying an existing WS-Security configuration” on page 2822.

Modifying an existing WS-Security configuration

You can add or modify the configuration details for a WS-Security configuration that is configured for use with service integration bus-enabled web services. You use WS-Security configurations to secure the SOAP messages that pass between service requesters (clients) and inbound services, and between outbound services and target web services.

About this task

WS-Security configurations specify the level of security that you require (for example “The body must be signed”). This level of security is then implemented through the run-time information contained in a WS-Security binding. You receive the security configuration information direct from the service requester or target service provider, in the form of an `ibm-webservicesclient-ext.xmi` file for the client, and an `ibm-webservices-ext.xmi` file for the target web service, which contain the information about the levels of security (integrity, confidentiality and identification) that are required. You extract the information from these `.xmi` files, then manually enter it into the WS-Security configuration forms.

Configurations are administered independently from any web service that uses them, so you can create a configuration then apply it to many web services. However, the security requirements for an inbound service (which acts as a target web service) are significantly different to those required for an outbound service (which acts as a client). Consequently, configurations are further divided by service type (inbound or outbound).

To list the WS-Security configurations, and to view and modify their configuration details, complete the following steps:

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Web services -> WS-Security configurations**. A list of WS-Security configurations is displayed in a WS-Security service configurations collection form.

   Each available configuration is flagged as either `Inbound` or `Outbound`. You use an inbound configuration to secure the SOAP messages that pass between a service requester (client) and an inbound service (which acts as a target web service). You use an outbound configuration to secure the SOAP messages that pass between an outbound service (which acts as a client) and a target web service.

   Each available configuration is also flagged as complying with either the Web Services Security (WS-Security) 1.0 specification or the WS-Security Draft 13 specification.

   Note: Use of WS-Security Draft 13 was deprecated in WebSphere Application Server Version 6.0. Use of WS-Security Draft 13 is deprecated, and you should only use it to allow continued use of an existing web services client application that has been written to the WS-Security Draft 13 specification.
3. Click the name of a WS-Security configuration in the list. The current settings for this WS-Security configuration are displayed.
4. Modify the configuration details for this WS-Security configuration. For detailed reference information about each value that you can set, click on the associated link in the following table:

Table 268. Value references for WS-Security configurations. The left hand column of this table lists the value references for the WS-Security 1.0 inbound configuration, and the right hand column lists the value references for the WS-Security 1.0 outbound configuration.

WS-Security 1.0 inbound configuration	WS-Security 1.0 outbound configuration
Request consumer • Required integrity – Message parts – Nonce – Time stamp • Required confidentiality – Message parts – Nonce – Time stamp • Required security token • Caller – Trust method - Properties – Properties • Add time stamp – Properties • Properties **Response generator** • Actor • Integrity – Message parts – Nonce – Time stamp • Confidentiality – Message parts – Nonce – Time stamp • Security Token • Add time stamp – Properties • Properties	**Request generator** • Actor • Integrity – Message parts – Nonce – Time stamp • Confidentiality – Message parts – Nonce – Time stamp • Security Token • Add time stamp – Properties • Properties **Response consumer** • Required integrity – Message parts – Nonce – Time stamp • Required confidentiality – Message parts – Nonce – Time stamp • Required security token • Caller – Trust method - Properties – Properties • Add time stamp – Properties • Properties

Table 269. Value references for WS-Security Draft 13 configurations. The left hand column of this table lists the value references for the WS-Security Draft 13 inbound configuration, and the right hand column lists the value references for the WS-Security Draft 13 outbound configuration.

WS-Security Draft 13 inbound configuration	WS-Security Draft 13 outbound configuration
Request receiver • Required integrity • Required confidentiality • Login configuration – Custom authentication methods • ID assertion • Add received time stamp • Properties **Response sender** • Actor • Integrity • Confidentiality • Add created time stamp • Properties	**Request sender** • Actor • Integrity • Confidentiality • Login configuration • ID assertion • Add created time stamp • Properties **Response receiver** • Required integrity • Required confidentiality • Add received time stamp • Properties

5. Save your changes to the master configuration.

Results

If the processing completes successfully, the list of WS-Security configurations is redisplayed. Otherwise, an error message is displayed.

Deleting WS-Security configurations

Delete WS-Security configurations that are configured for use with service integration bus-enabled web services.

About this task

When you remove a WS-Security configuration that is currently used by one or more web services on a service integration bus, the system removes the WS-Security configuration for each associated web service. To remove WS-Security configurations, complete the following steps:

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Web services -> WS-Security configurations**. A list of WS-Security configurations is displayed in a WS-Security service configurations collection form.
3. Select the check box for every WS-Security configuration that you want to remove.
4. Click **Delete**.

Results

If the processing completes successfully, the list of WS-Security configurations is updated. Otherwise, an error message is displayed.

Passing SOAP messages with attachments through the service integration bus

The service integration technologies support web services that use a SOAP binding to pass attachments in a MIME message.

Before you begin

See the restrictions detailed in Limitations in the support for SOAP with attachments.

About this task

The service integration bus supports SOAP messages that contain either old-style attachments (as described in the SOAP Messages with Attachments W3C Note) or attachments that use the Web Services-Interoperability (WS-I) Attachments Profile Version 1.0 (subject to the Limitations in the support for SOAP with attachments).

Attachments are carried through the service integration bus and passed to the inbound or outbound service. The content MIME type of each attachment is preserved. When the external target service for an outbound service is deployed to a Java API for XML-based Remote Procedure Call (JAX-RPC) compliant server, you can access the attachments on the target service by using the `javax.activation.DataHandler` handler.

If the bus receives a message that contains attachments, and the bus subsequently rewrites the message, then the generated message uses the same attachment style as the received message. To transform attachments from one style to another, you can use a mediation to modify the message.

For more information, see the following topics:

Procedure

- “SOAP Messages with Attachments: WSDL examples”
- “Supporting bound attachments: WSDL examples” on page 2826
- “Locating an attachment by using swaref”
- Writing a mediation that maps between attachment encoding styles

Locating an attachment by using swaref

Use this task to locate message attachments by retrieving the message URI and removing `cid:` from the beginning of the retrieved value.

About this task

When a Web Services-Interoperability (WS-I) Attachments Profile Version 1.0 message uses a SOAP with attachments reference (swaref) to refer to an attachment, the swaref might refer to either bound or non-bound attachments, and the swaref might refer to a single attachment several times. To enable you to locate the correct attachment, service integration technologies stores the value of the URI that is encoded in the message within the SDO data graph for the message body.

When storing the value of an element (or attribute) of type swaref in the data graph, service integration technologies stores the complete URI from the message instance. Therefore when you retrieve the URI you remove `cid:` from the beginning of the retrieved value to find the Content ID of the referenced attachment.

Example

The following example shows how to use the value of a swaref element to locate the correct attachment. This example uses the RPC/Literal WSDL and SOAP message from section 4.4 of Web Services-Interoperability (WS-I) Attachments Profile Version 1.0:

```
DataObject infoNode = graph.getRootObject().getDataObject("info");
String contentId = infoNode.getString("body/ClaimDetail/ClaimForm");

// Cut off the "cid:" part of the string
contentId = contentId.substring(4);

// Locate the value of the attachment
DataObject attachmentEntry =
    infoNode.getDataObject("attachments[contentId=" + contentId + "]");
byte[] data = attachmentEntry.getBytes("data");
```

SOAP Messages with Attachments: WSDL examples

Use this task to see an example and explanation of a WSDL file with an attachment.

Example

The following example WSDL illustrates a simple operation that has one attachment called `attch`:

```
<binding name="MyBinding" type="tns:abc" >
  <soap:binding style="rpc" transport="http://schemas.xmlsoap.org/soap/http"/>
  <operation name="MyOperation">
    <soap:operation soapAction=""/>
    <input>
      <mime:multipartRelated>
        <mime:part>
          <soap:body parts="part1 part2 ..." use="encoded" namespace="http://mynamespace"
            encodingStyle="http://schemas.xmlsoap.org/soap/encoding"/>
        </mime:part>
        <mime:part>
```

```
          <mime:content part="attch" type="text/html"/>
        </mime:part>
      </mime:multipartRelated>
    </input>
  </operation>
</binding>
```

In this type of WSDL extension:

- There must be a `part` attribute (in this example `attch`) on the input message for the operation (in this example `MyOperation`). There can be other input parts to `MyOperation` that are not attachments.
- In the binding input there must either be a `<soap:body>` tag or a `<mime:multipartRelated>` tag, but not both.
- For MIME messages, the `<soap:body>` tag is inside a `<mime:part>` tag. There must only be one `<mime:part>` tag that contains a `<soap:body>` tag in the binding input and that must not contain a `<mime:content>` tag as well, because a content type of `text/xml` is assumed for the `<soap:body>` tag.
- There can be multiple attachments in a MIME message, each described by a `<mime:part>` tag.
- Each `<mime:part>` tag that does not contain a `<soap:body>` tag contains a `<mime:content>` tag that describes the attachment itself. The `type` attribute inside the `<mime:content>` tag is not checked or used by the service integration bus. It is there to suggest, to the application that uses the service integration bus, what the attachment contains . Multiple `<mime:content>` tags inside a single `<mime:part>` tag means that the back end service expects a single attachment with a type specified by one of the `<mime:content>` tags inside that `<mime:part>` tag.
- The `parts="..."` attribute inside the `<soap:body>` tag is assumed to contain the names of all the SOAP parts in the message, but not the attachment parts. If there are only attachment parts, specify `parts=""` (empty string). If you omit the `parts` attribute altogether, then the service integration bus assumes ALL parts including the attachments - which causes the attachments to appear twice.

In your WSDL you might have defined a schema for the attachment (for instance as a `binary[]`). The service integration technologies silently ignore this mapping and treat the attachment as a Data Handler.

You do not have to mention unreferenced attachments in the WSDL bindings.

Supporting bound attachments: WSDL examples

Use this task to see examples of WSDL fragments with Web Services-Interoperability (WS-I) Attachments Profile Version 1.0 encoding and SOAP Messages with Attachments encoding.

About this task

Web Services-Interoperability (WS-I) Attachments Profile Version 1.0 defines a convention for constructing the Content ID for a bound attachment. This convention encodes the message part name. Consequently, service integration technologies can recognize a bound attachment whether or not the SOAP body contains elements representing that message part. The convention for constructing a Content ID is as follows:

name=uuid@domain

where *name* is the name of the message part that is being encoded, *uuid* is a globally unique identifier, and *domain* is a domain identifier (for example `my.example.com`).

Note: This approach differs from the SOAP Messages with Attachments encoding scheme, which does not define a conventions for the Content ID but does use elements within the SOAP body to indicate that the message part is encoded as an attachment.

In order to distinguish between the cases, service integration technologies assumes that if a message attachment follows the Version 1.0 convention for constructing the Content ID, then it is a Version 1.0 message.

Example

The following WSDL fragment is for a bound attachment, with message instances that follow both styles:

```
<wsdl:binding name="BoundSoapBinding" type="intf:BoundPortType">
    <soap:binding style="rpc"
                  transport="http://schemas.xmlsoap.org/soap/http"/>
    <wsdl:operation name="bound">
      <soap:operation soapAction=""/>
      <wsdl:input>
        <mime:multipartRelated>
          <mime:part>
            <soap:body parts="stringIn" namespace="http://bound"
                       use="literal"/>
          </mime:part>
          <mime:part>
            <mime:content part="attachIn" type="text/xml"/>
          </mime:part>
        </mime:multipartRelated>
      </wsdl:input>
```

The following WSDL fragment is for a SOAP instance that uses Version 1.0 encoding. In this fragment, the message body contains no mention of the `attachIn` part, and the Content ID of the attachment identifies the part that is being encoded.

```
--myBoundary
Content-Type: text/xml
Content-Transfer-Encoding: 7bit
Content-Id: <myStartID>

<SOAP-ENV:Envelope
 xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/">
  <SOAP-ENV:Body>
    <ns0:bound xmlns:ns0="http://bound">
      <stringIn>some string data</stringIn>
    </ns0:bound>
  </SOAP-ENV:Body>
</SOAP-ENV:Envelope>

--myBoundary
Content-Type: text/xml
Content-Transfer-Encoding: 7bit
Content-Id: <attachIn=someUUID@some.domain.name>

<someOtherXMLElement/>
--myBoundary--
```

The following WSDL fragment is for a SOAP instance that uses SOAP Messages with Attachments encoding. In this fragment, the message body does contain a reference to the bound attachment, and the Content ID of the attachment is not constrained.

```
--myBoundary
Content-Type: text/xml
Content-Transfer-Encoding: 7bit
Content-Id: <myStartID>

<SOAP-ENV:Envelope
 xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/">
  <SOAP-ENV:Body>
    <ns0:bound xmlns:ns0="http://bound">
      <stringIn>some string data</stringIn>
      <attachIn href="cid:notTheStart"/>
    </ns0:bound>
  </SOAP-ENV:Body>
</SOAP-ENV:Envelope>

--myBoundary
```

```
Content-Type: text/xml
Content-Transfer-Encoding: 7bit
Content-Id: <notTheStart>

<someOtherXMLElement/>
--myBoundary--
```

In the previous two cases there is sufficient information in the message to identify the bound attachment, and in both cases service integration technologies places a bound attachment entry in the attachments list, and places the data from the attachment into the body section of the data graph.

Connection Properties [Collection]

Connection properties define the manner in which an endpoint listener connects to the service integration bus.

To view this page in the console, click the following path:

Servers -> Server Types -> WebSphere application servers -> *server_name* -> Endpoint listeners -> *listener_name* -> Connection Properties.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

This panel contains a list of all the service integration buses that are currently connected to this endpoint listener.

Bus name
The name of this property.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Connection Properties [Settings]

Connection properties define the manner in which an endpoint listener connects to the service integration bus.

To view this page in the console, click the following path:

Servers -> Server Types -> WebSphere application servers -> *server_name* -> Endpoint listeners -> *listener_name* -> Connection Properties -> *connection-property_name*.

Use this panel to connect this endpoint listener to an available service integration bus.

The service properties define the manner in which the endpoint listener connects to the bus. However you do not currently have to use this option to set connection properties, for the following reasons:

- The only property name that is currently supported is `com.ibm.websphere.sib.webservices.replyDestination`, which defines the reply destination name used by the endpoint listener.
- This property is set automatically when the endpoint listener is configured for the service integration bus.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Bus name:

The name of this property.

Required	Yes
Data type	drop-down list

Endpoint listeners [Collection]

An endpoint listener receives requests from service requester applications within a specific application server or cluster.

To view this page in the console, click the following path:

Servers -> Server Types -> WebSphere application servers -> *server_name* -> Endpoint listeners.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

An endpoint listener is the point (address) at which incoming messages for a web service are received by a service integration bus. The endpoint listener acts as the ultimate receiver of a SOAP message. The resulting messages that pass across the service integration bus are not then SOAP messages, rather just the data and context that resulted from receiving the SOAP message. Each endpoint listener supports a particular binding. The endpoint listeners that are supplied with WebSphere Application Server support SOAP over HTTP and SOAP over JMS bindings.

Before you can use an endpoint listener, you must complete the following steps.

1. Install the endpoint listener application in WebSphere Application Server.
2. Configure the endpoint listener for an application server and (as part of the configuration) connect the endpoint listener to one or more available service integration buses.
3. On a service integration bus to which you have connected the endpoint listener:
   a. Configure an inbound service and (as part of the configuration) connect the service to a new inbound port.
   b. Associate the new inbound port with the newly-deployed endpoint listener.

A deployed endpoint listener is not used until you deploy a web service that uses the endpoint listener.

Name The name of this endpoint listener.

URL root
The root of the URL that should be used to build the endpoint addresses within WSDL documents to direct requesters to this endpoint listener.

Description
An optional description of the endpoint listener.

Buttons

New	Create a new endpoint listener.
Delete	Delete the selected items.

Endpoint listeners [Settings]

An endpoint listener receives requests from service requester applications within a specific application server or cluster.

To view this page in the console, click the following path:

Servers -> Server Types -> WebSphere application servers -> *server_name* -> Endpoint listeners -> *listener_name*.

An endpoint listener is the point (address) at which incoming SOAP messages for a web service are received by a service integration bus. Each endpoint listener supports a particular binding. Use this panel to configure an endpoint listener for an application server and, as part of the configuration process, connect the endpoint listener to one or more available service integration buses.

The endpoint listeners that you can create with WebSphere Application Server support SOAP over HTTP and SOAP over JMS bindings. Example values for these endpoint listeners are given in “Example values for endpoint listener configuration” on page 2792.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of this endpoint listener.

If you are installing your own endpoint listener application, rather than one that is supplied with WebSphere Application Server, then this name must match the name given in the endpoint listener application that you have installed (that is, the *display name* of the endpoint module within the endpoint application EAR file).

Required No
Data type String

Description:

An optional description of the endpoint listener.

Required No
Data type Text area

URL root:

The root of the URL that should be used to build the endpoint addresses within WSDL documents to direct requesters to this endpoint listener.

The address at which external clients access the endpoint listener endpoint. If external clients access the endpoint listener through an HTTP server or server cluster, by using default port 80, then specify the HTTP server name and no port number.For example (for SOAP over HTTP endpoint listener 1):

`http://www.yourcompany.com/wsgwsoaphttp1`

However, if you allow external clients to connect direct to your application server (for example because it is a stand-alone server or in a development or test environment) then specify the application server host name and port number.For example (for SOAP over HTTP endpoint listener 1):

`http://your.server.name:9080/wsgwsoaphttp1`

Required Yes
Data type Text

WSDL serving HTTP URL root:

WSDL serving HTTP URL root

The root of the web address for the WSDL files of the inbound services that are available at this endpoint listener. This address comprises the root of the HTTP address at which external clients access your endpoint listener application, followed by `/sibws`.

If external clients access the endpoint listener through an HTTP server or server cluster, typically by using default port 80, then this URL root includes the HTTP server name and no port number. For example:
`http://www.yourcompany.com/sibws`

However, if you allow external clients to connect direct to your application server (for example in a development or test environment) then this URL root includes the application server host name and port number. For example:
`http://your.server.name:9080/sibws`

Note: The WSDL serving HTTP URL root is only used internally by other components of WebSphere Application Server (notably the IBM UDDI registry). For all other uses, you access the WSDL file through the endpoint listener endpoint for the inbound service.

Required Yes
Data type Text

Additional Properties

Connection Properties

Connection properties define the manner in which an endpoint listener connects to the service integration bus.

The application that handles the requests for this endpoint listener.

JAX-RPC Handler Lists [Collection]

A JAX-RPC handler list defines an ordered list of JAX-RPC handlers to be invoked against requests and responses.

To view this page in the console, click the following path:

Service integration -> Web services -> JAX-RPC Handler Lists.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

A handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. To enable handlers to undertake more complex operations, you chain them together into handler lists. You associate each handler list with one or more ports, so that the handler list can monitor activity at the port, and take appropriate action depending upon the sender and content of each message that passes through the port.

When you remove a handler list that is currently used by one or more web services on a service integration bus, the system removes the handler list for each associated web service.

Name The name of this JAX-RPC handler list.

Description
An optional description of the JAX-RPC handler list.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

JAX-RPC Handler Lists [Settings]

A JAX-RPC handler list defines an ordered list of JAX-RPC handlers to be invoked against requests and responses.

To view this page in the console, click the following path:

Service integration -> Web services -> JAX-RPC Handler Lists -> *handler-list_name*.

A handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. To enable handlers to undertake more complex operations, you chain them together into handler lists. You associate each handler list with one or more ports, so that the handler list can monitor activity at the port, and take appropriate action depending upon the sender and content of each message that passes through the port.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of this JAX-RPC handler list.

This name must be unique, and it must obey the following syntax rules:

- It must not start with "." (a period).
- It must not start or end with a space.
- It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

When you change a handler list name, the system looks up all objects that refer to it and updates the name.

Required Yes
Data type String

Description :

An optional description of the JAX-RPC handler list.

Required No
Data type Text area

JAX-RPC Handlers:

The JAX-RPC handlers in this list.

Handlers are applied in the sequence in which they appear in the handler list.

Required No
Data type Custom

Buttons

Add	Add a selected handler to the handler list.
Remove	Remove a selected handler from the handler list.
Down	Move the selected handler down the handler list.
Up	Move the selected handler up the handler list.

JAX-WS Handler Lists [Collection]

A JAX-WS handler list defines an ordered list of JAX-WS handlers to be invoked against requests and responses.

To view this page in the console, click the following path:

Service integration -> WS-Notification -> JAX-WS Handler Lists.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

A handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. To enable handlers to undertake more complex operations, you chain them together into handler lists. You associate each handler list with one or more JAX-WS based Version 7.0 WS-Notification services or service points, so that the handler list can monitor WS-Notification activity and take appropriate action depending upon the sender and content of each inbound or outbound message.

When you remove a handler list that is currently used by one or more web services on a service integration bus, the system removes the handler list for each associated web service.

Name The name of the JAX-WS handler list

Description
Description of the JAX-WS handler list

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

JAX-WS Handler Lists [Settings]

A JAX-WS handler list defines an ordered list of JAX-WS handlers to be invoked against requests and responses.

To view this page in the console, click the following path:

Service integration -> WS-Notification -> JAX-WS Handler Lists -> *handler-list_name*.

A handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. To enable handlers to undertake more complex operations, you chain them together into handler lists. You associate each handler list with one or more JAX-WS based Version 7.0 WS-Notification services or service points, so that the handler list can monitor WS-Notification activity and take appropriate action depending upon the sender and content of each inbound or outbound message.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the JAX-WS handler list

This name must be unique, and it must obey the following syntax rules:

- It must not start with "." (a period).

- It must not start or end with a space.
- It must not contain any of the following characters: \ / , # $ @ : ; " * ? < > | = + & % '

When you change a handler list name, the system looks up all objects that refer to it and updates the name.

Required Yes
Data type String

Description:

Description of the JAX-WS handler list

Required No
Data type Text area

JAX-WS Handlers:

The JAX-WS handlers in the handler list

Handlers are applied in the sequence in which they appear in the handler list.

Required No
Data type Custom

Buttons

Add	Add a selected handler to the handler list.
Remove	Remove a selected handler from the handler list.
Down	Move the selected handler down the handler list.
Up	Move the selected handler up the handler list.

JAX-RPC Handlers [Collection]

A JAX-RPC handler provides customization of web service request or response handling.

To view this page in the console, click the following path:

Service integration -> Web services -> JAX-RPC Handlers.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

A handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. For more detailed information about JAX-RPC and JAX-RPC handlers, see the developerWorks article Support for J2EE Web Services in WebSphere Studio Application Developer V5.1 -- Part 3: JAX-RPC Handlers.

When you remove a handler that is currently used by one or more web services on a service integration bus, the system removes the handler from the handler lists for each associated web service.

Name The name of this JAX-RPC handler.

Class name
The name of the class that implements the JAX-RPC handler.

Description
An optional description of the JAX-RPC handler.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

JAX-RPC Handlers [Settings]

A JAX-RPC handler provides customization of web service request or response handling.

To view this page in the console, click the following path:

Service integration -> Web services -> JAX-RPC Handlers -> *handler_name*.

A handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of this JAX-RPC handler.

This name must be unique, and it must obey the following syntax rules:

- It must not start with "." (a period).
- It must not start or end with a space.
- It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

When you change a handler name, the system looks up all objects that refer to it and updates the name.

Required Yes
Data type String

Description:

An optional description of the JAX-RPC handler.

Required No
Data type Text area

Class name:

The name of the class that implements the JAX-RPC handler.

Before you can create a handler configuration, you must make the handler class available to the application server in one of the following ways:

- Copy the individual class file into a directory structure under *app_server_root*/classes that matches the package name of the class, where *app_server_root* is the root directory for the installation of WebSphere Application Server. For example a handler class com.ibm.jaxrpc.handler.TestHandler is copied into the *app_server_root*/classes/com/ibm/jaxrpc/handler directory.
- Package the class files for all your handlers as a JAR file, then copy it into the *app_server_root*/lib/app directory.

Required	Yes
Data type	String

Additional Properties

JAX-RPC Header
Defines the JAX-RPC headers against which this handler operates.

SOAP Roles
Defines the SOAP roles in which this handler acts

Custom properties
Specifies additional custom properties that you can configure for this service.

JAX-WS Handlers [Collection]

A JAX-WS handler provides customization of web service request or response handling.

To view this page in the console, click the following path:

Service integration -> WS-Notification -> JAX-WS Handlers.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

A handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request.

When you remove a handler that is currently used by one or more web services on a service integration bus, the system removes the handler from the handler lists for each associated web service.

Class name
The class name of the JAX-WS Handler

Description
Description of the JAX-WS Handler

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

JAX-WS Handlers [Settings]

A JAX-WS handler provides customization of web service request or response handling.

To view this page in the console, click the following path:

Service integration -> WS-Notification -> JAX-WS Handlers -> *handler_name*.

A handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the JAX-WS Handler

This name must be unique, and it must obey the following syntax rules:

- It must not start with "." (a period).
- It must not start or end with a space.
- It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

When you change a handler name, the system looks up all objects that refer to it and updates the name.

Required Yes
Data type String

Description:

Description of the JAX-WS Handler

Required No
Data type Text area

Class name:

The class name of the JAX-WS Handler

Before you can create a handler configuration, you must make the handler class available to the application server in one of the following ways:

- Copy the individual class file into a directory structure under *app_server_root*`/classes` that matches the package name of the class, where *app_server_root* is the root directory for the installation of

WebSphere Application Server. For example a handler class `com.ibm.jaxws.handler.TestHandler` is copied into the *app_server_root*`/classes/com/ibm/jaxws/handler` directory.

- Package the class files for all your handlers as a JAR file, then copy it into the *app_server_root*`/lib/app` directory.

Required	Yes
Data type	String

JAX-RPC Header [Collection]

Defines the JAX-RPC headers against which this handler operates.

To view this page in the console, click the following path:

Service integration -> Web services -> JAX-RPC Handlers -> *handler_name* -> JAX-RPC headers.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

JAX-RPC headers are SOAP headers that are processed by a JAX-RPC handler.

Namespace URI
The namespace of the header that is processed by this handler

Local part
The local part of the name of the header that is processed by this handler

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

JAX-RPC Header [Settings]

Defines the JAX-RPC headers against which this handler operates.

To view this page in the console, click the following path:

Service integration -> Web services -> JAX-RPC Handlers -> *handler_name* -> JAX-RPC headers -> *header_name*.

JAX-RPC headers are SOAP headers that are processed by a JAX-RPC handler.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Namespace URI:

The namespace of the header that is processed by this handler

Required	Yes
Data type	String

Local part:

The local part of the name of the header that is processed by this handler

Required	Yes
Data type	String

Inbound Ports [Collection]

An inbound port describes the web service enablement of a service destination on a specific endpoint listener, with associated configuration.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Services] Inbound Services -> *service_name* -> [Additional Properties] Inbound Ports.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Requests and responses to an inbound service can be sent across any binding (for example SOAP over HTTP or SOAP over JMS) that is available to the service integration bus. Each available binding is represented by a type of port.

Each inbound port is associated with an endpoint listener, and you can control which groups of users can access a particular inbound service by making the service available only through specific endpoint listeners.

You can associate JAX-RPC handler lists with ports, so that the handlers can monitor activity at the port, and take appropriate action depending upon the sender and content of each message that passes through the port.

You can set the levels of security to be applied to messages. The security level can be set independently for request and response messages.

Note: When a SOAP message is processed at the inbound port as specified in the SOAP specification, if the SOAP header has an actor attribute that is not intended for processing in the inbound port, the attribute is forwarded in the message.

Name The inbound port name. This name appears as the port name within the WSDL published for the inbound service.

Endpoint Listener
An endpoint listener receives requests from service requester applications within a specific application server or cluster.

Description
An optional description of the inbound port. This description appears in any published WSDL for this port.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Inbound Ports [Settings]

An inbound port describes the web service enablement of a service destination on a specific endpoint listener, with associated configuration.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Services] Inbound Services -> *service_name* -> [Additional Properties] Inbound Ports -> *port_name*.

Each inbound port is associated with an endpoint listener, and you can control which groups of users can access a particular inbound service by making the service available only through specific endpoint listeners.

You can set the levels of security to be applied to messages. The security level can be set independently for request and response messages.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The inbound port name. This name appears as the port name within the WSDL published for the inbound service.

This name must be unique, and it must obey the following syntax rules:

- It must not start with "." (a period).
- It must not start or end with a space.
- It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

Required Yes
Data type Text

Description:

An optional description of the inbound port. This description appears in any published WSDL for this port.

Required	No
Data type	Text area

Endpoint listener :

This defines the physical endpoint listener at which requests for this port are received.

Required	Yes
Data type	drop-down list

Template port name:

Name of the port in the template WSDL to use as a basis for this port's binding

Required	No
Data type	drop-down list

JAX-RPC handler list :

This defines which list of JAX-RPC handlers is to be invoked for this port.

You use JAX-RPC handlers to monitor activity at the port, and take appropriate action (for example logging, or re-routing) depending upon the sender and content of each message that passes through the port.

You configure the set of JAX-RPC handler lists by using the administrative console option **Service integration -> Web services -> JAX-RPC Handler Lists**.

Required	No
Data type	drop-down list

Security request binding :

The security binding to be used for requests received by this port.

You configure the security bindings in this list by using the administrative console option **Service integration -> Web services -> WS-Security bindings**.

Required	No
Data type	drop-down list

Security response binding :

The security binding to be used for responses sent by this port.

You configure the security bindings in this list by using the administrative console option **Service integration -> Web services -> WS-Security bindings**.

Required	No
Data type	drop-down list

Security configuration :

Specifies the details of how security is applied to requests and responses.

You define the security configurations in this list by using the administrative console option **Service integration -> Web services -> WS-Security configurations**.

Required	No
Data type	drop-down list

Additional Properties

Custom properties
Specifies additional custom properties that you can configure for this service.

By default, a timeout error is generated if an outbound service waits for more than 60 seconds for a response from a target web service. To change the timeout value for this inbound port from the default value of 60 seconds to a new value of (for example) 120 seconds, create the following custom property:

Name:
timeout

Value (in milliseconds):
120000

Inbound services [Collection]

An inbound service describes the web service enablement of a service destination. It provides the configuration of endpoint listeners within a port.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Services] Inbound Services.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

An inbound service is a web interface to a service that is provided internally (that is, a service provided by your own organization and hosted in a location that is directly available through a service integration bus destination). To configure a locally-hosted service as an inbound service, you first associate it with a service destination, then you configure one or more ports (each with an associated endpoint listener) through which service requests and responses are passed to the service. You can also choose to have the local service made available through one or more UDDI registries.

Name The inbound service name. This name appears as the service name within WSDL published for this inbound service.

Service destination name
The service destination to be enabled for web service access.

Published
Describes the manner in which the WSDL describing an inbound service is published to a UDDI registry.

Description

An optional description of the inbound service. This description appears in any published WSDL for this service.

Buttons

New	New
Delete	Delete the selected items.
Publish to UDDI	Create a new inbound service.
Unpublish from UDDI	Remove the inbound service from the UDDI registry.

Inbound services [Settings]

An inbound service describes the web service enablement of a service destination. It provides the configuration of endpoint listeners within a port.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Services] Inbound Services -> *service_name*.

An inbound service is a web interface to a service that is provided internally (that is, a service provided by your own organization and hosted in a location that is directly available through a service integration bus destination). To configure a locally-hosted service as an inbound service, you first associate it with a service destination, then you configure one or more ports (each with an associated endpoint listener) through which service requests and responses are passed to the service. You can also choose to have the local service made available through one or more UDDI registries.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

Buttons

Reload template WSDL	Reload the template WSDL for this inbound service.

General Properties

Name:

The inbound service name. This name appears as the service name within WSDL published for this inbound service.

This name must be unique, and it must obey the following syntax rules:

- It must not start with "." (a period).
- It must not start or end with a space.
- It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`
- It must not be longer than 250 characters.

Required Yes
Data type String

Service destination name:

The service destination to be enabled for web service access.

Required	No
Data type	drop-down list

Description:

An optional description of the inbound service. This description appears in any published WSDL for this service.

Required	No
Data type	Text area

Template WSDL location type:

The type of the template WSDL Location.

Specify the location type for the template WSDL file. The template WSDL file is either located at a web address, or through a UDDI registry. When service integration technologies deploys the web service, it use this template file as the basis for generating a WSDL file for the service.

Required	No
Data type	Radio button

Template WSDL location:

The URL location or UDDI service key of the template WSDL.

Depending upon which template WSDL location type you specified in the previous field, enter either the URL location or the service-specific part of the UDDI service key for the template WSDL file.

Here is an example of a full UDDI service key:

```
uddi:blade108node01cell:blade108node01:server1:default:6e3d106e-5394-44e3-be17-aca728ac1791
```

The service-specific part of this key is the final part:

```
6e3d106e-5394-44e3-be17-aca728ac1791
```

Required	Yes
Data type	Text

Template WSDL UDDI registry:

The UDDI registry containing the template WSDL. Required for UDDI location type.

If you specified a template WSDL location type of “UDDI”, select a UDDI reference from the drop-down list.

You configure the UDDI references in this list by using the administrative console option **Service integration -> Web services -> UDDI References**.

Required	No
Data type	drop-down list

Template WSDL service name:

The name of the service within the template WSDL. Only required if there is more than one service in the WSDL.

If the template WSDL contains more than one service, or the WSDL is located through a UDDI registry, type the service name.

Required	Yes
Data type	String

Template WSDL service namespace:

The namespace of the service within the template WSDL. Only required if there is more than one service in the WSDL.

If the template WSDL contains more than one service, or the WSDL is located through a UDDI registry, type the namespace of the service name.

Required	Yes
Data type	String

Enable operation level security:

Indicates whether the access control policy should be enforced.

If you enable this option you must also complete, for this web service, the steps described in the information center for password-protecting a web service operation.

Required	No
Data type	Boolean

Additional Properties

Inbound Ports
An inbound port describes the web service enablement of a service destination on a specific endpoint listener, with associated configuration.

UDDI Publication
Describes the manner in which the WSDL describing an inbound service is published to a UDDI registry.

Custom properties
Specifies additional custom properties that you can configure for this service.

Publish WSDL files to ZIP file
Publish the WSDL files for this service to a .zip file

Outbound Ports [Collection]

An outbound port represents a single port for a WSDL-defined service provider. It provides the configuration of invocation of the web service.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Services] Outbound Services -> *service_name* -> Outbound Ports.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Requests and responses to an outbound service can be sent across any binding (for example SOAP over HTTP or SOAP over JMS) that is available to both the service integration bus and the external web service. Each available binding is represented by a port.

You can associate JAX-RPC handler lists with ports, so that the handlers can monitor activity at the port, and take appropriate action depending upon the sender and content of each message that passes through the port. If the external web service requires HTTP basic authentication, you can use a JAX-RPC handler list to provide an HTTP basic authentication header.

You can set the levels of security to be applied to messages. The security level can be set independently for request and response messages.

Because the service is hosted externally, you might also have to enable proxy server authentication to get access to the Internet.

Name The port name.

Port destination name
The name of the port destination for this port.

Description
An optional description of the port.

Buttons

New	Create a new outbound port.
Delete	Delete the selected items.

Outbound Ports [Settings]

An outbound port represents a single port for a WSDL-defined service provider. It provides the configuration of invocation of the web service.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Services] Outbound Services -> *service_name* -> Outbound Ports -> *port_name*.

Requests and responses to an outbound service can be sent across any binding (for example SOAP over HTTP or SOAP over JMS) that is available to both the service integration bus and the external web service. Each available binding is represented by a port.

You can set the levels of security to be applied to messages. The security level can be set independently for request and response messages.

Because the service is hosted externally, you might also have to enable proxy server authentication to get permission to access the Internet.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The port name.

This name must be unique, and it must obey the following syntax rules:

- It must not start with "." (a period).
- It must not start or end with a space.
- It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

Required	Yes
Data type	Custom

Description:

An optional description of the port.

Required	No
Data type	Text area

Port destination name:

The name of the port destination for this port.

Required	Yes
Data type	Custom

Port destination point:

The application server or cluster for the port destination.

Required	Yes
Data type	Custom

Binding namespace:

The namespace of the binding for this point.

Required	No
Data type	String

Endpoint address:

The endpoint address for this port.

Required No
Data type String

JAX-RPC handler list:

This defines which list of JAX-RPC handlers is to be invoked for this port.

You use JAX-RPC handlers to monitor activity at the port, and take appropriate action (for example logging, or re-routing) depending upon the sender and content of each message that passes through the port. If the external web service requires HTTP basic authentication, you can use a JAX-RPC handler list to provide an HTTP basic authentication header.

You configure the set of JAX-RPC handler lists by using the administrative console option **Service integration -> Web services -> JAX-RPC Handler Lists**.

Required No
Data type drop-down list

Security request binding:

The security binding to be used with requests sent by this port.

You configure the security bindings in this list by using the administrative console option **Service integration -> Web services -> WS-Security bindings**.

Required No
Data type drop-down list

Security response binding:

The security binding to be used for responses received by this port.

You configure the security bindings in this list by using the administrative console option **Service integration -> Web services -> WS-Security bindings**.

Required No
Data type drop-down list

Security configuration:

Specifies the details of how security is applied to requests and responses.

You define the security configurations in this list by using the administrative console option **Service integration -> Web services -> WS-Security configurations**.

Required No
Data type drop-down list

Authenticating proxy host name :

The host name of the authenticating proxy used for invoking requests for this port.

The service integration technologies require access to the Internet for invoking outbound web services and for retrieval of service provider WSDL files. If you use a proxy server in support of Internet routing, and if your proxy server is configured to require authentication before it grants access to the Internet, then you must also complete, for this outbound port, the steps described in the information center for enabling proxy server authentication.

Required	No
Data type	String

Authenticating proxy port number :

The port number of the authenticating proxy.

Required	No
Data type	String

Authenticating proxy Authorization Alias:

The name of the authorization alias that contains the user name and password to use with the authenticating proxy.

Required	No
Data type	String

Additional Properties

Custom properties
Specifies additional custom properties that you can configure for this service.

Outbound services [Collection]

An outbound service represents a WSDL-described service.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Services] Outbound Services.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

An outbound service is a web service that is hosted externally, and is made available through a service integration bus. To configure an externally-hosted service for a bus, you first associate it with a service destination, then you configure one or more port destinations (one for each type of binding, for example SOAP over HTTP or SOAP over JMS) through which service requests and responses are passed to the external service.

Note: You get the port definitions from the WSDL, but you can choose which ones you want to create.

Because the service is hosted externally, you might also have to enable proxy server authentication for each port to get permission to access the Internet.

Name The outbound service name.

Service destination name
The name of the service destination for this outbound service.

Description
Description of the outbound service.

Buttons

New	Create a new outbound service.
Delete	Delete the selected items.

Outbound services [Settings]

An outbound service represents a WSDL-described service.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Services] Outbound Services -> *service_name*.

An outbound service is a web service that is hosted externally, and is made available through a service integration bus. To configure an externally-hosted service for a bus, you first associate it with a service destination, then you configure one or more port destinations (one for each type of binding, for example SOAP over HTTP or SOAP over JMS) through which service requests and responses are passed to the external service.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

Buttons

Reload WSDL	Refresh the details displayed with data from the WSDL file.

General Properties

Name:

The outbound service name.

This name must be unique, and it must obey the following syntax rules:

- It must not start with "." (a period).
- It must not start or end with a space.
- It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

Required Yes
Data type String

Description:

Description of the outbound service.

Required No
Data type Text area

Service destination name:

The name of the service destination for this outbound service.

Required No
Data type Custom

WSDL location type:

The web service WSDL location type.

Specify the location type for the service provider WSDL file that describes the web service. The WSDL file is either located at a web address, or through a UDDI registry.

Required No
Data type Radio button

WSDL location:

The URL location or the UDDI service key of the WSDL. When specifying a UDDI service key, provide only the last segment of the key. For example, for a service key of 'uddi:cell01:node01:server1:default:6e3d106e-5394-44e3-be17-aca728ac1791', supply a value of '6e3d106e-5394-44e3-be17-aca728ac1791'.

Depending upon which WSDL location type you specified in the previous field, enter either the URL location or the service-specific part of the UDDI service key for the service provider WSDL file.

Here is an example of a full UDDI service key:

```
uddi:blade108node01cell:blade108node01:server1:default:6e3d106e-5394-44e3-be17-aca728ac1791
```

The service-specific part of this key is the final part:

```
6e3d106e-5394-44e3-be17-aca728ac1791
```

Required Yes
Data type Text

WSDL UDDI Registry:

The UDDI registry containing the service provider's WSDL document. Required for UDDI Location Type.

If you specified a WSDL location type of “UDDI”, select a UDDI reference from the selection list.

You configure the UDDI references in this list by using the administrative console option **Service integration -> Web services -> UDDI References**.

Required No
Data type drop-down list

WSDL service name:

The name of the service within the WSDL. Required if there is more than one service in the WSDL.

If the service provider WSDL contains more than one service, or the WSDL is located through a UDDI registry, type the service name from the service provider WSDL.

Required	Yes
Data type	String

WSDL service namespace:

The namespace of the service within the WSDL. Required if there is more than one service in the WSDL.

If the service provider WSDL contains more than one service, or the WSDL is located through a UDDI registry, type the namespace of the service name from the service provider WSDL.

Required	Yes
Data type	Text

Default port name:

This port is used for all invocations unless it is overridden at runtime.

Requests and responses to this service can be sent across any binding (for example SOAP over HTTP or SOAP over JMS) that is available to both the service integration bus and the external web service. Each available binding is represented by a port. Select the default port that you want the service integration technologies to use for communicating with the external service.

Required	No
Data type	drop-down list

Port selection mediation:

The name of the port selection mediation that may override the default port for each request.

You can use a mediation to override the default port. For example, you can specify that requests from a particular client should always be routed to a particular port whether or not it is the default port.

Required	No
Data type	drop-down list

Bus member:

The bus member to which the port selection mediation is assigned.

Required	No
Data type	drop-down list

Enable operation level security:

Selects whether the access control policy should be enforced.

If you enable this option you must also complete, for this web service, the associated steps described in the information center for enabling operation-level authentication.

Required	No
Data type	Boolean

Additional Properties

Outbound Ports
Each port enabled within this service has its own configuration.

Custom properties
Specifies additional custom properties that you can configure for this service.

Publish WSDL files to ZIP file [Settings]

Publish the WSDL files for this service to a .zip file

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Services] Inbound Services -> *service_name* -> [Additional Properties] Publish WSDL files to ZIP file.

Use the publish WSDL files property to export the template WSDL for this inbound service to a compressed file.

The exported file includes a version of the WSDL file that has no ports (bindings) defined. This non-bound WSDL is intended for use by your colleagues preparing to deploy an inbound service. It gives you a convenient way of sharing information on the planned deployment details for the service among your team. When you finally deploy the inbound service, the associated WSDL must be complete (that is, it must include the binding information). For more information, see the topic “Non-bound WSDL” in the information center.

The non-bound WSDL file is always published in the exported compressed file for the inbound service, along with the bound WSDL file if the inbound service has any ports defined. The compressed file, named *inbound_service_name*.zip, therefore always contains the following files:

- *bus_name*.*inbound_service_name*NonBound.wsdl (this file contains the non-bound service, port and binding for the inbound service).
- *bus_name*.*inbound_service_name*PortTypes.wsdl (this file contains the port type definition for the inbound service).

If the inbound service has one or more ports, then the compressed file additionally contains the following files:

- *bus_name*.*inbound_service_name*Service.wsdl (this file contains the service and port elements for the inbound service).
- *bus_name*.*inbound_service_name*Bindings.wsdl (this file contains the binding elements that correspond to the ports for the inbound service).

If there is an error generating the WSDL then an error page is returned.

SOAP Roles [Collection]

Defines the SOAP roles in which this handler acts

To view this page in the console, click the following path:

Service integration -> Web services -> JAX-RPC Handlers -> *handler_name* -> SOAP roles.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

For more information, see the SOAP specification.

Role Defines the SOAP roles in which this handler acts

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

SOAP Roles [Settings]

Defines the SOAP roles in which this handler acts

To view this page in the console, click the following path:

Service integration -> Web services -> JAX-RPC Handlers -> *handler_name* -> SOAP roles -> *role_name*.

For more information, see the SOAP specification.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Role:

Defines the SOAP roles in which this handler acts

Required Yes
Data type String

UDDI Publication [Collection]

Describes the manner in which the WSDL describing an inbound service is published to a UDDI registry.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Services] Inbound Services -> *service_name* -> [Additional Properties] UDDI publication.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

For more general information about UDDI and UDDI registries, see the UDDI community at uddi.org.

Name The name of this UDDI publication property.

UDDI reference
The reference of the UDDI registry to which WSDL is to be published.

Published
Describes the manner in which the WSDL describing an inbound service is published to a UDDI registry.

Description
An optional description of the UDDI publication properties.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.
Publish to UDDI	Create a new inbound service.
Unpublish from UDDI	Remove the inbound service from the UDDI registry.

UDDI Publication [Settings]

Describes the manner in which the WSDL describing an inbound service is published to a UDDI registry.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Services] Inbound Services -> *service_name* -> [Additional Properties] UDDI publication -> *publication_name*.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of this UDDI publication property.

This name must be unique, and it must obey the following syntax rules:

- It must not start with "." (a period).
- It must not start or end with a space.
- It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

Required	Yes
Data type	String

Description:

An optional description of the UDDI publication properties.

Required	No
Data type	Text area

UDDI reference:

The reference of the UDDI registry to which WSDL is to be published.

A UDDI reference is a pointer to a UDDI registry. The UDDI references in the list are those that you added by using the administrative console option **Service integration -> Web services -> UDDI References**. Select a UDDI reference that can access the UDDI business category under which you want to publish this service.

Required	Yes
Data type	Custom

Business key:

The key of the business within which this service is to be published.

The business key identifies the business category under which you want your service to appear in UDDI. To get a list of valid business keys, look up businesses in a UDDI registry. Here is an example of a UDDI business key: `08A536DC-3482-4E18-BFEC-2E2A23630526`.

Required	Yes
Data type	Custom

Published service key:

The key of the service as published to the UDDI registry.

This is the service-specific part of the UDDI service key.

When a service is published to UDDI, the registry assigns a service key to the service.

After the service has been published you can get the service key from the target UDDI registry.

Here is an example of a full UDDI service key:

```
uddi:blade108node01cell:blade108node01:server1:default:6e3d106e-5394-44e3-be17-aca728ac1791
```

The service-specific part of this key is the final part:

```
6e3d106e-5394-44e3-be17-aca728ac1791
```

Required	No
Data type	String

Custom HTTP URL for WSDL publication:

The HTTP URL root of the servlet that is to serve the WSDL that describes this service.

Required	No
Data type	String

UDDI References [Collection]

A UDDI reference describes the parameters necessary to connect to a particular UDDI registry.

To view this page in the console, click the following path:

Service integration -> Web services -> UDDI References.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

A UDDI reference is a pointer to a UDDI registry. This registry can be a private UDDI registry such as the IBM WebSphere UDDI Registry, or a public UDDI registry.

For more general information about UDDI and UDDI registries, see the UDDI community at uddi.org.

Name The name of this UDDI reference.

Description
An optional description of the UDDI Registry.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

UDDI References [Settings]

A UDDI reference describes the parameters necessary to connect to a particular UDDI registry.

To view this page in the console, click the following path:

Service integration -> Web services -> UDDI References -> *UDDI-reference_name*.

A UDDI reference is a pointer to a UDDI registry. This registry can be a private UDDI registry such as the IBM WebSphere UDDI Registry, or a public UDDI registry.

In the UDDI model, web services are owned by businesses, and businesses are owned by Authorized Names. Each UDDI reference gives access to the web services that are owned by a single Authorized Name in a single UDDI registry.

For more general information about UDDI and UDDI registries, see the UDDI community at uddi.org.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of this UDDI reference.

This name must be unique, and it must obey the following syntax rules:

- It must not start with "." (a period).
- It must not start or end with a space.
- It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

You might need more than one UDDI reference for a given UDDI registry.

Required	Yes
Data type	String

Description:

An optional description of the UDDI Registry.

Required	No
Data type	Text area

Inquiry URL:

The URL that applications use to inquire on the UDDI registry.

This is the web address that provides access to this registry for the SOAP inquiry API.

Required	Yes
Data type	String

Publish URL:

The URL that applications use to publish to the UDDI registry.

This is the web address that provides access to this registry for the SOAP publish API.

Required	No

Data type String

Authentication Alias:

The user ID for accessing the UDDI repository

This is an authentication alias that you have previously defined for the user ID and password of a UDDI "Authorized Name" that has update access to this registry.

Required No
Data type drop-down list

Actor [Settings]

Defines the Actor URI to be included in the WS-Security headers of a generated message.

To view this page in the console, click one of the following paths:

- **Service integration -> Web services -> WS-Security configurations -> *draft13-inbound-config_name* -> [Response sender] Actor**
- **Service integration -> Web services -> WS-Security configurations -> *draft13-outbound-config_name* -> [Request sender] Actor**

This panel is one of a set of panels that you can use to configure the service integration bus in accordance with the WS-Security Draft 13 specification (also known as the Web Services Security Core Specification). However, use of the WS-Security Draft 13 specification is deprecated, and you should only use it to allow continued use of an existing web services client application that has been written to the WS-Security Draft 13 specification.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Actor:

Defines the Actor URI to be included in the WS-Security headers of a generated message.

Required No
Data type String

Add created time stamp [Settings]

Specifies whether a time stamp will be added to any sent message. The time stamp may also contain an expires value.

To view this page in the console, click one of the following paths:

- **Service integration -> Web services -> WS-Security configurations -> *draft13-inbound-config_name* -> [Response sender] Add created timestamp**
- **Service integration -> Web services -> WS-Security configurations -> *draft13-outbound-config_name* -> [Request sender] Add created timestamp**

This panel is one of a set of panels that you can use to configure the service integration bus in accordance with the WS-Security Draft 13 specification (also known as the Web Services Security Core Specification). However, use of the WS-Security Draft 13 specification is deprecated, and you should only use it to allow continued use of an existing web services client application that has been written to the WS-Security Draft 13 specification.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Enabled:

When selected, a time stamp will be added to the message.

Required	No
Data type	Boolean

Expires:

The expiration time of the time stamp, defined as an xsd:Duration type.

The expires value is defined as a type of xsd:Duration, and the format must match the following regular expression:

```
-?P([0-9]+Y)?([0-9]+M)?([0-9]+D)?(T([0-9]+H)?([0-9]+M)?([0-9]+(\\.[0-9]*)?S)?)
```

For example, to specify a timestamp expiration of three minutes, enter PT3M.

Required	No
Data type	String

Add received time stamp [Settings]

Specifies whether a time stamp will be added to any received message.

To view this page in the console, click one of the following paths:

- **Service integration -> Web services -> WS-Security configurations -> *draft13-inbound-config_name* -> [Request receiver] Add received timestamp**
- **Service integration -> Web services -> WS-Security configurations -> *draft13-outbound-config_name* -> [Response receiver] Add received timestamp**

This panel is one of a set of panels that you can use to configure the service integration bus in accordance with the WS-Security Draft 13 specification (also known as the Web Services Security Core Specification). However, use of the WS-Security Draft 13 specification is deprecated, and you should only use it to allow continued use of an existing web services client application that has been written to the WS-Security Draft 13 specification.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Enabled:

When selected, a time stamp will be added to the message.

Required	No
Data type	Boolean

Confidentiality [Settings]

Specifies the confidentiality constraints applied to sent messages. Indicates which parts of the message will be encrypted.

To view this page in the console, click one of the following paths:

- **Service integration -> Web services -> WS-Security configurations -> *draft13-inbound-config_name* -> [Response sender] Confidentiality**
- **Service integration -> Web services -> WS-Security configurations -> *draft13-outbound-config_name* -> [Request sender] Confidentiality**

This panel is one of a set of panels that you can use to configure the service integration bus in accordance with the WS-Security Draft 13 specification (also known as the Web Services Security Core Specification). However, use of the WS-Security Draft 13 specification is deprecated, and you should only use it to allow continued use of an existing web services client application that has been written to the WS-Security Draft 13 specification.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Body content:

Specifies that the body of the message must be encrypted.

Required	No
Data type	Boolean

Username token:

Specifies that the username token header must be encrypted.

Required	No
Data type	Boolean

Custom authentication methods [Collection]

Specifies custom authentication methods this service will accept.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *draft13-inbound-config_name* -> [Request receiver] Login configuration -> [Additional properties] Custom authentication methods.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

This panel is one of a set of panels that you can use to configure the service integration bus in accordance with the WS-Security Draft 13 specification (also known as the Web Services Security Core Specification).

Name The name of the custom authentication method to accept.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Custom authentication methods [Settings]

Specifies custom authentication methods this service will accept.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *draft13-inbound-config_name* -> [Request receiver] Login configuration -> [Additional properties] Custom authentication methods -> *method_name*.

This panel is one of a set of panels that you can use to configure the service integration bus in accordance with the WS-Security Draft 13 specification (also known as the Web Services Security Core Specification). However, use of the WS-Security Draft 13 specification is deprecated, and you should only use it to allow continued use of an existing web services client application that has been written to the WS-Security Draft 13 specification.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the custom authentication method to accept.

Required	Yes
Data type	String

ID assertion [Settings]

Specifies the signature method and trust mode to use when ID Assertion is set as an authentication method.

To view this page in the console, click one of the following paths:

- **Service integration -> Web services -> WS-Security configurations -> *draft13-inbound-config_name* -> [Request receiver] ID assertion**
- **Service integration -> Web services -> WS-Security configurations -> *draft13-outbound-config_name* -> [Request sender] ID assertion**

This panel is one of a set of panels that you can use to configure the service integration bus in accordance with the WS-Security Draft 13 specification (also known as the Web Services Security Core Specification). However, use of the WS-Security Draft 13 specification is deprecated, and you should only use it to allow continued use of an existing web services client application that has been written to the WS-Security Draft 13 specification.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Signature method:

Specifies the method by which the identity will be asserted.

Required	No
Data type	drop-down list

Trust mode:

Specifies the method by which the identity of the trusted party will be provided.

Required	No
Data type	drop-down list

Inbound WS-Security configuration [Settings]

WS-Security configuration for an inbound request. This defines WS-Security requirements for the request consumed from the client and the response generated. The objects created may be applied to one or more inbound ports.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *draft13-inbound-config_name*.

This panel is one of a set of panels that you can use to configure the service integration bus in accordance with the WS-Security Draft 13 specification (also known as the Web Services Security Core Specification). However, use of the WS-Security Draft 13 specification is deprecated, and you should only use it to allow continued use of an existing web services client application that has been written to the WS-Security Draft 13 specification.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

WS-Security version:

Identifies the version of the WS-Security specification this configuration uses.

Required	No
Data type	String

Service type:

The type of service the WS-Security configuration applies to.

Required	No
Data type	String

Name:

The name of the inbound WS-Security configuration.

This name must be unique across both WS-Security Version 1.0 and Draft 13 Inbound configurations, and it must obey the following syntax rules:

- It must not start with "." (a period).
- It must not start or end with a space.
- It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

Required	Yes
Data type	String

Actor URI:

WS-Security headers within the consumed request message will only be processed if they have the specified Actor URI.

Required	No
Data type	String

Request receiver

Required integrity
Specifies the integrity constraints received messages must meet. Indicates which parts of the message must be digitally signed.

Required confidentiality
Specifies the confidentiality constraints applied to sent messages. Indicates which parts of the message will be encrypted.

Login configuration
Specifies the authentication methods this service supports. Custom authentication methods can also be defined.

ID assertion
Specifies the signature method and trust mode to use when ID Assertion is set as an authentication method.

Add received time stamp
Specifies whether a time stamp will be added to any received message.

Properties
General properties for the inbound WS-Security configuration.

Response sender

Actor Defines the Actor URI to be included in the WS-Security headers of a generated message.

Integrity
Specifies the integrity constraints applied to sent messages. Indicates which parts of the message will be digitally signed.

Confidentiality
Specifies the confidentiality constraints applied to sent messages. Indicates which parts of the message will be encrypted.

Add created time stamp
Specifies whether a time stamp will be added to any sent message. The time stamp may also contain an expires value.

Properties
General properties for the inbound WS-Security configuration.

Integrity [Settings]

Specifies the integrity constraints applied to sent messages. Indicates which parts of the message will be digitally signed.

To view this page in the console, click one of the following paths:

- **Service integration -> Web services -> WS-Security configurations -> *draft13-inbound-config_name* -> [Response sender] Integrity**
- **Service integration -> Web services -> WS-Security configurations -> *draft13-outbound-config_name* -> [Request sender] Integrity**

This panel is one of a set of panels that you can use to configure the service integration bus in accordance with the WS-Security Draft 13 specification (also known as the Web Services Security Core Specification). However, use of the WS-Security Draft 13 specification is deprecated, and you should only use it to allow continued use of an existing web services client application that has been written to the WS-Security Draft 13 specification.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Body:

Specifies that the body of the message must be digitally signed.

Required	No
Data type	Boolean

Time stamp:

Specifies that the time stamp header must be digitally signed.

Required	No
Data type	Boolean

Security token:

Specifies that the security token header must be digitally signed.

Required	No
Data type	Boolean

Login configuration [Settings]

Specifies the authentication methods this service supports. Custom authentication methods can also be defined.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *draft13-inbound-config_name* -> [Request receiver] Login configuration.

This panel is one of a set of panels that you can use to configure the service integration bus in accordance with the WS-Security Draft 13 specification (also known as the Web Services Security Core Specification).

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Basic authentication:

Specifies that a username and password is used as an authentication method.

Required	No
Data type	Boolean

Basic authentication Nonce settings:

Specifies Nonce settings for when Basic Authentication is used. Nonce is a randomly generated value.

Required	No
Data type	Custom

ID assertion:

Specifies that ID Assertion is used as an authentication method. An ID Assertion configuration must also be set.

Required	No
Data type	Boolean

Signature:

Specifies that digital signature is used as an authentication method.

Required	No
Data type	Boolean

LTPA:

Specifies that Lightweight Third Party Authentication is used as an authentication method.

Required	No
Data type	Boolean

Additional Properties

Custom authentication methods
Specifies custom authentication methods this service will accept.

Login configuration [Settings]

Specifies the authentication methods this service supports. Custom authentication methods can also be defined.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *draft13-outbound-config_name* -> [Request sender] Login configuration.

This panel is one of a set of panels that you can use to configure the service integration bus in accordance with the WS-Security Draft 13 specification (also known as the Web Services Security Core Specification).

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Authentication method:

Specifies the predefined authentication method to use.

Required	Yes
Data type	Custom

Range

None No authentication process is used.

Basic authentication
A username and password is used to authenticate the user.

Use Nonce
Nonce is a randomly-generated, cryptographic token that is used to prevent replay attacks.

Nonce time stamp required
Attaches a time stamp element to the message.

ID assertion
This asserts the authenticated identity of the originating client from a web service to a downstream web service. When identity assertion is used, the authentication decision is performed based only on the name of the identity and not on other information such as passwords.

Signature
This refers to an X.509 certificate that is sent by the client to the server. The certificate is used to authenticate to the user registry that is configured at the server.

Custom authentication method
A custom authentication method can be entered by the user in a text format.

Outbound WS-Security configuration [Settings]

WS-Security configuration for an outbound request. This defines WS-Security requirements for the request generated and response consumed from the target. The objects created may be applied to one or more outbound ports.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *draft13-outbound-config_name*.

This panel is one of a set of panels that allow you to configure the service integration bus in accordance with WS-Security Draft 13 (also known as the Web Services Security Core Specification). However, use of the WS-Security Draft 13 specification is deprecated, and you should only use it to allow continued use of an existing web services client application that has been written to the WS-Security Draft 13 specification.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

WS-Security version:

Identifies the version of the WS-Security specification this configuration uses.

Required	No
Data type	String

Service type:

The type of service the WS-Security configuration applies to.

Required	No
Data type	String

Name:

The name of the outbound WS-Security configuration.

This name must be unique across both WS-Security Version 1.0 and Draft 13 Inbound configurations, and it must obey the following syntax rules:

- It must not start with "." (a period).
- It must not start or end with a space.
- It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

Required	Yes
Data type	String

Actor URI:

WS-Security headers within the consumed response message will only be processed if they have the specified actor URI.

Required	No
Data type	String

Request sender

Actor Defines the Actor URI to be included in the WS-Security headers of a generated message.

Integrity
Specifies the integrity constraints applied to sent messages. Indicates which parts of the message will be digitally signed.

Confidentiality
Specifies the confidentiality constraints applied to sent messages. Indicates which parts of the message will be encrypted.

Login configuration
Specifies the authentication method to use in the request. May be a predefined or custom authentication method.

ID assertion
Specifies the signature method and trust mode to use when ID Assertion is set as an authentication method.

Add created time stamp
Specifies whether a time stamp will be added to any sent message. The time stamp may also contain an expires value.

Properties
General properties for the outbound WS-Security configuration.

Response receiver

Required integrity
Specifies the integrity constraints received messages must meet. Indicates which parts of the message must be digitally signed.

Required confidentiality
Specifies the confidentiality constraints applied to sent messages. Indicates which parts of the message will be encrypted.

Add received time stamp
Specifies whether a time stamp will be added to any received message.

Properties
General properties for the outbound WS-Security configuration.

Required confidentiality [Settings]

Specifies the confidentiality constraints applied to sent messages. Indicates which parts of the message will be encrypted.

To view this page in the console, click one of the following paths:

- **Service integration -> Web services -> WS-Security configurations -> *draft13-inbound-config_name* -> [Request receiver] Required confidentiality**
- **Service integration -> Web services -> WS-Security configurations -> *draft13-outbound-config_name* -> [Response receiver] Required confidentiality**

This panel is one of a set of panels that you can use to configure the service integration bus in accordance with the WS-Security Draft 13 specification (also known as the Web Services Security Core Specification). However, use of the WS-Security Draft 13 specification is deprecated, and you should only use it to allow continued use of an existing web services client application that has been written to the WS-Security Draft 13 specification.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Body content:

Specifies that the body of the message must be encrypted.

Required	No
Data type	Boolean

Username token:

Specifies that the username token header must be encrypted.

Required	No
Data type	Boolean

Required integrity [Settings]

Specifies the integrity constraints received messages must meet. Indicates which parts of the message must be digitally signed.

To view this page in the console, click one of the following paths:

- **Service integration -> Web services -> WS-Security configurations -> *draft13-inbound-config_name* -> [Request receiver] Required integrity**
- **Service integration -> Web services -> WS-Security configurations -> *draft13-outbound-config_name* -> [Response receiver] Required integrity**

This panel is one of a set of panels that you can use to configure the service integration bus in accordance with the WS-Security Draft 13 specification (also known as the Web Services Security Core Specification). However, use of the WS-Security Draft 13 specification is deprecated, and you should only use it to allow continued use of an existing web services client application that has been written to the WS-Security Draft 13 specification.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Body:

Specifies that the body of the message must be digitally signed.

Required	No
Data type	Boolean

Time stamp:

Specifies that the time stamp header must be digitally signed.

Required	No
Data type	Boolean

Security token:

Specifies that the security token header must be digitally signed.

Required	No
Data type	Boolean

Actor [Settings]

Defines the Actor URI to be included in the WS-Security headers of a generated message.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name* -> [Request generator] Actor.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Actor:

Defines the Actor URI to be included in WS-Security headers of generated request.

Required	No
Data type	String

Actor [Settings]

Defines the Actor URI to be included in WS-Security headers of generated response.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name* -> [Response generator] Actor.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Actor:

Defines the Actor URI to be included in WS-Security headers of generated response.

Required	No
Data type	String

Add time stamp [Settings]

When add time stamp is specified for a consumer, a time stamp is added indicating when the message was consumed. For a generator, a time stamp is added indicating when the message was generated.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name* -> [Request consumer] Add timestamp.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Enabled:

If selected, a time stamp will be added to the message.

Required	No
Data type	Boolean

Dialect:

The expression dialect to use.

Required	No
Data type	drop-down list

Keyword:

Identifies the message part in a way defined by the chosen dialect.

When the `http://www.ibm.com/websphere/webservices/wssecurity/dialect-was` dialect value is selected, the following are valid keyword values:

action Specifies the wsa:Action element.

body Specifies the SOAP body element.

dsigkey
Specifies the key information element, which is used for digital signature.

enckey
Specifies the ds:KeyInfo element, which is used for encryption.

messageid
Specifies the wsa:MessageID element.

relatesto
Specifies the wsa:RelatesTo element.

securitytoken
Specifies any security token elements, for example the wsse:BinarySecurityToken element.

timestamp
Specifies the wsu:Timestamp element. This element determines whether the message is valid based upon the time that the message is sent and then received.

to Specifies the wsa:To element.

When the `http://www.w3.org/TR/1999/REC-xpath-1999116` dialect value is selected, then the keyword value can be any valid XPath expression that points to a part of the message. For example:

```
/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/' and local-name()='Envelope']
/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/' and local-name()='Body']
```

Required	No
Data type	String

Expires:

The expiration time of the time stamp, defined as an xsd:Duration type.

The expires value is defined as a type of xsd:Duration, and the format must match the following regular expression:

```
-?P([0-9]+Y)?([0-9]+M)?([0-9]+D)?(T([0-9]+H)?([0-9]+M)?([0-9]+(\\.[0-9]*)?S)?)
```

For example, to specify a timestamp expiration of three minutes, enter PT3M.

Required	No
Data type	String

Additional Properties

Properties

Properties associated with the added time stamp.

Add time stamp [Settings]

When add time stamp is specified for a consumer, a time stamp is added indicating when the message was consumed. For a generator, a time stamp is added indicating when the message was generated.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name* -> [Request generator] Add timestamp.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Enabled:

If selected, a time stamp will be added to the message.

Required	No
Data type	Boolean

Dialect:

The expression dialect to use.

Required	No

Additional Properties

Properties
Properties associated with the added time stamp.

Caller [Collection]

Specifies the security token, signed part or encrypted part used for authentication. If a signed or encrypted part is used, the value of the part attribute must be the name of a defined required integrity or required confidentiality constraint. If a stand-alone security token is used for authentication, then the URI and local name attributes must define the type of security token used for authentication.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name* -> [Request consumer] Caller.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Name The name of the caller.

Part Specifies the name of the required integrity or required confidentiality part within the message to be used for authentication.

URI Specifies the namespace URI of the security token to be used for authentication.

Local name
Specifies the local name of the security token to be used for authentication.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Caller [Collection]

Specifies the security token, signed part or encrypted part used for authentication. If a signed or encrypted part is used, the value of the part attribute must be the name of a defined required integrity or required confidentiality constraint. If a stand-alone security token is used for authentication, then the URI and local name attributes must define the type of security token used for authentication.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name* -> [Response consumer] Caller.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Name The name of the caller.

Part Specifies the name of the required integrity or required confidentiality part within the message to be used for authentication.

URI Specifies the namespace URI of the security token to be used for authentication.

Local name
Specifies the local name of the security token to be used for authentication.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Caller [Settings]

Specifies the security token, signed part or encrypted part used for authentication. If a signed or encrypted part is used, the value of the part attribute must be the name of a defined required integrity or required confidentiality constraint. If a stand-alone security token is used for authentication, then the URI and local name attributes must define the type of security token used for authentication.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name* -> [Request consumer] Caller -> *caller_name*.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Part:

Specifies the name of the required integrity or required confidentiality part within the message to be used for authentication.

Required No
Data type drop-down list

URI:

Specifies the namespace URI of the security token to be used for authentication.

If you specify a Username token or X.509 certificate security token, you do not have to specify a URI. If you specify a custom token, enter the URI of the `QName` for the value type. If you specify Lightweight Third Party Authentication (LTPA), enter the following WebSphere Application Server predefined value type URI: `http://www.ibm.com/websphere/appserver/tokentype/5.0.2`. If you specify Lightweight Third Party Authentication propagation (LTPA_PROPAGATION), enter the following WebSphere Application Server predefined value type URI: `http://www.ibm.com/websphere/appserver/tokentype`.

Required No
Data type String

Local name:

Specifies the local name of the security token to be used for authentication.

WebSphere Application Server has the following predefined **local name** value types:

Username token
`http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken`

X509 certificate token
`http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3`

 # X509 certificates in a PKIPath
`http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1`

A list of X509 certificates and CRLs in a PKCS#7
`http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7`

LTPA For Lightweight Third Party Authentication, the **local name** value type is LTPA.

LTPA_PROPAGATION
For Lightweight Third Party Authentication token propagation, the **local name** value type is LTPA_PROPAGATION.

Attention:

- If you enter LTPA in the **Local name** field, you must also specify the URI value http://www.ibm.com/websphere/appserver/tokentype/5.0.2 in the **URI** field.
- If you enter LTPA_PROPAGATION in the **Local name** field, you must also specify the URI value http://www.ibm.com/websphere/appserver/tokentype in the **URI** field.
- If you enter any of the other predefined local name value types, you can leave the **URI** field blank. For example, to specify “Username token”, enter http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken in the **Local name** field and do not enter a value in the **URI** field.
- If you specify a custom value type for a custom token, you must specify the local name and the URI of the Quality name (QName) of the value type. For example, you might enter Custom in the **Local name** field, and http://www.ibm.com/custom in the **URI** field.

Required	No
Data type	String

Additional Properties

Trust method
The trust method associated with this caller if IDAssertion is in use for verifying an asserted ID from an intermediary.

Properties
Properties associated with the caller.

Caller [Settings]

Specifies the security token, signed part or encrypted part used for authentication. If a signed or encrypted part is used, the value of the part attribute must be the name of a defined required integrity or required confidentiality constraint. If a stand-alone security token is used for authentication, then the URI and local name attributes must define the type of security token used for authentication.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name* -> [Response consumer] Caller > ***caller_name***.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the caller.

Required	Yes
Data type	String

Part:

Specifies the name of the required integrity or required confidentiality part within the message to be used for authentication.

Required	No
Data type	drop-down list

URI:

Specifies the namespace URI of the security token to be used for authentication.

Required	No
Data type	String

Local name:

Specifies the local name of the security token to be used for authentication.

Required	No
Data type	String

Additional Properties

Trust method
The trust method associated with this caller if IDAssertion is in use for verifying an asserted ID from an intermediary.

Properties
Properties associated with the caller.

Confidentiality [Collection]

Specifies the confidentiality constraints applied to generated messages. This includes specifying which message parts within the generated message must be encrypted, and the message parts to attach encrypted Nonce and time stamp elements to.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name* -> [Request generator] Confidentiality.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Name The name of the confidentiality constraint.

Order Specifies the processing order of this confidentiality element.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Confidentiality [Collection]

Specifies the confidentiality constraints applied to generated messages. This includes specifying which message parts within the generated message must be encrypted, and the message parts to attach encrypted Nonce and time stamp elements to.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name* -> [Response generator] Confidentiality.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Name The name of the confidentiality constraint.

Order Specifies the processing order of this confidentiality element.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Confidentiality [Settings]

Specifies the confidentiality constraints applied to generated messages. This includes specifying which message parts within the generated message must be encrypted, and the message parts to attach encrypted Nonce and time stamp elements to.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name* -> [Request generator] Confidentiality -> *confidentiality_name*.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the confidentiality constraint.

Required	Yes
Data type	String

Order:

Specifies the processing order of this confidentiality element.

Required	Yes
Data type	Integer
Range	0 through 9

Additional Properties

Message parts
Specifies parts of the message affected by this confidentiality constraint.

Nonce
Specifies the encrypted Nonce elements which must be inserted into the generated message, and what parts of the message they must be attached to. Nonce is a randomly generated value.

Time stamp
Specifies the encrypted time stamp elements which must be inserted in the generated message, and what parts of the message they must be attached to.

Confidentiality [Settings]

Specifies the confidentiality constraints applied to generated messages. This includes specifying which message parts within the generated message must be encrypted, and the message parts to attach encrypted Nonce and time stamp elements to.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name* -> [Response generator] Confidentiality -> *confidentiality_name*.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the confidentiality constraint.

Required	Yes
Data type	String

Order:

Specifies the processing order of this confidentiality element.

Required	Yes
Data type	Integer
Range	0 through 9

Additional Properties

Message parts
Specifies parts of the message affected by this confidentiality constraint.

Nonce
Specifies the encrypted Nonce elements which must be inserted into the generated message, and what parts of the message they must be attached to. Nonce is a randomly generated value.

Time stamp
Specifies the encrypted time stamp elements which must be inserted in the generated message, and what parts of the message they must be attached to.

Inbound WS-Security configuration [Settings]

WS-Security configuration for an inbound request. This defines WS-Security requirements for the request consumed from the client and the response generated. The objects created may be applied to one or more inbound ports.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name*.

You can configure the service integration bus for secure transmission of SOAP messages by using tokens, keys, signatures and encryption in accordance with the Web Services Security (WS-Security) 1.0 specification.

Alternatively, you can configure the bus in accordance with the previous WS-Security specification, WS-Security Draft 13 (also known as the Web Services Security Core Specification). However, use of the WS-Security Draft 13 specification is deprecated, and you should only use it to allow continued use of an existing web services client application that has been written to the WS-Security Draft 13 specification.

You use an inbound configuration to secure the SOAP messages that pass between a service requester (client) and an inbound service (which acts as a target web service). The configuration specifies the level of security that you require (for example “The body must be signed”). This level of security is then implemented through the run-time information contained in the following types of WS-Security binding:

For WS-Security Version 1.0:

- *request consumer*, for use when consuming requests from a client to an inbound service.
- *response generator*, for use when generating responses from an inbound service to a client.

For WS-Security Draft 13:
- *request receiver*, for use when receiving requests from a client to an inbound service.
- *response sender*, for use when sending responses from an inbound service to a client.

WS-Security configurations are administered independently from any web service that uses them, so you can create an inbound configuration then apply it to many inbound services.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

WS-Security version:

Identifies the version of the WS-Security specification this configuration uses.

Required	No
Data type	String

Service type:

The type of service the WS-Security configuration applies to.

Required	No
Data type	String

Name:

The name of the inbound WS-Security configuration.

This name must be unique across both WS-Security Version 1.0 and Draft 13 Inbound configurations, and it must obey the following syntax rules:
- It must not start with "." (a period).
- It must not start or end with a space.
- It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

Required	Yes
Data type	String

Actor URI:

WS-Security headers within the consumed request message will only be processed if they have the specified Actor URI.

Required	No
Data type	String

Request consumer

Required integrity
Specifies the integrity constraints consumed messages must meet. This includes specifying which message parts within the incoming message must be digitally signed, and the message parts to which attached digitally signed Nonce and time stamp elements are expected.

Required confidentiality
Specifies the confidentiality constraints consumed messages must meet. This includes specifying which message parts within the incoming message must be encrypted, and the message parts to which attached encrypted Nonce and time stamp elements are expected.

Required security token
Specifies accepted stand-alone security tokens within a consumed message. Stand-alone security tokens are those not already used for signature or encryption. Defining a required security token means that messages containing a token of that type will be processed according to the usage assertion. The security token will not be used for authentication unless it is also specified within a caller.

Caller
Specifies the security token, signed part or encrypted part used for authentication. If a signed or encrypted part is used, the value of the part attribute must be the name of a defined required integrity or required confidentiality constraint. If a stand-alone security token is used for authentication, then the URI and local name attributes must define the type of security token used for authentication.

Add time stamp
When add time stamp is specified for a consumer, a time stamp is added indicating when the message was consumed. For a generator, a time stamp is added indicating when the message was generated.

Properties
General properties for the inbound WS-Security configuration.

Response generator

Actor Defines the Actor URI to be included in WS-Security headers of generated response.

Integrity
Specifies the integrity constraints applied to generated messages. This includes specifying which message parts within the generated message must be digitally signed, and the message parts to attach digitally signed Nonce and time stamp elements to.

Confidentiality
Specifies the confidentiality constraints applied to generated messages. This includes specifying which message parts within the generated message must be encrypted, and the message parts to attach encrypted Nonce and time stamp elements to.

Security Token
Specifies stand-alone security tokens to insert into the generated message. Stand-alone security tokens are those not already used for signature or encryption. Standard and custom security tokens may be defined by URI and local name.

Add time stamp
When add time stamp is specified for a consumer, a time stamp is added indicating when the message was consumed. For a generator, a time stamp is added indicating when the message was generated.

Properties
General properties for the inbound WS-Security configuration.

Integrity [Collection]

Specifies the integrity constraints applied to generated messages. This includes specifying which message parts within the generated message must be digitally signed, and the message parts to attach digitally signed Nonce and time stamp elements to.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name* -> [Request generator] Integrity.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Name The name of the integrity constraint.

Order Specifies the processing order of this integrity constraint.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Integrity [Collection]

Specifies the integrity constraints applied to generated messages. This includes specifying which message parts within the generated message must be digitally signed, and the message parts to attach digitally signed Nonce and time stamp elements to.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name* -> [Response generator] Integrity.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Name The name of the integrity constraint.

Order Specifies the processing order of this integrity constraint.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Integrity [Settings]

Specifies the integrity constraints applied to generated messages. This includes specifying which message parts within the generated message must be digitally signed, and the message parts to attach digitally signed Nonce and time stamp elements to.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name* -> [Request generator] Integrity -> *integrity_name*.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the integrity constraint.

Required	Yes
Data type	String

Order:

Specifies the processing order of this integrity constraint.

Required	Yes
Data type	Integer
Range	0 through 9

Additional Properties

Message parts
Specifies parts of the message affected by this integrity constraint.

Nonce
Specifies the digitally signed Nonce elements which must be inserted into the generated message, and what parts of the message they must be attached to. Nonce is a randomly generated value.

Time stamp
Specifies the digitally signed time stamp elements which must be inserted in the generated message, and what parts of the message they must be attached to.

Integrity [Settings]

Specifies the integrity constraints applied to generated messages. This includes specifying which message parts within the generated message must be digitally signed, and the message parts to attach digitally signed Nonce and time stamp elements to.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name* -> [Response generator] Integrity -> *integrity_name*.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the integrity constraint.

Required	Yes
Data type	String

Order:

Specifies the processing order of this integrity constraint.

Required	Yes
Data type	Integer
Range	0 through 9

Additional Properties

Message parts
Specifies parts of the message affected by this integrity constraint.

Nonce
Specifies the digitally signed Nonce elements which must be inserted into the generated message, and what parts of the message they must be attached to. Nonce is a randomly generated value.

Time stamp
Specifies the digitally signed time stamp elements which must be inserted in the generated message, and what parts of the message they must be attached to.

Message parts [Collection]

Identifies a specific message part according to the specified dialect and keyword.

To view this page in the console, click one of the following paths:

- **Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name* -> [Request consumer] Required integrity -> *required-integrity_name* -> [Additional Properties] Message parts**
- **Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name* -> [Response consumer] Required integrity -> *integrity_name* -> [Additional Properties] Message parts**
- **Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name* -> [Request consumer] Required Confidentiality -> *required-confidentiality_name* -> [Additional Properties] Message parts**

- **Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name* -> [Response consumer] Required Confidentiality -> *confidentiality_name* -> [Additional Properties] Message parts**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Name The name of the message part definition.

Dialect
The expression dialect to use.

Keyword
Identifies the message part in a way defined by the chosen dialect.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Message Parts [Settings]

Identifies a specific message part according to the specified dialect and keyword.

To view this page in the console, click one of the following paths:

- **Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name* -> [Request consumer] Required integrity -> *required-integrity_name* -> [Additional Properties] Message parts -> *message_part_name***
- **Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name* -> [Response consumer] Required integrity -> *integrity_name* -> [Additional Properties] Message parts -> *message_part_name***
- **Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name* -> [Request consumer] Required Confidentiality -> *required-confidentiality_name* -> [Additional Properties] Message parts -> *message_part_name***
- **Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name* -> [Response consumer] Required Confidentiality -> *confidentiality_name* -> [Additional Properties] Message parts -> *message_part_name***

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the message part definition.

Required Yes

Data type String

Dialect:

The expression dialect to use.

Required Yes
Data type drop-down list

Keyword:

Identifies the message part in a way defined by the chosen dialect.

When the `http://www.ibm.com/websphere/webservices/wssecurity/dialect-was` dialect value is selected, the following are valid keyword values:

Required Integrity

action Specifies the wsa:Action element.

body Specifies the SOAP body element.

dsigkey
Specifies the key information element, which is used for digital signature.

enckey
Specifies the ds:KeyInfo element, which is used for encryption.

messageid
Specifies the wsa:MessageID element.

relatesto
Specifies the wsa:RelatesTo element.

securitytoken
Specifies any security token elements, for example the wsse:BinarySecurityToken element.

timestamp
Specifies the wsu:Timestamp element. This element determines whether the message is valid based upon the time that the message is sent and then received.

to Specifies the wsa:To element.

wsaall Specifies all of the WS-Addressing elements in the SOAP header.

wsafaultto
Specifies the `wsa:FaultTo` WS-Addressing element in the SOAP header.

wsafrom
Specifies the `wsa:From` WS-Addressing element in the SOAP header.

wsareplyto
Specifies the `wsa:ReplyTo` WS-Addressing element in the SOAP header.

wscontext
Specifies the WS-Context header for the SOAP header. For more information, see Propagating work area context over Web services.

Required Confidentiality

bodycontent
Specifies the SOAP body

digestvalue
Specifies the ds:DigestValue element within the ds:Signature element

signature
Specifies an entire signature. You can encrypt the signature element, ds:Signature, by selecting this message part.

Note: If the value of a ds:DigestValue element in a signature needs to be encrypted, the entire parent ds:Signature element must be encrypted. You can use the signature keyword to perform the encryption.

usernametoken
Specifies the wsse:UsernameToken element

When the http://www.w3.org/TR/1999/REC-xpath-1999116 dialect value is selected, then the keyword value can be any valid XPath expression that points to a part of the message. For example:

```
/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/' and local-name()='Envelope']
/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/' and local-name()='Body']
```

Note: Do not use this transform algorithm if you want your configured application to be compliant with the Basic Security Profile (BSP). Instead use http://www.w3.org/2002/06/xmldsig-filter2 to ensure compliance.

Required	Yes
Data type	String

Nonce [Collection]

Attaches a Nonce element to the message part specified by the dialect and keyword attributes. Nonce is a randomly generated value.

To view this page in the console, click one of the following paths:

- **Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name* -> [Request consumer] Required integrity -> *required-integrity_name* -> [Additional Properties] Nonce**
- **Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name* -> [Response consumer] Required integrity -> *integrity_name* -> [Additional Properties] Nonce**
- **Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name* -> [Request consumer] Required Confidentiality -> *required-confidentiality_name* -> [Additional Properties] Nonce**
- **Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name* -> [Response consumer] Required Confidentiality -> *confidentiality_name* -> [Additional Properties] Nonce**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Name The name of the Nonce element.

Dialect
The expression dialect to use.

Keyword
The message part to attach the Nonce element to, specified in a way defined by the chosen dialect.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Nonce [Settings]

Attaches a Nonce element to the message part specified by the dialect and keyword attributes. Nonce is a randomly generated value.

To view this page in the console, click one of the following paths:

- **Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name* -> [Request consumer] Required integrity -> *required-integrity_name* -> [Additional Properties] Nonce -> *nonce_name***
- **Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name* -> [Response consumer] Required integrity -> *integrity_name* -> [Additional Properties] Nonce -> *nonce_name***
- **Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name* -> [Request consumer] Required Confidentiality -> *required-confidentiality_name* -> [Additional Properties] Nonce -> *nonce_name***
- **Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name* -> [Response consumer] Required Confidentiality -> *confidentiality_name* -> [Additional Properties] Nonce -> *nonce_name***

When a Nonce is added to the specific parts of a message, it might prevent theft and replay attacks because a generated Nonce is unique. For example, without a Nonce, when a user name token is passed from one machine to another machine by using a non-secure transport, such as HTTP, the token might be intercepted and used in a replay attack. The user name token can be stolen even if you use XML digital signature and XML encryption. However, it might be prevented by adding a Nonce.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the Nonce element.

Required Yes
Data type String

Dialect:

The expression dialect to use.

Required Yes

Data type drop-down list

Keyword:

The message part to attach the Nonce element to, specified in a way defined by the chosen dialect.

When the `http://www.ibm.com/websphere/webservices/wssecurity/dialect-was` dialect value is selected, the following are valid keyword values:

action Specifies the wsa:Action element.

body Specifies the SOAP body element.

dsigkey
Specifies the key information element, which is used for digital signature.

enckey
Specifies the ds:KeyInfo element, which is used for encryption.

messageid
Specifies the wsa:MessageID element.

relatesto
Specifies the wsa:RelatesTo element.

securitytoken
Specifies any security token elements, for example the wsse:BinarySecurityToken element.

timestamp
Specifies the wsu:Timestamp element. This element determines whether the message is valid based upon the time that the message is sent and then received.

to Specifies the wsa:To element.

When the `http://www.w3.org/TR/1999/REC-xpath-1999116` dialect value is selected, then the keyword value can be any valid XPath expression that points to a part of the message. For example:

```
/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/' and local-name()='Envelope']
/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/' and local-name()='Body']
```

Required Yes
Data type String

Outbound WS-Security configuration [Settings]

WS-Security configuration for an outbound request. This defines WS-Security requirements for the request generated and response consumed from the target. The objects created may be applied to one or more outbound ports.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name*.

You can configure the service integration bus for secure transmission of SOAP messages by using tokens, keys, signatures and encryption in accordance with the Web Services Security (WS-Security) 1.0 specification.

Alternatively, you can configure the bus in accordance with the previous WS-Security specification, WS-Security Draft 13 (also known as the Web Services Security Core Specification). However, use of the

WS-Security Draft 13 specification is deprecated, and you should only use it to allow continued use of an existing web services client application that has been written to the WS-Security Draft 13 specification.

You use an outbound configuration to secure the SOAP messages that pass between an outbound service (which acts as a client) and a target web service. The configuration specifies the level of security that you require (for example “The body must be signed”). This level of security is then implemented through the run-time information contained in the following types of WS-Security binding:

For WS-Security Version 1.0:

- *request generator*, for use when generating requests from an outbound service to a target web service.
- *response consumer*, for use when consuming responses from a target web service to an outbound service.

For WS-Security Draft 13:

- *request sender*, for use when sending requests from an outbound service to a target web service.
- *response receiver*, for use when receiving responses from a target web service to an outbound service.

WS-Security configurations are administered independently from any web service that uses them, so you can create an outbound configuration then apply it to many outbound services.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

WS-Security version:

Identifies the version of the WS-Security specification this configuration uses.

Required	No
Data type	String

Service type:

The type of service the WS-Security configuration applies to.

Required	No
Data type	String

Name:

The name of the outbound WS-Security configuration.

This name must be unique across both WS-Security Version 1.0 and Draft 13 Inbound configurations, and it must obey the following syntax rules:

- It must not start with “.” (a period).
- It must not start or end with a space.
- It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

Required	Yes
Data type	String

Actor URI:

WS-Security headers within the consumed response message will only be processed if they have the specified actor URI.

Required	No
Data type	String

Request generator

Actor Defines the Actor URI to be included in the WS-Security headers of a generated message.

Integrity
Specifies the integrity constraints applied to generated messages. This includes specifying which message parts within the generated message must be digitally signed, and the message parts to attach digitally signed Nonce and time stamp elements to.

Confidentiality
Specifies the confidentiality constraints applied to generated messages. This includes specifying which message parts within the generated message must be encrypted, and the message parts to attach encrypted Nonce and time stamp elements to.

Security Token
Specifies stand-alone security tokens to insert into the generated message. Stand-alone security tokens are those not already used for signature or encryption. Standard and custom security tokens may be defined by URI and local name.

Add time stamp
When add time stamp is specified for a consumer, a time stamp is added indicating when the message was consumed. For a generator, a time stamp is added indicating when the message was generated.

Properties
General properties for the outbound WS-Security configuration.

Response consumer

Required integrity
Specifies the integrity constraints consumed messages must meet. This includes specifying which message parts within the incoming message must be digitally signed, and the message parts to which attached digitally signed Nonce and time stamp elements are expected.

Required confidentiality
Specifies the confidentiality constraints consumed messages must meet. This includes specifying which message parts within the incoming message must be encrypted, and the message parts to which attached encrypted Nonce and time stamp elements are expected.

Required security token
Specifies accepted stand-alone security tokens within a consumed message. Stand-alone security tokens are those not already used for signature or encryption. Defining a required security token means that messages containing a token of that type will be processed according to the usage assertion. The security token will not be used for authentication unless it is also specified within a caller.

Caller
Specifies the security token, signed part or encrypted part used for authentication. If a signed or encrypted part is used, the value of the part attribute must be the name of a defined required integrity or required confidentiality constraint. If a stand-alone security token is used for authentication, then the URI and local name attributes must define the type of security token used for authentication.

Add time stamp
When add time stamp is specified for a consumer, a time stamp is added indicating when the message was consumed. For a generator, a time stamp is added indicating when the message was generated.

Properties
General properties for the outbound WS-Security configuration.

Property collection

Custom properties for the type of service integration resource. Type the name and value of any custom properties that you need.

To view this pane in the console, click one of several paths; for example **Service integration -> Web services -> WS-Security configurations -> *draft13-inbound-config_name* -> [Response sender] Properties**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Use of WS-Security Draft 13 is deprecated, and you should only use it to allow continued use of an existing web services client application that has been written to the WS-Security Draft 13 specification.

Name The name of the custom property.

Value The value of the custom property.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Property settings

Custom properties for the type of service integration resource. Type the name and value of any custom properties that you need.

To view this pane in the console, click one of several paths; for example **Service integration -> Web services -> WS-Security configurations -> *draft13-inbound-config_name* -> [Response sender] Properties -> [Additional Properties] Properties**.

Use of WS-Security Draft 13 is deprecated, and you should only use it to allow continued use of an existing web services client application that has been written to the WS-Security Draft 13 specification.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the custom property.

Required	Yes
Data type	String

Value:

The value of the custom property.

Required	Yes
Data type	String

Request consumer binding [Settings]

WS-Security binding for the consumption of inbound requests from the caller.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security bindings -> *request-consumer-binding_name*.

You can configure the service integration bus for secure transmission of SOAP messages by using tokens, keys, signatures and encryption in accordance with the Web Services Security (WS-Security) 1.0 specification.

You use WS-Security bindings to secure the SOAP messages that pass between service requesters (clients) and inbound services, and between outbound services and target web services. Bindings provide the information that the run-time environment needs to implement the WS-Security configuration (for example “To sign the body, use this key”).

Bindings are administered independently from any web service that uses them, so you can create a binding then apply it to many web services.

You use a *request consumer* with an inbound configuration. A *request consumer* binding consumes the requests from a client to an inbound service.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

WS-Security version:

Identifies the version of the WS-Security specification this configuration uses.

Required	No
Data type	String

Binding Type:

The type of binding. This is one of request consumer, request generator, response consumer and response generator.

Required	No
Data type	String

Name:

The name of the binding.

This name must be unique, and it must obey the following syntax rules:

- It must not start with "." (a period).
- It must not start or end with a space.
- It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

Required	Yes
Data type	String

Use defaults:

Specifies whether to use the default binding information. When this option is enabled, Web Services Security uses the default binding information instead of the custom binding information that is defined here.

Required	No
Data type	Boolean

Additional Properties

Signing information
Specifies the configuration for the signing parameters. You also can use these parameters for X.509 certificate validation when the authentication method is IDAssertion and the ID type is X509Certificate in the server-level configuration. In such cases, only fill in the Certificate path field.

Encryption information
Specifies the configuration for the XML encryption and decryption parameters. If the data and key encryption algorithms are specified, the application server only accepts elements that are encrypted with those algorithms.

Token consumers
Specifies the parameters for the token consumer. The information is used only on the consumer side to process the security token. Because you can plug in a custom token consumer, you must specify a Java class name.

Key information
Specifies the related configuration that is needed to generate the key for XML digital signature or XML encryption.

Key locators
Specifies a list of key locator configurations that retrieve the key for signature and encryption. You can customize a key locator class to retrieve keys from other types of repositories. The default implementation retrieves keys from a keystore.

Collection certificate store
Specifies a list of untrusted, intermediate certificate files. This collection certificate store is used for certificate path validation of incoming X.509-formatted security tokens. The root-trusted certificates are specified in the Trust anchors panel.

Trust anchors
Specifies a list of keystore configurations that contain root-trusted certificates. These configurations are used for certificate path validation of the incoming X.509-formatted security tokens. You must create the keystore using the key tool utility. Do not use the key management utility because it does not create a keystore with the expected format.

Properties
Specifies additional properties for the configuration.

Request generator binding. [Settings]

WS-Security binding for the generation of outbound request to a target.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security bindings -> *request-generator-binding_name*.

You can configure the service integration bus for secure transmission of SOAP messages by using tokens, keys, signatures and encryption in accordance with the Web Services Security (WS-Security) 1.0 specification.

You use WS-Security bindings to secure the SOAP messages that pass between service requesters (clients) and inbound services, and between outbound services and target web services. Bindings provide the information that the run-time environment needs to implement the WS-Security configuration (for example “To sign the body, use this key”),

Bindings are administered independently from any web service that uses them, so you can create a binding then apply it to many web services.

You use a *request generator* with an outbound configuration. A *request generator* binding generates the requests from an outbound service to a target web service.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

WS-Security version:

Identifies the version of the WS-Security specification this configuration uses.

Required	No
Data type	String

Binding Type:

The type of binding. This is one of request consumer, request generator, response consumer and response generator.

Required	No
Data type	String

Name:

The name of the binding.

This name must be unique, and it must obey the following syntax rules:

- It must not start with "." (a period).
- It must not start or end with a space.
- It must not contain any of the following characters: \ / , # $ @ : ; " * ? < > | = + & % '

Required	Yes
Data type	String

Use defaults:

Specifies whether to use the default binding information. When this option is enabled, Web Services Security uses the default binding information instead of the custom binding information that is defined here.

Required	No
Data type	Boolean

Web Services Security namespace:

Specifies the namespace that is used by Web Services Security to send a request. However, this field configures only the name space value and does not enforce the semantics of the specification that is related to the namespace. Web Services Security uses the processing semantic only in draft 13 of the OASIS specification.

Required	Yes
Data type	drop-down list

Additional Properties

Signing information
Specifies the configuration for the signing parameters. You also can use these parameters for X.509 certificate validation when the authentication method is IDAssertion and the ID type is X509Certificate in the server-level configuration. In such cases, only fill in the Certificate path field.

Encryption information
Specifies the configuration for the XML encryption and decryption parameters. If the data and key encryption algorithms are specified, the application server only accepts elements that are encrypted with those algorithms.

Token generators
Specifies the parameters for the token generator. The information is used only on the generator side to generate the security token. Because you can plug in a custom token generator, you must specify a Java class name.

Key information
Specifies the related configuration that is needed to generate the key for XML digital signature or XML encryption.

Key locators
Specifies a list of key locator configurations that retrieve the key for signature and encryption. You can customize a key locator class to retrieve keys from other types of repositories. The default implementation retrieves keys from a keystore.

Collection certificate store
Specifies a list of untrusted, intermediate certificate files. This collection certificate store is used for certificate path validation of incoming X.509-formatted security tokens. The root-trusted certificates are specified in the Trust anchors panel.

Properties
Specifies additional properties for the configuration.

Request receiver [Settings]

Draft 13 WS-Security binding for the consumption of inbound requests from the caller.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security bindings -> *request-receiver-binding_name*.

This panel is one of a set of panels that allow you to configure the service integration bus in accordance with WS-Security Draft 13 (also known as the Web Services Security Core Specification). However, use of the WS-Security Draft 13 specification is deprecated, and you should only use it to allow continued use of an existing web services client application that has been written to the WS-Security Draft 13 specification.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

WS-Security version:

Identifies the version of the WS-Security specification this configuration uses.

Required	No
Data type	String

Binding Type:

The type of binding. This is one of request consumer, request generator, response consumer and response generator.

Required	No
Data type	String

Name:

The name of the binding.

Required	Yes
Data type	String

Additional Properties

Signing information
Specifies the configuration for the signing parameters. You also can use these parameters for

X.509 certificate validation when the authentication method is IDAssertion and the ID type is X509Certificate in the server-level configuration. In such cases, only fill in the Certificate path field.

Encryption information
Specifies the configuration for the XML encryption and decryption parameters. If the data and key encryption algorithms are specified, the application server only accepts elements that are encrypted with those algorithms.

Trust anchors
Specifies a list of keystore configurations that contain root-trusted certificates. These configurations are used for certificate path validation of the incoming X.509-formatted security tokens. You must create the keystore using the key tool utility. Do not use the key management utility because it does not create a keystore with the expected format.

Collection certificate store
Specifies a list of untrusted, intermediate certificate files. This collection certificate store is used for certificate path validation of incoming X.509-formatted security tokens. The root-trusted certificates are specified in the Trust anchors panel.

Key locators
Specifies a list of key locator configurations that retrieve the key for signature and encryption. You can customize a key locator class to retrieve keys from other types of repositories. The default implementation retrieves keys from a keystore.

Trusted ID evaluators
Specifies a list of trusted identity (ID) evaluators that determine whether the identity-asserting authority is trusted. You can use trusted ID evaluators for backward compatibility with Version 5 applications. However, it is recommended that you use a login module instead.

Login mappings
Specifies a list of configurations for validating security tokens within incoming messages.

Request sender [Settings]

Draft 13 WS-Security binding for the generation of requests to an outbound target.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security bindings -> *request-sender-binding_name*.

This panel is one of a set of panels that allow you to configure the service integration bus in accordance with WS-Security Draft 13 (also known as the Web Services Security Core Specification). However, use of the WS-Security Draft 13 specification is deprecated, and you should only use it to allow continued use of an existing web services client application that has been written to the WS-Security Draft 13 specification.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

WS-Security version:

Identifies the version of the WS-Security specification this configuration uses.

Required	No
Data type	String

Binding Type:

The type of binding. This is one of request consumer, request generator, response consumer and response generator.

Required	No
Data type	String

Name:

The name of the binding.

Required	Yes
Data type	String

Additional Properties

Signing information
Specifies the configuration for the signing parameters. You also can use these parameters for X.509 certificate validation when the authentication method is IDAssertion and the ID type is X509Certificate in the server-level configuration. In such cases, only fill in the Certificate path field.

Encryption information
Specifies the configuration for the XML encryption and decryption parameters. If the data and key encryption algorithms are specified, the application server only accepts elements that are encrypted with those algorithms.

Key locators
Specifies a list of key locator configurations that retrieve the key for signature and encryption. You can customize a key locator class to retrieve keys from other types of repositories. The default implementation retrieves keys from a keystore.

Login binding
Specifies the configuration that is used for sending the security tokens within the messages.

Required confidentiality [Collection]

Specifies the confidentiality constraints consumed messages must meet. This includes specifying which message parts within the incoming message must be encrypted, and the message parts to which attached encrypted Nonce and time stamp elements are expected.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name* -> [Request consumer] Required Confidentiality.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Name The name of the required confidentiality element.

Usage Indicates the assertion of the required confidentiality constraint.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Required confidentiality [Collection]

Specifies the confidentiality constraints consumed messages must meet. This includes specifying which message parts within the incoming message must be encrypted, and the message parts to which attached encrypted Nonce and time stamp elements are expected.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name* -> [Response consumer] Required Confidentiality.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Name The name of the required confidentiality element.

Usage Indicates the assertion of the required confidentiality constraint.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Required confidentiality [Settings]

Specifies the confidentiality constraints consumed messages must meet. This includes specifying which message parts within the incoming message must be encrypted, and the message parts to which attached encrypted Nonce and time stamp elements are expected.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name* -> [Request consumer] Required Confidentiality -> *required-confidentiality_name*.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the required confidentiality element.

Required Yes
Data type String

Usage:

Indicates the assertion of the required confidentiality constraint.

Required Yes
Data type drop-down list
Range

Optional
Both messages that meet or do not meet the required integrity constraint are accepted.

Required
The required integrity constraint must be met by the incoming message.

Additional Properties

Message parts
Specifies parts of the message affected by this required confidentiality constraint.

Nonce
Specifies the encrypted Nonce elements which must be present in the consumed message, and what parts of the message they must be attached to. Nonce is a randomly generated value.

Time stamp
Specifies the encrypted time stamp elements which must be present in the consumed message, and what parts of the message they must be attached to.

Required confidentiality [Settings]

Specifies the confidentiality constraints consumed messages must meet. This includes specifying which message parts within the incoming message must be encrypted, and the message parts to which attached encrypted Nonce and time stamp elements are expected.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name* -> [Response consumer] Required Confidentiality -> *confidentiality_name*.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the required confidentiality element.

Required Yes
Data type String

Usage:

Indicates the assertion of the required confidentiality constraint.

Required Yes
Data type drop-down list
Range

Optional
Both messages that meet or do not meet the required integrity constraint are accepted.

Required
The required integrity constraint must be met by the incoming message.

Additional Properties

Message parts
Specifies parts of the message affected by this required confidentiality constraint.

Nonce
Specifies the encrypted Nonce elements which must be present in the consumed message, and what parts of the message they must be attached to. Nonce is a randomly generated value.

Time stamp
Specifies the encrypted time stamp elements which must be present in the consumed message, and what parts of the message they must be attached to.

Required integrity [Collection]

Specifies the integrity constraints consumed messages must meet. This includes specifying which message parts within the incoming message must be digitally signed, and the message parts to which attached digitally signed Nonce and time stamp elements are expected.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name* -> [Request consumer] Required integrity.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Name The name of the required integrity element.

Usage Indicates the assertion of the required integrity constraint.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Required integrity [Collection]

Specifies the integrity constraints consumed messages must meet. This includes specifying which message parts within the incoming message must be digitally signed, and the message parts to which attached digitally signed Nonce and time stamp elements are expected.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name* -> [Response consumer] Required integrity.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Name The name of the required integrity element.

Message parts
Specifies parts of the message affected by this required integrity constraint.

Nonce
Specifies the digitally signed Nonce elements which must be present in the consumed message, and what parts of the message they must be attached to. Nonce is a randomly generated value.

Time stamp
Specifies the digitally signed time stamp elements which must be present in the consumed message, and what parts of the message they must be attached to.

Required security token [Collection]

Specifies accepted stand-alone security tokens within a consumed message. Stand-alone security tokens are those not already used for signature or encryption. Defining a required security token means that messages containing a token of that type will be processed according to the usage assertion. The security token will not be used for authentication unless it is also specified within a caller.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name* -> [Request consumer] Required Security Token.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Name The name of the security token.

Usage Indicates the assertion of the required security token constraint.

URI Specifies the namespace URI of the security token.

Local name
Specifies the local name of the security token.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Required security token [Collection]

Specifies accepted stand-alone security tokens within a consumed message. Stand-alone security tokens are those not already used for signature or encryption. Defining a required security token means that messages containing a token of that type will be processed according to the usage assertion. The security token will not be used for authentication unless it is also specified within a caller.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name* -> [Response consumer] Required Security Token.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Name The name of the security token.

Usage Indicates the assertion of the required security token constraint.

URI Specifies the namespace URI of the security token.

Local name
Specifies the local name of the security token.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Required security token [Settings]

Specifies accepted stand-alone security tokens within a consumed message. Stand-alone security tokens are those not already used for signature or encryption. Defining a required security token means that messages containing a token of that type will be processed according to the usage assertion. The security token will not be used for authentication unless it is also specified within a caller.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name* -> [Request consumer] Required Security Token -> *required-security-token_name*.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the security token.

Required	Yes
Data type	String

URI:

Specifies the namespace URI of the security token.

This is the namespace Uniform Resource Identifier (URI) of the security token within the consumed message.

If you specify a Username token or X.509 certificate security token, you do not have to specify a URI. If you specify a custom token, enter the URI of the `QName` for the value type. If you specify Lightweight Third Party Authentication (LTPA), enter the following WebSphere Application Server predefined value type URI: `http://www.ibm.com/websphere/appserver/tokentype/5.0.2`. If you specify Lightweight Third Party Authentication propagation (LTPA_PROPAGATION), enter the following WebSphere Application Server predefined value type URI: `http://www.ibm.com/websphere/appserver/tokentype`.

Required	No
Data type	String

Local name:

Specifies the local name of the security token.

WebSphere Application Server has the following predefined **local name** value types:

Username token
`http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken`

X509 certificate token
`http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3`

 # X509 certificates in a PKIPath
`http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1`

A list of X509 certificates and CRLs in a PKCS#7
`http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7`

LTPA For Lightweight Third Party Authentication, the **local name** value type is LTPA.

LTPA_PROPAGATION
For Lightweight Third Party Authentication token propagation, the **local name** value type is LTPA_PROPAGATION.

Attention:

- If you enter LTPA in the **Local name** field, you must also specify the URI value http://www.ibm.com/websphere/appserver/tokentype/5.0.2 in the **URI** field.
- If you enter LTPA_PROPAGATION in the **Local name** field, you must also specify the URI value http://www.ibm.com/websphere/appserver/tokentype in the **URI** field.
- If you enter any of the other predefined local name value types, you can leave the **URI** field blank. For example, to specify “Username token”, enter http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken in the **Local name** field and do not enter a value in the **URI** field.

- If you specify a custom value type for a custom token, you must specify the local name and the URI of the Quality name (QName) of the value type. For example, you might enter Custom in the **Local name** field, and http://www.ibm.com/custom in the **URI** field.

Required Yes
Data type String

Usage:

Indicates the assertion of the required security token constraint.

Required Yes
Data type drop-down list
Range

Optional
Both messages that meet or do not meet the required integrity constraint are accepted.

Required
The required integrity constraint must be met by the incoming message.

Required security token [Settings]

Specifies accepted stand-alone security tokens within a consumed message. Stand-alone security tokens are those not already used for signature or encryption. Defining a required security token means that messages containing a token of that type will be processed according to the usage assertion. The security token will not be used for authentication unless it is also specified within a caller.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name* -> [Response consumer] Required Security Token -> *security-token_name*.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the security token.

Required Yes
Data type String

URI:

Specifies the namespace URI of the security token.

Required No
Data type String

Local name:

Specifies the local name of the security token.

Required Yes
Data type String

Usage:

Indicates the assertion of the required security token constraint.

Required Yes
Data type drop-down list
Range

Optional
Both messages that meet or do not meet the required integrity constraint are accepted.

Required
The required integrity constraint must be met by the incoming message.

Response consumer binding [Settings]

WS-Security binding for consumption of responses from outbound target.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security bindings -> *response-consumer-binding_name*.

You can configure the service integration bus for secure transmission of SOAP messages by using tokens, keys, signatures and encryption in accordance with the Web Services Security (WS-Security) 1.0 specification.

You use WS-Security bindings to secure the SOAP messages that pass between service requesters (clients) and inbound services, and between outbound services and target web services. Bindings provide the information that the run-time environment needs to implement the WS-Security configuration (for example “To sign the body, use this key”),

Bindings are administered independently from any web service that uses them, so you can create a binding then apply it to many web services.

You use a *response consumer* with an outbound configuration. A *response consumer* binding consumes the responses from a target web service to an outbound service.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

WS-Security version:

Identifies the version of the WS-Security specification this configuration uses.

Required	No
Data type	String

Binding Type:

The type of binding. This is one of request consumer, request generator, response consumer and response generator.

Required	No
Data type	String

Name:

The name of the binding.

This name must be unique, and it must obey the following syntax rules:

- It must not start with "." (a period).
- It must not start or end with a space.
- It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

Required	Yes
Data type	String

Use defaults:

Specifies whether to use the default binding information. When this option is enabled, Web Services Security uses the default binding information instead of the custom binding information that is defined here.

Required	No
Data type	Boolean

Additional Properties

Signing information
Specifies the configuration for the signing parameters. You also can use these parameters for X.509 certificate validation when the authentication method is IDAssertion and the ID type is X509Certificate in the server-level configuration. In such cases, only fill in the Certificate path field.

Encryption information
Specifies the configuration for the XML encryption and decryption parameters. If the data and key encryption algorithms are specified, the application server only accepts elements that are encrypted with those algorithms.

Token consumers
Specifies the parameters for the token consumer. The information is used only on the consumer side to process the security token. Because you can plug in a custom token consumer, you must specify a Java class name.

Key information
Specifies the related configuration that is needed to generate the key for XML digital signature or XML encryption.

Key locators
Specifies a list of key locator configurations that retrieve the key for signature and encryption. You can customize a key locator class to retrieve keys from other types of repositories. The default implementation retrieves keys from a keystore.

Collection certificate store
Specifies a list of untrusted, intermediate certificate files. This collection certificate store is used for certificate path validation of incoming X.509-formatted security tokens. The root-trusted certificates are specified in the Trust anchors panel.

Trust anchors
Specifies a list of keystore configurations that contain root-trusted certificates. These configurations are used for certificate path validation of the incoming X.509-formatted security tokens. You must create the keystore using the key tool utility. Do not use the key management utility because it does not create a keystore with the expected format.

Properties
Specifies additional properties for the configuration.

Response generator binding configuration [Settings]

WS-Security binding for generation of responses to caller.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security bindings -> *response-generator-binding_name*.

You can configure the service integration bus for secure transmission of SOAP messages by using tokens, keys, signatures and encryption in accordance with the Web Services Security (WS-Security) 1.0 specification.

You use WS-Security bindings to secure the SOAP messages that pass between service requesters (clients) and inbound services, and between outbound services and target web services. Bindings provide the information that the run-time environment needs to implement the WS-Security configuration (for example “To sign the body, use this key”),

Bindings are administered independently from any web service that uses them, so you can create a binding then apply it to many web services.

You use a *response generator* with an inbound configuration. A *response generator* binding generates the responses from an inbound service to a client.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

WS-Security version:

Identifies the version of the WS-Security specification this configuration uses.

Required No

Data type String

Binding Type:

The type of binding. This is one of request consumer, request generator, response consumer and response generator.

Required No
Data type String

Name:

The name of the binding.

This name must be unique, and it must obey the following syntax rules:

- It must not start with "." (a period).
- It must not start or end with a space.
- It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

Additional Properties

Signing information
Specifies the configuration for the signing parameters. You also can use these parameters for X.509 certificate validation when the authentication method is IDAssertion and the ID type is X509Certificate in the server-level configuration. In such cases, only fill in the Certificate path field.

Encryption information
Specifies the configuration for the XML encryption and decryption parameters. If the data and key encryption algorithms are specified, the application server only accepts elements that are encrypted with those algorithms.

Token generators
Specifies the parameters for the token generator. The information is used only on the generator side to generate the security token. Because you can plug in a custom token generator, you must specify a Java class name.

Key information
Specifies the related configuration that is needed to generate the key for XML digital signature or XML encryption.

Key locators
Specifies a list of key locator configurations that retrieve the key for signature and encryption. You can customize a key locator class to retrieve keys from other types of repositories. The default implementation retrieves keys from a keystore.

Collection certificate store
Specifies a list of untrusted, intermediate certificate files. This collection certificate store is used for certificate path validation of incoming X.509-formatted security tokens. The root-trusted certificates are specified in the Trust anchors panel.

Properties
Specifies additional properties for the configuration.

Response receiver [Settings]

Draft 13 WS-Security binding for consumption of responses from a target.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security bindings -> *response-receiver-binding_name*.

This panel is one of a set of panels that allow you to configure the service integration bus in accordance with WS-Security Draft 13 (also known as the Web Services Security Core Specification). However, use of the WS-Security Draft 13 specification is deprecated, and you should only use it to allow continued use of an existing web services client application that has been written to the WS-Security Draft 13 specification.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

WS-Security version:

Identifies the version of the WS-Security specification this configuration uses.

Required	No
Data type	String

Binding Type:

The type of binding. This is one of request consumer, request generator, response consumer and response generator.

Required	No
Data type	String

Name:

The name of the binding.

Required	Yes
Data type	String

Additional Properties

Signing information
Specifies the configuration for the signing parameters. You also can use these parameters for X.509 certificate validation when the authentication method is IDAssertion and the ID type is X509Certificate in the server-level configuration. In such cases, only fill in the Certificate path field.

Encryption information
Specifies the configuration for the XML encryption and decryption parameters. If the data and key encryption algorithms are specified, the application server only accepts elements that are encrypted with those algorithms.

Trust anchors
Specifies a list of keystore configurations that contain root-trusted certificates. These configurations are used for certificate path validation of the incoming X.509-formatted security tokens. You must create the keystore using the key tool utility. Do not use the key management utility because it does not create a keystore with the expected format.

Collection certificate store
Specifies a list of untrusted, intermediate certificate files. This collection certificate store is used for certificate path validation of incoming X.509-formatted security tokens. The root-trusted certificates are specified in the Trust anchors panel.

Key locators
Specifies a list of key locator configurations that retrieve the key for signature and encryption. You can customize a key locator class to retrieve keys from other types of repositories. The default implementation retrieves keys from a keystore.

Response sender [Settings]

Draft 13 WS-Security binding for generation of responses to a caller.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security bindings -> *response-sender-binding_name*.

This panel is one of a set of panels that allow you to configure the service integration bus in accordance with WS-Security Draft 13 (also known as the Web Services Security Core Specification). However, use of the WS-Security Draft 13 specification is deprecated, and you should only use it to allow continued use of an existing web services client application that has been written to the WS-Security Draft 13 specification.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

WS-Security version:

Identifies the version of the WS-Security specification this configuration uses.

Required	No
Data type	String

Binding Type:

The type of binding. This is one of request consumer, request generator, response consumer and response generator.

Required	No
Data type	String

Name:

The name of the binding.

Required	Yes
Data type	String

Additional Properties

Signing information
Specifies the configuration for the signing parameters. You also can use these parameters for X.509 certificate validation when the authentication method is IDAssertion and the ID type is X509Certificate in the server-level configuration. In such cases, only fill in the Certificate path field.

Encryption information
Specifies the configuration for the XML encryption and decryption parameters. If the data and key encryption algorithms are specified, the application server only accepts elements that are encrypted with those algorithms.

Key locators
Specifies a list of key locator configurations that retrieve the key for signature and encryption. You can customize a key locator class to retrieve keys from other types of repositories. The default implementation retrieves keys from a keystore.

Security Token [Collection]

Specifies stand-alone security tokens to insert into the generated message. Stand-alone security tokens are those not already used for signature or encryption. Standard and custom security tokens may be defined by URI and local name.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name* -> [Request generator] Security Token.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Name The name of the security token

URI Specifies the namespace URI of the security token to insert.

Local Name
Specifies the local name of the security token to insert.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Security Token [Collection]

Specifies stand-alone security tokens to insert into the generated message. Stand-alone security tokens are those not already used for signature or encryption. Standard and custom security tokens may be defined by URI and local name.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name* -> [Response generator] Security Token.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Name The name of the security token

URI Specifies the namespace URI of the security token to insert.

Local Name
Specifies the local name of the security token to insert.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Security Token [Settings]

Specifies stand-alone security tokens to insert into the generated message. Stand-alone security tokens are those not already used for signature or encryption. Standard and custom security tokens may be defined by URI and local name.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name* -> [Request generator] Security Token -> *security-token_name*.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the security token

Required	Yes
Data type	String

URI:

Specifies the namespace URI of the security token to insert.

This is the namespace Uniform Resource Identifier (URI) of the security token to be inserted into the generated message.

If you specify a Username token or X.509 certificate security token, you do not have to specify a URI. If you specify a custom token, enter the URI of the `QName` for the value type. If you specify Lightweight Third Party Authentication (LTPA), enter the following WebSphere Application Server predefined value type URI: `http://www.ibm.com/websphere/appserver/tokentype/5.0.2`. If you specify Lightweight Third Party Authentication propagation (LTPA_PROPAGATION), enter the following WebSphere Application Server predefined value type URI: `http://www.ibm.com/websphere/appserver/tokentype`.

Required	No
Data type	String

Local Name:

Specifies the local name of the security token to insert.

WebSphere Application Server has the following predefined **local name** value types:

Username token
`http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken`

X509 certificate token
`http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3`

 # X509 certificates in a PKIPath
`http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1`

A list of X509 certificates and CRLs in a PKCS#7
`http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7`

LTPA For Lightweight Third Party Authentication, the **local name** value type is LTPA.

LTPA_PROPAGATION
For Lightweight Third Party Authentication token propagation, the **local name** value type is LTPA_PROPAGATION.

Attention:

- If you enter LTPA in the **Local name** field, you must also specify the URI value http://www.ibm.com/websphere/appserver/tokentype/5.0.2 in the **URI** field.
- If you enter LTPA_PROPAGATION in the **Local name** field, you must also specify the URI value http://www.ibm.com/websphere/appserver/tokentype in the **URI** field.

- If you enter any of the other predefined local name value types, you can leave the **URI** field blank. For example, to specify “Username token”, enter http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken in the **Local name** field and do not enter a value in the **URI** field.
- If you specify a custom value type for a custom token, you must specify the local name and the URI of the Quality name (QName) of the value type. For example, you might enter Custom in the **Local name** field, and http://www.ibm.com/custom in the **URI** field.

Required	Yes
Data type	String

Security Token [Settings]

Specifies stand-alone security tokens to insert into the generated message. Stand-alone security tokens are those not already used for signature or encryption. Standard and custom security tokens may be defined by URI and local name.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name* -> [Response generator] Security Token -> *security-token_name*.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the security token

Required	Yes
Data type	String

URI:

Specifies the namespace URI of the security token to insert.

Required	No
Data type	String

Local Name:

Specifies the local name of the security token to insert.

Required	Yes
Data type	String

Time stamp [Collection]

Attaches a time stamp element to the message part specified by the dialect and keyword attributes.

To view this page in the console, click one of the following paths:

- **Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name* -> [Request consumer] Required integrity -> *required-integrity_name* -> [Additional Properties] Timestamp**
- **Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name* -> [Response consumer] Required integrity -> *integrity_name* -> [Additional Properties] Timestamp**
- **Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name* -> [Request consumer] Required Confidentiality -> *required-confidentiality_name* -> [Additional Properties] Timestamp**
- **Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name* -> [Response consumer] Required Confidentiality -> *confidentiality_name* -> [Additional Properties] Timestamp**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Name The name of the time stamp element.

Dialect
The expression dialect to use.

Keyword
The message part to attach the time stamp element to, specified in a way defined by the chosen dialect.

Expires
The expiration time of the time stamp, defined as an xsd:Duration type.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Time stamp [Settings]

Attaches a time stamp element to the message part specified by the dialect and keyword attributes.

To view this page in the console, click one of the following paths:

- **Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name* -> [Request consumer] Required integrity -> *required-integrity_name* -> [Additional Properties] Timestamp -> *timestamp_name***
- **Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name* -> [Response consumer] Required integrity -> *integrity_name* -> [Additional Properties] Timestamp -> *timestamp_name***

- **Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name* -> [Request consumer] Required Confidentiality -> *required-confidentiality_name* -> [Additional Properties] Timestamp -> *timestamp_name***
- **Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name* -> [Response consumer] Required Confidentiality -> *confidentiality_name* -> [Additional Properties] Timestamp -> *timestamp_name***

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the time stamp element.

Required	Yes
Data type	String

Dialect:

The expression dialect to use.

Required	Yes
Data type	drop-down list

Keyword:

The message part to attach the time stamp element to, specified in a way defined by the chosen dialect.

When the `http://www.ibm.com/websphere/webservices/wssecurity/dialect-was` dialect value is selected, the following are valid keyword values:

action Specifies the wsa:Action element.

body Specifies the SOAP body element.

dsigkey
Specifies the key information element, which is used for digital signature.

enckey
Specifies the ds:KeyInfo element, which is used for encryption.

messageid
Specifies the wsa:MessageID element.

relatesto
Specifies the wsa:RelatesTo element.

securitytoken
Specifies any security token elements, for example the wsse:BinarySecurityToken element.

timestamp
Specifies the wsu:Timestamp element. This element determines whether the message is valid based upon the time that the message is sent and then received.

to Specifies the wsa:To element.

When the `http://www.w3.org/TR/1999/REC-xpath-1999116` dialect value is selected, then the keyword value can be any valid XPath expression that points to a part of the message. For example:

```
/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/' and local-name()='Envelope']
/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/' and local-name()='Body']
```

Required	Yes
Data type	String

Expires:

The expiration time of the time stamp, defined as an xsd:Duration type.

The expires value is defined as a type of xsd:Duration, and the format must match the following regular expression:

```
-?P([0-9]+Y)?([0-9]+M)?([0-9]+D)?(T([0-9]+H)?([0-9]+M)?([0-9]+(\\.[0-9]*)?S)?)
```

For example, to specify a timestamp expiration of three minutes, enter PT3M.

Required	Yes
Data type	String

Trust Method [Settings]

Defines a trust method used to validate the identity of a trusted intermediary asserting an ID on a downstream message. When a trust method is configured, the security token defined by the caller is expected to contain an identity to be asserted.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-inbound-config_name* -> [Request consumer] Caller -> *caller_name* -> [Additional Properties] Trust method.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Trust any:

If trust any is selected then all upstream intermediaries will be trusted by this consumer. This should only be selected if you are certain that all upstream intermediaries are trusted. Selecting trust any will automatically override all other attributes of this trust method.

If you do not select the **Trust any** check box, but you specify a value for any other field on this panel, then WS-Security identity assertion is enabled.

Required	No
Data type	Boolean

Name:

The name of the trust method.

There are two valid predefined names:

- `BasicAuth` (for basic authentication).
- `Signature`.

Required No
Data type String

Part:

Specifies the name of the required integrity or required confidentiality part within the message to be used to validate the intermediary.

Required No
Data type drop-down list

URI:

Specifies the URI of the security token to use to validate the intermediary.

If you specify `BasicAuth` or `Signature` as the trust method, you do not have to specify this option. If you specify a custom token, enter the URI of the `QName` for the value type.

Required No
Data type String

Local Name:

Specifies the local name of the security token to use to validate the intermediary.

If you enter a value in the **Local Name** field, you must define a trusted ID evaluator for the token consumer that is associated with this token.

WebSphere Application Server has the following predefined **local name** value types:

BasicAuth
`http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken`

Signature
`http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3`

Attention:

- If you enter one of the predefined **local name** value types, you can leave the **URI** field blank. For example, to specify “BasicAuth”, enter `http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken` in the **Local name** field and do not enter a value in the **URI** field.
- If you specify a custom value type for a custom token, you must specify the local name and the URI of the Quality name (QName) of the value type. For example, you might enter `Custom` in the **Local name** field, and `http://www.ibm.com/custom` in the **URI** field.

Required No
Data type String

Additional Properties

Properties
Properties associated with the trust method.

Trust Method [Settings]

Defines a trust method used to validate the identity of a trusted intermediary asserting an ID on a downstream message. When a trust method is configured, the security token defined by the caller is expected to contain an identity to be asserted.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations -> *v1-outbound-config_name* -> [Response consumer] Caller > ***caller_name*** **-> [Additional Properties] Trust method**.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Trust any:

If trust any is selected then all upstream intermediaries will be trusted by this consumer. This should only be selected if you are certain that all upstream intermediaries are trusted. Selecting trust any will automatically override all other attributes of this trust method.

Required	No
Data type	Boolean

Name:

The name of the trust method.

Required	Yes
Data type	String

Part:

Specifies the name of the required integrity or required confidentiality part within the message to be used to validate the intermediary.

Required	Yes
Data type	drop-down list

URI:

Specifies the URI of the security token to use to validate the intermediary.

Required	Yes
Data type	String

Local Name:

Specifies the local name of the security token to use to validate the intermediary.

Required	Yes
Data type	String

Additional Properties

Properties

Properties associated with the trust method.

WS-Security bindings [Collection]

WS-Security bindings for consumption and generation of requests and responses.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security bindings.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

You can configure the service integration bus for secure transmission of SOAP messages by using tokens, keys, signatures and encryption in accordance with the Web Services Security (WS-Security) 1.0 specification.

Alternatively, you can configure the bus in accordance with the previous WS-Security specification, WS-Security Draft 13 (also known as the Web Services Security Core Specification). However, use of the WS-Security Draft 13 specification is deprecated, and you should only use it to allow continued use of an existing web services client application that has been written to the WS-Security Draft 13 specification.

You use WS-Security bindings to secure the SOAP messages that pass between service requesters (clients) and inbound services, and between outbound services and target web services. Bindings provide the information that the run-time environment needs to implement the WS-Security configuration (for example “To sign the body, use this key”),

Bindings are administered independently from any web service that uses them, so you can create a binding then apply it to many web services. However, the security requirements for an inbound service (which acts as a target web service) are significantly different to those required for an outbound service (which acts as a client). Consequently, bindings are further divided into sub-types:

For WS-Security Version 1.0:

- *request consumer*, for use when consuming requests from a client to an inbound service.
- *request generator*, for use when generating requests from an outbound service to a target web service.
- *response consumer*, for use when consuming responses from a target web service to an outbound service.
- *response generator*, for use when generating responses from an inbound service to a client.

For WS-Security Draft 13:

- *request receiver*, for use when receiving requests from a client to an inbound service.
- *request sender*, for use when sending requests from an outbound service to a target web service.
- *response receiver*, for use when receiving responses from a target web service to an outbound service.
- *response sender*, for use when sending responses from an inbound service to a client.

Name The name of the WS-Security binding.

Binding Type
The type of binding. This is one of request consumer, request generator, response consumer and response generator.

Security version
Identifies the version of the WS-Security specification this configuration uses.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

WS-Security configurations [Collection]

WS-Security configurations for inbound and outbound services.

To view this page in the console, click the following path:

Service integration -> Web services -> WS-Security configurations.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

You can configure the service integration bus for secure transmission of SOAP messages by using tokens, keys, signatures and encryption in accordance with the Web Services Security (WS-Security) 1.0 specification.

Alternatively, you can configure the bus in accordance with the previous WS-Security specification, WS-Security Draft 13 (also known as the Web Services Security Core Specification). However, use of the WS-Security Draft 13 specification is deprecated, and you should only use it to allow continued use of an existing web services client application that has been written to the WS-Security Draft 13 specification.

You use WS-Security configurations to secure the SOAP messages that pass between service requesters (clients) and inbound services, and between outbound services and target Web services. Configurations specify the level of security that you require (for example “The body must be signed”). This level of security is then implemented through the run-time information contained in a WS-Security binding.

Configurations are administered independently from any web service that uses them, so you can create a configuration then apply it to many web services. However, the security requirements for an inbound service (which acts as a target web service) are significantly different to those required for an outbound service (which acts as a client). Consequently, configurations are further divided by service type (inbound or outbound).

Name The name of the WS-Security configuration.

Service type
The type of service the WS-Security configuration applies to.

Security version
Identifies the version of the WS-Security specification this configuration uses.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

SIBWebServices command group for the AdminTask object

Use command scripts to configure service integration bus-enabled web services.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Before and immediately after performing administrative commands that carry out publication to UDDI, save the configuration by using either the `AdminConfig.save()` command or an equivalent command from within the administrative console. This ensures consistency between what is published to UDDI and what is recorded in the service integration bus configuration as having been published to UDDI.

Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

Command-line help is provided for service integration bus commands:

- For a list of the available bus-enabled web services commands, plus a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('SIBWebServices')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

The following administrative commands are available in this command group.

- “createSIBWSOutboundService command” on page 2934
- “deleteSIBWSOutboundService command” on page 2935
- “addSIBWSOutboundPort command” on page 2936
- “removeSIBWSOutboundPort command” on page 2938
- “setDefaultSIBWSOutboundPort command” on page 2939
- “createSIBWSInboundService command” on page 2940
- “deleteSIBWSInboundService command” on page 2941
- “addSIBWSInboundPort command” on page 2943
- “removeSIBWSInboundPort command” on page 2944
- “refreshSIBWSOutboundServiceWSDL command” on page 2945
- “refreshSIBWSInboundServiceWSDL command” on page 2946

- “publishSIBWSInboundService command” on page 2947
- “unpublishSIBWSInboundService command” on page 2948
- “createSIBWSEndpointListener command” on page 2949
- “deleteSIBWSEndpointListener command” on page 2951
- “connectSIBWSEndpointListener command” on page 2952
- “disconnectSIBWSEndpointListener command” on page 2953

createSIBWSOutboundService command

Use the createSIBWSOutboundService command to create a new service integration bus-enabled web services outbound service configuration.

You can create a new outbound service configuration by using the wsadmin tool as described in this topic, or by using the administrative console as described in “Making an externally-hosted web service available internally” on page 2783.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available bus-enabled web services commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBWebServices')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command creates a new OutboundService object, that represents a protocol attachment to a service provider. When you run this command you must identify a single service element within a WSDL document.

Target object

ObjectName of the messaging bus within which the service is created.

If the WSDL is to be retrieved through a proxy, the server on which the command is running must have the system properties that identify the proxy server set correctly. If the proxy requires authentication, then the user ID and password can be set as parameters on the command.

After you have run this command, you use other commands to further configure the service. For example, to add an outbound port.

Required parameters

-name
The outbound service name.

-wsdlLocation
The location of the service provider WSDL file.

This is either a web address or the service-specific part of a UDDI service key. If you specify a UDDI reference, the WSDL location is assumed to be a UDDI service key.

Here is an example of a full UDDI service key:

```
uddi:blade108node01cell:blade108node01:server1:default:6e3d106e-5394-44e3-be17-aca728ac1791
```

The service-specific part of this key is the final part:

```
6e3d106e-5394-44e3-be17-aca728ac1791
```

Conditional parameters

-wsdlServiceName
The name of the service within the WSDL. Only required if the service provider WSDL contains more than one service, or the WSDL is located through a UDDI registry.

-wsdlServiceNamespace
The namespace of the service within the WSDL. Only required if the service provider WSDL contains more than one service, or the WSDL is located through a UDDI registry, or the service is not in the default namespace for the WSDL document.

Optional parameters

-uddiReference
If you specified a UDDI service key as the WSDL location, supply the UDDI reference for the target UDDI registry.

-destination
The name of the service destination.

Note: The command creates the service destination. If a destination with the specified or default name already exists, the command fails.

-userId
The user ID that you use to retrieve the WSDL.

-password
The password that you use to retrieve the WSDL.

Example

- Using Jython:

```
outService = AdminTask.createSIBWSOutboundService(bus, ["-name", "MyService",
 "-wsdlLocation", "http://myserver.com/MyService.wsdl"])
```

- Using Jacl:

```
set outService [$AdminTask createSIBWSOutboundService $bus {-name "MyService"
 -wsdlLocation "http://myserver.com/MyService.wsdl"}]
```

deleteSIBWSOutboundService command

Use the deleteSIBWSOutboundService command to delete a service integration bus-enabled web services outbound service configuration.

You can delete an outbound service configuration by using the wsadmin tool as described in this topic, or by using the administrative console as described in “Deleting outbound service configurations” on page 2788.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available bus-enabled web services commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBWebServices')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command deletes an OutboundService object, along with any associated OutboundPort objects.

Target object

ObjectName of the OutboundService object to be deleted.

The service and port destinations are deleted. Any messages on the service and port destinations are either deleted or sent to an exception destination as specified in the policy for the messaging bus.

Resources associated with the OutboundService and OutboundPorts (JAX-RPC handler lists, WS-Security configuration) are dissociated from the OutboundService and OutboundPorts, but are not themselves deleted.

Parameters

None.

Example

- Using Jython:

  ```
  AdminTask.deleteSIBWSOutboundService(outService)
  ```

- Using Jacl:

  ```
  $AdminTask deleteSIBWSOutboundService $outService
  ```

addSIBWSOutboundPort command

Use the addSIBWSOutboundPort command to add a service integration bus-enabled web services outbound port.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available bus-enabled web services commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBWebServices')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command adds the configuration for an OutboundPort to an OutboundService.

Target object

ObjectName of the OutboundService with which the port is to be associated.

If an OutboundPort for the OutboundService by the given name already exists, or the name of the port does not correspond to a port in the service element of the service provider WSDL (as defined on the OutboundService) the command fails.

The command creates the port destination. If a destination with the specified or default name already exists, the command fails.

If the WSDL is to be retrieved through a proxy server, the server on which the command is running must have the system properties that identify the proxy server set correctly. In addition, if the proxy server requires authentication, then the user ID and password can be set as parameters on the command.

If this is the first port for the OutboundService, then it is set as the default, and the service destination default routing is set to point to the port destination.

Required parameters

-name
The name of the port in the service provider WSDL.

Conditional parameters

-node
The node in which the port destination is localized.

-server
The server in which the port destination is localized.

Optional parameters

-destination
The name of the port destination.

-userId
The user ID that you use to retrieve the WSDL.

Note: This parameter is no longer required. If you have existing scripts that provide this parameter, they will continue to work.

-password
The password that you use to retrieve the WSDL.

Note: This parameter is no longer required. If you have existing scripts that provide this parameter, they will continue to work.

Example

- Using Jython:

```
outPort = AdminTask.addSIBWSOutboundPort(outService, ["-name", "MyServiceSoap",
 "-node", "MyNode", "-server", "server1"])
```

- Using Jacl:

```
set outPort [$AdminTask addSIBWSOutboundPort $outService {-name "MyServiceSoap"
 -node "MyNode" -server "server1"}]
```

removeSIBWSOutboundPort command

Use the removeSIBWSOutboundPort command to remove a service integration bus-enabled web services outbound port.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available bus-enabled web services commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBWebServices')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command removes the configuration for an OutboundPort.

Target object

ObjectName of the OutboundPort object that is to be removed.

The port destination is deleted. Any messages on the port destination are either deleted or sent to an exception destination as specified in the policy for the messaging bus.

If the port that is removed is the default for the OutboundService, then one of the remaining ports (if any) is chosen to be the default, and the default routing on the service destination is updated. If there are no more ports, the default is cleared from the OutboundService and the service destination.

Resources associated with the OutboundPort (JAX-RPC handler lists, WS-Security configuration) are dissociated from the OutboundPort, but not deleted.

Parameters

None.

Example

- Using Jython:

```
AdminTask.removeSIBWSOutboundPort(outPort)
```

- Using Jacl:

```
$AdminTask removeSIBWSOutboundPort $outPort
```

setDefaultSIBWSOutboundPort command

Use the setDefaultSIBWSOutboundPort command to set the default service integration bus-enabled web services outbound port.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available bus-enabled web services commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBWebServices')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command updates the default outbound port for an outbound service.

Target object

ObjectName of the OutboundService object whose default port is to be updated.

The default port is updated for the OutboundService, and the default routing on the service destination is updated to point at the port destination.

Required parameters

-name
The name of the port to be set as the default.

Conditional parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
AdminTask.setDefaultSIBWSOutboundPort(outService, ["-name", "MyServiceSoap"])
```

- Using Jacl:

```
$AdminTask setDefaultSIBWSOutboundPort $outService {-name "MyServiceSoap"}
```

createSIBWSInboundService command

Use the createSIBWSInboundService command to create a new service integration bus-enabled web services inbound service configuration.

You can create a new inbound service configuration by using the wsadmin tool as described in this topic, or by using the administrative console as described in “Making an internally-hosted service available as a web service” on page 2778.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available bus-enabled web services commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBWebServices')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command creates a new InboundService object that represents a protocol attachment to be used by service requesters. When you run this command you identify a single service element within a template WSDL document, and an existing service destination.

Target object

ObjectName of the service integration bus within which the service is created.

If the WSDL is to be retrieved through a proxy server, the server on which the command is running must have the system properties that identify the proxy server set correctly. If the proxy server requires authentication, then the user ID and password can be set as parameters on the command.

After you have run this command, you can use other commands to further configure the service. For example, you can add an inbound port.

Required parameters

-name
The inbound service name. This cannot be longer than 250 characters.

-destination
The name of the service destination. If the specified destination does not exist, the command fails.

-wsdlLocation
The location of the template WSDL file.

This is either a web address or the service-specific part of a UDDI service key. If you specify a UDDI reference, the WSDL location is assumed to be a UDDI service key.

Here is an example of a full UDDI service key:

```
uddi:blade108node01cell:blade108node01:server1:default:6e3d106e-5394-44e3-be17-aca728ac1791
```

The service-specific part of this key is the final part:

```
6e3d106e-5394-44e3-be17-aca728ac1791
```

Conditional parameters

-wsdlServiceName
The name of the service within the template WSDL. Only required if the template WSDL contains more than one service, or the WSDL is located through a UDDI registry

-wsdlServiceNamespace
The namespace of the service within the WSDL. Only required if the template WSDL contains more than one service, or the WSDL is located through a UDDI registry, or the service is not in the default namespace for the WSDL document.

Optional parameters

-uddiReference
If you specified a UDDI service key as the template WSDL location, supply the UDDI reference for the target UDDI registry.

-userId
The user ID that you use to retrieve the WSDL.

-password
The password that you use to retrieve the WSDL.

Example

- Using Jython:

```
inService = AdminTask.createSIBWSInboundService(bus, ["-name", "MyService",
 "-destination", "destName",
 "-wsdlLocation", "http://myserver.com/MyService.wsdl"] )
```

- Using Jacl:

```
set inService [$AdminTask createSIBWSInboundService $bus {-name "MyService"
 -destination $destName
 -wsdlLocation "http://myserver.com/MyService.wsdl"}]
```

deleteSIBWSInboundService command

Use the deleteSIBWSInboundService command to delete a service integration bus-enabled web services inbound service configuration.

You can delete an inbound service configuration by using the wsadmin tool as described in this topic, or by using the administrative console as described in “Deleting inbound services configurations” on page 2783.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available bus-enabled web services commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBWebServices')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command deletes an InboundService object, along with any associated InboundPort objects.

Target object

ObjectName of the InboundService object to be deleted.

Resources associated with the InboundService and its InboundPorts (JAX-RPC handler lists, WS-Security configuration) are dissociated from the InboundService and InboundPorts but are not themselves deleted.

The optional parameters user ID and password allow the unpublishing of WSDL from UDDI registries through an authenticating proxy server. This command fails if different UDDIPublication objects defined for the InboundService need different user IDs or passwords to get the appropriate access.

Required parameters

None.

Conditional parameters

None.

Optional parameters

-userId
The user ID that you use to interact with UDDI registries.

-password
The password that you use to interact with UDDI registries.

Example

- Using Jython:

  ```
  AdminTask.deleteSIBWSInboundService(inService)
  ```

- Using Jacl:

  ```
  $AdminTask deleteSIBWSInboundService $inService
  ```

addSIBWSInboundPort command

Use the addSIBWSInboundPort command to add a service integration bus-enabled web services inbound port.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available bus-enabled web services commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBWebServices')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command adds the configuration for an InboundPort to an InboundService.

If the port name is already in use by another InboundPort for the InboundService, or the specified endpoint listener does not exist, the command fails.

If the templatePort is specified but does not exist in the InboundService template WSDL, the command fails.

If there is no BusConnectionProperty for the InboundService bus, then one is created with the default reply destination name.

Target object

ObjectName of the InboundService to which the port is to be added.

Required parameters

-name
The name of the port.

-endpointListener
The name of the associated endpoint listener.

Conditional parameters

-node
The node in which the endpoint listener is located.

-server
The server in which the endpoint listener is located.

Optional parameters

-templatePort
The name of the port in the template WSDL to use as a basis for this port binding.

Example

- Using Jython:

```
inPort = AdminTask.addSIBWSInboundPort(inService, ["-name", "MyServiceSoap",
 "-endpointListener", "SOAPHTTP1", "-node", "MyNode", "-server", "server1"] )
```

- Using Jacl:

```
set inPort [$AdminTask addSIBWSInboundPort $inService {-name "MyServiceSoap"
 -endpointListener "SOAPHTTP1" -node "MyNode" -server "server1"}]
```

removeSIBWSInboundPort command

Use the removeSIBWSInboundPort command to remove a service integration bus-enabled web services inbound port.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available bus-enabled web services commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBWebServices')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command removes the configuration for an InboundPort.

Target object

ObjectName of the InboundPort object to be removed.

Resources associated with the InboundPort (JAX-RPC handler lists, WS-Security configuration) are dissociated from the InboundPort, but are not themselves deleted.

Parameters

None.

Example

- Using Jython:

```
AdminTask.removeSIBWSInboundPort(inPort)
```

- Using Jacl:

```
$AdminTask removeSIBWSInboundPort $inPort
```

refreshSIBWSOutboundServiceWSDL command

Use the refreshSIBWSOutboundServiceWSDL command to refresh a service integration bus-enabled web services outbound service WSDL file.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available bus-enabled web services commands, plus a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('SIBWebServices')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command loads the WSDL document from the OutboundService WSDLLocation parameters, and locates the WSDLLocation-specified service element.

Target object

ObjectName of the OutboundService object.

If the service element is not present, the command fails.

The OutboundPorts must be a subset of the ports in the loaded WSDL document, otherwise the command fails.

If the WSDL is to be retrieved through a proxy, the server on which the command is running must have the system properties that identify the proxy server set correctly. If the proxy requires authentication, then the user ID and password can be set as parameters on the command.

Required parameters

None.

Conditional parameters

None.

Optional parameters

-userId
The user ID that you use to retrieve the WSDL.

-password
The password that you use to retrieve the WSDL.

Example

- Using Jython:
  ```
  AdminTask.refreshSIBWSOutboundServiceWSDL(outService)
  ```
- Using Jacl:
  ```
  $AdminTask refreshSIBWSOutboundServiceWSDL $outService
  ```

refreshSIBWSInboundServiceWSDL command

Use the refreshSIBWSInboundServiceWSDL command to refresh a service integration bus-enabled web services inbound service WSDL file.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available bus-enabled web services commands, plus a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('SIBWebServices')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command loads the WSDL document from the InboundService WSDLLocation parameters, and locates the WSDLLocation-specified service element.

Target object

ObjectName of the InboundService object.

If the service element is not present, the command fails.

All templatePortName values in InboundPorts for the InboundService must correspond to ports in the loaded WSDL document, otherwise the command fails.

If the WSDL is to be retrieved through a proxy, the server on which the command is running must have the system properties that identify the proxy server set correctly. If the proxy requires authentication, then the user ID and password can be set as parameters on the command.

Required parameters

None.

Conditional parameters

None.

Optional parameters

-userId
The user ID that you use to retrieve the WSDL.

-password
The password that you use to retrieve the WSDL.

Example

- Using Jython:
  ```
  AdminTask.refreshSIBWSInboundServiceWSDL(inService)
  ```
- Using Jacl:
  ```
  $AdminTask refreshSIBWSInboundServiceWSDL $inService
  ```

publishSIBWSInboundService command

Use the publishSIBWSInboundService command to publish to UDDI a service integration bus-enabled web services inbound service WSDL file.

Before and immediately after performing this command, save the configuration by using either the `AdminConfig.save()` command or an equivalent command from within the administrative console. This ensures consistency between what is published to UDDI and what is recorded in the service integration bus configuration as having been published to UDDI.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available bus-enabled web services commands, plus a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('SIBWebServices')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command publishes the WSDL document for the InboundService, with all its ports, to the registry and business defined by the UDDIPublication object.

Target object

ObjectName of the InboundService object.

If the UDDI publish operation succeeds, the service key in the UDDIPublication object is updated and a warning message is produced indicating that the service is successfully published to UDDI, but that without a save of the configuration the system is in an inconsistent state.

If the UDDI publish operation fails, the service key is not updated and an error message is produced indicating that the publish operation failed.

If the UDDI publish operation succeeds, an information message is produced that contains sufficient details for the administrator to independently find the service in the UDDI registry if that becomes necessary.

If the WSDL is to be published through a proxy, the server on which the command is running must have the system properties that identify the proxy server set correctly. If the proxy requires authentication, then the user ID and password can be set as parameters on the command.

Required parameters

-uddiPublication
The name of the UDDI publication property for this service.

Conditional parameters

None.

Optional parameters

-userId
The user ID that you use to retrieve the WSDL.

-password
The password that you use to retrieve the WSDL.

Example

- Using Jython:

```
AdminTask.publishSIBWSInboundService(inService, ["-uddiPublication", "MyUddi"])
```

- Using Jacl:

```
$AdminTask publishSIBWSInboundService $inService {-uddiPublication "MyUddi"}
```

unpublishSIBWSInboundService command

Use the unpublishSIBWSInboundService command to remove from UDDI a service integration bus-enabled web services inbound service WSDL file.

Before and immediately after performing this command, save the configuration by using either the `AdminConfig.save()` command or an equivalent command from within the administrative console. This ensures consistency between what is published to UDDI and what is recorded in the service integration bus configuration as having been published to UDDI.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available bus-enabled web services commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBWebServices')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

This command removes the WSDL document for the InboundService, with all its ports, from the registry and business defined by the UDDIPublication object.

Target object

ObjectName of the InboundService object.

If the UDDIPublication object has no service key, the command fails.

If the UDDI removal operation succeeds, the service key in the UDDIPublication object is cleared and a warning message is produced indicating that the service is successfully removed from UDDI, but that without a save of the configuration the system is in an inconsistent state and the service must be republished to UDDI by using the GUI or publishToUDDI command.

If the UDDI removal operation fails because the service key is not found, the service key is cleared and a warning message is produced indicating that the service is not found.

If the UDDI removal operation fails for any other reason, the service key is not cleared and an error message is produced indicating that the removal failed.

If the WSDL is to be published through a proxy, the server on which the command is running must have the system properties that identify the proxy server set correctly. If the proxy requires authentication, then the user ID and password can be set as parameters on the command.

Required parameters

-uddiPublication
The name of the UDDI publication property for this service.

Conditional parameters

None.

Optional parameters

-userId
The user ID that you use to retrieve the WSDL.

-password
The password that you use to retrieve the WSDL.

Example

- Using Jython:

```
AdminTask.unpublishSIBWSInboundService(inService, ["-uddiPublication", "MyUddi"])
```

- Using Jacl:

```
$AdminTask unpublishSIBWSInboundService $inService {-uddiPublication "MyUddi"}
```

createSIBWSEndpointListener command

Use the createSIBWSEndpointListener command to create a new service integration bus-enabled web services endpoint listener configuration.

For every server that is to host an endpoint listener, you must install and configure a Service Data Objects (SDO) repository on the server.

If you want to change the default HTTP endpoint listener security role, do so before you configure the SOAP over HTTP endpoint listener.

Before you configure a SOAP over JMS endpoint listener, you should configure the associated JMS resources.

You can configure any number of endpoint listeners with values of your own choosing, including the values given in “Example values for endpoint listener configuration” on page 2792.

You can create a new endpoint listener configuration by using the wsadmin tool as described in this topic, or by using the administrative console as described in “Creating a new endpoint listener configuration” on page 2789.

Note: If you want to create an endpoint listener configuration for your own endpoint listener application, rather than for one of the listeners that is supplied with WebSphere Application Server, you must use the wsadmin tool.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available bus-enabled web services commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBWebServices')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command creates an endpoint listener configuration.

Target object

ObjectName of the server on which the endpoint listener is created.

The SIBWSEndpointListener object that is created has no associated SIBWSBusConnectionProperty objects. Use the administrative console to connect one or more service integration buses to this endpoint listener, as described in “Modifying an existing endpoint listener configuration” on page 2797.

Required parameters

-name

The name of the endpoint listener within the server. If you are installing your own endpoint listener application, rather than one that is supplied with WebSphere Application Server, then this name must match the name given in the endpoint listener application that you have installed (that is, the *display name* of the endpoint module within the endpoint application EAR file).

-urlRoot
The root of the web address that should be used to build the endpoint addresses within WSDL documents to direct requesters to this endpoint listener.

-wsdlUrlRoot
The root of the web address for the WSDL files of the inbound services that are provided by this endpoint listener.

Conditional parameters

-earFile
The location of the endpoint listener application. Specify this parameter if you are configuring an endpoint listener other than those supplied with WebSphere Application Server.

Optional parameters

None.

Example

- Using Jython:

```
epl = AdminTask.createSIBWSEndpointListener(server, ["-name", "soaphttp1",
 "-urlRoot", "http://myserver.com/wsgwsoaphttp1",
 "-wsdlUrlRoot", "http://myserver.com/wsgwsoaphttp1"] )
```

- Using Jacl:

```
set epl [$AdminTask createSIBWSEndpointListener $server {-name "soaphttp1"
 -urlRoot "http://myserver.com/wsgwsoaphttp1"
 -wsdlUrlRoot "http://myserver.com/wsgwsoaphttp1"}]
```

deleteSIBWSEndpointListener command

Use the deleteSIBWSEndpointListener command to delete a service integration bus-enabled web services endpoint listener configuration.

You can delete an endpoint listener configuration by using the wsadmin tool as described in this topic, or by using the administrative console as described in “Deleting endpoint listener configurations” on page 2799.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available bus-enabled web services commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBWebServices')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command deletes an endpoint listener configuration.

Target object

ObjectName of the endpoint listener that is to be deleted.

The command deletes a SIBWSEndpointListener object, along with any associated SIBWSBusConnectionProperty objects.

The command fails if there are any InboundPort objects associated with the endpoint listener.

Parameters

None.

Example

- Using Jython:
  ```
  AdminTask.deleteSIBWSEndpointListener(epl)
  ```
- Using Jacl:
  ```
  $AdminTask deleteSIBWSEndpointListener $epl
  ```

connectSIBWSEndpointListener command

Use the connectSIBWSEndpointListener command to connect a service integration bus-enabled web services endpoint listener to a service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available bus-enabled web services commands, plus a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('SIBWebServices')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command connects an endpoint listener to a service integration bus.

The command creates a SIBWSBusConnectionProperty object for the endpoint listener, and a reply destination. The command also sets the reply destination name in the bus connection properties.

Target object

ObjectName of the endpoint listener to be connected.

Required parameters

-bus
The name of the service integration bus to which the endpoint listener is to be connected.

Conditional parameters

None.

Optional parameters

-replyDestination
The name to use for the reply destination for this connection. If no destination name is specified, the command generates a name.

Example

- Using Jython:

```
busConn = AdminTask.connectSIBWSEndpointListener(epl, "[-bus myBus]")
```

- Using Jacl:

```
set busConn [$AdminTask connectSIBWSEndpointListener $epl {-bus "MyBus"}]
```

disconnectSIBWSEndpointListener command

Use the disconnectSIBWSEndpointListener command to disconnect a bus-enabled web services endpoint listener from a service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available bus-enabled web services commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBWebServices')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command disconnects an endpoint listener from a service integration bus.

Target object

ObjectName of the endpoint listener to be disconnected.

The command deletes the SIBWSBusConnectionProperty object for the endpoint listener, and also deletes the reply destination (if any) that is named in the bus connection properties.

Required parameters

-bus
The name of the service integration bus from which the endpoint listener is to be disconnected.

Conditional parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
AdminTask.disconnectSIBWSEndpointListener(epl, ["-bus", "MyBus"])
```

- Using Jacl:

```
$AdminTask disconnectSIBWSEndpointListener $epl {-bus "MyBus"}
```

Chapter 31. Administering web services - Invocation framework (WSIF)

The Web Services Invocation Framework (WSIF) is a Web Services Description Language (WSDL)-oriented Java™ API. You use this API to invoke web services dynamically, regardless of the service implementation format (for example enterprise bean) or the service access mechanism (for example Java Message Service (JMS)). Using WSIF, you can move away from the usual web services programming model of working directly with the SOAP APIs, towards a model where you interact with representations of the services. You can therefore work with the same programming model regardless of how the service is implemented and accessed.

Administering WSIF

An overview of where and how the Web Services Invocation Framework (WSIF) is installed as part of WebSphere Application Server, and information about configuring a WSIF client to invoke a web service through JMS, and modifying the contents of the wsif.properties file.

About this task

WSIF is a thin abstraction layer between application code and the relevant invocation infrastructure.

WSIF is provided in a JAR file named `com.ibm.ws.runtime.jar`. The JAR file contains the WSIF classes, and the Java, EJB, SOAP over HTTP and SOAP over JMS providers. Additional providers are packaged as separate JAR files. When you install WebSphere Application Server, the `com.ibm.ws.runtime.jar` file is put on the WebSphere or Java virtual machine (JVM) class path.

WSIF requires no further configuration, apart from the following administrative tasks:

Procedure

- Enable a WSIF client to invoke a web service through JMS.

  Use the administrative console to configure the JMS resources (a queue destination and a queue connection factory) that are required to enable a service to be invoked through JMS by a WSIF client application.
- Modify the contents of the wsif.properties file.

  You might have to modify the contents of this file, for example to change the default SOAP provider

Enabling a WSIF client to invoke a web service through JMS

The ways in which the Web Services Invocation Framework (WSIF) interacts with the Java Message Service (JMS), and the steps to take to enable a service to be invoked through JMS by a WSIF client application.

Before you begin

This topic assumes that you chose and configured a JMS provider when you installed WebSphere Application Server (either the default messaging provider, or another provider such as the WebSphere MQ messaging provider). If not, do so now as described in Choosing a messaging provider.

About this task

Here are the ways in which WSIF interacts with JMS:
- WSIF only supports input JMS properties.
- WSIF needs two queues when invoking an operation: one for the request message and one for the reply.

- The replyTo queue is by default a temporary queue, which WSIF creates on behalf of the application. You can specify a permanent queue by setting the **JMSReplyTo** property to the JNDI name of a queue.
- WSIF uses the default values for properties set by the JMS implementation.

To enable a service to be invoked through JMS by a WSIF client application, complete the following steps:

Procedure

1. Use the administrative console to create and configure a queue connection factory and a queue destination for your chosen messaging provider.

   For more information, see "Configuring resources for the default messaging provider" on page 516, "Configuring JMS resources for the WebSphere MQ messaging provider" on page 734 or Chapter 14, "Managing messaging with a third-party or (deprecated) V5 default messaging provider," on page 933.

   Note: In WebSphere MQ and some other JMS implementations, messages are persistent by default. The WSIF replyTo temporary queue is of type temporary dynamic by default, which means that your JMS provider cannot write a persistent response message to this queue. If you are using the WebSphere MQ messaging provider, create a temporary model queue that is of type permanent dynamic, then pass this model as the **tempmodel** of your queue connection factory. This ensures that persistent messages are written to a temporary replyTo queue that is of type permanent dynamic.
2. Use the administrative console to add the new queue destination to the list of JMS destination names for your application server. Ensure that the **Initial State** is started.
3. Put the JNDI names of the queue destination and queue connection factory, as well as your JNDI configuration, in the Web Services Description Language (WSDL) file.
4. Optional: If your client is running on an application server that has been migrated from WebSphere Application Server Version 5, you might get basic authentication errors and therefore have to modify your security settings. For more information see Web Services Invocation Framework troubleshooting tips.

Configuring resources for the default messaging provider

Use the following tasks to configure JMS connection factories, activation specifications, and destinations for the default messaging provider.

About this task

Use these tasks to configure administrative JMS resources provided by the default messaging provider.

These administrative JMS resources are in addition to any temporary JMS destinations created by applications.

- List JMS resources.
- Configure a unified connection factory.
- Configure a queue connection factory.
- Configure a topic connection factory.
- Configure a queue.
- Configure a topic.
- Configure an activation specification.

Configuring JMS resources for the WebSphere MQ messaging provider

Use the WebSphere Application Server administrative console to configure activation specifications, connection factories and destinations for the WebSphere MQ JMS provider.

Before you begin

This task assumes that you are working in a mixed WebSphere Application Server and WebSphere MQ environment, and that you have decided to use the WebSphere MQ messaging provider to handle JMS

messaging between the two systems. If your business uses WebSphere MQ, and you want to integrate WebSphere Application Server messaging applications into a predominately WebSphere MQ network, the WebSphere MQ messaging provider is the natural choice. However, there can be benefits in using another provider. If you are not sure which provider combination is best suited to your needs, see Choosing messaging providers for a mixed environment.

You can configure JMS resources for the WebSphere MQ messaging provider through the administrative console as described in this task, or you can configure JMS resources for the WebSphere MQ messaging provider through the WebSphere MQ administrative commands.

About this task

Using the administrative console, you can set the scope of the WebSphere MQ messaging provider to restrict the range of resources that are displayed:

- If you set the scope to contain only WebSphere Application Server Version 6 or Version 7.0 or later nodes, you can configure JMS 1.1 resources and properties. This includes unified JMS connection factories for use by both point-to-point and publish/subscribe JMS 1.1 applications. With JMS 1.1, this approach is preferred to the domain-specific queue connection factory and topic connection factory.
- If you set the scope to contain only WebSphere Application Server Version 7.0 or later nodes, you can also configure JMS activation specifications.
- If you set the scope to a WebSphere Application Server Version 5 node, you can only configure domain-specific JMS resources, and the subset of properties that apply to WebSphere Application Server Version 5.

Note:

There are two ways of specifying the information needed by WebSphere MQ messaging provider messaging resources so that they can connect to a WebSphere MQ queue manager. It can either be specified manually, or by providing the WebSphere MQ messaging provider resource with a uniform resource locator (URL) that points to a client channel definition table (CCDT).

A CCDT is a binary file that contains information about how to create a client connection channel to one or more queue managers. The file contains information such as the hostname, port, and name of the target queue manager, as well as more advanced configuration information like the SSL attributes that should be used.

Creating WebSphere MQ messaging provider resources using CCDTs provides the following benefits:

- Flexibility, because client connection channel information is contained in a single place. If any of the information changes, such as the host name of the machine on which the WebSphere MQ queue manager resides, only the CCDT needs to be updated. When it is updated, all WebSphere MQ messaging provider resources that make use of the CCDT pick up the change.
- Reliability, because less information is needed for a CCDT there is a reduced chance of configuration errors. When using a CCDT to enter connection information, all that is required are the CCDT URL and an optional queue manager name. If you configure a WebSphere MQ messaging provider resource manually, much more information is required -- especially if you are configuring SSL.

For further information about generating a CCDT, see the WebSphere MQ information center.

Maintenance note: The WebSphere MQ messaging provider uses code provided by the WebSphere MQ resource adapter, which is automatically installed as part of the product.

Procedure

- “Creating an activation specification for the WebSphere MQ messaging provider” on page 736
- “Configuring an activation specification for the WebSphere MQ messaging provider” on page 738
- “Migrating a listener port to an activation specification for use with the WebSphere MQ messaging provider” on page 758
- “Creating a connection factory for the WebSphere MQ messaging provider” on page 759
- “Configuring a unified connection factory for the WebSphere MQ messaging provider” on page 761
- “Configuring a queue connection factory for the WebSphere MQ messaging provider” on page 789
- “Configuring a topic connection factory for the WebSphere MQ messaging provider” on page 813
- “Configuring a queue for the WebSphere MQ messaging provider” on page 840
- “Configuring a topic for the WebSphere MQ messaging provider” on page 852
- “Configuring custom properties for WebSphere MQ messaging provider JMS resources” on page 862

Managing messaging with a third-party or (deprecated) V5 default messaging provider

For messaging between application servers, most requirements are best met by either the default messaging provider or the WebSphere MQ messaging provider. However, you can instead use a third-party messaging provider (that is, use another company's product as the provider). You might want to do this, for example, if you have existing investments. For backwards compatibility with earlier releases, there is also support for the V5 default messaging provider.

Before you begin

If you are not sure which provider combination is best suited to your needs, see Types of messaging providers.

About this task

Enterprise applications in WebSphere Application Server can use asynchronous messaging through services based on Java Message Service (JMS) messaging providers and their related messaging systems. These messaging providers conform to the JMS Version 1.1 specification.

The choice of provider depends on what your JMS application needs to do, and on other factors relating to your business environment and planned changes to that environment.

Procedure

- Choose a third-party messaging provider.

  To administer a third-party messaging provider, you use either the resource adaptor (for a Java EE Connector Architecture (JCA) 1.5-compliant messaging provider) or the client (for a non-JCA messaging provider) that is supplied by the third party. You use the WebSphere Application Server administrative console to administer the activation specifications, connection factories and destinations that are within WebSphere Application Server, but you cannot use the administrative console to administer the JMS provider itself, or any of its resources that are outside of WebSphere Application Server.

  To use message-driven beans, third-party messaging providers must either provide an inbound JCA 1.5-compliant resource adapter, or (for non-JCA messaging providers) include Application Server Facility (ASF), an optional feature that is part of the JMS Version 1.1 specification.

  To work with a third-party provider, choose one of the following options:

  1. Manage messaging with a third-party JCA 1.5-compliant messaging provider.
  2. Manage messaging with a third-party non-JCA messaging provider.
- Choose the (deprecated) V5 default messaging provider.

  This deprecated provider is identical to the WebSphere Application Server Version 5 default provider. Only the name has changed. It provides backwards compatibility that enables WebSphere Application

Server Version 6 or later applications to connect to WebSphere Application Server Version 5 resources in a mixed cell. It also allows WebSphere Application Server Version 5 applications to connect to WebSphere Application Server Version 6 or later resources in a mixed cell. To configure and manage messaging to interoperate with WebSphere Application Server Version 5, see “Maintaining (deprecated) Version 5 default messaging resources” on page 959.

wsif.properties file - Initial contents

The Web Services Invocation Framework (WSIF) properties are stored in the `com.ibm.ws.runtime.jar` file, in a properties file named `wsif.properties`. You might have to modify the contents of this file, for example to change the default SOAP provider, so for reference here is a copy of the “as shipped” contents of the `wsif.properties` file.

The `com.ibm.ws.runtime.jar` file is located in the *app_server_root*`/plugins` directory, where *app_server_root* is the root directory for your installation of IBM WebSphere Application Server.

You must keep the `wsif.properties` file on the class path, so that WSIF can find it and the client administrator can use it to configure WSIF. However if you make any changes to the file, you do not replace the original copy in the `com.ibm.ws.runtime.jar` file. Instead, you save the modified version in the *app_server_root*`/lib/properties` directory.

The following code is the initial contents of the `wsif.properties` file. All the possible properties are listed and described.

```
# Two properties are used to override which WSIFProvider is selected when there
# exists multiple providers supporting the same namespace URI. These properties are:
#
#    wsif.provider.default.CLASSNAME=N
#    wsif.provider.uri.M.CLASSNAME=URI
#
# CLASSNAME is the WSIFProvider class name
# N is the number of following default wsif.provider.uri.M.CLASSNAME properties
# M is a number from 1 to N to uniquely identify each wsif.provider.uri.M.CLASSNAME
#   property key.
# For example the following two properties would override the default SOAP provider
# to be the Apache SOAP provider:
#
# wsif.provider.default.org.apache.wsif.providers.soap.ApacheSOAP.WSIFDynamicProvider_ApacheSOAP=1
# wsif.provider.uri.1.org.apache.wsif.providers.soap.ApacheSOAP.WSIFDynamicProvider_ApacheSOAP=\
# http://schemas.xmlsoap.org/wsdl/soap/
#

# maximum number of milliseconds to wait for a response to a synchronous request.
# Default value if not defined is to wait forever.
# Timeout properties are only used by providers that support timeouts.
wsif.syncrequest.timeout=10000

# maximum number of seconds to wait for a response to an async request.
# if not defined on invalid defaults to no timeout
# Timeout properties are only used by providers that support timeouts.
wsif.asyncrequest.timeout=60
```

To enable your existing web services to continue to work with WSIF, you might have to change the default WSIF SOAP provider back to the former Apache SOAP provider.

Chapter 32. Administering web services - Notification (WS-Notification)

WS-Notification enables web services to use the publish and subscribe messaging pattern.You use publish and subscribe messaging to publish one message to many subscribers. In this pattern a producing application inserts (publishes) a message (event notification) into the messaging system having marked it with a topic that indicates the subject area of the message. Consuming applications that have subscribed to the topic in question, and have appropriate authority, all receive an independent copy of the message that was published by the producing application.

Using WS-Notification for publish and subscribe messaging for web services

WS-Notification enables web services to use the publish and subscribe messaging pattern.

About this task

You use publish and subscribe messaging to publish one message to many subscribers. In this pattern a producing application inserts (publishes) a message (event notification) into the messaging system having marked it with a topic that indicates the subject area of the message. Consuming applications that have subscribed to the topic in question, and have appropriate authority, all receive an independent copy of the message that was published by the producing application.

Through the implementation of WS-Notification in WebSphere Application Server, you can achieve the following goals:

- Use existing service integration technologies and web services components to deliver WS-Notification functions.
- Interoperate with other publish and subscribe messaging clients (for example Java Message Service (JMS), WebSphere MQ) and with alternative message brokering products.

For more information about using WS-Notification, see the following topics:

Procedure

- “WS-Notification” on page 2964
- “Accomplishing common WS-Notification tasks” on page 2962
- “Configuring WS-Notification resources” on page 2985
- “Securing WS-Notification” on page 2970
- Developing applications that use WS-Notification

What to do next

Note:

- For development use on a single server only, you can use a script to configure the necessary resources to get up and running quickly with WS-Notification.
- In WebSphere Application Server Version 6.1, support for WS-Notification is based on a pre-final approval public review draft of the WS-Notification standards. In later versions, this support is extended to cover the final approved standards. The differences between the two versions of the standards are small, and your existing WS-Notification services and client applications will continue to work unchanged. However, you might choose to upgrade your existing applications as described in WebSphere Application Server Version 6.1 client applications must handle the additional error conditions introduced in the final Version 1.3 WS-Notification standards.

Accomplishing common WS-Notification tasks

This overview topic provides a set of links to information about the most common WS-Notification tasks. The tasks are divided into 3 groups by role: solution architect, system administrator and application developer.

About this task

Follow the links to view the detailed steps for each of the following tasks. For more information about the roles, see "WS-Notification roles and goals."

Procedure

- "Solution architect" on page 2963 sub-tasks:
  - "WS-Notification" on page 2964.
  - Selecting a hardware and software product combination for the enterprise that supports the WS-Notification standards.
  - Designing a server topology to host the applications, in accordance with particular WS-Notification topologies.
- "System administrator" on page 2963 sub-tasks:
  - "Using a script to get up and running quickly with WS-Notification" on page 2964.
  - "Configuring a WS-Notification service for use only by WS-Notification applications" on page 2968.
  - "Providing access for WS-Notification applications to an existing bus topic space" on page 2969.
  - "Securing WS-Notification" on page 2970.
  - "Configuring JAX-WS handlers" on page 2972.
  - "Applying a JAX-WS handler list to a WS-Notification service" on page 2973.
  - "Configuring a Version 7.0 WS-Notification service with Web service QoS" on page 2974.
  - "Configuring WS-Notification for reliable notification" on page 2976.
  - "Migrating a Version 6.1 WS-Notification configuration from WebSphere Application Server Version 6.1 to Version 7.0 or later" on page 2977.
  - "Preparing a migrated Version 6.1 WS-Notification configuration for reliable notification" on page 2978.
  - "Interacting at run time with WS-Notification" on page 2982.
  - "Publishing the WSDL files for a WS-Notification application to a compressed file" on page 2984.
- "Application developer" on page 2963 sub-tasks:
  - Developing applications that use WS-Notification
  - Writing a WS-Notification application that exposes a web service endpoint.
  - Writing a WS-Notification application that does not expose a web service endpoint.
  - Filtering the message content of publications.

WS-Notification roles and goals

This topics lists a set of computing roles that members of your organization might perform, and explains how you can use WS-Notification to help meet the goals of each role.

For a general description of each of the following roles, see WebSphere Application Server roles and goals.

Enterprise architect

IT environments are currently evolving towards the following concepts:

- Service Oriented Architecture (SOA)
- Enterprise Service Bus (ESB)

The goal of the enterprise architect might be to guide their organization towards appropriate utilization of these concepts to maximize the efficiency and responsiveness of the business as a whole.

WS-Notification enables publish and subscribe communication patterns (such as a stock ticker) to be exposed by using web services in an SOA environment. This is done through open standards, enabling straightforward replacement of the service implementation. It promotes easy exchange of data between suppliers and customers through use of standard web service operations and prevents vendor lock-in or adoption of proprietary standards.

WebSphere Application Server also allows WS-Notification to be used as an on- or off-ramp to an ESB, providing seamless interchange of data between different types of client connected to the bus.

Solution architect

The main goal of the solution architect is to design a solution that supports the specification set by the enterprise architect. This might include providing an environment in which web service applications can participate in publish and subscribe messaging patterns. This participation might also include the requirement to be able to exchange event notifications between web service clients and other clients of the enterprise service bus.

To create a design, the solution architect completes the following broad steps:

- Learn about the support provided for WS-Notification in WebSphere Application Server.
- Select a hardware and software product combination for the enterprise that supports the WS-Notification standards.
- Design a server topology to host the applications, in accordance with the particular WS-Notification topologies that are to be implemented.

System administrator

For the specific steps that the system administrator performs to help implement common WS-Notification tasks, see the following topics:

- “Using a script to get up and running quickly with WS-Notification” on page 2964.
- “Configuring a WS-Notification service for use only by WS-Notification applications” on page 2968.
- “Providing access for WS-Notification applications to an existing bus topic space” on page 2969.
- “Securing WS-Notification” on page 2970.
- “Configuring JAX-WS handlers” on page 2972.
- “Applying a JAX-WS handler list to a WS-Notification service” on page 2973.
- “Configuring a Version 7.0 WS-Notification service with Web service QoS” on page 2974.
- “Configuring WS-Notification for reliable notification” on page 2976.
- “Migrating a Version 6.1 WS-Notification configuration from WebSphere Application Server Version 6.1 to Version 7.0 or later” on page 2977.
- “Preparing a migrated Version 6.1 WS-Notification configuration for reliable notification” on page 2978.
- “Interacting at run time with WS-Notification” on page 2982.
- “Publishing the WSDL files for a WS-Notification application to a compressed file” on page 2984.

Application developer

If the solution architect specifies a requirement to insert event notifications into the system (that is publish messages) or receive event notifications from the system as a result of creating a subscription containing an interest profile, then the application developer can use WS-Notification to meet this requirement.

There are various patterns of producing and consuming application defined by WS-Notification that are available for use by the application developer, depending upon the exact requirements of the application in question. These options are explored in the following common WS-Notification tasks:

- Writing a WS-Notification application that exposes a web service endpoint.
- Writing a WS-Notification application that does not expose a web service endpoint.

See also Developing applications that use WS-Notification and Filtering the message content of publications.

WS-Notification

WS-Notification enables web services to use the publish and subscribe messaging pattern. Use these topics to learn more about WS-Notification.

You use publish and subscribe messaging to publish one message to many subscribers. In this pattern a producing application inserts (publishes) a message (event notification) into the messaging system having marked it with a topic that indicates the subject area of the message. Consuming applications that have subscribed to the topic in question, and have appropriate authority, all receive an independent copy of the message that was published by the producing application.

Using a script to get up and running quickly with WS-Notification

Use a jython script to configure the necessary resources to get up and running quickly with WS-Notification in WebSphere Application Server.

Before you begin

The example script provided in this topic is intended for development use on a single server only, and not for use in production or network deployment environments.

About this task

You can use the example script to configure a default set of resources that enable you to connect WS-Notification applications for development purposes. When executed, the script takes the following actions:

1. It searches in the configuration for an existing service integration bus, and creates one if necessary.
2. It searches for an existing bus member, and if one is not found it adds the (stand-alone) server to the bus, and uses the default data source.
3. It searches for an existing service integration bus topic space destination, and creates one if necessary.

4. It creates a Version 6.1 or Version 7.0 WS-Notification service.
5. It creates a Version 6.1 or Version 7.0 WS-Notification service point on the local server for a SOAP over HTTP binding.
6. It creates a WS-Notification permanent topic namespace to reference the service integration bus topic space that was found or created in step 3.
7. It saves the configuration, and describes where to find the WSDL for the new notification broker web service that has been exposed.

To use the example script, complete the following steps:

Procedure

1. Save the script to the file system and use a name of your choice (for example `wsnQuickStart.py`).
2. Modify the *hostRoot* variable defined at the top of the script to point to the HTTP port of the local server (usually 9080).
3. Install and configure the SDO repository.
4. Start the server, then execute the following command. If you saved the script with a name other than `wsnQuickStart.py`, then use that name instead.

   ```
   wsadmin -f wsnQuickStart.py
   ```

Example

Here is the example script:

```
#############################################################################
# WS-Notification QuickStart script                                         #
#                                                                           #
# This Jython script will quickly create the basic resources required in order to    #
# start using WS-Notification in WebSphere Application Server Version 6.1 or later   #
#                                                                           #
# Before executing it you must modify the variables defined below to match your      #
# configuration settings.                                                   #
#                                                                           #
# Note:                                                                     #
#    - This script is not intended for production use, and is intended for use on    #
#      a stand-alone server (not network deployment) only.                    #
#    - The script will search the configuration for an existing bus, and if one is   #
#      not found then a new bus will be created                             #
#    - It will then look for an existing Bus Member on the chosen bus. If one is not #
#      found then one will be created using the default File Store           #
#    - It will then look for an existing service integration bus topic space. If one #
#      is not found then it will create one.                                #
#                                                                           #
# Execute the script by typing;                                             #
#   wsadmin -f wsnQuickStart.py                                             #
#                                                                           #
#############################################################################

#########################################################
# Configuration variables                               #
#                                                       #
# Set the following variables to match your configuration #

Configuring a WS-Notification service for use only by WS-Notification applications

Define all the necessary objects to configure a WS-Notification service and associated service points.

Before you begin

This task assumes that you have already configured one or more application servers, and that there are no other messaging resources configured.

For Version 6.1 WS-Notification services, you must also create an endpoint listener configuration on each application server that you want to use to host a WS-Notification service.

About this task

You can configure one or more servers, each hosting a WS-Notification service to which web services applications can connect, as described in the Simple web services topology.

Procedure

1. Use the information given in “Creating a bus” on page 1884 to create a service integration bus and add your existing server or servers as bus members. When you add a bus member, a messaging engine is created in the server. You choose the database that hosts the persistent storage required by the messaging engine. You can either use the default JDBC data source and Apache Derby JDBC provider, or you can configure a data source for use with your preferred database product.
2. Using the administrative console, navigate to **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services**. The “WS-Notification services [Collection]” on page 3047 form for this bus is displayed.
3. Click **New**. The New WS-Notification service wizard is displayed.
4. Complete steps 1 to 4 of the wizard, as described in “Creating a new Version 6.1 WS-Notification service” on page 2995 or “Creating a new Version 7.0 WS-Notification service” on page 2987. Pay particular attention to the following settings:
   - In wizard step 1: “Configure name, description, service integration bus and dynamic topic namespace settings”, you select the service integration bus to use to host the messaging resources. Choose the bus that you created at the beginning of this task.
   - In wizard step 4: “Create WS-Notification service points”, you select the bus member that is to host the new service. On a single server system there is only one option here. For Version 6.1 WS-Notification services, you also select the endpoint listener application to use to expose the service. Choose the endpoint listener application that you configured before you began this task.

5. Optional: In wizard step 5: “Create permanent topic namespaces”, configure the WS-Notification topic namespace to provide access to a service integration bus topic space:
   - Enter the topic namespace URI that you want WS-Notification applications to use when referring to the service integration bus topic space. This must be unique within the WS-Notification service, and is conventionally a URI related to your organization. For example `http://www.myorganization.com`.
   - Because there are no existing service integration bus topic spaces in your bus the “Use an existing service integration bus topic space” radio button and associated drop-down list are not available. To create a new bus topic space, enter your chosen name.
6. Complete wizard step 6: “Summary”.

   Check that the summary of the actions taken by the wizard is as you expected, then click **Finish**. If the processing completes successfully, the list of WS-Notification services is updated to include the new WS-Notification service. Otherwise, an error message is displayed.
7. Save your changes to the master configuration. You do not have to restart the server for these changes to take effect. However, you must start the endpoint listener or enterprise application associated with the service point that was created in step 4 of the wizard.

What to do next

For JAX-WS based Version 7.0 WS-Notification services, you can view the URL to which WS-Notification applications connect by looking in the `NotificationBroker.wsdl` file for the NotificationBroker application. To view this file, see “Publishing the WSDL files for a WS-Notification application to a compressed file” on page 2984.

For JAX-RPC based Version 6.1 WS-Notification services, you can view the URL to which WS-Notification applications connect by navigating to **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name* -> NotificationBroker inbound port settings**.

To extend this configuration so that web service applications can interact with non-web service applications, see “Providing access for WS-Notification applications to an existing bus topic space.”

Providing access for WS-Notification applications to an existing bus topic space

Configure a solution such that web services clients can share event notifications with other clients of a service integration bus.

Before you begin

This task assumes that you have an existing service integration bus, configured with at least one bus member and a bus topic space. For more information, see “Creating a bus” on page 1884.

About this task

This task focuses on the “Create permanent topic namespaces” step that is part of the New WS-Notification service wizard.

You can configure WS-Notification so that web service applications receive event notifications generated by other clients of the service integration bus such as JMS clients. Similarly, web service applications can generate notifications to be received by other client types. This configuration is described in the Topology for WS-Notification as an entry or exit point to the service integration bus. You achieve this configuration by creating a permanent topic namespace that allows messages to be shared between web service and non-web service clients of the bus. Specifically, you create a permanent topic namespace that links the service integration bus topic space used by messaging clients to a WS-Notification topic namespace URI.

For more information about programming the client applications, see Interacting with JMS message types.

Procedure

1. Start the administrative console.
2. Navigate to **Service integration -> WS-Notification -> Services** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services**. The “WS-Notification services [Collection]” on page 3047 form is displayed.
3. Click **New**. The New WS-Notification service wizard is displayed.
4. Complete steps 1 to 4 of the wizard, as described in “Creating a new Version 6.1 WS-Notification service” on page 2995 or “Creating a new Version 7.0 WS-Notification service” on page 2987.
5. In wizard step 5:“ Create permanent topic namespaces”, configure the WS-Notification topic namespace to provide access to the existing service integration bus topic space:
   - Enter the topic namespace URI that you want WS-Notification applications to use when referring to the service integration bus topic space. This must be unique within the WS-Notification service, and is conventionally a URI related to your organization. For example `http://www.myorganization.com`.
   - Select the “Use an existing service integration bus topic space” radio button, then from the drop-down list select the name of your chosen service integration bus topic space.
6. Complete wizard step 6: “Summary”.

   Check that the summary of the actions taken by the wizard is as you expected, then click **Finish**. If the processing completes successfully, the list of WS-Notification services is updated to include the new WS-Notification service. Otherwise, an error message is displayed.
7. Save your changes to the master configuration. You do not have to restart the server for these changes to take effect. However, you must start the endpoint listener or enterprise application associated with the service point that was created in step 4 of the wizard.

Results

WS-Notification applications can now connect to the WS-Notification service point and insert or receive event notifications from the service integration bus topic space.

What to do next

For JAX-WS based Version 7.0 WS-Notification services, you can view the URL to which WS-Notification applications connect by looking in the `NotificationBroker.wsdl` file for the NotificationBroker application. To view this file, see “Publishing the WSDL files for a WS-Notification application to a compressed file” on page 2984.

For JAX-RPC based Version 6.1 WS-Notification services, you can view the URL to which WS-Notification applications connect by navigating to **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name* -> NotificationBroker inbound port settings**.

Securing WS-Notification

The WS-Notification security implementation requires that a user identity is flowed in requests for WS-Notification services. This identity is used to authenticate the client application and check that the client is authorized to invoke the requested operation, and to access the underlying service integration bus topic spaces and topic resources.

About this task

WS-Notification uses the same mechanisms as other Web services to provide an authenticated identity. For example WS-Security or HTTP Basic Authentication.

There are three parts to configuring secure access to WS-Notification:

- Securing the communication channel between the application and the server.

- Authorizing the application to invoke the NotificationBroker.
- Authorizing the application to access the resources of the service integration bus.

If messaging security is enabled, and the WS-Security or HTTP Basic Authentication components are not configured to flow a user identity in WS-Notification requests, then all such requests are treated as unauthenticated and can only access messaging resources that are accessible by the WebSphere Application Server “everyone” group.

Procedure

1. Secure the communication between the application and the server:
   a. Provide security for inbound requests and associated responses by configuring the WS-Notification service point.
      - For JAX-WS based Version 7.0 WS-Notification service points, attach security-enabled policy sets to the application associated with the service point. For JAX-RPC based Version 6.1 WS-Notification service points, configure security for the inbound ports associated with the service point.
      - If you are using SOAP over HTTP as the binding for your WS-Notification service point, modify it to use SOAP over HTTPS as described in Configuring secure access to WS-Notification service points by using SOAP over HTTPS.
      - If you are using SOAP over JMS as the binding (for Version 6.1 WS-Notification services), configure the JMS connection factory used by the client application to use a secure communication protocol to communicate with the JMS provider. Exactly how you do this depends upon the JMS provider. If you are using the service integration bus as the JMS provider, configure the client to use SSL to communicate with the server by setting the **target inbound transport chain** to `InboundSecureMessaging` as described in How JMS applications connect to a messaging engine on a bus and its related tasks.
   b. Provide security for outbound requests (for example notifications from the server to subscribed consumers) by configuring the WS-Notification service.
      - For JAX-WS based Version 7.0 WS-Notification services, the steps involved are similar to those for applying security to JAX-WS web service clients except that any binding or configuration created is applied to the WS-Notification service. For more information, see Securing JAX-WS web services using message-level security.
      - For JAX-RPC based Version 6.1 WS-Notification services, the steps involved are similar to those for applying security to service integration bus-enabled web services outbound ports except that any binding or configuration created is applied to the WS-Notification service. For more information, see Securing bus-enabled web services and its sub-topics, notably Invoking outbound services over HTTPS.
   c. You can also use WS-Security to sign or encrypt SOAP messages.
      - For JAX-WS based Version 7.0 WS-Notification services, see Signing and encrypting message parts using policy sets.
      - For JAX-RPC based Version 6.1 WS-Notification services, see Configuring secure transmission of SOAP messages by using WS-Security.
2. Authorize the application to invoke the NotificationBroker:
   a. Configure the client application to provide an appropriate identity.

      To authorize a web service application to communicate with the server, the application must identify itself as running as a particular authenticated identity. The mechanism for doing this depends upon the type of web service binding you are using:
      - If you are using SOAP over HTTP web service bindings, use either HTTP Basic Authentication or WS-Security to provide the authenticated identity.
      - If you are using SOAP over JMS web service bindings (for Version 6.1 WS-Notification services), use WS-Security to provide an authenticated identity.

b. Configure the server to authorize the client application identity to carry out the required operations.
   - For JAX-WS based Version 7.0 WS-Notification services, you can use Web services policy sets such as the “Username WS-I RSP default” or “Username WSSecurity default” policy sets to apply authorization to the Web services that are deployed in the enterprise application associated with a service point. See also the IBMdeveloperWorks article Configuring JAX-WS applications with WS-Security for WS-Notification.
   - For JAX-RPC based Version 6.1 WS-Notification services, you can apply authorization to the whole of an inbound service (for example the NotificationBroker endpoint of a WS-Notification service point) as described in Password-protecting inbound services, or configure authorization constraints independently for each Web service operation as described in Password-protecting a web service operation.

3. Authorize the application to access the resources of the service integration bus.

   Service integration bus security uses role-based authorization. When a user is assigned to a role, the user is granted all of the permissions that the role contains. By administering authorization permissions, you can control user access to a bus and to its resources when messaging security is enabled.

   a. Authorize the application identity to be able to connect to the service integration bus, as described in Administering the bus connector role.
   b. When the application can connect to the bus, grant the application access to the appropriate destinations on the bus.

      You can determine which service integration bus topic spaces are required, by checking which WS-Notification topic namespaces are used by the application then looking at the appropriate WS-Notification permanent topic namespace to find the service integration bus topic space to which it maps. You can then grant authorization (for example the Sender or Receiver roles) for the authenticated identity to access that topic space as described in “Administering destination roles” on page 1991.
   c. After the client application has been authorized to access the appropriate topic space destination, you might also need to authorize the client application to access the individual topics within the topic space destination as described in Administering topic roles.

   For general information about configuring access to the service integration bus, see Securing service integration.

Configuring JAX-WS handlers

A JAX-WS handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. You can create JAX-WS handlers, chain them together in the form of a handler list, then apply the handler list to a JAX-WS based Version 7.0 WS-Notification service point (for inbound invocation handling) or WS-Notification service (for outbound invocation handling).

About this task

The Java API for XML-based Web Services (JAX-WS) provides you with a standard way of developing interoperable and portable web services. To create a JAX-WS handler, you can use a tool such as IBM Rational Application Developer. To enable handlers to undertake more complex operations, you chain them together into handler lists. You associate each handler list with one or more JAX-WS based Version 7.0 WS-Notification services or service points, so that the handler list can monitor WS-Notification activity and take appropriate action depending upon the sender and content of each inbound or outbound message.

Detailed instructions on how to configure JAX-WS handlers and handler lists for use with JAX-WS based Version 7.0 WS-Notification services are provided in the following topics:

Procedure

- Load JAX-WS handler classes.
- Create a new JAX-WS handler configuration.
- Modify an existing JAX-WS handler configuration.
- Delete JAX-WS handler configurations.
- Create a new JAX-WS handler list.
- Modify an existing JAX-WS handler list.
- Delete JAX-WS handler lists.

Applying a JAX-WS handler list to a WS-Notification service

To handle the messages that flow to and from an existing JAX-WS based Version 7.0 WS-Notification service, you must create JAX-WS handlers, chain them together in the form of a handler list, then apply the handler list to a NotificationBroker, PublisherRegistrationManager or SubscriptionManager endpoint at a Version 7.0 WS-Notification service point (for inbound invocation handling), or apply the handler list to a WS-Notification service (for outbound invocation handling).

Before you begin

This task assumes that you have already created a Version 7.0 WS-Notification service.

About this task

To create a JAX-WS handler, you can use a tool such as IBM Rational Application Developer. To enable handlers to undertake more complex operations, you chain them together into handler lists. You associate each handler list with one or more JAX-WS based Version 7.0 WS-Notification services or service points, so that the handler list can monitor WS-Notification activity and take appropriate action depending upon the sender and content of each inbound or outbound message. For example:

- You can use a handler list on the NotificationBroker web service to log all notification messages received by this service point.
- You can use a handler list on a SubscriptionManager web service to log all unsubscribe requests received by this service point.
- You can use a handler list on a PublisherRegistrationManager web service to log all publisher deregistration requests received by this service point.

Procedure

1. Create one or more JAX-WS handlers. You can do this using IBM Rational Application Developer or a similar tool.
2. Load JAX-WS handler classes. A JAX-WS handler interacts with messages through a JAX-WS based Version 7.0 WS-Notification service point (for inbound invocation handling) or WS-Notification service (for outbound invocation handling), therefore you must make the handler class available to the server or cluster that hosts the WS-Notification service point or service that you want to monitor.
3. Create a new JAX-WS handler configuration by using the administrative console or by using the “createJAXWSHandler command” on page 3086. By creating a new handler configuration, you make WebSphere Application Server aware of your handler, and you make the handler available for inclusion in one or more handler lists.
4. Create a new JAX-WS handler list. The approach taken in WebSphere Application Server is to assign handler lists (rather than individual handlers) to WS-Notification service points (for inbound invocation handling) or WS-Notification services (for outbound invocation handling).
5. Optional: To apply a JAX-WS handler list to a service provider endpoint (NotificationBroker, PublisherRegistrationManager or SubscriptionManager) associated with a service point, use the administrative console to complete the following substeps:

a. Navigate to **Service integration -> WS-Notification -> Services -> *service_name* -> [Additional Properties] WS-Notification service points** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Additional Properties] WS-Notification service points**. The "WS-Notification service points [Collection]" on page 3043 form is displayed. This form shows all the service points configured for this Version 7.0 WS-Notification service.

b. In the content pane, click the name of a JAX-WS based Version 7.0 WS-Notification service point in the list. The current settings for this Version 7.0 WS-Notification service point are displayed in the "WS-Notification service points [Settings]" on page 3043 form.

c. Apply the JAX-WS handler list by selecting it from the list box for one or more of the following general properties:

NotificationBroker JAX-WS handler list

The JAX-WS handler list that is applied to inbound requests from an application to the NotificationBroker endpoint of the WS-Notification service point.

SubscriptionManager JAX-WS handler list

The JAX-WS handler list that is applied to inbound requests from an application to the SubscriptionManager endpoint of the WS-Notification service point.

PublisherRegistrationManager JAX-WS handler list

The JAX-WS handler list that is applied to inbound requests from an application to the PublisherRegistrationManager endpoint of the WS-Notification service point.

6. Optional: To apply a JAX-WS handler list to a WS-Notification service, use the administrative console to complete the following substeps:

a. Navigate to **Service integration -> WS-Notification -> Services** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services**. The "WS-Notification services [Collection]" on page 3047 form is displayed.

b. In the content pane, click the name of a JAX-WS based Version 7.0 WS-Notification service in the list. The current settings for this Version 7.0 WS-Notification service are displayed in the "WS-Notification services [Settings]" on page 3047 panel.

c. Apply the JAX-WS handler list by selecting it from the list box for the following general property:

JAX-WS handler list

The JAX-WS handler list that is applied to outbound requests from the WS-Notification service.

Configuring a Version 7.0 WS-Notification service with Web service QoS

You use the administrative console to configure web service qualities of service (QoS) such as reliability or security by applying policy sets to a Version 7.0 WS-Notification service. The configuration of policy sets for WS-Notification can be split into two types: service provider (for Version 7.0 WS-Notification service points) and service client (for Version 7.0 WS-Notification service clients). Policy set configuration for these two elements of a WS-Notification service is handled differently.

Before you begin

This task assumes that you have already created a Version 7.0 WS-Notification service. You must also have configured policy sets that meet your quality of service requirements. You can reuse existing policy sets within your organization, use the default policy sets provided by WebSphere Application Server, or create new policy sets. For more information, see "Managing policy sets using the administrative console" on page 2666.

About this task

Version 7.0 WS-Notification service points (NotificationBrokers, PublisherRegistrationManagers and SubscriptionManagers) are implemented as JAX-WS applications that are deployed to servers or clusters, and the management of the policy sets for these WS-Notification service points is configured by using the policy set administrative infrastructure for service providers (both panels and wsadmin commands). In the Service provider [settings] panel for a WS-Notification service provider, there is a link to the associated WS-Notification service point application. You can use the service provider settings panel to attach policy sets to each NotificationBroker, PublisherRegistrationManager and SubscriptionManager.

Version 7.0 WS-Notification services are implemented as two configurable service clients (OutboundNotificationService and OutboundRemotePublisherService) for each WS-Notification service. Events that need outgoing web service invocations occur at the service integration bus level rather than the bus member level, even though notifications of the events occur within a particular bus member. The two service clients that a WS-Notification service implements are therefore configured by using the policy set administrative infrastructure for service clients. In the Service client policy sets and bindings [collection] panel, the two service clients for a given WS-Notification service are listed in a tree structure, along with their endpoints and operations. You can use this panel to attach policy sets to each service client, or to both service clients for the WS-Notification service.

Procedure

1. Start the administrative console.
2. Navigate to **Service integration -> WS-Notification -> Services** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services**. The “WS-Notification services [Collection]” on page 3047 form is displayed.
3. In the content pane, click the name of the Version 7.0 WS-Notification service to which to apply web service qualities of service. The current settings for this Version 7.0 WS-Notification service are displayed in the “WS-Notification services [Settings]” on page 3047 panel.
4. Optional: To configure web service QoS for inbound requests, apply policy sets to the service provider applications (NotificationBroker, PublisherRegistrationManager and SubscriptionManager) associated with a service point:

   Click **[Additional Properties] WS-Notification service points**. The “WS-Notification service points [Collection]” on page 3043 form is displayed. This form shows all the service points configured for this Version 7.0 WS-Notification service.

   Repeat the following steps, as required, to configure the policy set and binding information for one or more service provider applications for one or more service points:

   a. In the content pane, click the name of a Version 7.0 WS-Notification service point in the list. The current settings for this Version 7.0 WS-Notification service point are displayed in the “WS-Notification service points [Settings]” on page 3043 form.

   b. Click **[Additional Properties] Policy set configuration.** A link to each of the service provider applications (NotificationBroker, PublisherRegistrationManager and SubscriptionManager) for this service point is displayed in the Service provider [Collection] form.

   c. Click the name of one of the applications. An indented list of endpoints and operations for this service is displayed in the Service provider [settings] form.

   d. Select one or more items in the list (service, endpoint or operations), then perform one of the three available operations on the items you have selected:

      - Attach policy set
      - Detach policy set
      - Assign binding

      For more information, see “Managing policy sets using the administrative console” on page 2666.

   e. Restart the service provider application.

5. Optional: To configure web service QoS for outbound requests, apply policy sets to one or both of the web service clients associated with the WS-Notification service:
   a. If necessary, navigate back to the "WS-Notification services [Settings]" on page 3047 panel for this Version 7.0 WS-Notification service.
   b. Click **[Additional Properties] Outbound request policy sets and bindings**. The two service clients for this WS-Notification service are listed in a tree structure, along with their endpoints and operations, in the Service client policy set and bindings [collection] form.
   c. Select one or both service clients, then perform one of the three available operations on the items you have selected:
      - Attach client policy set
      - Detach client policy set
      - Assign binding

      For WS-Notification service clients, policy set attachments are not supported at the endpoint (port) or operation level. Therefore endpoints or operations are not selectable, and are shown as inheriting any policy set or binding that is attached to the service client. For more information, see "Managing policy sets using the administrative console" on page 2666.

      Note: Using the Service client policy set and bindings [collection] form, you can configure the policy set and binding information for both service clients for the selected service. Alternatively, you can configure the policy set and binding information for a single Version 7.0 WS-Notification service client by clicking **Services -> Service clients -> *ws-notification_service_client_name*** and using the WS-Notification service client [settings] panel. This panel also provides links to the associated service integration bus and WS-Notification service.

Results

The WS-Notification service has been successfully enabled with the required web service QoS.

Configuring WS-Notification for reliable notification

To ensure that WS-Notification web service interactions are performed in a reliable way, you configure a JAX-WS based Version 7.0 WS-Notification service, JAX-WS client, and JAX-WS based WS-Notification consumer web service (through policy set functions) to use WS-ReliableMessaging.

Before you begin

This task assumes that you have created a Version 7.0 WS-Notification service and service point, and that you have created two JAX-WS applications:

- A JAX-WS client application, created from the WSDL of the new service point.
- A JAX-WS based WS-Notification consumer web service.

For more information about how to create these applications, see "Using JAX-WS clients and web services with new Version 7.0 WS-Notification service points" on page 2981.

About this task

Reliable notification refers to the reliable transmission of messages to and from the IBM WS-Notification implementation. You enable this reliability to mitigate the problems inherent in network transmission protocols such as HTTP.

Note: This reliability does not include the behavior of the application server itself. For more information, see WS-Notification and end-to-end reliability.

To enable reliable notification, you apply policy sets that include the WS-ReliableMessaging policy to the service point, service client, and service consumer applications.

You can configure policy sets for JAX-WS clients for both application server and client environments, including thin clients. For more information, see “Managing policy sets using the administrative console” on page 2666.

Procedure

1. Configure policy sets that meet your reliable messaging requirements.

   You can reuse existing policy sets within your organization, use the WS-ReliableMessaging default policy sets provided by WebSphere Application Server, or create new policy sets. For more information, see “Configuring a WS-ReliableMessaging policy set by using the administrative console” on page 3117.
2. Configure the Version 7.0 WS-Notification service and service points for reliable notification.

   Apply policy sets that include the WS-ReliableMessaging policy.
3. Configure the JAX-WS based WS-Notification client application so that it interacts reliably with its target web service by using WS-ReliableMessaging.

   Apply policy sets that include the WS-ReliableMessaging policy, as described in “Configuring a Version 7.0 WS-Notification service with Web service QoS” on page 2974 and “Attaching and binding a WS-ReliableMessaging policy set to a web service application by using the administrative console” on page 3122.
4. Configure the JAX-WS based WS-Notification consumer web service application so that it interacts reliably with clients that attempt to communicate with it.

   Apply policy sets that include the WS-ReliableMessaging policy, as described in “Attaching and binding a WS-ReliableMessaging policy set to a web service application by using the administrative console” on page 3122.
5. Configure the WS-Notification client application (which has been configured to interact reliably) to communicate with the WS-Notification service point (which has similarly been configured to receive messages reliably).
6. Prompt the WS-Notification client application to subscribe on behalf on the (reliably configured) WS-Notification consumer web service.

   Note: The WS-Notification consumer web service might also act as a client to perform its own subscription. This client would require additional policy set configuration if reliable interactions were required.
7. Initiate notification message publications from the WS-Notification client application.

Results

The JAX-WS based Version 7.0 WS-Notification service point receives the notification messages in a reliable way from the WS-Notification client, and publishes the notification messages in a reliable way to the WS-Notification consumer web service.

Migrating a Version 6.1 WS-Notification configuration from WebSphere Application Server Version 6.1 to Version 7.0 or later

You can migrate an existing Version 6.1 WS-Notification configuration to run in a WebSphere Application Server Version 7.0 or later environment.

Before you begin

This topic assumes that you have the following configuration:

- An existing server or cluster installation of WebSphere Application Server Version 6.1 that is ready for migration, including at least one WS-Notification service, service point, and underlying service integration bus.
- Existing subscriptions with associated messages pending notification.
- Existing operational WS-Notification client and web service applications that are known to transmit and receive notifications through the existing Version 6.1 WS-Notification service.

About this task

When you migrate your system from WebSphere Application Server Version 6.1 to Version 7.0 or later, any existing WS-Notification configuration (for example WS-Notification services, service points, administered subscribers), and the associated service integration bus resources (for example inbound services and endpoint listeners) are automatically migrated to valid configuration elements within the new installation. The services and service points are migrated to Version 6.1 WS-Notification services and service points, the endpoint URLs for the service points are unchanged, and the functions supported are exactly the same as in WebSphere Application Server Version 6.1. For example, reliable notification is not possible with Version 6.1 WS-Notification services and service points.

Any messages pending notification are delivered following the update and server startup sequence.

Procedure

1. Migrate your product configuration from WebSphere Application Server Version 6.1 to Version 7.0 or later.
2. Check that notifications are being published and consumed correctly in your migrated system.

   Initiate the program, process, or application that includes the WS-Notification client (or clients), and that causes notifications to be requested and transmitted.

Results

The WS-Notification services and resources are migrated to Version 6.1 WS-Notification services and resources that run under WebSphere Application Server Version 7.0 or later. Any messages pending notification are delivered.

What to do next

You are now ready (optionally) to prepare your migrated Version 6.1 WS-Notification configuration for reliable notification.

Preparing a migrated Version 6.1 WS-Notification configuration for reliable notification

You can gradually introduce JAX-WS based client and provider entities such that a migrated Version 6.1 WS-Notification configuration is ready to be configured for reliable notification.

Before you begin

This topic assumes that you have an existing server or cluster installation of WebSphere Application Server Version 7.0 or later, including at least one WS-Notification service, service point, and underlying service integration bus that has been migrated to this version of the product as described in “Migrating a Version 6.1 WS-Notification configuration from WebSphere Application Server Version 6.1 to Version 7.0 or later” on page 2977.

About this task

For reliable notification, you apply policy sets that include WS-ReliableMessaging to your WS-Notification configuration. You can only use policy sets with Java API for XML-based Web Services (JAX-WS) applications, and with Version 7.0 WS-Notification services and service points.

The WS-Notification implementation in WebSphere Application Server Version 6.1 uses service integration bus-enabled web services to expose the WS-Notification service endpoint, so that it can be invoked by applications and configured with specific attributes such as WS-Security or JAX-RPC handlers. However, the Version 6.1 implementation is not compatible with JAX-WS handlers or applications, and it cannot compose with WS-ReliableMessaging.

To prepare a migrated Version 6.1 WS-Notification configuration for reliable notification, you must recreate your Version 6.1 WS-Notification services and service points as Version 7.0 WS-Notification services and service points, and recreate each JAX-RPC client application to which you want to apply a policy set as a JAX-WS application. Note that you can continue to use JAX-RPC applications with Version 7.0 WS-Notification services and service points, and that you only have to recreate those applications that must work with policy sets.

For information about coding JAX-RPC and JAX-WS client applications to perform specific WS-Notification tasks, see ../ae/tjwsn_devapp.dita. You might also find it useful to learn about JAX-WS and the JAX-WS client programming model. This should help you to determine the effort involved in porting client code from JAX-RPC to JAX-WS, or to validate JAX-WS client to JAX-RPC web service interoperability.

To support a phased approach to preparing for reliable notification, and to describe the four main configurations that you might want to achieve, this task is divided into four subtasks:

Procedure

- "Using JAX-WS clients and web services with migrated service points."
- "Using JAX-RPC clients and web services with new Version 7.0 WS-Notification service points" on page 2980.
- "Using JAX-WS clients and web services with new Version 7.0 WS-Notification service points" on page 2981.
- "Sharing notifications between Version 6.1 and Version 7.0 WS-Notification service points" on page 2982.

What to do next

When you have completed these subtasks, you have a collection of WS-Notification client and server entities that are prepared for reliable notification, and you are ready to configure WS-Notification for reliable notification.

Using JAX-WS clients and web services with migrated service points:
Procedure

1. Publish notification messages through a migrated Version 6.1 WS-Notification service point, from a JAX-WS client application.
   a. Create a JAX-WS WS-Notification client application by using the WSDL of the migrated service point.

      For more information, see Example: Publishing a WS-Notification message, Developing a JAX-WS client from a WSDL file and "Publishing the WSDL files for a WS-Notification application to a compressed file" on page 2984.
   b. Run the application.
   c. Initiate one or more notification messages.

The system accepts and publishes the notification messages from the JAX-WS client.

2. Receive notification messages in a new JAX-WS based WS-Notification consumer application, from a migrated Version 6.1 WS-Notification service point.

   This validates that your Version 6.1 WS-Notification service point can deliver notifications to a JAX-WS consumer web service.

   a. Create a new JAX-WS based WS-Notification consumer web service from the standard WS-Notification WSDL.

      For more information, see Example: Subscribing a WS-Notification consumer, Implementing web services applications from existing WSDL files with JAX-WS and "Publishing the WSDL files for a WS-Notification application to a compressed file" on page 2984.

   b. Create a subscription for the new consumer service through the Version 6.1 WS-Notification service point.

   c. Prompt the WS-Notification service point to generate notifications (for example by using a WS-Notification client application).

   The system transmits the notifications to the new JAX-WS consumer application correctly.

Using JAX-RPC clients and web services with new Version 7.0 WS-Notification service points:
Procedure

1. Create a new Version 7.0 WS-Notification service.

   You can configure a Version 7.0 WS-Notification service and service points with policy sets to compose with WS-ReliableMessaging for reliable notification. The system creates and configures a new Version 7.0 WS-Notification service. This includes the creation of a Version 7.0 WS-Notification service point that exposes the service from a particular service integration bus member. Version 6.1 and Version 7.0 WS-Notification service points can coexist in WebSphere Application Server Version 7.0 or later.

2. Publish notification messages through the new Version 7.0 WS-Notification service point, from a JAX-RPC client application.

   This validates the behavior of the Version 7.0 WS-Notification service point.

   a. Create the application by using the WSDL of the new Version 7.0 WS-Notification service point.

      For more information, see Example: Publishing a WS-Notification message, Developing client bindings from a WSDL file for a JAX-RPC Web services client and "Publishing the WSDL files for a WS-Notification application to a compressed file" on page 2984.

      Note: Instead of creating a new JAX-RPC client application, you might choose to update an existing JAX-RPC client application from the WSDL of the new service point. The WSDL for a Version 7.0 WS-Notification service point contains a number of minor changes compared to a Version 6.1 service point, so you must modify your existing JAX-WS client application to take account of these changes. Specifically, you must regenerate the java proxy classes from the WSDL, and update any use of class names and methods that have changed. For example, there might be changes in the generated classes that include a port type or service from the WSDL.

   b. Run the application.

   c. Initiate one or more notification messages.

   The system accepts and publishes the notification messages from the JAX-RPC client.

3. Receive notification messages in a JAX-RPC based WS-Notification consumer application, from the new Version 7.0 WS-Notification service point.

   This validates that your Version 7.0 WS-Notification service point can deliver notifications to a JAX-RPC consumer web service.

   a. Create a new JAX-RPC based WS-Notification consumer web service from the standard WS-Notification WSDL.

For more information, see Example: Subscribing a WS-Notification consumer, Implementing web services applications from existing WSDL files with JAX-WS and “Publishing the WSDL files for a WS-Notification application to a compressed file” on page 2984.

Note: Instead of creating a new JAX-RPC consumer application, you can use an existing JAX-RPC consumer application from (for example) a Version 6.1 WS-Notification configuration.

b. Create a subscription for the new consumer service through the new Version 7.0 WS-Notification service point.

c. Prompt the WS-Notification service point to generate notifications (for example by using a WS-Notification client application).

The system transmits the notifications to the new JAX-RPC consumer application correctly.

Using JAX-WS clients and web services with new Version 7.0 WS-Notification service points:
Before you begin

Note that with this configuration you can compose with policy sets for reliable notification.

Procedure

1. Publish notification messages through the new Version 7.0 WS-Notification service point, from a JAX-WS client application.

   a. Create a JAX-WS WS-Notification client application by using the WSDL of the new Version 7.0 WS-Notification service point.

   For more information, see Example: Publishing a WS-Notification message, Developing a JAX-WS client from a WSDL file and “Publishing the WSDL files for a WS-Notification application to a compressed file” on page 2984.

   Note: Instead of creating a new JAX-WS client application, you might choose to update the JAX-WS client application that you created in the subtask “Using JAX-WS clients and web services with migrated service points” on page 2979. The WSDL for a Version 7.0 WS-Notification service point contains a number of minor changes compared to a Version 6.1 service point, so you must modify your existing JAX-WS client application to take account of these changes. Specifically, you must regenerate the java proxy classes from the WSDL, and update any use of class names and methods that have changed. For example, there might be changes in the generated classes that include a port type or service from the WSDL.

   b. Run the application.

   c. Initiate one or more notification messages.

   The system accepts and publishes the notification messages from the JAX-WS client.

2. Receive notification messages in a new JAX-WS based WS-Notification consumer application, from a new Version 7.0 WS-Notification service point.

   This validates that your Version 7.0 WS-Notification service point can deliver notifications to a JAX-WS consumer web service.

   a. Create a new JAX-WS based WS-Notification consumer web service from the standard WS-Notification WSDL.

   For more information, see Example: Subscribing a WS-Notification consumer, Implementing web services applications from existing WSDL files with JAX-WS and “Publishing the WSDL files for a WS-Notification application to a compressed file” on page 2984.

   Note: Instead of creating a new JAX-WS consumer application, you might choose to update the JAX-WS consumer application that you created in the subtask “Using JAX-WS clients and web services with migrated service points” on page 2979. The WSDL for a Version 7.0

WS-Notification service point contains a number of minor changes compared to a Version 6.1 service point, so you must modify your existing JAX-WS client application to take account of these changes. Specifically, you must regenerate the java proxy classes from the WSDL, and update any use of class names and methods that have changed. For example, there might be changes in the generated classes that include a port type or service from the WSDL.

b. Create a subscription for the new consumer service through the new Version 7.0 WS-Notification service point.
c. Prompt the WS-Notification service point to generate notifications (for example by using a WS-Notification client application).

The system transmits the notifications to the new JAX-WS consumer application correctly.

Sharing notifications between Version 6.1 and Version 7.0 WS-Notification service points:
About this task

You can configure WS-Notification so that notifications received through migrated Version 6.1 WS-Notification service points are published through the new Version 7.0 service. You might want to do this so that (for example) you can receive notifications through existing, unreliable connections then publish them through new connections made reliable through WS-ReliableMessaging. To enable this configuration, the new Version 7.0 WS-Notification service needs to use the same service integration bus topic space as the migrated Version 6.1 WS-Notification service. You use a permanent topic namespace to statically define the association between a WS-Notification topic namespace URI and a service integration bus topic space destination. You configure a permanent topic namespace as a property of a WS-Notification service.

Procedure

1. Discover which bus topic spaces the migrated Version 6.1 WS-Notification service is using. If none, create a new permanent topic namespace to connect to a bus topic space. For more information, see “Modifying a Version 6.1 WS-Notification service” on page 2998.
2. Create a new permanent topic namespace for the new Version 7.0 WS-Notification service, that connects to the same bus topic space. For more information, see “Modifying a Version 7.0 WS-Notification service” on page 2991.

Results

Notifications received by either the new or migrated service point are now published to subscriptions made on either WS-Notification service.

Interacting at run time with WS-Notification

View (and in some cases delete) at run time the active items associated with WS-Notification service points.

Before you begin

This task assumes that you have a fully configured and operational WS-Notification service point.

About this task

A WS-Notification service point defines access to a WS-Notification service on a given bus member through a specified web service binding (for example SOAP over HTTP). Applications use the bus members associated with the WS-Notification service point to connect to the WS-Notification service. The existence of a WS-Notification service point on a bus member implies that a WS-Notification web service is exposed from that bus member, and causes web service endpoints for the notification broker,

subscription manager and publisher registration manager for this WS-Notification service to be exposed on the bus member with which the service point is associated. WS-Notification applications use these endpoints to interact with the WS-Notification service.

You can use the administrative console to interact at run time with the following active items associated with WS-Notification service points:

Publisher registrations
A runtime list of existing publisher registrations is provided. This includes, for each publisher registration, the information that was used to create it and when it will terminate.

Pull points
A runtime list is provided of the pull points that have been created. This includes, for each pull point, its current termination time and a link to the associated subscription.

Subscriptions
A runtime view is provided for subscriptions that have been created by applications. This includes, for each subscription, the information that was used to create it and an indication of its current state.

Administered subscribers
A runtime list is provided of the administered subscribers for a given WS-Notification service point. This includes, for each administered subscriber, an indication of its current state; for example whether the subscription was successfully initialized at start time.

For each WS-Notification service point, runtime information is available for subscriptions, registrations, pull points and administered subscribers. **For each WS-Notification service**, runtime information is available - aggregated for all service points for the service - for subscriptions, registrations and pull points. There is no aggregated view for administered subscribers at the WS-Notification service level.

To access and use the runtime information for active items associated with WS-Notification service points, use the administrative console to complete the following steps:

Procedure

1. Choose between information for a particular service point, or information aggregated for all service points for a particular service, by completing one of the following substeps:
   a. Optional: For runtime information for a particular service point, navigate to either **Service integration -> WS-Notification -> Services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name*** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name***, then click the **Runtime** tab. A panel is displayed that contains links to runtime information about subscriptions, registrations, pull points and administered subscribers for this WS-Notification service point.
   b. Optional: For runtime information aggregated for all service points for a particular service, navigate to either **Service integration -> WS-Notification -> Services -> *service_name*** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name*** then click the **Runtime** tab. A panel is displayed that contains links to runtime information about subscriptions, registrations and pull points for this WS-Notification service.
2. Click **Subscriptions** , **Publisher registrations**, **Pull points** or (for a particular service point) **Administered subscribers**.
   - If you click **Subscriptions**, a panel is displayed that lists the durable subscriptions that have been created by a WS-Notification service point in response to “Subscribe” requests from WS-Notification applications. You can view the subscription name (ID), topic and other information associated with the subscription, and you can view messages held on the durable subscription pending delivery. You can also delete subscriptions.

Note: Both the WS-Notification subscription and publisher registration resources include the concept of scheduled termination, in which the application indicates a period of time after which the resource is destroyed. “Badly-behaved” in this case describes an application that requests an infinite lifetime for a resource and then does not explicitly delete the resource before it goes away (never to return).

- If you click **Publisher registrations**, a panel is displayed that lists the publisher registrations that are currently in effect on this WS-Notification service or service point (that is, applications that have registered as publishers). You can view the basic properties of the registration record. You can also delete a publisher registration record.
- If you click **Pull points**, a panel is displayed that lists the pull points that are currently active on this WS-Notification service or service point. You can view basic properties of the pull point such as the subscription with which it is associated and the time at which it is currently set to expire, and you can navigate to the associated subscriptions where appropriate. You can also delete pull points.
- For a particular service point, if you click **Administered subscribers**, a panel is displayed that lists the administered subscribers that are currently in effect on this WS-Notification service point. You can use this information to see whether a given subscriber has been successfully initialized.

What to do next

For more detailed information about working with individual runtime panels, see the following topics:

- “Listing or deleting active WS-Notification subscriptions” on page 3027.
- “Listing or deleting active WS-Notification publisher registrations” on page 3029.
- “Listing or deleting active WS-Notification pull points” on page 3030.
- “Listing active WS-Notification administered subscribers” on page 3031.

Publishing the WSDL files for a WS-Notification application to a compressed file

Use the administrative console to download a compressed file with a `.zip` file extension that contains the published WSDL files for a WS-Notification application.

About this task

The ability to publish these WSDL files to a compressed file is particularly useful in the following circumstances:

- Writing a WS-Notification application that invokes web service operations against the NotificationBroker application, as described in Writing a WS-Notification application that does not expose a web service endpoint.
- Running the wsimport command against the exported `PublisherRegistrationManager.wsdl` file to generate a client stub for the PublisherRegistrationManager.
- Viewing the endpoint URLs to which WS-Notification applications connect, by looking in the WSDL file for the NotificationBroker application for Version 7.0 services, or the inbound service for Version 6.1 services.

Note:

When you run the wsimport command against the exported `PublisherRegistrationManager.wsdl` file you must include the `ibm-wsn-jaxws.xml` file as an argument to wsimport. If you omit this bindings file, the wsimport command fails with a naming conflict error concerning the ResourceNotDestroyedFault elements referred to in the `PublisherRegistrationManager.wsdl` file. For more information about why this exception occurs, see the following troubleshooting tip: The PublisherRegistrationManager.wsdl file is not successfully parsed by wsimport unless you include a JAX-WS bindings file.

The `ibm-wsn-jaxws.xml` file is located in the *app_server_root*`/util` directory. For example: `c:\was\util\ibm-wsn-jaxws.xml`. This bindings file expects to find the WSDL file to which it refers

in the same directory as itself, so before you run the wsimport command you must copy the bindings file to the directory that holds your `PublisherRegistrationManager.wsdl` file. Here is an example of how to run the wsimport command to include the `ibm-wsn-jaxws.xml` file:

```
c:\was\bin\wsimport -b ibm-wsn-jaxws.xml -keep PublisherRegistrationManager.wsdl
```

Procedure

1. Start the administrative console.
2. Navigate to the "Publish WSDL files to .zip file [Settings]" form for the WS-Notification application.

   For JAX-WS based Version 7.0 WS-Notification services, click one of the following paths:

   - **Service integration -> WS-Notification -> Services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name* -> [Additional Properties] Publish WSDL files to zip**
   - **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name* -> [Additional Properties] Publish WSDL files to zip**

   For JAX-RPC based Version 6.1 WS-Notification services, click one of the following paths:

   - **Service integration -> WS-Notification -> Services -> *service_name* -> [Related Items] Notification broker inbound service settings** > **[Additional Properties] Publish WSDL files to ZIP file**
   - **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Related Items] Notification broker inbound service settings** > **[Additional Properties] Publish WSDL files to ZIP file**
3. Click on the file name to download a zip file that contains the application's published WSDL files.

Configuring WS-Notification resources

You can configure individual WS-Notification resources by using the administrative console or by using the wsadmin tool.

About this task

To complete the tasks described in "Accomplishing common WS-Notification tasks" on page 2962, you configure the following types of WS-Notification resource:

- WS-Notification service
- WS-Notification service point
- WS-Notification administered subscriber
- Permanent WS-Notification topic namespace
- WS-Notification topic namespace document

You can configure individual WS-Notification resources by using the administrative console or by using the wsadmin tool, as described in the following tasks:

Procedure

- Configure WS-Notification resources by using the administrative console.
- Configure WS-Notification resources by using the wsadmin tool.
- Interact at run time with WS-Notification.
- Configure a JAX-WS client to resolve a WS-Notification service WSDL without following web links.

Configuring WS-Notification resources by using the administrative console

Use the administrative console to configure individual WS-Notification services, service points, administered subscribers, permanent topic namespaces, topic namespace documents and JAX-WS handlers.

Before you begin

Decide which method to use to configure these resources. You can configure WS-Notification resources by using the administrative console as described in this task, or by using the commands in the “WSNotificationCommands command group for the AdminTask object” on page 3053.

About this task

WS-Notification enables web services to use the publish and subscribe messaging pattern. For more information, see ../ae/cjwsn_overview.dita and “WS-Notification” on page 2964.

For high-level configuration of WS-Notification, see “Accomplishing common WS-Notification tasks” on page 2962. Use the steps for this task to configure individual instances of each type of WS-Notification resource.

You access the WS-Notification panels through the **Service integration** section of the administrative console navigation pane:

- To see a list of all the WS-Notification services, click **Service integration -> WS-Notification -> Services**.
- To see a list of all the WS-Notification services for a particular service integration bus, click **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services**.

To support the Java API for XML-based Web Services (JAX-WS) and composition with WS-ReliableMessaging, you create your WS-Notification services as JAX-WS applications. The implementation of WS-Notification in WebSphere Application Server Version 6.1 uses JAX-RPC applications, so there are now two different implementations of the WS-Notification service and service point:

- **Version 7.0**: Use this type of service if you want to compose a JAX-WS WS-Notification service with web service qualities of service (QoS) via policy sets, or if you want to apply JAX-WS handlers to your WS-Notification service. This is the recommended type of service for new deployments. This WS-Notification option has been available in WebSphere Application Server from Version 7.0.
- **Version 6.1**: Use this type of service if you want to expose a JAX-RPC WS-Notification service that uses the same technology provided in WebSphere Application Server Version 6.1, including the ability to apply JAX-RPC handlers to the service. This WS-Notification option has been available in WebSphere Application Server from Version 6.1.

To configure specific WS-Notification resources, use the administrative console to complete any of the following tasks:

Procedure

- Configure a WS-Notification service.

  Complete any of the following tasks:
  - Create a new Version 7.0 WS-Notification service.
  - Modify a Version 7.0 WS-Notification service.
  - Create a new Version 6.1 WS-Notification service.
  - Modify a Version 6.1 WS-Notification service.
  - Delete WS-Notification services.
- Configure a WS-Notification service point.

  Complete any of the following tasks:
  - Create a new Version 7.0 WS-Notification service point.
  - Modify a Version 7.0 WS-Notification service point.
  - Create a new Version 6.1 WS-Notification service point.

  - Modify a Version 6.1 WS-Notification service point.
  - Delete WS-Notification service points.
- Configure a WS-Notification administered subscriber.
  Complete any of the following tasks:
  - Create a new WS-Notification administered subscriber.
  - Modify a WS-Notification administered subscriber.
  - Delete WS-Notification administered subscribers.
- Configure a permanent WS-Notification topic namespace.
  Complete any of the following tasks:
  - Create a new permanent WS-Notification topic namespace.
  - Show the properties of a permanent WS-Notification topic namespace.
  - Delete WS-Notification permanent topic namespaces.
- Configure a WS-Notification topic namespace document.
  Complete any of the following tasks:
  - Apply a WS-Notification topic namespace document.
  - Show the contents of a WS-Notification topic namespace document.
  - Delete WS-Notification topic namespace documents.
- Configure JAX-WS handlers and handler lists.
  Complete any of the following tasks:
  - Load JAX-WS handler classes.
  - Create a new JAX-WS handler configuration.
  - Modify an existing JAX-WS handler configuration.
  - Delete JAX-WS handler configurations.
  - Create a new JAX-WS handler list.
  - Modify an existing JAX-WS handler list.
  - Delete JAX-WS handler lists.

Creating a new Version 7.0 WS-Notification service:

Create a new WS-Notification service and the associated objects that form the infrastructure of the WS-Notification configuration. Use this type of service if you want to compose a JAX-WS WS-Notification service with web service qualities of service (QoS) via policy sets, or if you want to apply JAX-WS handlers to your WS-Notification service. This is the recommended type of service for new deployments. This WS-Notification option has been available in WebSphere Application Server from Version 7.0.

Before you begin

Decide which method to use to configure these resources. You can create a new Version 7.0 WS-Notification service by using the administrative console as described in this task, or by using the “createWSNService command” on page 3054.

This task assumes that you have an existing service integration bus, configured with at least one bus member.

You usually configure one WS-Notification service for a service integration bus, but you can configure more than one. For more information, see Reasons to create multiple WS-Notification services in a bus.

Defining a Version 7.0 WS-Notification service is not the same as exposing a NotificationBroker (WSDL) port to which web services applications can connect. To do this, create one or more Version 7.0 WS-Notification service points as described in this task.

About this task

A WS-Notification service provides the ability to expose some or all of the messaging resources defined on a service integration bus for use by WS-Notification applications.

To support the Java API for XML-based Web Services (JAX-WS) and composition with WS-ReliableMessaging, you create your WS-Notification services as JAX-WS applications, then use this task to create a Version 7.0 WS-Notification service, one or more service points, and (optionally) a permanent topic namespace.

You can also apply JAX-WS handler lists to WS-Notification service points (for inbound invocation handling) and WS-Notification services (for outbound invocation handling).

When you create a Version 7.0 WS-Notification service, the wizard creates and deploys a JAX-WS based provider application. This application exposes the WS-Notification web service interfaces for each of the three WS-Notification service roles:

- Notification broker
- Subscription manager
- Publisher registration manager

Procedure

1. Start the administrative console.
2. Navigate to **Service integration -> WS-Notification -> Services** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services**. The "WS-Notification services [Collection]" on page 3047 form is displayed.
3. In the content pane, click **New**. The "New WS-Notification service" wizard is displayed. For more information about the properties that you set with the wizard, see "WS-Notification services [Settings]" on page 3047.
4. Step 1: Configure name, description, service integration bus and dynamic topic namespace settings.
   a. Enter your chosen name and an optional description.

      The name forms part of the endpoint on which the service is exposed (that is, the URL used to access the WS-Notification service points that are defined under the service). For Version 6.1 WS-Notification services, the service name is unique within a bus. For Version 7.0 WS-Notification services the service name is unique within the cell, which matches the administration model used for policy sets and therefore supports composition of Version 7.0 WS-Notification services with WS-ReliableMessaging.

   b. Select or deselect the option **Enable dynamic topic namespaces?**.

      Indicates whether dynamic topic namespaces can be used within the WS-Notification service. That is, whether this service allows dynamic topic namespaces to be created at run time. For more information, see Dynamic topic namespace.

      Use this option to tightly control the topic namespaces that are used when connecting to a particular WS-Notification service (for example for security or auditing requirements). If you deselect this option, any applications that connect to the WS-Notification service and request topics from a dynamic topic namespace are stopped from publishing or receiving messages.

      All messages published to a dynamic topic namespace are inserted with the default message reliability setting of reliable persistent. If this value is not acceptable, create a permanent topic namespace and manually configure the attribute to the appropriate value.

      Note: The dynamic topic namespaces used on a particular WS-Notification service are backed by a service integration bus topic space that is created automatically when you create the topic namespace. The syntax of topics used within this topic space is internal to the WS-Notification service implementation.

c. Select or deselect the option **Requires registration**.

   Indicates whether publisher applications are required to register with the broker before they can publish notifications.

d. Select a service integration bus from the drop-down list.

e. Click **Next**.

5. Step 2: Select WS-Notification service type.

   Select **Version 7.0** as the type of service that you want to create.

6. Step 3: Configure handler and web service policy settings.

   These settings are applied to the event notifications exchanged with WS-Notification client applications.

   a. Optional: Choose a JAX-WS handler list.

      The JAX-WS handler list that is applied to outbound requests from the WS-Notification service. A handler list defines the handlers that are applied when making outbound web service invocations, for example monitoring outbound event notification (in response to a subscribe operation) and controlling demand-based publishers (subscribe, pause and resume). For more information about handler lists, see “Configuring JAX-WS handlers” on page 2972.

   b. Enable or clear the **Query WSDL** option.

      Indicates whether the Version 7.0 WS-Notification service queries the WSDL of other WS-Notification web services when interacting with them. By default, this option is enabled. By clearing this option, you can improve performance by avoiding expensive WSDL queries. However, you should note the following considerations when WSDL querying is not enabled:

      - WS-Notification attempts to discover binding information (which is usually discovered through the WSDL) by using other means. WS-Notification uses the SOAP version associated with the WS-Notification service point where subscriptions were made (by other web services), or where administered subscriptions were created (by an administrator).
      - There are some circumstances in which WS-Notification might be unable to determine binding information. This can happen when cleaning up subscriptions where the associated service point has been deleted and configuration information is no longer available. Under these circumstances WS-Notification makes a “best guess” at binding information to use to clean up the subscriptions.
      - There is one scenario where incorrect binding information is used. That is, when a subscriber subscribes to use a particular SOAP binding, on behalf of a NotificationConsumer that expects notifications through a different SOAP binding.

   c. Enter a dynamic topic space name.

      The name of the service integration bus topic space to be used as the dynamic topic space for this WS-Notification service. That is, the name of the bus topic space that is used to host the ad-hoc topic namespace, and to host dynamic topic namespaces if they are permitted. A default name of `WSN_dynamic_this_service_name` is offered.

   d. Click **Next**.

7. Step 4: Create WS-Notification service points.

   A WS-Notification service point defines access to a WS-Notification service on a given bus member through a specified web service binding (for example SOAP over HTTP). Applications use the bus members associated with the WS-Notification service point to connect to the WS-Notification service. The existence of a WS-Notification service point on a bus member implies that a WS-Notification web service is exposed from that bus member, and causes web service endpoints for the notification broker, subscription manager and publisher registration manager for this WS-Notification service to be exposed on the bus member with which the service point is associated. WS-Notification applications use these endpoints to interact with the WS-Notification service. For more information, see WS-Notification service point.

   a. Select **Yes** to create a new WS-Notification service point, then click **Next**.

      A WS-Notification service must have at least one service point.

b. Supply a name and (optional) description for the WS-Notification service point, and from the drop-down list select the bus member on which the service point is to be configured, then click **Next**.

The service point name forms part of the URL used to access the service point. On a single server system there is only one bus member in the list.

c. Select the transport settings for the new service point.

Service point accessed via HTTP proxy
If the service point is accessed through a proxy, select the check box, and type the root of the externally visible endpoint address URL for web services accessed through this endpoint.

The URL for the proxy is used to populate the WSDL endpoint address fields when publishing WSDL files to a compressed file.

SOAP Version
Select the version of SOAP that is supported by the service point. This affects the WSDL definition that is exposed by the web service.

d. Optional: Select the JAX-WS handler list settings for the new service point.

NotificationBroker JAX-WS handler list

The JAX-WS handler list that is applied to inbound requests from an application to the NotificationBroker endpoint of the WS-Notification service point.

SubscriptionManager JAX-WS handler list

The JAX-WS handler list that is applied to inbound requests from an application to the SubscriptionManager endpoint of the WS-Notification service point.

PublisherRegistrationManager JAX-WS handler list

The JAX-WS handler list that is applied to inbound requests from an application to the PublisherRegistrationManager endpoint of the WS-Notification service point.

e. Click **Next**. The new service point is added to the list of service points for this WS-Notification service.

f. Optional: To create another service point, repeat the previous substeps.

g. When you have finished creating service points for this WS-Notification service, select **No** for the option to create another service point, then click **Next**.

8. Optional: Step 5: Create permanent topic namespaces.

For more information, see Permanent topic namespace. When you create a new WS-Notification permanent topic namespace, you specify the namespace and associate it with one of the service integration bus topic spaces configured on the bus on which the parent WS-Notification service is defined. You cannot modify a permanent topic namespace after it has been created, other than to apply or remove topic namespace documents.

a. Select **Yes** to create a new permanent topic namespace, then click **Next**.

b. Enter a name for the permanent topic namespace.

This is the URI by which WS-Notification applications refer to topics hosted by this namespace.

c. Associate this new permanent topic namespace with the service integration bus topic space that you want to use to publish and receive messages.

From the service integration bus topic space drop-down list, complete one of the following actions:

- Select the name of an existing bus topic space.
- Select the option to `Create a new topic space`, then enter a name for the new topic space.

d. Select from the drop-down list the service integration bus reliability (quality of service) that is assigned to messages published through this topic namespace.

You can choose one of five values, each representing one of the service integration bus message reliability levels. The default value is `reliable persistent`, which is the value used by default for JMS Persistent messages.

e. Click **Next**.

The new permanent topic namespace is added to a list of permanent topic namespaces for this Version 7.0 WS-Notification service, and you are asked whether you want to create another permanent topic namespace (default is **Yes**).

f. Optional: To create another permanent topic namespace, repeat the previous substeps.

g. When you have finished creating permanent topic namespaces for this Version 7.0 WS-Notification service, select **No** for the option to create another permanent topic namespace, then click **Next**.

9. Step 6: Summary.

Check that the summary of the actions taken by the wizard is as you expected, then click **Finish**. If the processing completes successfully, the list of Version 7.0 WS-Notification services is updated to include the new Version 7.0 WS-Notification service. Otherwise, an error message is displayed.

10. Save your changes to the master configuration.

11. Optional: Restart the server if either of the following conditions apply:
    - A new bus or new bus member has been created as part of this task.
    - **Configuration reload** is not enabled for the bus.

What to do next

To undertake advanced configuration tasks for this WS-Notification service (for example, adding additional service points and applying topic namespace documents to permanent topic namespaces), see “Modifying a Version 7.0 WS-Notification service.”

To undertake advanced configuration tasks for the WS-Notification service point that you created as part of this task (for example, adding administered subscribers, publishing WSDL files to a compressed file, and configuring the enterprise application associated with this service point), see “Modifying a Version 7.0 WS-Notification service point” on page 3003.

To configure this WS-Notification service or service point with web service qualities of service (QoS) such as reliability or security, see “Configuring a Version 7.0 WS-Notification service with Web service QoS” on page 2974.

Modifying a Version 7.0 WS-Notification service:

Modify the **description**, **Enabled dynamic topic namespaces?**, **Requires registration**, **JAX-WS handler list** and **Query WSDL** properties of a Version 7.0 WS-Notification service, and follow links to complete advanced configuration such as adding additional WS-Notification service points, applying topic namespace documents to permanent topic namespaces, and applying policy sets to enable WS-ReliableMessaging.

About this task

A WS-Notification service provides the ability to expose some or all of the messaging resources defined on a service integration bus for use by WS-Notification applications.

A handler list defines the handlers that are applied when making outbound web service invocations, for example monitoring outbound event notification (in response to a subscribe operation) and controlling demand-based publishers (subscribe, pause and resume).

When you create a Version 7.0 WS-Notification service, the wizard creates and deploys a JAX-WS based provider application. This application exposes the WS-Notification web service interfaces for each of the three WS-Notification service roles:

- Notification broker
- Subscription manager
- Publisher registration manager

You can also configure custom properties to specify a timeout time for outbound requests, and to determine the strictness of the syntax checking of topics used under this Version 7.0 WS-Notification service.

Procedure

1. Start the administrative console.
2. Navigate to **Service integration -> WS-Notification -> Services** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services**. The "WS-Notification services [Collection]" on page 3047 form is displayed.
3. In the content pane, click the name of a Version 7.0 WS-Notification service in the list. The current settings for this Version 7.0 WS-Notification service are displayed in the "WS-Notification services [Settings]" on page 3047 panel.
4. Modify the following general properties:

   Description
   An optional description of the WS-Notification service.

   Enable dynamic topic namespaces?

   Indicates whether dynamic topic namespaces can be used within the WS-Notification service. That is, whether this service allows dynamic topic namespaces to be created at run time. For more information, see Dynamic topic namespace.

   Use this option to tightly control the topic namespaces that are used when connecting to a particular WS-Notification service (for example for security or auditing requirements). If you deselect this option, any applications that connect to the WS-Notification service and request topics from a dynamic topic namespace are stopped from publishing or receiving messages.

   All messages published to a dynamic topic namespace are inserted with the default message reliability setting of reliable persistent. If this value is not acceptable, create a permanent topic namespace and manually configure the attribute to the appropriate value.

   Note: The dynamic topic namespaces used on a particular WS-Notification service are backed by a service integration bus topic space that is created automatically when you create the topic namespace. The syntax of topics used within this topic space is internal to the WS-Notification service implementation.

   Requires registration
   Indicates whether publisher applications are required to register with the broker before they can publish notifications.

   JAX-WS handler list

   The JAX-WS handler list that is applied to outbound requests from the WS-Notification service.

   A handler list defines the handlers that are applied when making outbound web service invocations, for example monitoring outbound event notification (in response to a subscribe operation) and controlling demand-based publishers (subscribe, pause and resume). For more information about handler lists, see "Configuring JAX-WS handlers" on page 2972.

   Query WSDL

Indicates whether the Version 7.0 WS-Notification service queries the WSDL of other WS-Notification web services when interacting with them. By default, this option is enabled. By clearing this option, you can improve performance by avoiding expensive WSDL queries. However, you should note the following considerations when WSDL querying is not enabled:

- WS-Notification attempts to discover binding information (which is usually discovered through the WSDL) by using other means. WS-Notification uses the SOAP version associated with the WS-Notification service point where subscriptions were made (by other web services), or where administered subscriptions were created (by an administrator).
- There are some circumstances in which WS-Notification might be unable to determine binding information. This can happen when cleaning up subscriptions where the associated service point has been deleted and configuration information is no longer available. Under these circumstances WS-Notification makes a “best guess” at binding information to use to clean up the subscriptions.
- There is one scenario where incorrect binding information is used. That is, when a subscriber subscribes to use a particular SOAP binding, on behalf of a NotificationConsumer that expects notifications through a different SOAP binding.

5. Modify the additional properties:

WS-Notification service points

Select this link to configure the deployment of WS-Notification service points on one or more servers. For more information, see “Creating a new Version 7.0 WS-Notification service point” on page 3001 or “Modifying a Version 7.0 WS-Notification service point” on page 3003.

Permanent topic namespaces

Select this link to configure permanent topic namespaces for the WS-Notification service. For more information, see Permanent topic namespace. When you create a new WS-Notification permanent topic namespace, you specify the namespace and associate it with one of the service integration bus topic spaces configured on the bus on which the parent WS-Notification service is defined. You cannot modify a permanent topic namespace after it has been created, other than to apply or remove topic namespace documents.

Custom properties

Select this link to configure additional custom properties for this WS-Notification service. These custom properties are name and value pairs that you can use to set internal system configuration properties. In each pair, the name is a property key and the value is a string value.

To specify a timeout time for outbound requests sent from this WS-Notification service, set the following custom property:

outbound.timeout

The value of this property is the timeout time in milliseconds. If the property is not set, a default timeout of 2 minutes is used.

To determine the strictness of the syntax checking of topics used under this WS-Notification service, set the following custom property:

com.ibm.ws.sib.wsn.strictTopicChecking

Valid values for this property are TRUE and FALSE:

- If the property value is set to TRUE, the topic syntax rules defined in the WS-Topics standard are strictly enforced. Note that there is a performance cost compared to the default setting, because each character of a topic is validated against a large list of permitted Unicode characters.
- If the property is omitted or set to FALSE, syntax checking only ensures that the basic topic structure is valid, and character checking is relaxed to allow any character except * (asterisk) and . (dot) as a topic name part.

Outbound request policy sets and bindings

The outbound request policy sets and bindings for the two WS-Notification service clients associated with this WS-Notification service. For reliable web service transmission of notification messages, use this option to associate the WS-Notification service client with a policy set that enables WS-ReliableMessaging.

For more information, see “Configuring a Version 7.0 WS-Notification service with Web service QoS” on page 2974.

6. Apply any changes, then click **OK**. If the processing completes successfully, the list of WS-Notification services is redisplayed. Otherwise, an error message is displayed.
7. Save your changes to the master configuration. You need not restart the server for the changes to fully take effect if **configuration reload** is enabled for the service integration bus.

Deleting WS-Notification services:

Remove all configuration associated with one or more WS-Notification services. A WS-Notification service provides access to service integration bus resources for web services publish and subscribe clients.

Before you begin

Decide which method to use to configure these resources. You can delete a WS-Notification service by using the administrative console as described in this task, or by using the “deleteWSNService command” on page 3057.

About this task

When you delete a Version 6.1 WS-Notification service, the associated inbound services and inbound ports are also deleted. The associated endpoint listeners are deleted if they were created in the process of creating a WS-Notification service point and are not used by any other configuration object. When you delete a Version 7.0 WS-Notification service, the associated service point provider applications and service points are also deleted. Do not delete these resources manually, because this might leave the associated configuration information in an inconsistent state.

For both types of WS-Notification service, you choose whether the associated service integration bus topic spaces are deleted.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> WS-Notification -> Services** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services**. A list of all the WS-Notification services is displayed in a “WS-Notification services [Collection]” on page 3047 form.
3. Select the check box for every WS-Notification service that you want to remove.
4. Click **Delete**. A panel is displayed asking if the service integration bus topic spaces associated with the WS-Notification service (including those associated with all the WS-Notification topic namespaces) should also be deleted.
5. Optional: Select the check box if you want to delete the associated service integration bus topic spaces.

   Note: Deleting a service integration bus topic space causes exception messages to be generated for WS-Notification applications that reference the topic space, as described in Failures as a result of changes in topic space and topic namespace configurations.
6. Click **Delete**. If the processing completes successfully, the list of WS-Notification services is updated. Otherwise, an error message is displayed.
7. Save your changes to the master configuration.

Creating a new Version 6.1 WS-Notification service:

Create a new WS-Notification service and the associated objects that form the infrastructure of the WS-Notification configuration. Use this type of service if you want to expose a JAX-RPC WS-Notification service that uses the same technology provided in WebSphere Application Server Version 6.1, including the ability to apply JAX-RPC handlers to the service. This WS-Notification option has been available in WebSphere Application Server from Version 6.1.

Before you begin

Ensure that you have successfully configured an SDO repository, as described in “Installing and configuring the SDO repository” on page 2772. The SDO repository is used to store WSDL documents during the creation of the WS-Notification service. If you do not configure the repository, an error message appears when you create the service.

Decide which method to use to configure these resources. You can create a new Version 6.1 WS-Notification service by using the administrative console as described in this task, or by using the “createWSNService command” on page 3054.

This task assumes that you have an existing service integration bus, configured with at least one bus member.

You usually configure one WS-Notification service for a service integration bus, but you can configure more than one. For more information, see Reasons to create multiple WS-Notification services in a bus.

Defining a WS-Notification service on a bus is not the same as exposing a NotificationBroker (WSDL) port to which web services applications can connect. To do this, create one or more WS-Notification service points as described in this task.

About this task

A WS-Notification service provides the ability to expose some or all of the messaging resources defined on a service integration bus for use by WS-Notification applications.

A JAX-RPC handler list and WS-Security bindings define the parameters and security policy that are used when making outbound web service invocations, for example monitoring outbound event notification (in response to a subscribe operation) and controlling demand-based publishers (subscribe, pause and resume).

When you create a Version 6.1 WS-Notification service, the wizard configures three service integration bus inbound services for the WS-Notification service, one for each of the three WS-Notification service roles:

- Notification broker
- Subscription manager
- Publisher registration manager

These inbound services are defined on the same service integration bus as the Version 6.1 WS-Notification service, and each of these inbound services refers to the same bus destination.

Procedure

1. Start the administrative console.
2. Navigate to **Service integration -> WS-Notification -> Services** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services**. The “WS-Notification services [Collection]” on page 3047 form is displayed.

3. In the content pane, click **New**. The “New WS-Notification service” wizard is displayed. For more information about the properties that you set with the wizard, see “WS-Notification services [Settings]” on page 3047.
4. Step 1: Configure name, description, service integration bus and dynamic topic namespace settings.
   a. Enter your chosen name and an optional description.

      The name forms part of the endpoint on which the service is exposed (that is, the URL used to access the WS-Notification service points that are defined under the service). For Version 6.1 WS-Notification services, the service name is unique within a bus. For Version 7.0 WS-Notification services the service name is unique within the cell, which matches the administration model used for policy sets and therefore supports composition of Version 7.0 WS-Notification services with WS-ReliableMessaging.
   b. Select or deselect the option **Enable dynamic topic namespaces?**.

      Indicates whether dynamic topic namespaces can be used within the WS-Notification service. That is, whether this service allows dynamic topic namespaces to be created at run time. For more information, see Dynamic topic namespace.

      Use this option to tightly control the topic namespaces that are used when connecting to a particular WS-Notification service (for example for security or auditing requirements). If you deselect this option, any applications that connect to the WS-Notification service and request topics from a dynamic topic namespace are stopped from publishing or receiving messages.

      All messages published to a dynamic topic namespace are inserted with the default message reliability setting of reliable persistent. If this value is not acceptable, create a permanent topic namespace and manually configure the attribute to the appropriate value.

      Note: The dynamic topic namespaces used on a particular WS-Notification service are backed by a service integration bus topic space that is created automatically when you create the topic namespace. The syntax of topics used within this topic space is internal to the WS-Notification service implementation.
   c. Select or deselect the option **Requires registration**.

      Indicates whether publisher applications are required to register with the broker before they can publish notifications.
   d. Select a service integration bus from the drop-down list.
   e. Click **Next**.
5. Step 2: Select WS-Notification service type.

   Select **Version 6.1** as the type of service that you want to create.
6. Step 3: Configure handler and web service policy settings.

   These settings are applied to the event notifications exchanged with WS-Notification client applications.
   a. Optional: Choose a JAX-RPC handler list.

      The JAX-RPC handler list that is applied to outbound requests from the WS-Notification service - for example the broker delivering notifications to a consumer. For more information about handler lists, see “Working with JAX-RPC handlers and clients” on page 2799.
   b. Optional: Choose a WS-Security configuration and bindings:

      Outbound security request binding
      The security binding to be used with consumer notifications and remote publisher requests sent by this WS-Notification service.

      Outbound security response binding
      The security binding to be used with remote publisher responses received by this WS-Notification service.

      Outbound security configuration
      Specifies the details of how security is applied to requests and responses.

For more information about Web Services Security resources, see Configuring secure transmission of SOAP messages by using WS-Security.

c. Enter a dynamic topic space name.

The name of the service integration bus topic space to be used as the dynamic topic space for this WS-Notification service. That is, the name of the bus topic space that is used to host the ad-hoc topic namespace, and to host dynamic topic namespaces if they are permitted. A default name of `WSN_dynamic_this_service_name` is offered.

d. Click **Next**.

7. Step 4: Create WS-Notification service points.

A WS-Notification service point defines access to a WS-Notification service on a given bus member through a specified web service binding (for example SOAP over HTTP). Applications use the bus members associated with the WS-Notification service point to connect to the WS-Notification service. The existence of a WS-Notification service point on a bus member implies that a WS-Notification web service is exposed from that bus member, and causes web service endpoints for the notification broker, subscription manager and publisher registration manager for this WS-Notification service to be exposed on the bus member with which the service point is associated. WS-Notification applications use these endpoints to interact with the WS-Notification service. For more information, see WS-Notification service point.

a. Select **Yes** to create a new WS-Notification service point, then click **Next**.

A WS-Notification service must have at least one service point.

b. Supply a name and (optional) description for the WS-Notification service point, and from the drop-down list select the bus member on which the service point is to be configured, then click **Next**.

The service point name forms part of the URL used to access the service point (that is, the address of the web service that is exposed on the chosen server). On a single server system there is only one bus member in the list.

c. Select a listener application to use to expose the service. Either select an existing endpoint listener for this bus member, or **Create a new endpoint listener**.

For more information, see “Creating a new endpoint listener configuration” on page 2789.

d. Click **Next**. The new service point is added to the list of service points for this WS-Notification service.

e. Optional: To create another service point, repeat the previous substeps.

f. When you have finished creating service points for this WS-Notification service, select **No** for the option to create another service point, then click **Next**.

8. Optional: Step 5: Create permanent topic namespaces.

When you create a new WS-Notification permanent topic namespace, you specify the namespace and associate it with one of the service integration bus topic spaces configured on the bus on which the parent WS-Notification service is defined. You cannot modify a permanent topic namespace after it has been created, other than to apply or remove topic namespace documents. For more information, see Permanent topic namespace.

a. Select **Yes** to create a new permanent topic namespace, then click **Next**.

b. Enter a name for the permanent topic namespace.

This is the URI by which WS-Notification applications refer to topics hosted by this namespace.

c. Associate this new permanent topic namespace with the service integration bus topic space that you want to use to publish and receive messages.

From the service integration bus topic space drop-down list, complete one of the following actions:

- Choose the name of an existing bus topic space.
- Choose the option to `Create a new topic space`, then enter a name for the new topic space.

d. Select from the drop-down list the service integration bus reliability (quality of service) that is assigned to messages published through this topic namespace.

You can choose one of five values, each representing one of the service integration bus message reliability levels. The default value is `reliable persistent`, which is the value used by default for JMS Persistent messages.

e. Click **Next**.

The new permanent topic namespace is added to a list of permanent topic namespaces for this WS-Notification service, and you are asked whether you want to create another permanent topic namespace (default is **Yes**).

f. Optional: To create another permanent topic namespace, repeat the previous substeps.

g. When you have finished creating permanent topic namespaces for this WS-Notification service, select **No** for the option to create another permanent topic namespace, then click **Next**.

9. Step 6: Summary.

Check that the summary of the actions taken by the wizard is as you expected, then click **Finish**. If the processing completes successfully, the list of WS-Notification services is updated to include the new Version 6.1 WS-Notification service. Otherwise, an error message is displayed.

10. Save your changes to the master configuration.

11. Optional: Restart the server if either of the following conditions apply:
    - A new bus or new bus member has been created as part of this task.
    - **Configuration reload** is not enabled for the bus.

What to do next

To undertake advanced configuration tasks for this WS-Notification service (for example adding additional WS-Notification service points, or applying topic namespace documents to permanent topic namespaces), see “Modifying a Version 6.1 WS-Notification service.”

Modifying a Version 6.1 WS-Notification service:

Modify the **description**, **Enabled dynamic topic namespaces?** and **Requires registration** properties of a WS-Notification service, and follow links to complete advanced configuration of the WS-Notification service such as adding additional WS-Notification service points, or applying topic namespace documents to permanent topic namespaces.

About this task

A WS-Notification service provides the ability to expose some or all of the messaging resources defined on a service integration bus for use by WS-Notification applications.

A JAX-RPC handler list and WS-Security bindings define the parameters and security policy that are used when making outbound web service invocations, for example monitoring outbound event notification (in response to a subscribe operation) and controlling demand-based publishers (subscribe, pause and resume).

When you create a Version 6.1 WS-Notification service, the wizard configures three service integration bus inbound services for the WS-Notification service, one for each of the three WS-Notification service roles:

- Notification broker
- Subscription manager
- Publisher registration manager

These inbound services are defined on the same service integration bus as the Version 6.1 WS-Notification service, and each of these inbound services refers to the same bus destination.

You can make web services-specific modifications to the WS-Notification service behavior by modifying the three associated inbound services. You can also configure a custom property that determines the strictness of the syntax checking of topics used under this WS-Notification service.

To modify a WS-Notification service use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Service integration -> WS-Notification -> Services** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services**. The "WS-Notification services [Collection]" on page 3047 form is displayed.
2. In the content pane, click the name of a WS-Notification service in the list. The current settings for this WS-Notification service are displayed in the "WS-Notification services [Settings]" on page 3047 panel.
3. Modify the following general properties:

   Description
   An optional description of the WS-Notification service.

   Enable dynamic topic namespaces?

   Indicates whether dynamic topic namespaces can be used within the WS-Notification service. That is, whether this service allows dynamic topic namespaces to be created at run time. For more information, see Dynamic topic namespace.

   Use this option to tightly control the topic namespaces that are used when connecting to a particular WS-Notification service (for example for security or auditing requirements). If you deselect this option, any applications that connect to the WS-Notification service and request topics from a dynamic topic namespace are stopped from publishing or receiving messages.

   All messages published to a dynamic topic namespace are inserted with the default message reliability setting of reliable persistent. If this value is not acceptable, create a permanent topic namespace and manually configure the attribute to the appropriate value.

   Note: The dynamic topic namespaces used on a particular WS-Notification service are backed by a service integration bus topic space that is created automatically when you create the topic namespace. The syntax of topics used within this topic space is internal to the WS-Notification service implementation.

   Requires registration
   Indicates whether publisher applications are required to register with the broker before they can publish notifications.
4. Modify the JAX-RPC handler list and Web Services Security settings. These settings are applied to the event notifications exchanged with WS-Notification client applications. For more information about handler lists, see "Working with JAX-RPC handlers and clients" on page 2799. For more information about Web Services Security resources, see Configuring secure transmission of SOAP messages by using WS-Security.

   JAX-RPC handler list
   The JAX-RPC handler list that is applied to outbound requests from the WS-Notification service - for example the broker delivering notifications to a consumer.

   Outbound security request binding
   The security binding to be used with consumer notifications and remote publisher requests sent by this WS-Notification service.

   Outbound security response binding
   The security binding to be used with remote publisher responses received by this WS-Notification service.

   Outbound security configuration
   Specifies the details of how security is applied to requests and responses.

5. Modify the additional properties:

   WS-Notification service points
   Select this link to configure the deployment of WS-Notification service points on one or more servers. For more information, see “Modifying a Version 6.1 WS-Notification service point” on page 3006.

   Permanent topic namespaces
   Select this link to configure permanent topic namespaces for the WS-Notification service. For more information, see Permanent topic namespace. When you create a new WS-Notification permanent topic namespace, you specify the namespace and associate it with one of the service integration bus topic spaces configured on the bus on which the parent WS-Notification service is defined. You cannot modify a permanent topic namespace after it has been created, other than to apply or remove topic namespace documents.

   Custom properties
   Select this link to configure additional custom properties for this WS-Notification service. These custom properties are name and value pairs that you can use to set internal system configuration properties. In each pair, the name is a property key and the value is a string value.

   To specify a timeout time for outbound requests sent from this WS-Notification service, set the following custom property:

   `outbound.timeout`

   The value of this property is the timeout time in milliseconds. If the property is not set, a default timeout of 2 minutes is used.

   To determine the strictness of the syntax checking of topics used under this WS-Notification service, set the following custom property:

   `com.ibm.ws.sib.wsn.strictTopicChecking`

   Valid values for this property are TRUE and FALSE:

   - If the property value is set to TRUE, the topic syntax rules defined in the WS-Topics standard are strictly enforced. Note that there is a performance cost compared to the default setting, because each character of a topic is validated against a large list of permitted Unicode characters.
   - If the property is omitted or set to FALSE, syntax checking only ensures that the basic topic structure is valid, and character checking is relaxed to allow any character except * (asterisk) and . (dot) as a topic name part.

6. Modify the inbound service settings for the notification broker, subscription manager or publisher registration manager. For more information, see “Modifying an existing inbound service configuration” on page 2780.
7. Apply any changes, then click **OK**. If the processing completes successfully, the list of WS-Notification services is redisplayed. Otherwise, an error message is displayed.
8. Save your changes to the master configuration. You need not restart the server for the changes to fully take effect if **configuration reload** is enabled for the service integration bus.

Deleting WS-Notification services:

Remove all configuration associated with one or more WS-Notification services. A WS-Notification service provides access to service integration bus resources for web services publish and subscribe clients.

Before you begin

Decide which method to use to configure these resources. You can delete a WS-Notification service by using the administrative console as described in this task, or by using the “deleteWSNService command” on page 3057.

About this task

When you delete a Version 6.1 WS-Notification service, the associated inbound services and inbound ports are also deleted. The associated endpoint listeners are deleted if they were created in the process of creating a WS-Notification service point and are not used by any other configuration object. When you delete a Version 7.0 WS-Notification service, the associated service point provider applications and service points are also deleted. Do not delete these resources manually, because this might leave the associated configuration information in an inconsistent state.

For both types of WS-Notification service, you choose whether the associated service integration bus topic spaces are deleted.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> WS-Notification -> Services** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services**. A list of all the WS-Notification services is displayed in a “WS-Notification services [Collection]” on page 3047 form.
3. Select the check box for every WS-Notification service that you want to remove.
4. Click **Delete**. A panel is displayed asking if the service integration bus topic spaces associated with the WS-Notification service (including those associated with all the WS-Notification topic namespaces) should also be deleted.
5. Optional: Select the check box if you want to delete the associated service integration bus topic spaces.

   Note: Deleting a service integration bus topic space causes exception messages to be generated for WS-Notification applications that reference the topic space, as described in Failures as a result of changes in topic space and topic namespace configurations.
6. Click **Delete**. If the processing completes successfully, the list of WS-Notification services is updated. Otherwise, an error message is displayed.
7. Save your changes to the master configuration.

Creating a new Version 7.0 WS-Notification service point:

You can add an additional Version 7.0 WS-Notification service point to an existing Version 7.0 WS-Notification service. A WS-Notification service point defines access to a WS-Notification service on a given bus member through a specified web service binding (for example SOAP over HTTP). Applications use the bus members associated with the WS-Notification service point to connect to the WS-Notification service. The existence of a WS-Notification service point on a bus member implies that a WS-Notification web service is exposed from that bus member, and causes web service endpoints for the notification broker, subscription manager and publisher registration manager for this WS-Notification service to be exposed on the bus member with which the service point is associated. WS-Notification applications use these endpoints to interact with the WS-Notification service.

Before you begin

Decide which method to use to configure these resources. You can create a new Version 7.0 WS-Notification service point by using the administrative console as described in this task, or by using the “createWSNServicePoint command” on page 3061.

About this task

You can define any number of WS-Notification service points for a given WS-Notification service. Each service point defined for the same WS-Notification service represents an alternative entry point to the service. Event notifications published to a particular WS-Notification service point are received by all applications connected to any service point of the same WS-Notification service (subject to subscription on the correct topic) regardless of the particular service point to which they are connected. For more information, see Reasons to create multiple WS-Notification service points.

When you create a Version 7.0 WS-Notification service point you select a bus member on which the WS-Notification service point is configured. You also choose the SOAP version that is supported by the service point, and (optionally) apply JAX-WS handler lists to the NotificationBroker, SubscriptionManager or PublisherRegistrationManager that are exposed through this service point.

Procedure

1. Start the administrative console.
2. Navigate to **Service integration -> WS-Notification -> Services -> *service_name* -> [Additional Properties] WS-Notification service points** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Additional Properties] WS-Notification service points**. The "WS-Notification service points [Collection]" on page 3043 form is displayed. This form shows all the Version 7.0 WS-Notification service points configured for this Version 7.0 WS-Notification service.
3. In the content pane, click **New**. The New WS-Notification service point wizard is displayed. For more information about the properties that you set with the wizard, see "WS-Notification service points [Settings]" on page 3043.
4. Step 1: Configure name, description and select a bus member.
   a. Supply a name and (optional) description for the WS-Notification service point. The service point name forms part of the URL used to access the service point.
   b. From the drop-down list, select the bus member on which the service point is to be configured. On a single server system there is only one bus member in the list.
   c. Click **Next**.
5. Step 2: Define transport settings.
   a. Select the transport settings for the new service point.

      Service point accessed via HTTP proxy
      If the service point is accessed through a proxy, select the check box, and type the root of the externally visible endpoint address URL for web services accessed through this endpoint.

      The URL for the proxy is used to populate the WSDL endpoint address fields when publishing WSDL files to a compressed file.

      SOAP Version
      Select the version of SOAP that is supported by the service point. This affects the WSDL definition that is exposed by the web service.

   b. Optional: Select the JAX-WS handler list settings for the new service point.

      NotificationBroker JAX-WS handler list

      The JAX-WS handler list that is applied to inbound requests from an application to the NotificationBroker endpoint of the WS-Notification service point.

      SubscriptionManager JAX-WS handler list

      The JAX-WS handler list that is applied to inbound requests from an application to the SubscriptionManager endpoint of the WS-Notification service point.

PublisherRegistrationManager JAX-WS handler list

The JAX-WS handler list that is applied to inbound requests from an application to the PublisherRegistrationManager endpoint of the WS-Notification service point.

6. Click **Finish**. If the processing completes successfully, the list of Version 7.0 WS-Notification service points for this Version 7.0 WS-Notification service is updated to include the new service point. Otherwise, an error message is displayed.
7. Save your changes to the master configuration.

What to do next

To undertake advanced configuration tasks for this WS-Notification service point (for example, adding administered subscribers, publishing WSDL files to a compressed file, and configuring the enterprise application associated with this service point), see "Modifying a Version 7.0 WS-Notification service point."

To configure this WS-Notification service point with web service qualities of service (QoS) such as reliability or security, see "Configuring a Version 7.0 WS-Notification service with Web service QoS" on page 2974.

You can also use the administrative console to work with runtime information for service points. For more information, see "Interacting at run time with WS-Notification" on page 2982.

Modifying a Version 7.0 WS-Notification service point:

Modify the **description**, **SOAP Version**, and **JAX-WS handler list** properties of a Version 7.0 WS-Notification service point, and follow links to complete advanced configuration such as modifying the administered subscribers, applying policy sets to enable WS-ReliableMessaging, publishing the WSDL files to compressed files, and configuring the enterprise application that is associated with this service point.

About this task

A WS-Notification service point defines access to a WS-Notification service on a given bus member through a specified web service binding (for example SOAP over HTTP). Applications use the bus members associated with the WS-Notification service point to connect to the WS-Notification service. The existence of a WS-Notification service point on a bus member implies that a WS-Notification web service is exposed from that bus member, and causes web service endpoints for the notification broker, subscription manager and publisher registration manager for this WS-Notification service to be exposed on the bus member with which the service point is associated. WS-Notification applications use these endpoints to interact with the WS-Notification service.

Procedure

1. Start the administrative console.
2. Navigate to **Service integration -> WS-Notification -> Services -> *service_name* -> [Additional Properties] WS-Notification service points** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Additional Properties] WS-Notification service points**. The "WS-Notification service points [Collection]" on page 3043 form is displayed. This form shows all the service points configured for this Version 7.0 WS-Notification service.
3. In the content pane, click the name of a Version 7.0 WS-Notification service point in the list. The current settings for this Version 7.0 WS-Notification service point are displayed in the "WS-Notification service points [Settings]" on page 3043 form.
4. Modify the following general properties:

   Description

   An optional description of the WS-Notification service point.

Associated bus member
The name of the bus member on which this WS-Notification service point is deployed.

SOAP Version

Defines the version of SOAP supported by the service point. This affects the WSDL definition that will be exposed by the web service. Permitted values are 1.1 for SOAP 1.1 (the default), and 1.2 for SOAP 1.2.

NotificationBroker JAX-WS handler list

The JAX-WS handler list that is applied to inbound requests from an application to the NotificationBroker endpoint of the WS-Notification service point.

SubscriptionManager JAX-WS handler list

The JAX-WS handler list that is applied to inbound requests from an application to the SubscriptionManager endpoint of the WS-Notification service point.

PublisherRegistrationManager JAX-WS handler list

The JAX-WS handler list that is applied to inbound requests from an application to the PublisherRegistrationManager endpoint of the WS-Notification service point.

5. Modify the additional properties:

Administered subscribers
An administered subscriber provides a mechanism for the WS-Notification service point to subscribe to an external notification producer at server startup time. For more information, see "Modifying a WS-Notification administered subscriber" on page 3010.

Custom properties
Select this link to configure additional custom properties for this WS-Notification service point.

Policy set configuration
The policy set configuration associated with this WS-Notification service point. You can configure policy set and binding information for each port relating to this service point. For more information, see "Configuring a Version 7.0 WS-Notification service with Web service QoS" on page 2974.

Publish WSDL files to zip
Publish the WSDL files for this service point to a compressed file.

Note: When you run the wsimport command against the exported `PublisherRegistrationManager.wsdl` file you must include the `ibm-wsn-jaxws.xml` file as an argument to wsimport.

For more information, see "Publishing the WSDL files for a WS-Notification application to a compressed file" on page 2984.

Service point application
The application associated with this WS-Notification service point. For Version 7.0 WS-Notification services, enterprise applications are used to expose the web services associated with the WS-Notification service.

6. Apply any changes, then click **OK**. If the processing completes successfully, the list of WS-Notification service points for this Version 7.0 WS-Notification service is redisplayed. Otherwise, an error message is displayed.
7. Save your changes to the master configuration.

What to do next

You can also use the administrative console to work with runtime information for service points. For more information, see "Interacting at run time with WS-Notification" on page 2982.

Deleting WS-Notification service points:

Delete one or more WS-Notification service points and the associated resources (Version 7.0 service point provider applications, or Version 6.1 inbound services and endpoint listeners).

Before you begin

Decide which method to use to configure these resources. You can delete a WS-Notification service point by using the administrative console as described in this task, or by using the “deleteWSNServicePoint command” on page 3064.

Do not use this task to delete service points as part of the process of deleting a WS-Notification service. When you delete a WS-Notification service, the associated service points and resources are automatically deleted.

About this task

A WS-Notification service point defines access to a WS-Notification service on a given bus member through a specified web service binding (for example SOAP over HTTP). Applications use the bus members associated with the WS-Notification service point to connect to the WS-Notification service. When you delete a WS-Notification service point, the associated resources (Version 7.0 service point provider applications, or Version 6.1 inbound services and endpoint listeners) are automatically deleted. Do not delete these resources manually, because this might leave the associated configuration information in an inconsistent state.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> WS-Notification -> Services -> *service_name* -> [Additional Properties] WS-Notification service points** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Additional Properties] WS-Notification service points**. A list of all the WS-Notification service points is displayed in a “WS-Notification service points [Collection]” on page 3043 form.
3. Select the check box for every WS-Notification service point that you want to remove.
4. Click **Delete**. If the processing completes successfully, the list of WS-Notification service points for this WS-Notification service is updated. Otherwise, an error message is displayed.
5. Save your changes to the master configuration.

Creating a new Version 6.1 WS-Notification service point:

You can add an additional Version 6.1 WS-Notification service point to an existing Version 6.1 WS-Notification service. A WS-Notification service point defines access to a WS-Notification service on a given bus member through a specified web service binding (for example SOAP over HTTP). Applications use the bus members associated with the WS-Notification service point to connect to the WS-Notification service. The existence of a WS-Notification service point on a bus member implies that a WS-Notification web service is exposed from that bus member, and causes web service endpoints for the notification broker, subscription manager and publisher registration manager for this WS-Notification service to be exposed on the bus member with which the service point is associated. WS-Notification applications use these endpoints to interact with the WS-Notification service.

Before you begin

Decide which method to use to configure these resources. You can create a new Version 6.1 WS-Notification service point by using the administrative console as described in this task, or by using the “createWSNServicePoint command” on page 3061.

About this task

You can define any number of WS-Notification service points for a given WS-Notification service. Each service point defined for the same WS-Notification service represents an alternative entry point to the service. Event notifications published to a particular WS-Notification service point are received by all applications connected to any service point of the same WS-Notification service (subject to subscription on the correct topic) regardless of the particular service point to which they are connected. For more information, see Reasons to create multiple WS-Notification service points.

When you create a Version 6.1 WS-Notification service point you select a bus member on which the WS-Notification service point is configured. You allocate a service point to a given bus member by specifying an endpoint listener that is configured for that bus member. You also choose the type of web service binding (SOAP over HTTP or SOAP over JMS) that is used for the WS-Notification service point.

The existence of a WS-Notification service point on a bus member implies that a WS-Notification web service is exposed from that bus member, and causes web service endpoints for the notification broker, subscription manager and publisher registration manager for this WS-Notification service to be exposed on the bus member with which the service point is associated. WS-Notification applications use these endpoints to interact with the WS-Notification service.

Procedure

1. Start the administrative console
2. Navigate to **Service integration -> WS-Notification -> Services -> *service_name* -> [Additional Properties] WS-Notification service points** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Additional Properties] WS-Notification service points**. The “WS-Notification service points [Collection]” on page 3043 form is displayed. This form shows all the Version 6.1 WS-Notification service points configured for this Version 6.1 WS-Notification service.
3. In the content pane, click **New**. The New WS-Notification service point wizard is displayed. For more information about the properties that you set with the wizard, see “WS-Notification service points [Settings]” on page 3043.
4. Use the wizard to create the new Version 6.1 WS-Notification service point configuration by completing the following steps.
   a. Supply a name and (optional) description for the WS-Notification service point, and from the drop-down list select the bus member on which the service point is to be configured, then click **Next**. The service point name forms part of the URL used to access the service point (that is, the address of the web service that is exposed on the chosen server). On a single server system there is only one bus member in the list.
   b. Select a listener application to use to expose the service. Either select an existing endpoint listener for this bus member, or **Create a new endpoint listener**. For more information, see “Creating a new endpoint listener configuration” on page 2789.
5. Click **Finish**. If the processing completes successfully, the list of Version 6.1 WS-Notification service points for this Version 6.1 WS-Notification service is updated to include the new service point. Otherwise, an error message is displayed.
6. Save your changes to the master configuration.

What to do next

You can also use the administrative console to work with runtime information for service points. For more information, see “Interacting at run time with WS-Notification” on page 2982.

Modifying a Version 6.1 WS-Notification service point:

Modify an existing WS-Notification service point. A WS-Notification service point defines access to a WS-Notification service on a given bus member through a specified web service binding (for example SOAP over HTTP). Applications use the bus members associated with the WS-Notification service point to connect to the WS-Notification service.

About this task

You can define any number of WS-Notification service points for a given WS-Notification service. Each service point defined for the same WS-Notification service represents an alternative entry point to the service. Event notifications published to a particular WS-Notification service point are received by all applications connected to any service point of the same WS-Notification service (subject to subscription on the correct topic) regardless of the particular service point to which they are connected. For more information, see Reasons to create multiple WS-Notification service points.

The existence of a WS-Notification service point on a bus member implies that a WS-Notification web service is exposed from that bus member, and causes web service endpoints for the notification broker, subscription manager and publisher registration manager for this WS-Notification service to be exposed on the bus member with which the service point is associated. WS-Notification applications use these endpoints to interact with the WS-Notification service.

To modify a WS-Notification service point use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Service integration -> WS-Notification -> Services -> *service_name* -> [Additional Properties] WS-Notification service points** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Additional Properties] WS-Notification service points**. The “WS-Notification service points [Collection]” on page 3043 form is displayed. This form shows all the WS-Notification service points configured for this WS-Notification service.
2. In the content pane, click the name of a WS-Notification service point in the list. The current settings for this WS-Notification service point are displayed in the “WS-Notification service points [Settings]” on page 3043 form.
3. Modify the general properties. The only general property that you can modify is the **description** property.
4. Modify the additional properties:
   a. Modify the administered subscribers that are associated with this WS-Notification service point. An administered subscriber provides a mechanism for the WS-Notification service point to subscribe to an external notification producer at server startup time. For more information, see “Modifying a WS-Notification administered subscriber” on page 3010.
   b. Modify the custom properties, if any, that you have set for this WS-Notification service point. These custom properties are name and value pairs that you can use to set internal system configuration properties. In each pair, the name is a property key and the value is a string value.
   a. Modify the inbound ports that are associated with this WS-Notification service point.

      An inbound port describes the web service enablement of a service destination on a specific endpoint listener, with associated configuration. Each inbound port is associated with an endpoint listener, and you can control which groups of users can access a particular inbound service by making the service available only through specific endpoint listeners. For more information, see Endpoint listeners and inbound ports: Entry points to the service integration bus.

      You can use a JAX-RPC handler list to monitor activity at the port, and take appropriate action (for example logging, or rerouting) depending upon the sender and content of each message that passes through the port. For more information, see Bus-enabled web services and JAX-RPC handlers.

You can use WS-Security to set the levels of security to be applied to messages. The security level can be set independently for request and response messages. For more information, see Service integration technologies and WS-Security.

See also Inbound ports settings.

5. Apply any changes, then click **OK**. If the processing completes successfully, the list of WS-Notification service points for this WS-Notification service is redisplayed. Otherwise, an error message is displayed.
6. Save your changes to the master configuration.

What to do next

You can also use the administrative console to work with runtime information for service points. For more information, see "Interacting at run time with WS-Notification" on page 2982.

Deleting WS-Notification service points:

Delete one or more WS-Notification service points and the associated resources (Version 7.0 service point provider applications, or Version 6.1 inbound services and endpoint listeners).

Before you begin

Decide which method to use to configure these resources. You can delete a WS-Notification service point by using the administrative console as described in this task, or by using the "deleteWSNServicePoint command" on page 3064.

Do not use this task to delete service points as part of the process of deleting a WS-Notification service. When you delete a WS-Notification service, the associated service points and resources are automatically deleted.

About this task

A WS-Notification service point defines access to a WS-Notification service on a given bus member through a specified web service binding (for example SOAP over HTTP). Applications use the bus members associated with the WS-Notification service point to connect to the WS-Notification service. When you delete a WS-Notification service point, the associated resources (Version 7.0 service point provider applications, or Version 6.1 inbound services and endpoint listeners) are automatically deleted. Do not delete these resources manually, because this might leave the associated configuration information in an inconsistent state.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> WS-Notification -> Services -> *service_name* -> [Additional Properties] WS-Notification service points** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Additional Properties] WS-Notification service points**. A list of all the WS-Notification service points is displayed in a "WS-Notification service points [Collection]" on page 3043 form.
3. Select the check box for every WS-Notification service point that you want to remove.
4. Click **Delete**. If the processing completes successfully, the list of WS-Notification service points for this WS-Notification service is updated. Otherwise, an error message is displayed.
5. Save your changes to the master configuration.

Creating a new WS-Notification administered subscriber:

As part of the configuration of a WS-Notification service point you can configure any number of administered subscribers for that service point. An administered subscriber provides a mechanism for the WS-Notification service point to subscribe to an external notification producer at server startup time.

Before you begin

Decide which method to use to configure these resources. You can create a new administered subscriber by using the administrative console as described in this task, or by using the "createWSNAdministeredSubscriber command" on page 3068.

You should not define an administered subscriber for any of the endpoints exposed by the WS-Notification service on which it is being defined, because this would result in infinite looping of messages through the notification broker.

About this task

An administered subscriber contains the name of a NotificationProducer application or a (different) NotificationBroker endpoint and details of a subscription request (for example topic) that the WS-Notification service point should register as part of the server startup procedure. This enables you to pre-configure links between the NotificationBroker and a NotificationProducer, which can be a remote NotificationBroker or a NotificationProducer application.

To create a new administered subscriber, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Service integration -> WS-Notification -> Services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name* -> Administered subscribers** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name* -> Administered subscribers**. The "Administered subscribers [Collection]" on page 3033 form is displayed.
2. In the content pane, click **New**.
3. Specify the following properties for this administered subscriber.

   External web service endpoint
   The URL of the external web service to which the service should subscribe. That is, the endpoint reference (web address) of a notification producer or notification broker application. For example `http://remoteproducer.com`.

   Dialect
   The dialect in which the topic is expressed. The options are Simple, Concrete, or Full, as defined by the WS-Topics standard.

   Topic The topic on which the service should subscribe. This describes the class of notification messages that are delivered to the WS-Notification service point. For example `stock/IBM`. This property can include wildcards if they are supported by the topic dialect that you select.

   Topic namespace
   The URI that describes the topic namespace in which the specified topic is defined.

   Remote subscription timeout
   The length of time in hours after which the remote subscription will expire if not renewed by the server. This timeout minimizes the potential for orphaned subscriptions in the remote web service if the local server is uninstalled. Note that this field does not indicate the time at which the remote subscription is due to expire. Set the timeout length to something larger than the maximum length of time that the server is expected to remain offline, otherwise the stream of messages from the remote web service might be interrupted. While the server is running it

occasionally renews the remote subscription termination time (with the specified timeout) to prevent it from expiring during normal operation. If not specified, this timeout defaults to 24 (hours).

4. Click **OK**. If the processing completes successfully, the list of administered subscribers associated with the WS-Notification service point is updated to include the new administered subscriber. Otherwise, an error message is displayed.
5. Save your changes to the master configuration.

What to do next

You can also use the administrative console to list runtime information for administered subscribers. For more information, see "Listing active WS-Notification administered subscribers" on page 3031.

Modifying a WS-Notification administered subscriber:

As part of the configuration of a WS-Notification service point you can configure any number of administered subscribers for that service point. An administered subscriber provides a mechanism for the WS-Notification service point to subscribe to an external notification producer at server startup time.

About this task

An administered subscriber contains the name of a NotificationProducer application or a (different) NotificationBroker endpoint and details of a subscription request (for example topic) that the WS-Notification service point should register as part of the server startup procedure. This enables you to pre-configure links between the NotificationBroker and a NotificationProducer, which can be a remote NotificationBroker or a NotificationProducer application.

To modify an administered subscriber, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Service integration -> WS-Notification -> Services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name* -> Administered subscribers** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name* -> Administered subscribers**. The "Administered subscribers [Collection]" on page 3033 form is displayed. This form shows all the administered subscribers configured for this WS-Notification service point.
2. In the content pane, click the name of an administered subscriber in the list. The current settings for this administered subscriber are displayed in the **Configuration** panel.
3. Modify the properties for this administered subscriber.

   External web service endpoint
   The URL of the external web service to which the service should subscribe. That is, the endpoint reference (web address) of a notification producer or notification broker application. For example `http://remoteproducer.com`.

   Dialect
   The dialect in which the topic is expressed. The options are Simple, Concrete, or Full, as defined by the WS-Topics standard.

   Topic The topic on which the service should subscribe. This describes the class of notification messages that are delivered to the WS-Notification service point. For example `stock/IBM`. This property can include wildcards if they are supported by the topic dialect that you select.

   Topic namespace
   The URI that describes the topic namespace in which the specified topic is defined.

Remote subscription timeout

The length of time in hours after which the remote subscription will expire if not renewed by the server. This timeout minimizes the potential for orphaned subscriptions in the remote web service if the local server is uninstalled. Note that this field does not indicate the time at which the remote subscription is due to expire. Set the timeout length to something larger than the maximum length of time that the server is expected to remain offline, otherwise the stream of messages from the remote web service might be interrupted. While the server is running it occasionally renews the remote subscription termination time (with the specified timeout) to prevent it from expiring during normal operation. If not specified, this timeout defaults to 24 (hours).

4. Apply any changes, then click **OK**. If the processing completes successfully, the list of administered subscribers associated with the WS-Notification service point is redisplayed. Otherwise, an error message is displayed.
5. Save your changes to the master configuration.

What to do next

You can also use the administrative console to list runtime information for administered subscribers. For more information, see “Listing active WS-Notification administered subscribers” on page 3031.

Deleting WS-Notification administered subscribers:

Delete one or more WS-Notification administered subscribers. An administered subscriber provides a mechanism for the WS-Notification service point to subscribe to an external notification producer at server startup time.

Before you begin

Decide which method to use to configure these resources. You can delete an administered subscriber by using the administrative console as described in this task, or by using the “deleteWSNAdministeredSubscriber command” on page 3070.

About this task

To delete one or more administered subscribers, use the administrative console to complete the following steps :

Procedure

1. In the navigation pane, click **Service integration -> WS-Notification -> Services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name* -> Administered subscribers** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name* -> Administered subscribers**. A list of all the administered subscribers is displayed in an “Administered subscribers [Collection]” on page 3033 form.
2. Select the check box for every administered subscriber that you want to remove.
3. Click **Delete**. If the processing completes successfully, the list of administered subscribers for this WS-Notification service is updated. Otherwise, an error message is displayed.
4. Save your changes to the master configuration.

Creating a new WS-Notification permanent topic namespace:

Create a new permanent topic namespace. A topic namespace is a grouping of topics that allows information to be shared between applications. You use a permanent topic namespace to statically define the association between a WS-Notification topic namespace URI and a service integration bus topic space destination.

Before you begin

Decide which method to use to configure these resources. You can create a new WS-Notification permanent topic namespace by using the administrative console as described in this task, or by using the “createWSNTopicNamespace command” on page 3074.

You can create many to many relationships between the set of permanent topic namespaces defined in a cell (that is for all WS-Notification services defined in that cell) and the service integration bus topic spaces with which they are associated. These relationships can become quite complex depending upon the topologies required by the applications that connect to the WS-Notification service. For guidance on when certain configurations might or might not be appropriate, see Options for associating a permanent topic namespace with a bus topic space.

About this task

A permanent topic namespace has the following characteristics:

- You can use it to expose an existing service integration bus topic space for use by WS-Notification clients, thus permitting interoperation between the WS-Notification applications and existing publish and subscribe applications connected to the bus such as JMS.
- You can use it to restrict the structure and content of the topic namespace by applying one or more topic namespace documents that describe the required structure.
- You can use it as part of a topic space mapping configured on a service integration bus link (between two service integration buses) or a topic mapping as part of a publish and subscribe bridge between a service integration bus and a WebSphere MQ network.

When you create a new WS-Notification permanent topic namespace, you specify the namespace and associate it with one of the service integration bus topic spaces configured on the bus on which the parent WS-Notification service is defined. You cannot modify a permanent topic namespace after it has been created, other than to apply or remove topic namespace documents.

You can also set a configuration attribute of a permanent topic namespace to control the reliability setting (persistence or non persistence) that is applied to any messages that use a given topic namespace.

To create a new WS-Notification permanent topic namespace, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Service integration -> WS-Notification -> Services -> *service_name* -> Permanent topic namespaces** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> Permanent topic namespaces**. The “Permanent topic namespaces [Collection]” on page 3035 form is displayed.
2. In the content pane, click **New**.
3. Specify the following properties for this permanent WS-Notification topic namespace:
   a. Enter a name for the permanent topic namespace. The URI string by which this topic namespace is known. That is, the namespace URI by which WS-Notification applications refer to topics hosted by this namespace. For example `http://widgetproducer.com/prices`.
   b. Associate this new permanent topic namespace with the service integration bus topic space that you want to use to publish and receive messages. From the service integration bus topic space drop-down list, complete one of the following actions:
      - Select the name of an existing bus topic space.
      - Select the offered default name of *this_service_name*`TopicSpace` for a new bus topic space.
      - Select the option to `Create a new topic space`, then enter a name for the new topic space.

c. Select from the drop-down list the service integration bus reliability (quality of service) that is assigned to messages published through this topic namespace. You can choose one of five values. Each value represents one of the service integration bus message reliability levels. The default value is `reliable persistent`, which is the value used by default for JMS Persistent messages.

4. Click **OK**. If the processing completes successfully, the list of permanent WS-Notification topic namespaces is updated to include the new topic namespace. Otherwise, an error message is displayed.
5. Save your changes to the master configuration.

What to do next

To view the configuration of the associated service integration bus topic space, see "Showing the properties of a permanent WS-Notification topic namespace." To apply a topic namespace document, see "Applying a WS-Notification topic namespace document" on page 3015

Showing the properties of a permanent WS-Notification topic namespace:

A topic namespace is a grouping of topics that allows information to be shared between applications.You use a permanent topic namespace to statically define the association between a WS-Notification topic namespace URI and a service integration bus topic space destination.

Before you begin

Decide which method to use to configure these resources. You can show the properties of a permanent WS-Notification topic namespace by using the administrative console as described in this task, or by using the "showWSNTopicNamespace command" on page 3078.

About this task

A permanent topic namespace has the following characteristics:

- You can use it to expose an existing service integration bus topic space for use by WS-Notification clients, thus permitting interoperation between the WS-Notification applications and existing publish and subscribe applications connected to the bus such as JMS.
- You can use it to restrict the structure and content of the topic namespace by applying one or more topic namespace documents that describe the required structure.
- You can use it as part of a topic space mapping configured on a service integration bus link (between two service integration buses) or a topic mapping as part of a publish and subscribe bridge between a service integration bus and a WebSphere MQ network.

When you create a new WS-Notification permanent topic namespace, you specify the namespace and associate it with one of the service integration bus topic spaces configured on the bus on which the parent WS-Notification service is defined. You cannot modify a permanent topic namespace after it has been created, other than to apply or remove topic namespace documents.

To show the properties of a permanent WS-Notification topic namespace, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Service integration -> WS-Notification -> Services -> *service_name* -> Permanent topic namespaces** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> Permanent topic namespaces**. The "Permanent topic namespaces [Collection]" on page 3035 form is displayed. This form shows all the permanent topic namespaces configured for this WS-Notification service.

2. Optional: To view the configuration of the service integration bus topic space that is associated with a given permanent topic namespace, click the link in the **Service integration bus topic space** column. For more information, see “Topic space [Settings]” on page 2178
3. Optional: To view the configuration of the namespace documents that are associated with a given permanent topic namespace, click the link in the **Namespace documents** column.

   Note: This link also shows the number of namespace documents (0 or more) that are currently applied.

   The “Topic namespace document [Collection]” on page 3041 form is displayed. Use this form to apply, show or delete topic namespace documents.

Deleting WS-Notification permanent topic namespaces:

Delete topic namespace definitions from a WS-Notification service. A topic namespace is a grouping of topics that allows information to be shared between applications.You use a permanent topic namespace to statically define the association between a WS-Notification topic namespace URI and a service integration bus topic space destination.

Before you begin

Decide which method to use to configure these resources. You can delete a WS-Notification permanent topic namespace using the administrative console as described in this task, or you can delete a WS-Notification permanent topic namespace using the wsadmin tool.

About this task

Deleting the topic namespace mapping that was used to establish a (currently active) subscription has the same effect as deleting the underlying service integration bus topic space, and subscriptions that were created using this namespace mapping are deleted. For more information about the effect that deleting a topic namespace has upon new and existing WS-Notification applications, see Failures as a result of changes in topic space and topic namespace configurations.

To delete one or more permanent topic namespaces, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Service integration -> WS-Notification -> Services -> *service_name* -> Permanent topic namespaces** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> Permanent topic namespaces**. A list of all the permanent topic namespaces for this WS-Notification service is displayed in a “Permanent topic namespaces [Collection]” on page 3035 form.
2. Select the check box for every permanent topic namespace that you want to remove.
3. Click **Delete**.

   For each selected namespace, if the associated service integration bus topic space was created explicitly by the permanent topic namespace then you are asked whether or not to automatically delete the bus topic space. If the bus topic space was not created by the permanent topic namespace then you are not asked this question and the topic space is not deleted.

   Note: Deleting a service integration bus topic space causes exception messages to be generated for WS-Notification applications that reference the topic space, as described in Failures as a result of changes in topic space and topic namespace configurations.

   If the processing completes successfully, the list of permanent topic namespaces for this WS-Notification service is updated. Otherwise, an error message is displayed.
4. Save your changes to the master configuration.

Applying a WS-Notification topic namespace document:

A topic namespace can optionally have topic namespace documents applied to it that define the structure of the topics that are permitted within the namespace. Use the administrative console to apply a topic namespace document to an existing topic namespace.

Before you begin

This task assumes that you have already created the topic namespace document that you want to apply.

Decide which method to use to configure these resources. You can apply a topic namespace document by using the administrative console as described in this task, or by using the “createWSNTopicDocument command” on page 3079.

About this task

For more information about the relationship between a permanent topic namespace and a topic namespace document, see Chapter 5 of the WS-Topics standard.

To apply a topic namespace document to an existing topic namespace, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Service integration -> WS-Notification -> Services -> *service_name* -> Permanent topic namespaces -> *namespace_name* -> Topic namespace documents** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> Permanent topic namespaces -> *namespace_name* -> Topic namespace documents**. The “Topic namespace document [Collection]” on page 3041 form is displayed. This form shows all the topic namespace documents configured for this permanent topic namespace.
2. In the content pane, click **New**. The “Topic namespace document [Settings]” on page 3042 form is displayed.
3. Specify the following properties for this topic namespace document:
   a. URL of topic namespace document The URL of the topic namespace document that should be loaded.
   b. Optional: Description An optional description of the topic namespace document.
4. Click **OK**. If the processing completes successfully, the list of topic namespace documents for this permanent topic namespace is updated to include the new document. Otherwise, an error message is displayed.
5. Save your changes to the master configuration.

Showing the contents of a WS-Notification topic namespace document:

A topic namespace can optionally have topic namespace documents applied to it that define the structure of the topics that are permitted within the namespace. Use the administrative console to show the contents of a topic namespace document.

Before you begin

Decide which method to use to configure these resources. You can show the contents of a topic namespace document by using the administrative console as described in this task, or by using the “showWSNTopicDocument command” on page 3083.

About this task

For more information about the relationship between a permanent topic namespace and a topic namespace document, see Chapter 5 of the WS-Topics standard.

To show the contents of a WS-Notification topic namespace document, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Service integration -> WS-Notification -> Services -> *service_name* -> Permanent topic namespaces -> *namespace_name* -> Topic namespace documents** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> Permanent topic namespaces -> *namespace_name* -> Topic namespace documents**. The "Topic namespace document [Collection]" on page 3041 form is displayed. This form shows all the topic namespace documents configured for this permanent topic namespace.
2. In the content pane, click the name of a topic namespace document in the list. The contents of this topic namespace document are displayed.

Deleting WS-Notification topic namespace documents:

A topic namespace can optionally have topic namespace documents applied to it that define the structure of the topics that are permitted within the namespace. Use the administrative console to delete one or more WS-Notification topic namespace documents.

Before you begin

Decide which method to use to configure these resources. You can delete a WS-Notification topic namespace document by using the administrative console as described in this task, or by using the "deleteWSNTopicDocument command" on page 3081.

About this task

To delete one or more WS-Notification topic namespace documents, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Service integration -> WS-Notification -> Services -> *service_name* -> Permanent topic namespaces -> *namespace_name* -> Topic namespace documents** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> Permanent topic namespaces -> *namespace_name* -> Topic namespace documents**. A list of all the WS-Notification topic namespace documents is displayed in a "Topic namespace document [Collection]" on page 3041 form.
2. Select the check box for every WS-Notification topic namespace document that you want to remove.
3. Click **Delete**. If the processing completes successfully, the list of WS-Notification topic namespace documents for this WS-Notification topic namespace is updated. Otherwise, an error message is displayed.
4. Save your changes to the master configuration.

Publishing the WSDL files for a WS-Notification application to a compressed file:

Use the administrative console to download a compressed file with a `.zip` file extension that contains the published WSDL files for a WS-Notification application.

About this task

The ability to publish these WSDL files to a compressed file is particularly useful in the following circumstances:

- Writing a WS-Notification application that invokes web service operations against the NotificationBroker application, as described in Writing a WS-Notification application that does not expose a web service endpoint.
- Running the wsimport command against the exported `PublisherRegistrationManager.wsdl` file to generate a client stub for the PublisherRegistrationManager.
- Viewing the endpoint URLs to which WS-Notification applications connect, by looking in the WSDL file for the NotificationBroker application for Version 7.0 services, or the inbound service for Version 6.1 services.

Note:

When you run the wsimport command against the exported `PublisherRegistrationManager.wsdl` file you must include the `ibm-wsn-jaxws.xml` file as an argument to wsimport. If you omit this bindings file, the wsimport command fails with a naming conflict error concerning the ResourceNotDestroyedFault elements referred to in the `PublisherRegistrationManager.wsdl` file. For more information about why this exception occurs, see the following troubleshooting tip: The PublisherRegistrationManager.wsdl file is not successfully parsed by wsimport unless you include a JAX-WS bindings file.

The `ibm-wsn-jaxws.xml` file is located in the *app_server_root*`/util` directory. For example: `c:\was\util\ibm-wsn-jaxws.xml`. This bindings file expects to find the WSDL file to which it refers in the same directory as itself, so before you run the wsimport command you must copy the bindings file to the directory that holds your `PublisherRegistrationManager.wsdl` file. Here is an example of how to run the wsimport command to include the `ibm-wsn-jaxws.xml` file:

```
c:\was\bin\wsimport -b ibm-wsn-jaxws.xml -keep PublisherRegistrationManager.wsdl
```

Procedure

1. Start the administrative console.
2. Navigate to the “Publish WSDL files to .zip file [Settings]” form for the WS-Notification application.
   For JAX-WS based Version 7.0 WS-Notification services, click one of the following paths:
   - **Service integration -> WS-Notification -> Services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name* -> [Additional Properties] Publish WSDL files to zip**
   - **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name* -> [Additional Properties] Publish WSDL files to zip**

   For JAX-RPC based Version 6.1 WS-Notification services, click one of the following paths:
   - **Service integration -> WS-Notification -> Services -> *service_name* -> [Related Items] Notification broker inbound service settings** > **[Additional Properties] Publish WSDL files to ZIP file**
   - **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Related Items] Notification broker inbound service settings** > **[Additional Properties] Publish WSDL files to ZIP file**
3. Click on the file name to download a zip file that contains the application's published WSDL files.

Configuring JAX-WS handlers:

A JAX-WS handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. You can create JAX-WS

handlers, chain them together in the form of a handler list, then apply the handler list to a JAX-WS based Version 7.0 WS-Notification service point (for inbound invocation handling) or WS-Notification service (for outbound invocation handling).

About this task

The Java API for XML-based Web Services (JAX-WS) provides you with a standard way of developing interoperable and portable web services. To create a JAX-WS handler, you can use a tool such as IBM Rational Application Developer. To enable handlers to undertake more complex operations, you chain them together into handler lists. You associate each handler list with one or more JAX-WS based Version 7.0 WS-Notification services or service points, so that the handler list can monitor WS-Notification activity and take appropriate action depending upon the sender and content of each inbound or outbound message.

Detailed instructions on how to configure JAX-WS handlers and handler lists for use with JAX-WS based Version 7.0 WS-Notification services are provided in the following topics:

Procedure

- Load JAX-WS handler classes.
- Create a new JAX-WS handler configuration.
- Modify an existing JAX-WS handler configuration.
- Delete JAX-WS handler configurations.
- Create a new JAX-WS handler list.
- Modify an existing JAX-WS handler list.
- Delete JAX-WS handler lists.

Loading JAX-WS handler classes:

A JAX-WS handler interacts with messages through a JAX-WS based Version 7.0 WS-Notification service point (for inbound invocation handling) or WS-Notification service (for outbound invocation handling), therefore you must make the handler class available to the server or cluster that hosts the WS-Notification service point or service that you want to monitor.

Before you begin

This task assumes that you have already created your handler. You can do this by using IBM Rational Application Developer or a similar tool.

About this task

Before you can configure a JAX-WS handler for use with WS-Notification, you must make the handler class available to the server or cluster that hosts the WS-Notification service point or service that you want to monitor. To do this, you create a shared library for the class then add the shared library to the class loader for the server.

Procedure

1. Package the class file for your handler as a JAR file, then copy the JAR file into a convenient directory.

   Make the handler class available to the application server in one of the following ways:
   - Copy the individual class file into a directory structure under *app_server_root*/classes that matches the package name of the class, where *app_server_root* is the root directory for the installation of WebSphere Application Server. For example a handler class com.ibm.jaxws.handler.TestHandler is copied into the *app_server_root*/classes/com/ibm/jaxws/handler directory.
   - Package the class files for all your handlers as a JAR file, then copy it into the *app_server_root*/lib/app directory.

2. Start the administrative console.
3. Create a shared library for the JAR file.
   a. Navigate to **Environment -> Shared libraries**.
   b. Set the scope at which you want the new library to be visible, then click **New**.
   c. Give the new library a name.
   d. Set the class path to the directory and file name for your handler JAR file.
   e. Save your changes to the master configuration.

   For more information, see Creating shared libraries.
4. Create a class loader for the server on which you want to make the JAR file available.
   a. Navigate to **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server Infrastructure] Java and Process Management -> Class loader**.
   b. Click **New**.
   c. Click **OK**.
   d. Save your changes to the master configuration.

   For more information, see Configuring class loaders of a server.
5. Add the shared library to the class loader for the server.
   a. Navigate to **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server Infrastructure] Java and Process Management -> Class loader -> *class_loader_name*** > **[Additional Properties] Shared library references**.
   b. Click **Add**.
   c. Click on the name of your new library, then click **OK**.
   d. Save your changes to the master configuration.

   For more information, see Associating shared libraries with servers.

What to do next

You are now ready to create a new JAX-WS handler configuration by using the administrative console or by using the “createJAXWSHandler command” on page 3086.

Creating a new JAX-WS handler configuration:

Create a Java API for XML-based Web Services (JAX-WS) handler configuration for use, as part of a handler list, with JAX-WS based Version 7.0 WS-Notification services.

Before you begin

You can create a new JAX-WS handler configuration by using the administrative console as described in this topic, or by using the “createJAXWSHandler command” on page 3086.

This task assumes that you have already created your handler. You can do this by using IBM Rational Application Developer or a similar tool. You must also make the handler class available to the server or cluster that hosts the WS-Notification service points (for inbound invocation handling) or WS-Notification services (for outbound invocation handling) that you want to monitor, as detailed in “Loading JAX-WS handler classes” on page 3018.

About this task

A Java API for XML-based Web Services (JAX-WS) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. To make WebSphere Application Server aware of your handler, and to make the handler available

for inclusion in one or more handler lists, you use the administrative console to create a new handler configuration.

Procedure

1. Start the administrative console.
2. Navigate to **Service integration -> WS-Notification -> JAX-WS Handlers**. The JAX-WS handlers collection form is displayed.
3. Click **New**. The JAX-WS handlers settings form is displayed.
4. Type the following general properties:
   Name Type the name by which the handler is known.

   This name must be unique at cell scope, and it must obey the following syntax rules:
   - It must not start with "." (a period).
   - It must not start or end with a space.
   - It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

   For example `TestHandler`.

   Description
   Type the (optional) description of the handler.

   Class name
   Type the name of the class that is to be instantiated. This name must be a fully qualified java class name. For example `com.ibm.jaxws.handler.TestHandler`.

   Note: You can configure multiple instances of a handler by creating each instance with a different handler name, and pointing to the same handler class.
5. Click **OK**. The general properties for this item are saved, and the additional properties options are made available.
6. Save your changes to the master configuration.

Results

If the processing completes successfully, the list of handlers is updated to include the new handler. Otherwise, an error message is displayed.

What to do next

To use this handler, add it to a handler list as described in Creating a new JAX-WS handler list or Modifying an existing JAX-WS handler list.

Modifying an existing JAX-WS handler configuration:

Modify a Java API for XML-based Web Services (JAX-WS) handler configuration for a handler that is used, as part of a handler list, with JAX-WS based Version 7.0 WS-Notification services.

Before you begin

You can modify a JAX-WS handler configuration by using the administrative console as described in this topic, or by using the "modifyJAXWSHandler command" on page 3088.

If you modify a handler class but do not change the class name, you do not have to modify the handler configuration as described in this topic. You just have to stop then restart the servers or clusters that host the services or service points that this handler monitors.

About this task

A Java API for XML-based Web Services (JAX-WS) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. You can use the administrative console to list existing handler configurations, and to view and modify their configuration details.

Procedure

1. Start the administrative console.
2. Navigate to **Service integration -> WS-Notification -> JAX-WS Handlers**. A list of handlers is displayed in a JAX-WS handlers collection form.
3. Click the name of a handler in the list. The current JAX-WS handlers settings for this handler are displayed.
4. Modify the following general properties:
   Name Modify the name of the handler.

   This name must be unique at cell scope, and it must obey the following syntax rules:
   - It must not start with "." (a period).
   - It must not start or end with a space.
   - It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

   Note: When you change a handler name, the system looks up all objects that refer to it and updates the name.

   Description
   Modify the (optional) description of the handler.

   Class name
   Change the name of the class that is to be instantiated.

   If you change the class name, you must also make the new handler class available to the server or cluster that hosts the WS-Notification service points (for inbound invocation handling) or WS-Notification services (for outbound invocation handling) that you want to monitor, as detailed in "Loading JAX-WS handler classes" on page 3018.

   Note: You can configure multiple instances of a handler by creating each instance with a different handler name, and pointing to the same handler class.
5. Save your changes to the master configuration.

Results

If the processing completes successfully, the list of handlers is redisplayed. Otherwise, an error message is displayed.

Deleting JAX-WS handler configurations:

Delete the configuration for one or more Java API for XML-based Web Services (JAX-WS) handlers that are configured for use, as part of a handler list, with JAX-WS based Version 7.0 WS-Notification services.

Before you begin

You can delete a JAX-WS handler configuration by using the administrative console as described in this topic, or by using the "deleteJAXWSHandler command" on page 3089.

About this task

A Java API for XML-based Web Services (JAX-WS) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request.

When you remove a handler that is currently used by one or more web services on a service integration bus, the system removes the handler from the handler lists for each associated web service.

You can use the administrative console to remove one or more handler configurations.

Procedure

1. Start the administrative console.
2. Navigate to **Service integration -> WS-Notification -> JAX-WS Handlers**. A list of handlers is displayed in a JAX-WS handlers collection form.
3. Select the check box for every handler that you want to remove.
4. Click **Delete**.

Results

If the processing completes successfully, the list of handlers is updated. Otherwise, an error message is displayed.

Creating a new JAX-WS handler list:

Create a Java API for XML-based Web Services (JAX-WS) handler list for use with JAX-WS based Version 7.0 WS-Notification services.

Before you begin

You can create a new JAX-WS handler list by using the administrative console as described in this topic, or by using the “createJAXWSHandlerList command” on page 3092.

You can only add previously-configured handlers to a handler list. To configure a handler, see “Creating a new JAX-WS handler configuration” on page 3019.

About this task

A Java API for XML-based Web Services (JAX-WS) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. To enable handlers to undertake more complex operations, you chain them together into handler lists. The approach taken in WebSphere Application Server is to assign handler lists (rather than individual handlers) to WS-Notification service points (for inbound invocation handling) or WS-Notification services (for outbound invocation handling).

Procedure

1. Start the administrative console.
2. Navigate to **Service integration -> WS-Notification -> JAX-WS Handler Lists**. The JAX-WS handler lists collection form is displayed.
3. Click **New**. The JAX-WS handler lists settings form is displayed.
4. Type the following general properties:
   Name Type the name by which the handler list is known.

   This name must be unique at cell scope, and it must obey the following syntax rules:
   - It must not start with “.” (a period).

- It must not start or end with a space.
- It must not contain any of the following characters: \ / , # $ @ : ; " * ? < > | = + & % '

For example TestList.

Description

Type the (optional) description of the handler list.

JAX-WS handlers

In the JAX-WS handlers pane, complete the following steps:

a. Select one or more handlers from the list of available JAX-WS handlers, then click **Add** to move the selected handlers into the list of handlers for this JAX-WS handler list.
b. Select a handler in the list of handlers for this JAX-WS handler list, then click **Up** or **Down** to change the position of the handler within the list.

Handlers are applied in the sequence in which they appear in the handler list.

Note: If you click **Reset**, only the **Name** and **Description** fields are reset to their state when the form was first loaded. The two lists of available and assigned handlers are not reset.

5. Click **OK**. The general properties for this item are saved.
6. Save your changes to the master configuration.

Results

If the processing completes successfully, the list of handler lists is updated to include the new handler list. Otherwise, an error message is displayed.

What to do next

To apply this handler list to inbound notification requests received at a Version 7.0 WS-Notification point, associate it with the service point as described in “Creating a new Version 7.0 WS-Notification service point” on page 3001 or “Modifying a Version 7.0 WS-Notification service point” on page 3003. To apply this handler list to outbound notification requests sent by your Version 7.0 WS-Notification service, associate the handler list with the service as described in “Creating a new Version 7.0 WS-Notification service” on page 2987 or “Modifying a Version 7.0 WS-Notification service” on page 2991.

For an overview of the end-to-end task of creating JAX-WS handlers, chaining them together in a handler list, then applying the handler list to a Version 7.0 WS-Notification service point or service, see “Applying a JAX-WS handler list to a WS-Notification service” on page 2973.

Modifying an existing JAX-WS handler list:

Modify the configuration details for a Java API for XML-based Web Services (JAX-WS) handler list that is configured for use with JAX-WS based Version 7.0 WS-Notification services.

Before you begin

You can modify a JAX-WS handler list by using the administrative console as described in this topic, or by using the “modifyJAXWSHandlerList command” on page 3093.

You can only add previously-configured handlers to a handler list. To configure a handler, see “Creating a new JAX-WS handler configuration” on page 3019.

About this task
