A Java API for XML-based Web Services (JAX-WS) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. To enable handlers to undertake more complex operations, you chain them together into handler

lists. The approach taken in WebSphere Application Server is to assign handler lists (rather than individual handlers) to WS-Notification service points (for inbound invocation handling) or WS-Notification services (for outbound invocation handling).

You can use the administrative console to list existing handler lists, and to view and modify their configuration details.

Procedure

1. Start the administrative console.
2. Navigate to **Service integration -> WS-Notification -> JAX-WS Handler Lists**. A list of all the handler lists is displayed in a JAX-WS handler lists collection form.
3. Click the name of a handler list in the list. The current JAX-WS handler lists settings for this handler are displayed.
4. Modify the following general properties:
   Name Modify the name of the handler list.

   This name must be unique at cell scope, and it must obey the following syntax rules:
   - It must not start with "." (a period).
   - It must not start or end with a space.
   - It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

   When you change a handler list name, the system looks up all objects that refer to it and updates the name.

   Description
   Modify the (optional) description of the handler list.

   JAX-WS handlers
   In the JAX-WS handlers pane, complete the following steps:
   a. Select one or more previously-configured handlers from either the list of available JAX-WS handlers or the list of handlers for this JAX-WS handler list, then click **Add** or **Remove** to modify the list of handlers for this JAX-WS handler list.
   b. Select a handler in the list of handlers for this JAX-WS handler list, then click **Up** or **Down** to change the position of the handler within the list.

   Handlers are applied in the sequence in which they appear in the handler list.

   Note: If you click **Reset**, only the **Name** and **Description** fields are reset to their state when the form was first loaded. The two lists of available and assigned handlers are not reset.
5. Save your changes to the master configuration.

Results

If the processing completes successfully, the list of handler lists is redisplayed. Otherwise, an error message is displayed.

What to do next

To apply this handler list to inbound notification requests received at a Version 7.0 WS-Notification point, associate it with the service point as described in "Creating a new Version 7.0 WS-Notification service point" on page 3001 or "Modifying a Version 7.0 WS-Notification service point" on page 3003. To apply this handler list to outbound notification requests sent by your Version 7.0 WS-Notification service, associate the handler list with the service as described in "Creating a new Version 7.0 WS-Notification service" on page 2987 or "Modifying a Version 7.0 WS-Notification service" on page 2991.

For an overview of the end-to-end task of creating JAX-WS handlers, chaining them together in a handler list, then applying the handler list to a Version 7.0 WS-Notification service point or service, see "Applying a JAX-WS handler list to a WS-Notification service" on page 2973.

Deleting JAX-WS handler lists:

DeleteJava API for XML-based Web Services (JAX-WS) handler lists that are configured for use with JAX-WS based Version 7.0 WS-Notification services.

Before you begin

You can delete a JAX-WS handler list by using the administrative console as described in this topic, or by using the “deleteJAXWSHandlerList command” on page 3095.

About this task

A Java API for XML-based Web Services (JAX-WS) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request.

When you remove a handler list that is currently used by one or more web services on a service integration bus, the system removes the handler list for each associated web service.

You can use the administrative console to remove one or more handler list configurations.

Procedure

1. Start the administrative console.
2. Navigate to **Service integration -> WS-Notification -> JAX-WS Handler Lists**. A list of handler lists is displayed in a JAX-WS handler lists collection form.
3. Select the check box for every handler list that you want to remove.
4. Click **Delete**.

Results

If the processing completes successfully, the list of handler lists is updated. Otherwise, an error message is displayed.

Interacting at run time with WS-Notification

View (and in some cases delete) at run time the active items associated with WS-Notification service points.

Before you begin

This task assumes that you have a fully configured and operational WS-Notification service point.

About this task

A WS-Notification service point defines access to a WS-Notification service on a given bus member through a specified web service binding (for example SOAP over HTTP). Applications use the bus members associated with the WS-Notification service point to connect to the WS-Notification service. The existence of a WS-Notification service point on a bus member implies that a WS-Notification web service is exposed from that bus member, and causes web service endpoints for the notification broker, subscription manager and publisher registration manager for this WS-Notification service to be exposed on the bus member with which the service point is associated. WS-Notification applications use these endpoints to interact with the WS-Notification service.

You can use the administrative console to interact at run time with the following active items associated with WS-Notification service points:

Publisher registrations
A runtime list of existing publisher registrations is provided. This includes, for each publisher registration, the information that was used to create it and when it will terminate.

Pull points
A runtime list is provided of the pull points that have been created. This includes, for each pull point, its current termination time and a link to the associated subscription.

Subscriptions
A runtime view is provided for subscriptions that have been created by applications. This includes, for each subscription, the information that was used to create it and an indication of its current state.

Administered subscribers
A runtime list is provided of the administered subscribers for a given WS-Notification service point. This includes, for each administered subscriber, an indication of its current state; for example whether the subscription was successfully initialized at start time.

For each WS-Notification service point, runtime information is available for subscriptions, registrations, pull points and administered subscribers. **For each WS-Notification service**, runtime information is available - aggregated for all service points for the service - for subscriptions, registrations and pull points. There is no aggregated view for administered subscribers at the WS-Notification service level.

To access and use the runtime information for active items associated with WS-Notification service points, use the administrative console to complete the following steps:

Procedure

1. Choose between information for a particular service point, or information aggregated for all service points for a particular service, by completing one of the following substeps:
   a. Optional: For runtime information for a particular service point, navigate to either **Service integration -> WS-Notification -> Services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name*** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name***, then click the **Runtime** tab. A panel is displayed that contains links to runtime information about subscriptions, registrations, pull points and administered subscribers for this WS-Notification service point.
   b. Optional: For runtime information aggregated for all service points for a particular service, navigate to either **Service integration -> WS-Notification -> Services -> *service_name*** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name*** then click the **Runtime** tab. A panel is displayed that contains links to runtime information about subscriptions, registrations and pull points for this WS-Notification service.
2. Click **Subscriptions** , **Publisher registrations**, **Pull points** or (for a particular service point) **Administered subscribers**.
   - If you click **Subscriptions**, a panel is displayed that lists the durable subscriptions that have been created by a WS-Notification service point in response to “Subscribe” requests from WS-Notification applications. You can view the subscription name (ID), topic and other information associated with the subscription, and you can view messages held on the durable subscription pending delivery. You can also delete subscriptions.

     Note: Both the WS-Notification subscription and publisher registration resources include the concept of scheduled termination, in which the application indicates a period of time after which the resource is destroyed. “Badly-behaved” in this case describes an application that requests an infinite lifetime for a resource and then does not explicitly delete the resource before it goes away (never to return).

- If you click **Publisher registrations**, a panel is displayed that lists the publisher registrations that are currently in effect on this WS-Notification service or service point (that is, applications that have registered as publishers). You can view the basic properties of the registration record. You can also delete a publisher registration record.
- If you click **Pull points**, a panel is displayed that lists the pull points that are currently active on this WS-Notification service or service point. You can view basic properties of the pull point such as the subscription with which it is associated and the time at which it is currently set to expire, and you can navigate to the associated subscriptions where appropriate. You can also delete pull points.
- For a particular service point, if you click **Administered subscribers**, a panel is displayed that lists the administered subscribers that are currently in effect on this WS-Notification service point. You can use this information to see whether a given subscriber has been successfully initialized.

What to do next

For more detailed information about working with individual runtime panels, see the following topics:
- "Listing or deleting active WS-Notification subscriptions."
- "Listing or deleting active WS-Notification publisher registrations" on page 3029.
- "Listing or deleting active WS-Notification pull points" on page 3030.
- "Listing active WS-Notification administered subscribers" on page 3031.

Listing or deleting active WS-Notification subscriptions:

List the subscriptions that exist at run time for a particular WS-Notification service point, or for all service points for a particular WS-Notification service.

About this task

The runtime panels for WS-Notification subscriptions list the durable subscriptions that have been created by a WS-Notification service point in response to "Subscribe" requests from WS-Notification applications. You can view the subscription name (ID), topic and other information associated with the subscription, and you can view messages held on the durable subscription pending delivery. You can also delete subscriptions. For example, to tidy up after a badly-behaved application.

Note: Both the WS-Notification subscription and publisher registration resources include the concept of scheduled termination, in which the application indicates a period of time after which the resource is destroyed. "Badly-behaved" in this case describes an application that requests an infinite lifetime for a resource and then does not explicitly delete the resource before it goes away (never to return).

A subscription created by a WS-Notification application can contain more than one topic expression, and each of these topic expressions can be in a different namespace, which can result in service integration bus subscriptions being created in multiple topic spaces.

To display a list of WS-Notification subscriptions that exist at run time, use the administrative console to complete the following steps:

Procedure

1. Choose between information for a particular service point, or information aggregated for all service points for a particular service, by completing one of the following substeps:
   a. Optional: For runtime information for a particular service point, navigate to either **Service integration -> WS-Notification -> Services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name*** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name***, then click the **Runtime** tab. A panel is displayed

that contains links to runtime information about subscriptions, registrations, pull points and administered subscribers for this WS-Notification service point.

b. Optional: For runtime information aggregated for all service points for a particular service, navigate to either **Service integration -> WS-Notification -> Services -> *service_name*** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name***, then click the **Runtime** tab. A panel is displayed that contains links to runtime information about subscriptions, registrations and pull points for this WS-Notification service.

2. Click **Subscriptions** The "Subscriptions [Collection]" on page 3040 form is displayed. This form shows all the currently active subscriptions for this WS-Notification service point or service. This collection form contains the following information about each list item:

Subscription id
The unique identifier of the subscription.

Topics
An array of topic names. Note that this will usually only contain one element.

Delivery state
The current runtime state of the subscription. In normal operation the subscription will show a state of **OK**. Other states are **PAUSED**, indicating that the application has paused the subscription as defined by the WS-Notification standards, or **ERROR**, indicating that the last attempt to deliver an event notification to the notification consumer was not successful. In the error case, more information about the cause of the failure can be found in the `SystemOut` log.

Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

Consumer EPR
The endpoint reference to which event notifications matching the subscription are sent. That is, the endpoint reference to which notification messages are delivered as specified on the subscribe call.

Creation time
The time at which the subscription was created.

Termination time
The time at which the subscription will be deleted.

Pull type
Indicates whether the subscription is being used in pull mode. That is, whether this subscription is being accessed by a pull point. If the asynchronous (push) subscription model is being used, this field displays "No". If a pull point is being used, this field displays "Yes".

Service integration bus subscriptions
The service integration bus durable subscription or subscriptions that are associated with the WS-Notification subscription. This is a link to the service integration bus durable subscription detail panel for the subscriptions that contain data for this object.

3. Optional: To observe the runtime state of each of the service integration bus durable subscriptions that have been created, click the link in the **SIBus subscriptions** field.

If only one durable subscription has been created, the bus durable subscription detail panel is displayed. For more information, see "Administering durable subscriptions" on page 2002.

If multiple durable subscriptions have been created, for example if the WS-Notification subscription is spanned across multiple service integration bus topic spaces, a runtime collection form is displayed

that shows the individual bus durable subscriptions. This form shows all the currently active publisher registrations for this WS-Notification service point or service.

SIBus subscription
The service integration bus durable subscription ID. This links to the associated bus durable subscription detail panel. For more information, see “Administering durable subscriptions” on page 2002.

Topics
The list of topics that are contained within a single service integration bus topic space (and thus durable subscription).

What to do next

To delete one or more WS-Notification subscriptions, and the associated service integration bus durable subscriptions, select the check box next to each subscription name then click **Delete**.

Listing or deleting active WS-Notification publisher registrations:

List the publisher registrations that exist at run time for a particular WS-Notification service point, or for all service points for a particular WS-Notification service.

About this task

A WS-Notification application can register itself as a publisher in order to check that it is permitted to publish on the specified list of topics, or to initiate the demand based publisher pattern.

The runtime panels for WS-Notification publisher registrations list the publisher registrations that are currently in effect on this WS-Notification service or service point (that is, applications that have registered as publishers). You can view the basic properties of the registration record. You can also delete a publisher registration record. For example, to tidy up after a badly-behaved application.

Note: Both the WS-Notification subscription and publisher registration resources include the concept of scheduled termination, in which the application indicates a period of time after which the resource is destroyed. “Badly-behaved” in this case describes an application that requests an infinite lifetime for a resource and then does not explicitly delete the resource before it goes away (never to return).

To display a list of WS-Notification publisher registrations that exist at run time, use the administrative console to complete the following steps:

Procedure

1. Choose between information for a particular service point, or information aggregated for all service points for a particular service, by completing one of the following substeps:
   a. Optional: For runtime information for a particular service point, navigate to either **Service integration -> WS-Notification -> Services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name*** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name***, then click the **Runtime** tab. A panel is displayed that contains links to runtime information about subscriptions, registrations, pull points and administered subscribers for this WS-Notification service point.
   b. Optional: For runtime information aggregated for all service points for a particular service, navigate to either **Service integration -> WS-Notification -> Services -> *service_name*** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name***, then click the **Runtime** tab. A panel is displayed that contains links to runtime information about subscriptions, registrations and pull points for this WS-Notification service.

2. Click **Publisher registrations** The "Publisher registrations [Collection]" on page 3038 form is displayed. This form shows all the currently active publisher registrations for this WS-Notification service point or service. This collection form contains the following information about each list item:

   Publisher ID
   The unique identifier of this publisher registration.

   Topic The topic on which the publisher is registered to publish. That is, the list of topics that are contained within a single service integration bus topic space (and thus durable subscription).

   Creation time
   The time at which the registration was created.

   Termination time
   The time at which the registration will be deleted.

   Demand based
   Indicates whether this is a demand based publisher. This displays "Yes" or "No".

   Producer EPR
   Additional publisher related data. The endpoint reference of the producer that created this registration.

What to do next

To delete one or more publisher registrations, select the check box next to each registration ID then click **Delete**.

Listing or deleting active WS-Notification pull points:

List the pull points that exist at run time for a particular WS-Notification service point, or for all service points for a particular WS-Notification service.

About this task

To use the synchronous delivery mechanism described by the WS-Notification standards, a WS-Notification application creates a pull point against the notification broker.

The runtime panels for WS-Notification pull points list the pull points that are currently active on this WS-Notification service or service point. You can view basic properties of the pull point such as the subscription with which it is associated and the time at which it is currently set to expire, and you can navigate to the associated subscriptions where appropriate. You can also delete pull points.

To display a list of WS-Notification pull points that exist at run time, use the administrative console to complete the following steps:

Procedure

1. Choose between information for a particular service point, or information aggregated for all service points for a particular service, by completing one of the following substeps:
   a. Optional: For runtime information for a particular service point, navigate to either **Service integration -> WS-Notification -> Services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name*** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name***, then click the **Runtime** tab. A panel is displayed that contains links to runtime information about subscriptions, registrations, pull points and administered subscribers for this WS-Notification service point.
   b. Optional: For runtime information aggregated for all service points for a particular service, navigate to either **Service integration -> WS-Notification -> Services -> *service_name*** or **Service**

integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name*, then click the **Runtime** tab. A panel is displayed that contains links to runtime information about subscriptions, registrations and pull points for this WS-Notification service.

2. Click **pull points** The "Pull points [Collection]" on page 3039 form is displayed. This form shows all the currently active pull points for this WS-Notification service point or service. This collection form contains the following information about each list item:

   Pull point id
   The unique identifier of the pull point.

   Creation time
   The time at which the pull point was created.

   Termination time
   The time at which the pull point will be deleted.

   Subscription id
   The unique identifier of the subscription associated with the pull point. If the pull point has not yet been supplied to a subscription, the text `Not Associated` is displayed.

What to do next

To delete one or more pull points, select the check box next to each pull point ID then click **Delete**.

Listing active WS-Notification administered subscribers:

List the administered subscribers that exist at run time for a particular WS-Notification service point. An administered subscriber provides a mechanism for the WS-Notification service point to subscribe to an external notification producer at server startup time.

About this task

The runtime panels for WS-Notification administered subscribers list the administered subscribers that are currently in effect on this WS-Notification service point. You can use this information to see whether a given subscriber has been successfully initialized.

Administered Subscribers are defined on individual WS-Notification service points. There is no aggregated view for administered subscribers at the WS-Notification service level.

To display a list of WS-Notification administered subscribers that exist at run time, use the administrative console to complete the following steps:

Procedure

1. For runtime information for a particular service point, navigate to either **Service integration -> WS-Notification -> Services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name*** or **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name***, then click the **Runtime** tab. A panel is displayed that contains links to runtime information about subscriptions, registrations, pull points and administered subscribers for this WS-Notification service point.
2. Click **Administered subscribers** The "Administered subscribers [Collection]" on page 3033 form is displayed. This form shows all the currently active administered subscribers for this WS-Notification service point. This collection form contains the following information about each list item:

   Producer EPR
   The endpoint reference of the remote web service application from which event notifications are received. That is, the endpoint reference (web address) of a notification producer or

notification broker application. For example `http://remoteproducer.com`. You provided this reference when you created the administered subscriber.

Topic The topic for which event notifications have been requested.

Subscription reference
The string form of the endpoint reference that was returned by the remote service as a result of the subscribe, if successfully created.

State The current runtime state of the administered subscriber. An icon indicator that displays either green or red to indicate whether the administered subscriber is OK or has failed. Move the mouse pointer over this icon to see a description of the current state. In the OK case, it describes the last successful operation - initially the time at which the subscription was contacted (for server startup) and subsequently the time the last message was received for this subscriber. In the failed case, it describes the details of the last failure.

Subscription timeout
The length of time in hours after which the remote subscription will expire if not renewed by the server. This timeout minimizes the potential for orphaned subscriptions in the remote web service if the local server is uninstalled. Note that this field does not indicate the time at which the remote subscription is due to expire. Set the timeout length to something larger than the maximum length of time that the server is expected to remain offline, otherwise the stream of messages from the remote web service might be interrupted. While the server is running it occasionally renews the remote subscription termination time (with the specified timeout) to prevent it from expiring during normal operation. If not specified, this timeout defaults to 24 (hours).

Configuring a JAX-WS client to resolve a WS-Notification service WSDL without following web links

You can configure a Java API for XML-based Web Services (JAX-WS) WS-Notification application (that is, a publisher, subscriber or consumer application) to resolve the WSDL parts for a Version 7.0 WS-Notification service from a local copy of the associated `jax-ws-catalog.xml` file and `wsdl` directory, rather than by following a series of web links.

About this task

When a JAX-WS WS-Notification client application gets the WSDL file from a Version 7.0 WS-Notification service, the client application expects to resolve the imported WSDL parts by following web links. However, if you copy the `jax-ws-catalog.xml` file and the `wsdl` directory for the WS-Notification service into the local file system for the client application, then the client application can resolve the imported WSDL parts from the local copy.

Procedure

1. Open a command prompt.
2. Navigate to directory *profile_root*`/config/cells/`*cell_name*`/buses/`*bus_name*`/wsn/`*wsn_service_name*`/META-INF`, where *profile_root* is the directory in which profile-specific information is stored.
3. Copy the `jax-ws-catalog.xml` file and the `wsdl` directory from this directory to the `WEB-INF` directory for your application.

Results

Your JAX-WS WS-Notification client application can resolve the WSDL parts for the WS-Notification service from the local copy of the catalog.

Administered subscribers [Collection]

An administered subscriber provides a mechanism for the WS-Notification service point to subscribe to an external notification producer at server startup time.

To view this page in the console, click one of the following paths:

- **Service integration -> WS-Notification -> Services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name* -> Administered subscribers**
- **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name* -> Administered subscribers**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

An administered subscriber contains the name of a NotificationProducer application or a (different) NotificationBroker endpoint and details of a subscription request (for example topic) that the WS-Notification service point should register as part of the server startup procedure. This enables you to pre-configure links between the NotificationBroker and a NotificationProducer, which can be a remote NotificationBroker or a NotificationProducer application.

External web service endpoint
The URL of the external web service to which the service should subscribe.

Dialect
The dialect in which the topic is expressed.

Topic The topic on which the service should subscribe.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Administered subscribers [Collection]

An administered subscriber provides a mechanism for the WS-Notification service point to subscribe to an external notification producer at server startup time.

To view this page in the console, click one of the following paths:

- **Service integration -> WS-Notification -> Services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name* -> Runtime > Administered subscribers**
- **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name* -> Runtime > Administered subscribers**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

External web service endpoint
The URL of the external web service to which the service should subscribe.

Topic The topic for which event notifications have been requested.

State The current runtime state of the administered subscriber.

Administered subscribers [Settings]

An administered subscriber provides a mechanism for the WS-Notification service point to subscribe to an external notification producer at server startup time.

To view this page in the console, click one of the following paths:

- **Service integration -> WS-Notification -> Services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name* -> Administered subscribers -> *subscriber_name***
- **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name* -> Administered subscribers -> *subscriber_name***

An administered subscriber contains the name of a NotificationProducer application or a (different) NotificationBroker endpoint and details of a subscription request (for example topic) that the WS-Notification service point should register as part of the server startup procedure. This enables you to pre-configure links between the NotificationBroker and a NotificationProducer, which can be a remote NotificationBroker or a NotificationProducer application.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

External web service endpoint:

The URL of the external web service to which the service should subscribe.

That is, the endpoint reference (web address) of a notification producer or notification broker application. For example `http://remoteproducer.com`.

Required	Yes
Data type	String

Dialect:

The dialect in which the topic is expressed.

Required	Yes
Data type	drop-down list

Topic:

The topic on which the service should subscribe.

This describes the class of notification messages that are delivered to the WS-Notification service point. For example `stock/IBM`. This property can include wildcards if they are supported by the topic dialect that you select.

Required	Yes
Data type	String

Topic namespace:

The URI that describes the topic namespace in which the specified topic is defined.

Required	No
Data type	Custom

Remote subscription timeout:

The length of time in hours after which the remote subscription will expire if not renewed by the server.

This timeout minimizes the potential for orphaned subscriptions in the remote web service if the local server is uninstalled. Note that this field does not indicate the time at which the remote subscription is due to expire. Set the timeout length to something larger than the maximum length of time that the server is expected to remain offline, otherwise the stream of messages from the remote web service might be interrupted. While the server is running it occasionally renews the remote subscription termination time (with the specified timeout) to prevent it from expiring during normal operation. If not specified, this timeout defaults to 24 (hours).

Required	Yes
Data type	Integer
Range	1 through 2147483647

Permanent topic namespaces [Collection]

A topic namespace is a grouping of topics that allows information to be shared between applications.

To view this page in the console, click one of the following paths:

- **Service integration -> WS-Notification -> Services -> *service_name* -> Permanent topic namespaces**
- **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> Permanent topic namespaces**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

You use a permanent topic namespace to statically define the association between a WS-Notification topic namespace URI and a service integration bus topic space destination.

A permanent topic namespace has the following characteristics:

- You can use it to expose an existing service integration bus topic space for use by WS-Notification clients, thus permitting interoperation between the WS-Notification applications and existing publish and subscribe applications connected to the bus such as JMS.
- You can use it to restrict the structure and content of the topic namespace by applying one or more topic namespace documents that describe the required structure.
- You can use it as part of a topic space mapping configured on a service integration bus link (between two service integration buses) or a topic mapping as part of a publish and subscribe bridge between a service integration bus and a WebSphere MQ network.

When you create a new WS-Notification permanent topic namespace, you specify the namespace and associate it with one of the service integration bus topic spaces configured on the bus on which the parent WS-Notification service is defined. You cannot modify a permanent topic namespace after it has been created, other than to apply or remove topic namespace documents.

Namespace
The URI string by which this topic namespace is known.

Service integration bus topic space
The service integration bus topic space with which this namespace is associated.

Message reliability
The service integration bus reliability to apply to messages published to this topic namespace.

Topic namespace documents
The collection of topic namespace documents that define the structure of the topic namespace.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Permanent topic namespace [Settings]

A topic namespace is a grouping of topics that allows information to be shared between applications.

To view this page in the console, click one of the following paths:

- **Service integration -> WS-Notification -> Services -> *service_name* -> Permanent topic namespaces -> *namespace_name***
- **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> Permanent topic namespaces -> *namespace_name***

You use a permanent topic namespace to statically define the association between a WS-Notification topic namespace URI and a service integration bus topic space destination.

A permanent topic namespace has the following characteristics:

- You can use it to expose an existing service integration bus topic space for use by WS-Notification clients, thus permitting interoperation between the WS-Notification applications and existing publish and subscribe applications connected to the bus such as JMS.
- You can use it to restrict the structure and content of the topic namespace by applying one or more topic namespace documents that describe the required structure.
- You can use it as part of a topic space mapping configured on a service integration bus link (between two service integration buses) or a topic mapping as part of a publish and subscribe bridge between a service integration bus and a WebSphere MQ network.

When you create a new WS-Notification permanent topic namespace, you specify the namespace and associate it with one of the service integration bus topic spaces configured on the bus on which the parent WS-Notification service is defined. You cannot modify a permanent topic namespace after it has been created, other than to apply or remove topic namespace documents.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Namespace:

The URI string by which this topic namespace is known.

That is, the namespace URI by which WS-Notification applications refer to topics hosted by this namespace. For example `http://widgetproducer.com/prices`.

Required	Yes
Data type	Text

Service integration bus topic space:

The service integration bus topic space with which this namespace is associated.

That is, the bus topic space that is used by this topic namespace.

Required	Yes
Data type	Custom

Message reliability:

The service integration bus reliability to apply to messages published to this topic namespace.

Required	Yes
Data type	drop-down list

Range

Assured persistent
Messages are not discarded.

Reliable persistent
Messages might be discarded when a messaging engine fails.

Reliable non-persistent
Messages are discarded when a messaging engine stops or fails.

Express non-persistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Best effort non-persistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Publisher registrations [Collection]

The set of applications that are currently registered as publishers with the notification broker.

To view this page in the console, click one of the following paths:

For information for a particular service point:

- **Service integration -> WS-Notification -> Services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name* -> Runtime** > **Publisher registrations**
- **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name* -> Runtime** > **Publisher registrations**

For information aggregated for all service points for a particular service:

- **Service integration -> WS-Notification -> Services -> *service_name*** > **Runtime** > **Publisher registrations**
- **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> Runtime** > **Publisher registrations**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Publisher ID
The unique identifier of this publisher registration.

Topic The topic on which the publisher is registered to publish.

Creation time
The time at which the registration was created.

Termination time
The time at which the registration will be deleted.

Demand based
Indicates whether this is a demand based publisher.

Producer EPR
Additional publisher related data.The endpoint reference of the producer that created this registration.

Buttons

Delete	Delete the selected items.

Pull points [Collection]

This collection lists the pull points that have been created on the associated bus member or members by WS-Notification applications. Use this panel to view the information about a pull point, such as the subscription with which it is associated and the time at which it is currently set to expire. You can also delete a pull point using the button provided.

To view this page in the console, click one of the following paths:

For information for a particular service point:

- **Service integration -> WS-Notification -> Services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name* -> Runtime** > **Pull points**
- **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name* -> Runtime** > **Pull points**

For information aggregated for all service points for a particular service:

- **Service integration -> WS-Notification -> Services -> *service_name* -> Runtime** > **Pull points**
- **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> Runtime** > **Pull points**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Pull point id
The unique identifier of the pull point.

Creation time
The time at which the pull point was created.

Termination time
The time at which the pull point will be deleted.

Subscription id
The unique identifier of the subscription associated with the pull point.

If the pull point has not yet been supplied to a subscription, the text `Not Associated` is displayed.

Buttons

Delete	Delete the selected items.

Service integration bus subscriptions [Collection]

This collection lists the service integration bus subscriptions associated with the previously selected WS-Notification subscription.

To view this pane in the console, complete the following steps:

1. Display “Subscriptions [Collection].” For example, click **Service integration -> WS-Notification -> Services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name* -> Runtime** > **Subscriptions**
2. For a given WS-Notification service, click the link in the Service integration bus subscriptions column.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Subscription id
The unique identifier of the subscription.

Topic(s)
The topics on which the subscription is registered.

Subscriptions [Collection]

This collection lists the subscriptions that have been created on the associated bus member or members by WS-Notification applications. Use this panel to view the information about a subscription, such as the topic on which the subscription is registered and the time at which it is currently set to expire. You can also delete a subscription using the button provided.

To view this page in the console, click one of the following paths:

For information for a particular service point:

- **Service integration -> WS-Notification -> Services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name* -> Runtime** > **Subscriptions**
- **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name* -> Runtime** > **Subscriptions**

For information aggregated for all service points for a particular service:

- **Service integration -> WS-Notification -> Services -> *service_name* -> Runtime** > **Subscriptions**
- **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> Runtime** > **Subscriptions**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Subscription id
The unique identifier of the subscription.

Topic(s)
The topics on which the subscription is registered.

Delivery state
The current runtime state of the subscription.

Consumer EPR
The endpoint reference to which event notifications matching the subscription are sent.

Creation time
The time at which the subscription was created.

Termination time
The time at which the subscription will be deleted.

Pull type
Indicates whether the subscription is being used in pull mode.

Service integration bus subscriptions
The service integration bus durable subscription or subscriptions that are associated with the WS-Notification subscription.

Buttons

Delete	Delete the selected items.

Topic namespace document [Collection]

A topic namespace can optionally have topic namespace documents applied to it that define the structure of the topics that are permitted within the namespace.

To view this page in the console, click one of the following paths:

- **Service integration -> WS-Notification -> Services -> *service_name* -> Permanent topic namespaces -> *namespace_name* -> Topic namespace documents**
- **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> Permanent topic namespaces -> *namespace_name* -> Topic namespace documents**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Document name
The name of the file from which the topic namespace document was originally loaded.

Description
An optional description of the topic namespace document.

Buttons

New	Create a new administrative object of this type.

Delete	Delete the selected items.

Topic namespace document [Settings]

A topic namespace can optionally have topic namespace documents applied to it that define the structure of the topics that are permitted within the namespace.

To view this page in the console, click one of the following paths:

- **Service integration -> WS-Notification -> Services -> *service_name* -> Permanent topic namespaces -> *namespace_name* -> Topic namespace documents -> *document_name* > Upload**
- **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> Permanent topic namespaces -> *namespace_name* -> Topic namespace documents -> *document_name* > Upload**

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Associated permanent topic namespace:

The topic namespace to which this document is applied.

Required	No
Data type	String

URL of topic namespace document:

The URL of the topic namespace document that should be loaded.

Required	Yes
Data type	Text

Description:

An optional description of the topic namespace document.

Required	No
Data type	Text area

Topic namespace document [Settings]

A topic namespace can optionally have topic namespace documents applied to it that define the structure of the topics that are permitted within the namespace.

To view this page in the console, click one of the following paths:

- **Service integration -> WS-Notification -> Services -> *service_name* -> Permanent topic namespaces -> *namespace_name* -> Topic namespace documents -> *document_name* > View**

- **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> Permanent topic namespaces -> *namespace_name* -> Topic namespace documents -> *document_name* > View**

WS-Notification service points [Collection]

A WS-Notification service point defines access to a WS-Notification service on a given bus member through a specified web service binding (for example SOAP over HTTP). Applications use the bus members associated with the WS-Notification service point to connect to the WS-Notification service.

To view this page in the console, click one of the following paths:

- **Service integration -> WS-Notification -> Services -> *service_name* -> [Additional Properties] WS-Notification service points**
- **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Additional Properties] WS-Notification service points**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

You can define any number of WS-Notification service points for a given WS-Notification service. Each service point defined for the same WS-Notification service represents an alternative entry point to the service. Event notifications published to a particular WS-Notification service point are received by all applications connected to any service point of the same WS-Notification service (subject to subscription on the correct topic) regardless of the particular service point to which they are connected.

Name The name of the WS-Notification service point. This appears as part of the address of the web service that is exposed on the chosen server.

Associated bus member
The name of the bus member on which this WS-Notification service point is deployed.

Description
An optional description of the WS-Notification service point.

Buttons

New	Create a new service point.
Delete	Delete the selected items.
Copy	Copy the service point.

WS-Notification service points [Settings]

A WS-Notification service point defines access to a WS-Notification service on a given bus member through a specified web service binding (for example SOAP over HTTP). Applications use the bus members associated with the WS-Notification service point to connect to the WS-Notification service.

To view this page in the console, click one of the following paths:

- **Service integration -> WS-Notification -> Services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name***

- **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name* -> [Additional Properties] WS-Notification service points -> *point_name***

You can define any number of WS-Notification service points for a given WS-Notification service. Each service point defined for the same WS-Notification service represents an alternative entry point to the service. Event notifications published to a particular WS-Notification service point are received by all applications connected to any service point of the same WS-Notification service (subject to subscription on the correct topic) regardless of the particular service point to which they are connected.

The existence of a WS-Notification service point on a bus member implies that a WS-Notification web service is exposed from that bus member, and causes web service endpoints for the notification broker, subscription manager and publisher registration manager for this WS-Notification service to be exposed on the bus member with which the service point is associated. WS-Notification applications use these endpoints to interact with the WS-Notification service.

In this implementation of WS-Notification there are two types of WS-Notification service configuration:

- **Version 7.0**: Use this type of service if you want to compose a JAX-WS WS-Notification service with web service qualities of service (QoS) via policy sets, or if you want to apply JAX-WS handlers to your WS-Notification service. This is the recommended type of service for new deployments. This WS-Notification option has been available in WebSphere Application Server from Version 7.0.
- **Version 6.1**: Use this type of service if you want to expose a JAX-RPC WS-Notification service that uses the same technology provided in WebSphere Application Server Version 6.1, including the ability to apply JAX-RPC handlers to the service. This WS-Notification option has been available in WebSphere Application Server from Version 6.1.

Some of the fields are specific to the type of WS-Notification service that you are viewing.

- When you create a Version 6.1 WS-Notification service point you select a bus member on which the WS-Notification service point is configured. You allocate a service point to a given bus member by specifying an endpoint listener that is configured for that bus member. You also choose the type of web service binding (SOAP over HTTP or SOAP over JMS) that is used for the WS-Notification service point.
- When you create a Version 7.0 WS-Notification service point you select a bus member on which the WS-Notification service point is configured. You also choose the SOAP version that is supported by the service point, and (optionally) apply JAX-WS handler lists to the NotificationBroker, SubscriptionManager or PublisherRegistrationManager that are exposed through this service point.
- “Configuration tab”
- “Runtime tab” on page 3046

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the WS-Notification service point. This appears as part of the address of the web service that is exposed on the chosen server.

You cannot modify the name.

Required	Yes
Data type	String

Description:

An optional description of the WS-Notification service point.

Required	No
Data type	Text area

Associated bus member:

The name of the bus member on which this WS-Notification service point is deployed.

Required	No
Data type	String

General properties that are specific to Version 7.0 WS-Notification service points:

SOAP Version

Defines the version of SOAP supported by the service point. This affects the WSDL definition that will be exposed by the web service. Permitted values are 1.1 for SOAP 1.1 (the default), and 1.2 for SOAP 1.2.

Required	No
Data type	String

NotificationBroker JAX-WS handler list

The JAX-WS handler list that is applied to inbound requests from an application to the NotificationBroker endpoint of the WS-Notification service point.

Required	No
Data type	drop-down list

SubscriptionManager JAX-WS handler list

The JAX-WS handler list that is applied to inbound requests from an application to the SubscriptionManager endpoint of the WS-Notification service point.

Required	No
Data type	drop-down list

PublisherRegistrationManager JAX-WS handler list

The JAX-WS handler list that is applied to inbound requests from an application to the PublisherRegistrationManager endpoint of the WS-Notification service point.

Required	No
Data type	drop-down list

Additional Properties

Administered subscribers

An administered subscriber provides a mechanism for the WS-Notification service point to subscribe to an external notification producer at server startup time.

Custom properties

Select this link to configure additional custom properties for this WS-Notification service point.

Additional properties that are specific to Version 7.0 WS-Notification service points:

Policy set configuration
The policy set configuration associated with this WS-Notification service point. You can configure policy set and binding information for each port relating to this service point.

Publish WSDL files to zip
Publish the WSDL files for this service point to a compressed file.

Note: When you run the wsimport command against the exported `PublisherRegistrationManager.wsdl` file you must include the `ibm-wsn-jaxws.xml` file as an argument to wsimport.

For more information, see "Publishing the WSDL files for a WS-Notification application to a compressed file" on page 2984.

Service point application
The application associated with this WS-Notification service point. For Version 7.0 WS-Notification services, enterprise applications are used to expose the web services associated with the WS-Notification service.

Additional properties that are specific to Version 6.1 WS-Notification service points:

Notification broker inbound port settings
The inbound port defined for the notification broker role of this WS-Notification service point.

Publisher registration manager inbound port settings
The inbound port defined for the publisher registration manager role of this WS-Notification service point.

Subscription manager instance inbound port settings
The inbound port defined for the subscription manager role of this WS-Notification service point.

Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

Additional Properties

Subscriptions
This collection lists the subscriptions that have been created on the associated bus member or members by WS-Notification applications. Use this panel to view the information about a subscription, such as the topic on which the subscription is registered and the time at which it is currently set to expire. You can also delete a subscription using the button provided.

Publisher registrations
The set of applications that are currently registered as publishers with the notification broker.

Pull points
This collection lists the pull points that have been created on the associated bus member or members by WS-Notification applications. Use this panel to view the information about a pull point, such as the subscription with which it is associated and the time at which it is currently set to expire. You can also delete a pull point using the button provided.

Administered subscribers
An administered subscriber provides a mechanism for the WS-Notification service point to subscribe to an external notification producer at server startup time.

WS-Notification services [Collection]

A WS-Notification service provides access to service integration bus resources for web services publish and subscribe clients.

To view this page in the console, click one of the following paths:

- **Service integration -> WS-Notification -> Services**
- **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

A WS-Notification service provides the ability to expose some or all of the messaging resources defined on a service integration bus for use by WS-Notification applications.

Name The name of the WS-Notification service.

Service integration bus name
The name of the service integration bus with which the WS-Notification service is associated.

Type The type of the WS-Notification service.

- **Version 7.0**: Use this type of service if you want to compose a JAX-WS WS-Notification service with web service qualities of service (QoS) via policy sets, or if you want to apply JAX-WS handlers to your WS-Notification service. This is the recommended type of service for new deployments. This WS-Notification option has been available in WebSphere Application Server from Version 7.0.
- **Version 6.1**: Use this type of service if you want to expose a JAX-RPC WS-Notification service that uses the same technology provided in WebSphere Application Server Version 6.1, including the ability to apply JAX-RPC handlers to the service. This WS-Notification option has been available in WebSphere Application Server from Version 6.1.

Description
An optional description of the WS-Notification service.

Buttons

New	Create a new WS-Notification service.
Delete	Delete the selected items.

WS-Notification services [Settings]

A WS-Notification service provides access to service integration bus resources for web services publish and subscribe clients.

To view this page in the console, click one of the following paths:

- **Service integration -> WS-Notification -> Services -> *service_name***
- **Service integration -> Buses -> *bus_name* -> [Services] WS-Notification services -> *service_name***

A WS-Notification service provides the ability to expose some or all of the messaging resources defined on a service integration bus for use by WS-Notification applications.

In this implementation of WS-Notification there are two types of WS-Notification service configuration:

- **Version 7.0**: Use this type of service if you want to compose a JAX-WS WS-Notification service with web service qualities of service (QoS) via policy sets, or if you want to apply JAX-WS handlers to your WS-Notification service. This is the recommended type of service for new deployments. This WS-Notification option has been available in WebSphere Application Server from Version 7.0.
- **Version 6.1**: Use this type of service if you want to expose a JAX-RPC WS-Notification service that uses the same technology provided in WebSphere Application Server Version 6.1, including the ability to apply JAX-RPC handlers to the service. This WS-Notification option has been available in WebSphere Application Server from Version 6.1.

Some of the fields are specific to the type of WS-Notification service that you are viewing. For example, inbound service settings are specific to Version 6.1 WS-Notification services because Version 6.1 WS-Notification services use inbound services to expose the web services associated with the WS-Notification service. For Version 7.0 WS-Notification services, enterprise applications are used to expose the web services, and the configuration of these applications is accessed solely through the service point panels.

- "Configuration tab"
- "Runtime tab" on page 3052

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the WS-Notification service.

The name forms part of the endpoint on which the service is exposed (that is, the URL used to access the WS-Notification service points that are defined under the service). You cannot modify the name. For Version 6.1 WS-Notification services, the service name is unique within a bus. For Version 7.0 WS-Notification services the service name is unique within the cell, which matches the administration model used for policy sets and therefore supports composition of Version 7.0 WS-Notification services with WS-ReliableMessaging.

Required	Yes
Data type	String

Service integration bus name:

The name of the service integration bus with which the WS-Notification service is associated.

You cannot modify the service integration bus name.

Required	Yes
Data type	String

Type:

The type of the WS-Notification service.

- **Version 7.0**: Use this type of service if you want to compose a JAX-WS WS-Notification service with web service qualities of service (QoS) via policy sets, or if you want to apply JAX-WS handlers to your

WS-Notification service. This is the recommended type of service for new deployments. This WS-Notification option has been available in WebSphere Application Server from Version 7.0.

- **Version 6.1**: Use this type of service if you want to expose a JAX-RPC WS-Notification service that uses the same technology provided in WebSphere Application Server Version 6.1, including the ability to apply JAX-RPC handlers to the service. This WS-Notification option has been available in WebSphere Application Server from Version 6.1.

You choose the type when you create the service. You cannot modify the type for an existing service.

Required	Yes
Data type	String

Description:

An optional description of the WS-Notification service.

Required	No
Data type	Text area

Enable dynamic topic namespaces?:

Indicates whether dynamic topic namespaces can be used within the WS-Notification service.

That is, whether this service allows dynamic topic namespaces to be created at run time.

A dynamic topic namespace does not require manual administration by using the administration console or scripting. A dynamic topic namespace is used automatically in response to a request from a WS-Notification application for a topic namespace URI that has not been defined as a permanent topic namespace (assuming the WS-Notification service has been configured to permit use of dynamic namespaces).

A dynamic topic namespace has the following characteristics:

- It does not support interoperation between WS-Notification applications and other clients of the bus such as JMS.
- It is not possible to apply topic namespace documents to this topic space, and thus the structure and content of the topic space are unrestricted.
- It cannot be used as part of the configuration of service integration bus links or a publish and subscribe bridge.

Use this option to tightly control the topic namespaces that are used when connecting to a particular WS-Notification service (for example for security or auditing requirements). If you deselect this option, any applications that connect to the WS-Notification service and request topics from a dynamic topic namespace are stopped from publishing or receiving messages.

All messages published to a dynamic topic namespace are inserted with the default message reliability setting of reliable persistent. If this value is not acceptable, create a permanent topic namespace and manually configure the attribute to the appropriate value.

Note: The dynamic topic namespaces used on a particular WS-Notification service are backed by a service integration bus topic space that is created automatically when you create the topic namespace. The syntax of topics used within this topic space is internal to the WS-Notification service implementation.

Required	No

Data type Boolean

Dynamic topic space name:

The name of the service integration bus topic space to be used as the dynamic topic space for this WS-Notification service.

That is, the name of the bus topic space that is used to host the ad-hoc topic namespace, and to host dynamic topic namespaces if they are permitted. You cannot modify the dynamic topic space name.

Required No
Data type String

Requires registration:

Indicates whether publisher applications are required to register with the broker before they can publish notifications.

Required No
Data type Boolean

Fixed topic set:

Indicates whether the list of topics supported by the notification broker is fixed or may vary at runtime.

You cannot modify the setting for the fixed topic set.

Required No
Data type Boolean

Topic expression dialects:

List of topic dialects supported by this WS-Notification service.

That is, the name of the chosen topic dialect as defined by the WS-Topics standard:

- *Simple topics*. That is, single-level root topics with no wildcards. For example “stock”.
- *Concrete topics*. That is, multi-level topics with no wildcards. For example “stock/IBM”, “sport/football/results”.
- *Full topics*. That is, multi-level topics with wildcards and conjunctions. For example “stock//.”, “sport/football/*”, “sport/*/results”, “t1/t3 | t3/t4”.

You cannot modify the list of supported topic dialects.

Required Yes
Data type Text area

General properties that are specific to Version 7.0 WS-Notification services:

JAX-WS handler list

The JAX-WS handler list that is applied to outbound requests from the WS-Notification service.

A handler list defines the handlers that are applied when making outbound web service invocations, for example monitoring outbound event notification (in response to a subscribe operation) and controlling demand-based publishers (subscribe, pause and resume).

Required	No
Data type	drop-down list

Query WSDL

Indicates whether the Version 7.0 WS-Notification service queries the WSDL of other WS-Notification web services when interacting with them. By default, this option is enabled. By clearing this option, you can improve performance by avoiding expensive WSDL queries. However, you should note the following considerations when WSDL querying is not enabled:

- WS-Notification attempts to discover binding information (which is usually discovered through the WSDL) by using other means. WS-Notification uses the SOAP version associated with the WS-Notification service point where subscriptions were made (by other web services), or where administered subscriptions were created (by an administrator).
- There are some circumstances in which WS-Notification might be unable to determine binding information. This can happen when cleaning up subscriptions where the associated service point has been deleted and configuration information is no longer available. Under these circumstances WS-Notification makes a “best guess” at binding information to use to clean up the subscriptions.
- There is one scenario where incorrect binding information is used. That is, when a subscriber subscribes to use a particular SOAP binding, on behalf of a NotificationConsumer that expects notifications through a different SOAP binding.

Required	No
Data type	Boolean

General properties that are specific to Version 6.1 WS-Notification services:

JAX-RPC handler list

The JAX-RPC handler list that is applied to outbound requests from the WS-Notification service - for example the broker delivering notifications to a consumer.

A handler list defines the handlers that are applied when making outbound web service invocations, for example monitoring outbound event notification (in response to a subscribe operation) and controlling demand-based publishers (subscribe, pause and resume).

Required	No
Data type	drop-down list

Outbound security request binding

The security binding to be used with consumer notifications and remote publisher requests sent by this WS-Notification service.

WS-Security bindings define the security policy that is used when making outbound web service invocations, for example controlling demand-based publishers (subscribe, pause and resume).

Required	No
Data type	drop-down list

Outbound security response binding

The security binding to be used with remote publisher responses received by this WS-Notification service.

Required	No
Data type	drop-down list

Outbound security configuration

Specifies the details of how security is applied to requests and responses.

Required	No
Data type	drop-down list

Additional Properties

WS-Notification service points
Select this link to configure the deployment of WS-Notification service points on one or more servers.

Permanent topic namespaces
Select this link to configure permanent topic namespaces for the WS-Notification service.

Custom properties
Select this link to configure additional custom properties for this WS-Notification service.

Additional properties that are specific to Version 7.0 WS-Notification services:

Outbound request policy sets and bindings
The outbound request policy sets and bindings for the two WS-Notification service clients associated with this WS-Notification service. For reliable web service transmission of notification messages, use this option to associate the WS-Notification service client with a policy set that enables WS-ReliableMessaging.

Additional properties that are specific to Version 6.1 WS-Notification services:

Notification broker inbound service settings
The inbound service defined for the notification broker role of this WS-Notification service.

Publisher registration manager inbound service settings
The inbound service defined for the publisher registration manager role of this WS-Notification service.

Subscription manager inbound service settings
The inbound service defined for the subscription manager role of this WS-Notification service.

Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

Additional Properties

Subscriptions
This collection lists the subscriptions that have been created on the associated bus member or members by WS-Notification applications. Use this panel to view the information about a subscription, such as the topic on which the subscription is registered and the time at which it is currently set to expire. You can also delete a subscription using the button provided.

Publisher registrations
The set of applications that are currently registered as publishers with the notification broker.

Pull points

This collection lists the pull points that have been created on the associated bus member or members by WS-Notification applications. Use this panel to view the information about a pull point, such as the subscription with which it is associated and the time at which it is currently set to expire. You can also delete a pull point using the button provided.

WSNotificationCommands command group for the AdminTask object

Decide which method to use to configure these resources. You can configure WS-Notification resources by using wsadmin command scripts as described in this topic, or you can configure WS-Notification resources by using the administrative console.

Although not part of the set of WS-Notification commands, the common task “Using a script to get up and running quickly with WS-Notification” on page 2964 also involves running a wsadmin command.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('WSNotificationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

The following administrative commands are available in this command group. Target objects and parameters are required unless otherwise stated.

- “createWSNService command” on page 3054
- “deleteWSNService command” on page 3057
- “listWSNServices command” on page 3058
- “showWSNService command” on page 3059
- “createWSNServicePoint command” on page 3061
- “deleteWSNServicePoint command” on page 3064
- “listWSNServicePoints command” on page 3065
- “showWSNServicePoint command” on page 3067
- “createWSNTopicNamespace command” on page 3074
- “deleteWSNTopicNamespace command” on page 3076
- “listWSNTopicNamespaces command” on page 3077
- “showWSNTopicNamespace command” on page 3078
- “createWSNAdministeredSubscriber command” on page 3068
- “deleteWSNAdministeredSubscriber command” on page 3070
- “listWSNAdministeredSubscribers command” on page 3071
- “showWSNAdministeredSubscriber command” on page 3072
- “createWSNTopicDocument command” on page 3079
- “deleteWSNTopicDocument command” on page 3081

- “listWSNTopicDocuments command” on page 3082
- “showWSNTopicDocument command” on page 3083
- “getWSN_SIBWSInboundService command” on page 3084
- “getWSN_SIBWSInboundPort command” on page 3085

createWSNService command

Use the createWSNService command to create a new WS-Notification service and the associated objects that form the infrastructure of the WS-Notification configuration. A WS-Notification service provides access to service integration bus resources for web services publish and subscribe clients.

You can create a new WS-Notification service by using the wsadmin tool as described in this topic, or by using the administrative console as described in “Creating a new Version 6.1 WS-Notification service” on page 2995 and “Creating a new Version 7.0 WS-Notification service” on page 2987.

If you are creating a Version 6.1 WS-Notification service, you must first ensure that you have successfully configured an SDO repository as described in “Installing and configuring the SDO repository” on page 2772. The SDO repository is used to store WSDL documents during the creation of the Version 6.1 WS-Notification service. If you do not configure the repository, an error message is displayed when you create the service.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('WSNotificationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command creates a new WS-Notification service on a service integration bus. If you are creating a Version 6.1 WS-Notification service, the command also creates the three service integration bus inbound services that represent the three roles played by the broker, and creates the association between these objects and the new WS-Notification service.

Target object

An existing service integration bus (conditional - must be provided if the **bus** parameter is not supplied).

Required parameters

-name

The name to be given to the new WS-Notification service. The name forms part of the endpoint on which the service is exposed (that is, the URL used to access the WS-Notification service points that are defined under the service).

For Version 6.1 WS-Notification services, the service name is unique within a bus. For Version 7.0 WS-Notification services the service name is unique within the cell, which matches the administration model used for policy sets and therefore supports composition of Version 7.0 WS-Notification services with WS-ReliableMessaging.

Conditional parameters

-bus

The name of the service integration bus that is to host the WS-Notification service. This can be an existing bus, or the name of a new bus that you want the command to create for you. This parameter should only be specified if a Target object is not provided.

Optional parameters

-type

The type of WS-Notification service that is created. Permitted values are V7.0 and V6.1 (the default).

- **Version 7.0**: Use this type of service if you want to compose a JAX-WS WS-Notification service with web service qualities of service (QoS) via policy sets, or if you want to apply JAX-WS handlers to your WS-Notification service. This is the recommended type of service for new deployments. This WS-Notification option has been available in WebSphere Application Server from Version 7.0.
- **Version 6.1**: Use this type of service if you want to expose a JAX-RPC WS-Notification service that uses the same technology provided in WebSphere Application Server Version 6.1, including the ability to apply JAX-RPC handlers to the service. This WS-Notification option has been available in WebSphere Application Server from Version 6.1.

Only specify the following optional parameters if the service type is Version 6.1:

- **-jaxrpcHandlerList**
- **-outboundSecurityConfigName**
- **-outboundSecurityRequestBindingName**
- **-outboundSecurityResponseBindingName**

Note: For Version 7.0 WS-Notification services, equivalent functions to the Version 6.1 outbound security attributes are provided through policy set configuration.

Only specify the following optional parameters if the service type is Version 7.0:

- **-jaxwsHandlerListName**
- **-queryWSDL**

-description

An optional description of the WS-Notification service.

-permitsDynamicTopicNamespace

Indicates whether dynamic topic namespaces can be used within the WS-Notification service. That is, whether this service allows dynamic topic namespaces to be created at run time. For more information, see Dynamic topic namespace. Permitted values are TRUE (the default) and FALSE

Use this option to tightly control the topic namespaces that are used when connecting to a particular WS-Notification service (for example for security or auditing requirements). If you deselect this option, any applications that connect to the WS-Notification service and request topics from a dynamic topic namespace are stopped from publishing or receiving messages.

All messages published to a dynamic topic namespace are inserted with the default message reliability setting of reliable persistent. If this value is not acceptable, create a permanent topic namespace and manually configure the attribute to the appropriate value.

Note: The dynamic topic namespaces used on a particular WS-Notification service are backed by a service integration bus topic space that is created automatically when you create the topic namespace. The syntax of topics used within this topic space is internal to the WS-Notification service implementation.

-dynamicTopicSpace
The name of the service integration bus topic space to be used as the dynamic topic space for this WS-Notification service. That is, the name of the bus topic space that is used to host the ad-hoc topic namespace, and to host dynamic topic namespaces if they are permitted. If not specified, this value defaults to `WSN_dynamic_this_service_name`.

-requiresRegistration
Boolean flag. Indicates whether publisher applications are required to register with the broker before they can publish notifications. Permitted values are TRUE and FALSE (the default).

-jaxwsHandlerListName
The JAX-WS handler list that is applied to outbound requests from the WS-Notification service. A handler list defines the handlers that are applied when making outbound web service invocations, for example monitoring outbound event notification (in response to a subscribe operation) and controlling demand-based publishers (subscribe, pause and resume). For more information about handler lists, see “Configuring JAX-WS handlers” on page 2972.

Only specify this parameter for Version 7.0 WS-Notification services.

-jaxrpcHandlerListName
The JAX-RPC handler list that is applied to outbound requests from the WS-Notification service - for example the broker delivering notifications to a consumer. For more information about handler lists, see “Working with JAX-RPC handlers and clients” on page 2799.

Only specify this parameter for Version 6.1 WS-Notification services.

-outboundSecurityRequestBindingName
The security binding to be used with consumer notifications and remote publisher requests sent by this WS-Notification service.

Only specify this parameter for Version 6.1 WS-Notification services.

-outboundSecurityResponseBindingName
The security binding to be used with remote publisher responses received by this WS-Notification service.

Only specify this parameter for Version 6.1 WS-Notification services.

-outboundSecurityConfigName
Specifies the details of how security is applied to requests and responses.

Only specify this parameter for Version 6.1 WS-Notification services.

-queryWSDL
Boolean flag. Indicates whether the Version 7.0 WS-Notification service queries the WSDL of other WS-Notification web services when interacting with them. Permitted values are TRUE (the default) and FALSE.

By setting this parameter to FALSE you can improve performance by avoiding expensive WSDL queries. However, you should note the following considerations when WSDL querying is not enabled:

- WS-Notification attempts to discover binding information (which is usually discovered through the WSDL) by using other means. WS-Notification uses the SOAP version associated with the WS-Notification service point where subscriptions were made (by other web services), or where administered subscriptions were created (by an administrator).
- There are some circumstances in which WS-Notification might be unable to determine binding information. This can happen when cleaning up subscriptions where the associated service point

has been deleted and configuration information is no longer available. Under these circumstances WS-Notification makes a “best guess” at binding information to use to clean up the subscriptions.

- There is one scenario where incorrect binding information is used. That is, when a subscriber subscribes to use a particular SOAP binding, on behalf of a NotificationConsumer that expects notifications through a different SOAP binding.

Only specify this parameter for Version 7.0 WS-Notification services.

Examples

Create a Version 6.1 WS-Notification service (equivalent to omitting the **-type** parameter):

```
newService = AdminTask.createWSNService(["-bus", "bus1", "-name",
"NewWSNService", "-type", "V6.1"] )
```

Create a Version 7.0 WS-Notification service that allows composition with WS-ReliableMessaging:

```
newService = AdminTask.createWSNService(["-bus", "bus1", "-name",
"NewWSNService", "-type", "V7.0"] )
```

Create a Version 7.0 WS-Notification service with a non-null handler list:

```
newService = AdminTask.createWSNService(["-bus", "bus1", "-name",
"NewWSNService", "-type", "V7.0", "-jaxwsHandlerListName", "myHandlerList"] )
```

Create a Version 7.0 WS-Notification service that does not query WSDL:

```
newService = AdminTask.createWSNService(["-bus", "bus1", "-name",
"NewWSNService", "-type", "V7.0", "-queryWSDL", "false"] )
```

Set the custom property to enable strict topic checking on this WS-Notification service:

- Using Jython:

  ```
  propName = ["name", "com.ibm.ws.sib.wsn.strictTopicChecking"]
  propValue = ["value", "TRUE"]
  propAttrs = [propName, propValue]
  AdminConfig.create("Property", newService, propAttrs)
  ```

- Using Jacl:

  ```
  set propName [list name "com.ibm.ws.sib.wsn.strictTopicChecking"]
  set propValue [list value "TRUE"]
  set propAttrs [list $propName $propValue]
  $AdminConfig create Property $newService $propAttrs
  ```

deleteWSNService command

Use the deleteWSNService command to delete a WS-Notification service and associated resources. A WS-Notification service provides access to service integration bus resources for web services publish and subscribe clients.

You can delete a WS-Notification service by using the wsadmin tool as described in this topic, or by using the administrative console as described in “Deleting WS-Notification services” on page 2994.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('WSNotificationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command deletes the specified WS-Notification service and all the objects configured on the service:

- For Version 7.0 WS-Notification services, the WS-Notification service points and the associated service point application are deleted.
- For Version 6.1 WS-Notification services, the WS-Notification service points and the associated service integration bus inbound ports are deleted.
- WS-Notification permanent topic namespaces and any service integration bus topic spaces that were created by the topic namespace are deleted.
- Topic namespace documents defined for the permanent topic namespaces, and (for Version 6.1 WS-Notification services) the associated XML documents stored in an SDO repository are deleted.

Target object

WSNService

Required parameters

None.

Conditional parameters

None.

Optional parameters

-deleteSIBTopicSpaces
TRUE or FALSE. Indicates whether service integration bus topic spaces created by definition of a WS-Notification permanent topic namespace should also be deleted (default is FALSE).

Example

Delete the WS-Notification service `newService` created in the example from topic “Creating a new WS-Notification service by using the wsadmin tool”.

- Using Jython:
  ```
  AdminTask.deleteWSNService(newService, ["-deleteSIBTopicSpaces", "TRUE"])
  ```
- Using Jacl:

```
$AdminTask deleteWSNService $newService {-deleteSIBTopicSpaces TRUE}
```

listWSNServices command

Use the listWSNServices command to list WS-Notification services. A WS-Notification service provides access to service integration bus resources for web services publish and subscribe clients.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('WSNotificationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command lists all the WS-Notification services in the configuration that match the specified input parameters. This command can be used to obtain a reference to one or more WS-Notification services that have already been created in the configuration in order to work with the service further, for example to add a new WS-Notification topic namespace definition.

Target object

WS-Notification services that match the requested pattern.

Required parameters

None.

Conditional parameters

None.

Optional parameters

-bus
The name of the service integration bus by which the list of WS-Notification services is filtered.

-name
The name of the WS-Notification service by which the list of WS-Notification services is filtered.

-type
The type of WS-Notification service by which the list of WS-Notification services is filtered. Permitted values are V7.0 and V6.1. By default, services of all types are listed.

Examples

List all WS-Notification services of any type on `bus1`:

```
wsnServiceList = AdminTask.listWSNServices(["-bus", "bus1"] )
```

List all Version 7.0 WS-Notification services on `bus1`:

```
wsnServiceList = AdminTask.listWSNServices(["-bus", "bus1", "-type", "V7.0"] )
```

showWSNService command

Use the showWSNService command to show the properties of a WS-Notification service. A WS-Notification service provides access to service integration bus resources for web services publish and subscribe clients.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('WSNotificationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command shows the properties of a WS-Notification service in a human-readable form. There are two patterns for use of this command:

- The required WS-Notification service is determined by the target object used.
- The required WS-Notification service is determined by the values specified on the parameters.

Target object

WSNService (conditional - must be provided if the **bus** and **name** parameters are not provided).

Required parameters

None.

Conditional parameters

-bus
The name of the service integration bus on which the WS-Notification service is located. This must be specified if a target object is not specified.

-name
The name of the WS-Notification service to be displayed. This must be specified if a target object is not specified.

Optional parameters

None.

Examples

Display the WS-Notification service obtained in the example from topic “Listing WS-Notification services by using the wsadmin tool”, by using the target object pattern.

- Using Jython:

  ```
  AdminTask.showWSNService(wsnServiceList)
  ```

- Using Jacl:

```
$AdminTask showWSNService $wsnServiceList
```

Display the WS-Notification service obtained in the example from topic “Listing WS-Notification services by using the wsadmin tool”, by using the parameters pattern.

- Using Jython:

  ```
  AdminTask.showWSNService(["-bus", "bus1", "-name", "NewWSNService"])
  ```

- Using Jacl:

```
$AdminTask showWSNService {-bus bus1 -name NewWSNService}
```

createWSNServicePoint command

Use the createWSNServicePoint command to create a new WS-Notification service point. A WS-Notification service point defines access to a WS-Notification service on a given bus member through a specified web service binding (for example SOAP over HTTP). Applications use the bus members associated with the WS-Notification service point to connect to the WS-Notification service.

You can create a new WS-Notification service point by using the wsadmin tool as described in this topic, or by using the administrative console as described in “Creating a new Version 6.1 WS-Notification service point” on page 3005 and “Creating a new Version 7.0 WS-Notification service point” on page 3001.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('WSNotificationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The existence of a WS-Notification service point on a bus member implies that a WS-Notification web service is exposed from that bus member, and causes web service endpoints for the notification broker, subscription manager and publisher registration manager for this WS-Notification service to be exposed on the bus member with which the service point is associated. WS-Notification applications use these endpoints to interact with the WS-Notification service.

This command creates the following resources:

- It creates a new WS-Notification service point on a WS-Notification service.
- For a Version 7.0 WS-Notification service point, it causes Web service endpoints for the three roles played by the broker to be exposed on the bus member.
- For a Version 6.1 WS-Notification service point, it creates the three service integration bus inbound ports that represent the three roles played by the broker, it creates a service integration bus endpoint listener if required, and it connects the new or existing endpoint listener to the service integration bus with which the WS-Notification service is associated.

If the service type is Version 7.0, do not specify the following optional parameters, which relate to JAX-RPC configuration:

-eplName
-eplURLRoot
-eplWSDLServingURLRoot

If the service type is Version 6.1, do not specify the following optional parameters, which relate to JAX-WS configuration:

-transportURLRoot
-transportSoapVersion
-jaxwsHandlerListNB
-jaxwsHandlerListSM
-jaxwsHandlerListPRM

You can only create service points for Version 7.0 WS-Notification services on WebSphere Application Server Version 7.0 or later bus members.

You can create service points for Version 6.1 WS-Notification services on WebSphere Application Server Version 6.1 or later application servers.

Target object

WSNService

Required parameters

-name
The name of the WS-Notification service point. This appears as part of the address of the web service that is exposed on the chosen server.

Conditional parameters

-server
Name of the server on which the WS-Notification service point is created.

- If you specify the **copyServicePoint** parameter, then you need not specify this parameter.
- If this parameter is used then the **node** parameter must be specified.

-node
Name of the node on which the server is located.

- If you specify the **copyServicePoint** parameter, then you need not specify this parameter.
- If this parameter is used then the **server** parameter must be specified.

For a Version 6.1 WS-Notification service, choose either to configure a new endpoint listener or use an existing one:

-eplName
Name of an endpoint listener.

- If you specify the **copyServicePoint** parameter, then you need not specify this parameter.
- If this endpoint listener has already been defined on the chosen server, then the **eplURLRoot** and **eplWSDLServingURLRoot** parameters should not be specified. Otherwise, the **eplURLRoot** and **eplWSDLServingURLRoot** parameters must both be specified.

Only specify this parameter for Version 6.1 WS-Notification services.

-eplURLRoot
Root of the externally visible endpoint address URL for web services that are accessed through this endpoint listener.

- If you specify the **copyServicePoint** parameter, then you need not specify this parameter.
- If the endpoint listener has already been defined on the chosen server, then this parameter should not be specified.

Only specify this parameter for Version 6.1 WS-Notification services.

-eplWSDLServingURLRoot
Root of the externally visible HTTP URL where the WSDL file associated with this endpoint listener is

located. In most circumstances this is `http://host_name:port_number/SIBWS`. For more information, see “Creating a new endpoint listener configuration” on page 2789 or “createSIBWSEndpointListener command” on page 2949.

- If you specify the **copyServicePoint** parameter, then you need not specify this parameter.
- If the endpoint listener has already been defined on the chosen server, then this parameter should not be specified.

Only specify this parameter for Version 6.1 WS-Notification services.

For a Version 7.0 WS-Notification service, configure the web service endpoint:

-transportURLRoot
Root of the externally visible endpoint address for the WS-Notification service point, in the following format:

protocol://*host_nameport_number/service_location*

where *protocol* is either `http` or `https`. For example:

```
http://myhostname:9080/ctx123/mySvc
```

You can use this parameter to associate a particular external web address with the WS-Notification service when you publish WSDL to a compressed file through the administrative console. Note that this address might not be the same as the address at which the WS-Notification service is exposed. This address is required when the WS-Notification service is accessed through a proxy.

If you do not specify this parameter, the underlying JAX-WS implementation creates an appropriate URL based on information provided as part of the service point installation process.

If you specify the **copyServicePoint** parameter, then you need not specify this parameter.

This attribute is the equivalent of the **eplURLRoot** parameter for service points created on Version 6.1 WS-Notification services. Only specify this parameter for Version 7.0 WS-Notification services.

-transportSoapVersion
Defines the version of SOAP supported by the service point. This affects the WSDL definition that will be exposed by the web service. Permitted values are 1.1 for SOAP 1.1 (the default), and 1.2 for SOAP 1.2.

If you specify the **copyServicePoint** parameter, then you need not specify this parameter.

Only specify this parameter for Version 7.0 WS-Notification services.

Copy the configuration from an existing WS-Notification service point definition:

-copyServicePoint
The name of an existing service point configured on the WS-Notification Service from which the other configuration attributes are copied. If you specify this parameter, then you only have to specify the **name** parameter. All other values are taken from the nominated existing service point.

Optional parameters

-description
An optional description of the WS-Notification service point.

-jaxwsHandlerListNB
The JAX-WS handler list that is applied to inbound requests from an application to the NotificationBroker endpoint of the WS-Notification service point.

If you specify the **copyServicePoint** parameter, then you need not specify this parameter.

Only specify this parameter for Version 7.0 WS-Notification services.

-jaxwsHandlerListSM
The JAX-WS handler list that is applied to inbound requests from an application to the SubscriptionManager endpoint of the WS-Notification service point.

If you specify the **copyServicePoint** parameter, then you need not specify this parameter.

Only specify this parameter for Version 7.0 WS-Notification services.

-jaxwsHandlerListPRM
The JAX-WS handler list that is applied to inbound requests from an application to the PublisherRegistrationManager endpoint of the WS-Notification service point.

If you specify the **copyServicePoint** parameter, then you need not specify this parameter.

Only specify this parameter for Version 7.0 WS-Notification services.

Examples

In the following examples, the WS-Notification service point uses the WS-Notification service `newService` created in the example from topic "Creating a new WS-Notification service by using the wsadmin tool".

Create a Version 6.1 WS-Notification service point on `server1` on `node1` and create a new endpoint listener that uses SOAP over HTTP on channel 1, where the host address of the server is `http://myHost:9080`:

```
newServicePoint = AdminTask.createWSNServicePoint(newService,
["-name", "newServicePoint", "-node", "node1", "-server", "server1", "-eplName", "myNewEPL",
"-eplURLRoot", "http://myhost:9080/wsn", "-eplWSDLServingURLRoot", "http://myhost:9080/sibws"] )
```

Create a Version 7.0 WS-Notification service point on `server1` on `node1` (minimum set of parameters):

```
newServicePoint = AdminTask.createWSNServicePoint(newService,
["-name", "newServicePoint", "-node", "node1", "-server", "server1",
"-transportURLRoot", "http://myhost:9080/myWSN"] )
```

Create a Version 7.0 WS-Notification service point on `server1` on `node1` (full set of parameters):

```
newServicePoint = AdminTask.createWSNServicePoint(newService,
["-name", "newServicePoint", "-node", "node1", "-server", "server1",
"-transportURLRoot", "http://myhost:9080/myWSN", "-transportSoapVersion", "1.1",
"-jaxwsHandlerListNB", "nbList", "-jaxwsHandlerListSM", "smList", "-jaxwsHandlerListPRM", "prmList"] )
```

deleteWSNServicePoint command

Use the deleteWSNServicePoint command to delete a WS-Notification service point and the associated resources. A WS-Notification service point defines access to a WS-Notification service on a given bus member through a specified web service binding (for example SOAP over HTTP). Applications use the bus members associated with the WS-Notification service point to connect to the WS-Notification service.

You can delete a WS-Notification service point by using the wsadmin tool as described in this topic, or by using the administrative console as described in "Deleting WS-Notification service points" on page 3005.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('WSNotificationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The existence of a WS-Notification service point on a bus member implies that a WS-Notification web service is exposed from that bus member, and causes web service endpoints for the notification broker, subscription manager and publisher registration manager for this WS-Notification service to be exposed on the bus member with which the service point is associated. WS-Notification applications use these endpoints to interact with the WS-Notification service.

This command deletes the specified WS-Notification service point and all the objects configured on the service point:

- For Version 7.0 WS-Notification services, the associated service point application is deleted.
- For Version 6.1 WS-Notification services, the associated service integration bus inbound ports are deleted.
- For both versions, any associated WS-Notification administered subscribers are deleted.

Target object

WSNServicePoint and associated objects.

Required parameters

None.

Conditional parameters

None.

Optional parameters

None.

Example

Delete the WS-Notification service point `newServicePoint`, created in the example from topic “Creating a new WS-Notification service point by using the wsadmin tool”.

- Using Jython:

```
AdminTask.deleteWSNServicePoint(newServicePoint)
```

- Using Jacl:

```
$AdminTask deleteWSNServicePoint $newServicePoint
```

listWSNServicePoints command

Use the listWSNServicePoints command to list the WS-Notification service points in the configuration of the target WS-Notification service that match the specified input parameters. A WS-Notification service point defines access to a WS-Notification service on a given bus member through a specified web service binding (for example SOAP over HTTP). Applications use the bus members associated with the WS-Notification service point to connect to the WS-Notification service.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('WSNotificationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Purpose

The existence of a WS-Notification service point on a bus member implies that a WS-Notification web service is exposed from that bus member, and causes web service endpoints for the notification broker, subscription manager and publisher registration manager for this WS-Notification service to be exposed on the bus member with which the service point is associated. WS-Notification applications use these endpoints to interact with the WS-Notification service.

This command lists all the WSNServicePoint objects in the configuration of the target WSNService that match the specified input parameters. This command can be used to obtain a reference to one or more WSNServicePoint objects that have already been created in the configuration in order to work with the WSNServicePoint further - for example to add a new WSNTopicNamespace definition.

Target object

WSNServicePoint objects that match the requested pattern.

Required parameters

None.

Conditional parameters

None.

Optional parameters

-name
The name of the WSNServicePoint by which the list is filtered. Omitting this parameter results in the listing of all WSNServicePointsfor the target WSNService.

Example

Obtain a reference to the first WSNServicePoint defined against the wsnService object.

- Using Jython:

  ```
  wsnServicePointList = AdminTask.listWSNServicePoints(wsnService)
  wsnServicePoint = wsnServicePointList.split("\n")[0].rstrip()
  ```

- Using Jacl:

```
set wsnServicePointList [$AdminTask listWSNServicePoints $wsnService]
set wsnServicePoint [ lindex $wsnServicePointList 0 ]
```

showWSNServicePoint command

Use the showWSNServicePoint command to show the properties of a WS-Notification service point. A WS-Notification service point defines access to a WS-Notification service on a given bus member through a specified web service binding (for example SOAP over HTTP). Applications use the bus members associated with the WS-Notification service point to connect to the WS-Notification service.

Before you begin

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('WSNotificationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Purpose

The existence of a WS-Notification service point on a bus member implies that a WS-Notification web service is exposed from that bus member, and causes web service endpoints for the notification broker, subscription manager and publisher registration manager for this WS-Notification service to be exposed on the bus member with which the service point is associated. WS-Notification applications use these endpoints to interact with the WS-Notification service.

This command shows the properties of a WS-Notification service point in a human-readable form. There are two patterns for use of this command:

- The required service point is determined by the target service point.
- The required service point is determined by a combination of the target WS-Notification service, and the service point name provided as a parameter.

Target object

There are two choices for the target type of this command:

- WSNServicePoint (explicitly nominates the WS-Notification service point to be shown).
- WSNService (determines the required WS-Notification service; must be used in combination with the **name** parameter).

Required parameters

None.

Conditional parameters

-name

The name of the WS-Notification service point to be displayed. This must be specified if the target type is WSNService, and must not be specified if a WSNServicePoint target is supplied.

Optional parameters

None.

Examples

Show the properties of the WS-Notification service point `newServicePoint` created in the example from topic “Creating a new WS-Notification service point by using the wsadmin tool”:

- Using Jython:

```
AdminTask.showWSNServicePoint(newServicePoint)
```

- Using Jacl:

```
$AdminTask showWSNServicePoint $newServicePoint
```

Show the properties of the WS-Notification service point `newServicePoint`, created in the example from topic “Creating a new WS-Notification service point by using the wsadmin tool”, by using the WSNService target pattern:

- Using Jython:

```
AdminTask.showWSNServicePoint(newService, ["-name", "newServicePoint"])
```

- Using Jacl:

```
$AdminTask showWSNServicePoint $newService {-name newServicePoint}
```

createWSNAdministeredSubscriber command

Use the createWSNAdministeredSubscriber command to create a new administered subscriber. An administered subscriber provides a mechanism for the WS-Notification service point to subscribe to an external notification producer at server startup time.

You can create a new WS-Notification administered subscriber by using the wsadmin tool as described in this topic, or by using the administrative console as described in “Creating a new WS-Notification administered subscriber” on page 3008.

You should not define an administered subscriber for any of the endpoints exposed by the WS-Notification service on which it is being defined, because this would result in infinite looping of messages through the notification broker.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WSNotificationCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command adds a new WS-Notification administered subscriber to the target WS-Notification service point.

Target Object

WSNServicePoint

Required parameters

-endpoint
The URL of the external web service to which the service should subscribe. That is, the endpoint reference (web address) of a notification producer or notification broker application. For example `http://remoteproducer.com`.

-topic
The topic on which the service should subscribe. This describes the class of notification messages that are delivered to the WS-Notification service point. For example `stock/IBM`. This property can include wildcards if they are supported by the topic dialect that you select.

-dialect
The dialect in which the topic is expressed. That is, the name of the chosen topic dialect as defined by the WS-Topics standard. Values of this parameter are SIMPLE, CONCRETE, FULL. For more information, see WS-Topics.

Conditional parameters

None.

Optional parameters

-topicNamespace
The URI that describes the topic namespace in which the specified topic is defined. Omitting this field indicates that the topic is contained in the ad-hoc topic namespace.

-remoteSubscriptionTimeout
The length of time in hours after which the remote subscription will expire if not renewed by the server. This timeout minimizes the potential for orphaned subscriptions in the remote web service if the local server is uninstalled. Note that this field does not indicate the time at which the remote subscription is due to expire. Set the timeout length to something larger than the maximum length of time that the server is expected to remain offline, otherwise the stream of messages from the remote web service might be interrupted. While the server is running it occasionally renews the remote subscription termination time (with the specified timeout) to prevent it from expiring during normal operation. If not specified, this timeout defaults to 24 (hours).

Example

Create an administered subscriber on the WS-Notification service point `newServicePoint` created in the example from topic “Creating a new WS-Notification service point by using the wsadmin tool”:

- Using Jython:

```
newAdminSub = AdminTask.createWSNAdministeredSubscriber(newServicePoint,
["-endpoint", "http://myremotehost:9080/producerEP", "-dialect", "SIMPLE",
 "-topic", "stock", "-topicNamespace", "http://example.org/mynamespace",
 "-remoteSubscriptionTimeout", 48] )
```

- Using Jacl:

```
set newAdminSub [ $AdminTask createWSNAdministeredSubscriber $newServicePoint
{ -endpoint http://myremotehost:9080/producerEP -dialect SIMPLE
 -topic stock -topicNamespace http://example.org/mynamespace
 -remoteSubscriptionTimeout 48 } ]
```

deleteWSNAdministeredSubscriber command

Use the deleteWSNAdministeredSubscriber command to delete a WS-Notification administered subscriber. An administered subscriber provides a mechanism for the WS-Notification service point to subscribe to an external notification producer at server startup time.

You can delete a WS-Notification administered subscriber by using the wsadmin tool as described in this topic, or by using the administrative console as described in “Deleting WS-Notification administered subscribers” on page 3011.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('WSNotificationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command deletes a WS-Notification administered subscriber.

Target object

WSNAdministeredSubscriber

Required parameters

None.

Conditional parameters

None.

Optional parameters

None.

Example

Delete the administered subscriber `newAdminSub` created in the example from topic “Creating a new WS-Notification administered subscriber by using the wsadmin tool”:

- Using Jython:

  ```
  AdminTask.deleteWSNAdministeredSubscriber(newAdminSub)
  ```

- Using Jacl:

  ```
  $AdminTask deleteWSNAdministeredSubscriber $newAdminSub
  ```

listWSNAdministeredSubscribers command

Use the listWSNAdministeredSubscribers command to list the WS-Notification administered subscribers in the configuration of the target WS-Notification service point that match the specified input parameters. An administered subscriber provides a mechanism for the WS-Notification service point to subscribe to an external notification producer at server startup time.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('WSNotificationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command lists all the administered subscribers in the configuration of the target WS-Notification service point that match the specified input parameters. You can use this command to obtain a reference to one or more administered subscribers that have already been created in the configuration in order to work with the administered subscriber further, for example to delete the definition.

Target object

WSNServicePoint

Required parameters

None.

Conditional parameters

None.

Optional parameters

-endpoint
The remote web service endpoint by which the list is filtered. That is, the endpoint reference (web address) of a notification producer or notification broker application. For example `http://remoteproducer.com`.

-topic
Topic expression describing the class of notification messages by which the list is filtered. This describes the class of notification messages that are delivered to the WS-Notification service point. For example `stock/IBM`. This property can include wildcards if they are supported by the topic dialect that you select.

-topicNamespace
The namespace URI by which the list is filtered.

-dialect
The dialect in which the topic is expressed. That is, the name of the chosen topic dialect as defined by the WS-Topics standard, by which the list is filtered. Values of this parameter are SIMPLE, CONCRETE, FULL. For more information, see WS-Topics.

Examples

Obtain a reference to the first administered subscriber defined against the `newServicePoint` object:

- Using Jython:

```
wsnSubscriberList = AdminTask.listWSNAdministeredSubscribers(newServicePoint)
wsnSubscriber = wsnSubscriberList.split("\n")[0].rstrip()
```

- Using Jacl:

```
set wsnSubscriberList [$AdminTask listWSNAdministeredSubscribers $newServicePoint]
set wsnSubscriber [ lindex $wsnSubscriberList 0 ]
```

Obtain a reference to the first administered subscriber defined against the `newServicePoint` object with a given topic:

- Using Jython:

```
wsnSubscriberList = AdminTask.listWSNAdministeredSubscribers(newServicePoint, ["-topic", "stock"])
wsnSubscriber = wsnSubscriberList.split("\n")[0].rstrip()
```

- Using Jacl:

```
set wsnSubscriberList [$AdminTask listWSNAdministeredSubscribers $newServicePoint {-topic stock}]
set wsnSubscriber [ lindex $wsnSubscriberList 0 ]
```

showWSNAdministeredSubscriber command

Use the showWSNAdministeredSubscriber command to show the properties of an administered subscriber. An administered subscriber provides a mechanism for the WS-Notification service point to subscribe to an external notification producer at server startup time.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('WSNotificationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command shows the properties of a WS-Notification administered subscriber object in a human-readable form. There are two patterns for use of this command:

- The required administered subscriber is determined by the target WSNAdministeredSubscriber object.
- The required administered subscriber is determined by a combination of the target WS-Notification service point, and the **endpoint**, **topic**, **topicNamespace** and **dialect** provided as parameters.

Target object

There are two choices for the target type of this command:

- WSNAdministeredSubscriber (explicitly nominates the administered subscriber to be shown).
- WSNServicePoint (determines the required WS-Notification service point; must be used in combination with the conditional parameters).

Required parameters

None.

Conditional parameters

-endpoint
The remote web service endpoint by which the list is filtered. That is, the endpoint reference (web address) of a notification producer or notification broker application. For example `http://remoteproducer.com`. This parameter must be specified if the target type is WSNServicePoint, and must not be specified if a WSNAdministeredSubscriber target is supplied.

-topic
Topic expression describing the class of notification messages by which the list is filtered. This describes the class of notification messages that are delivered to the WS-Notification service point. For example `stock/IBM`. This property can include wildcards if they are supported by the topic dialect that you select. This parameter must be specified if the target type is WSNServicePoint, and must not be specified if a WSNAdministeredSubscriber target is supplied.

-topicNamespace
The namespace URI by which the list is filtered. This parameter must be specified if the target type is WSNServicePoint, and must not be specified if a WSNAdministeredSubscriber target is supplied.

-dialect
The dialect in which the topic is expressed. That is, the name of the chosen topic dialect as defined by the WS-Topics standard, by which the list is filtered. Values of this parameter are SIMPLE, CONCRETE, FULL. For more information, see WS-Topics. This parameter must be specified if the target type is WSNServicePoint, and must not be specified if a WSNAdministeredSubscriber target is supplied.

Optional parameters

None.

Examples

Show the properties of the administered subscriber `newAdminSub` created in the example from topic "Creating a new WS-Notification administered subscriber by using the wsadmin tool":

- Using Jython:

```
AdminTask.showWSNAdministeredSubscriber(newAdminSub)
```

- Using Jacl:

```
$AdminTask showWSNAdministeredSubscriber $newAdminSub
```

Show the properties of the administered subscriber `newAdminSub`, created in the example from topic "Creating a new WS-Notification administered subscriber by using the wsadmin tool", by using the WSNServicePoint target pattern:

- Using Jython:

```
AdminTask.showWSNAdministeredSubscriber(newServicePoint, ["-topic", "stock"])
```

- Using Jacl:

```
$AdminTask showWSNAdministeredSubscriber $newServicePoint {-topic stock}
```

createWSNTopicNamespace command

Use the createWSNTopicNamespace command to create a new WS-Notification permanent topic namespace. A topic namespace is a grouping of topics that allows information to be shared between applications. You use a permanent topic namespace to statically define the association between a WS-Notification topic namespace URI and a service integration bus topic space destination.

You can create a new WS-Notification permanent topic namespace by using the wsadmin tool as described in this topic, or by using the administrative console as described in "Creating a new WS-Notification permanent topic namespace" on page 3011.

You can create many to many relationships between the set of permanent topic namespaces defined in a cell (that is for all WS-Notification services defined in that cell) and the service integration bus topic spaces with which they are associated. These relationships can become quite complex depending upon the topologies required by the applications that connect to the WS-Notification service. For guidance on when certain configurations might or might not be appropriate, see Options for associating a permanent topic namespace with a bus topic space.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WSNotificationCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command creates the following resources:

- It creates a new WS-Notification topic namespace on a WS-Notification service and associates it with the specified service integration bus topic space.
- It creates the specified service integration bus topic space if it does not already exist.

You can also set a configuration attribute of a permanent topic namespace to control the reliability setting (persistence or non persistence) that is applied to any messages that use a given topic namespace.

Target Object

WSNService

Required parameters

-namespace
The URI string by which this topic namespace is known. That is, the namespace URI by which WS-Notification applications refer to topics hosted by this namespace. For example `http://widgetproducer.com/prices`.

-busTopicSpace
The service integration bus topic space with which this namespace is associated. That is, the bus topic space that is used by this topic namespace.

Conditional parameters

None.

Optional parameters

-reliability
The service integration bus reliability to apply to messages published to this topic namespace. Valid values for this property are as follows:

BEST_EFFORT_NONPERSISTENT

EXPRESS_NONPERSISTENT

RELIABLE_NONPERSISTENT

RELIABLE_PERSISTENT

ASSURED_PERSISTENT

Each value represents one of the service integration bus message reliability levels.

Examples

In the following examples, the WS-Notification topic namespace uses the WS-Notification service `newService` created in the example from topic “Creating a new WS-Notification service by using the wsadmin tool”.

Create a WS-Notification topic namespace on the WS-Notification service `newService`:

- Using Jython:

```
newTopicNamespace = AdminTask.createWSNTopicNamespace(newService,
["-namespace", "http://example.org/topicNamespace/example1",
"-busTopicSpace", "mySIBTopicspace"] )
```

- Using Jacl:

```
set newTopicNamespace [ $AdminTask createWSNTopicNamespace $newService
{ -namespace http://example.org/topicNamespace/example1
-busTopicSpace mySIBTopicspace } ]
```

Create a WS-Notification topic namespace on the WS-Notification service `newService` with a specific reliability:

- Using Jython:

```
newTopicNamespace = AdminTask.createWSNTopicNamespace(newService,
["-namespace", "http://example.org/topicNamespace/example1",
"-busTopicSpace", "mySIBTopicspace", "-reliability", "EXPRESS_NONPERSISTENT"] )
```

- Using Jacl:

```
set newTopicNamespace [ $AdminTask createWSNTopicNamespace $newService
{ -namespace http://example.org/topicNamespace/example1
-busTopicSpace mySIBTopicspace -reliability EXPRESS_NONPERSISTENT} ]
```

deleteWSNTopicNamespace command

Use the deleteWSNTopicNamespace command to delete a WS-Notification permanent topic namespace and the associated resources. A topic namespace is a grouping of topics that allows information to be shared between applications. You use a permanent topic namespace to statically define the association between a WS-Notification topic namespace URI and a service integration bus topic space destination.

You can delete WS-Notification permanent topic namespaces by using the wsadmin tool as described in this topic, or by using the administrative console as described in “Deleting WS-Notification permanent topic namespaces” on page 3014.

Deleting the topic namespace mapping that was used to establish a (currently active) subscription has the same effect as deleting the underlying service integration bus topic space, and subscriptions that were created using this namespace mapping are deleted. For more information about the effect that deleting a topic namespace has upon new and existing WS-Notification applications, see Failures as a result of changes in topic space and topic namespace configurations.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('WSNotificationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command deletes all the objects associated with the specified WS-Notification topic namespace, including any linked topic namespace documents.

Target object

WSNTopicNamespace and associated objects.

Required parameters

None.

Conditional parameters

None.

Optional parameters

-deleteSIBTopicSpace
TRUE or FALSE. Indicates whether the associated service integration bus topic space is deleted with this object if the WS-Notification topic namespace was responsible for creating it. If the bus topic space existed before the WS-Notification topic namespace was created then this parameter has no effect and the bus topic space is not deleted.

Example

Delete the WS-Notification topic namespace `newTopicNamespace` created in the example from topic "Creating a new permanent WS-Notification topic namespace by using the wsadmin tool".

- Using Jython:

```
AdminTask.deleteWSNTopicNamespace(newTopicNamespace)
```

- Using Jacl:

```
$AdminTask deleteWSNTopicNamespace $newTopicNamespace
```

listWSNTopicNamespaces command

Use the listWSNTopicNamespaces command to list the WS-Notification topic namespaces in the configuration of the target WS-Notification service that match the specified input parameters. A topic namespace is a grouping of topics that allows information to be shared between applications.You use a permanent topic namespace to statically define the association between a WS-Notification topic namespace URI and a service integration bus topic space destination.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WSNotificationCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

This command lists all the WS-Notification topic namespaces in the configuration of the target WS-Notification service that match the specified input parameters. This command can be used to obtain a reference to one or more WS-Notification topic namespaces that have already been created in the configuration in order to work with the topic namespace further, for example to add a new topic namespace document definition.

Target Object

WSNService

Required parameters

None.

Conditional parameters

None.

Optional parameters

-namespace
The namespace URI of the WS-Notification topic namespace by which the list should be filtered. Omitting this parameter results in the listing of all WS-Notification topic namespaces for the target WS-Notification service.

Examples

Obtain a reference to the first WS-Notification topic namespace defined against the wsnService object:

- Using Jython:

```
AdminTask.listWSNTopicNamespaces(wsnService)
wsnNamespace = wsnNamespaceList.split("\n")[0].rstrip()
```

- Using Jacl:

```
set wsnNamespaceList [$AdminTask listWSNTopicNamespaces $wsnService]
set wsnNamespace [ lindex $wsnNamespaceList 0 ]
```

Obtain a reference to the WS-Notification topic namespace defined against the wsnService object with a given namespace:

- Using Jython:

```
wsnNamespaceList = AdminTask.listWSNTopicNamespaces(wsnService,
["-namespace", "http://example.org/topicNamespace/example1"] )
wsnNamespace = wsnNamespaceList.split("\n")[0].rstrip()
```

- Using Jacl:

```
set wsnNamespaceList [$AdminTask listWSNTopicNamespaces $wsnService
{-namespace http://example.org/topicNamespace/example1}]
set wsnNamespace [ lindex $wsnNamespaceList 0 ]
```

showWSNTopicNamespace command

Use the showWSNTopicNamespace command to show the properties of a WS-Notification topic namespace. A topic namespace is a grouping of topics that allows information to be shared between applications.You use a permanent topic namespace to statically define the association between a WS-Notification topic namespace URI and a service integration bus topic space destination.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WSNotificationCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

This command shows the properties of a WS-Notification topic namespace in a human-readable form. There are two patterns for use of this command:

- The required WS-Notification topic namespace is determined by the target WS-Notification topic namespace.
- The required WS-Notification topic namespace is determined by a combination of the target WS-Notification service, and the namespace of the WS-Notification topic namespace provided as a parameter.

Target object

There are two choices for the target type of this command:

- WSNTopicNamespace (explicitly nominates the WS-Notification topic namespace to be shown).
- WSNService (determines the required WS-Notification service; must be used in combination with the **namespace** parameter).

Required parameters

None.

Conditional parameters

-namespace
The namespace of the WS-Notification topic namespace to be displayed. This must be specified if the target type is WSNService, and must not be specified if a WSNTopicNamespace target is supplied.

Optional parameters

None.

Examples

Show the properties of the WS-Notification topic namespace `newTopicNamespace` created in the example from topic “Creating a new permanent WS-Notification topic namespace by using the wsadmin tool”:

- Using Jython:

```
AdminTask.showWSNTopicNamespace(newTopicNamespace)
```

- Using Jacl:

```
$AdminTask showWSNTopicNamespace $newTopicNamespace
```

Show the properties of the WS-Notification topic namespace `newTopicNamespace` created in the example from topic “Creating a new permanent WS-Notification topic namespace by using the wsadmin tool” using the WSNService target pattern:

- Using Jython:

```
AdminTask.showWSNTopicNamespace(newService,
 ["-namespace", "http://example.org/topicNamespace/example1"] )
```

- Using Jacl:

```
$AdminTask showWSNTopicNamespace $newService
{-namespace http://example.org/topicNamespace/example1 }
```

createWSNTopicDocument command

A topic namespace can optionally have topic namespace documents applied to it that define the structure of the topics that are permitted within the namespace. Use the createWSNTopicDocument command to apply a topic namespace document to an existing topic namespace.

You can apply a WS-Notification topic namespace document to an existing topic namespace by using the wsadmin tool as described in this topic, or by using the administrative console as described in “Applying a WS-Notification topic namespace document” on page 3015.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('WSNotificationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command adds a new WS-Notification topic namespace document to an existing WS-Notification topic namespace.

Target object

WSNTopicNamespace

Required parameters

-url
The URL of the topic namespace document that should be loaded. This URL must address a valid topic namespace document as defined in the WS-Topics Version 1.3 OASIS Standard

Conditional parameters

None.

Optional parameters

-description
An optional description of the topic namespace document.

Example

Create a new topic namespace document on the WS-Notification topic namespace `newTopicNamespace` created in the example from topic “Creating a new permanent WS-Notification topic namespace by using the wsadmin tool”:

- Using Jython:

  ```
  newTopicDoc = AdminTask.createWSNTopicDocument(newTopicNamespace,
  ["-url", "http://www.example.org/instance_doc1.xml"] )
  ```

- Using Jacl:

```
set newTopicDoc [ $AdminTask createWSNTopicDocument $newTopicNamespace
{ -url http://www.example.org/instance_doc1.xml } ]
```

Note that you must change the **url** parameter to point to a valid topic namespace document as defined in the WS-Topics Version 1.3 OASIS Standard.

deleteWSNTopicDocument command

A topic namespace can optionally have topic namespace documents applied to it that define the structure of the topics that are permitted within the namespace. Use the deleteWSNTopicDocument command to delete a WS-Notification topic namespace document and the associated resources.

You can delete a WS-Notification topic namespace document by using the wsadmin tool as described in this topic, or by using the administrative console as described in “Deleting WS-Notification topic namespace documents” on page 3016.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('WSNotificationCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command removes the XML file associated with the WS-Notification topic namespace document.

Target object

WSNTopicDocument and associated objects.

Required parameters

None.

Conditional parameters

None.

Optional parameters

None.

Example

Delete the topic namespace document `newTopicDoc` created in the example from topic “Applying a WS-Notification topic namespace document by using the wsadmin tool”:

- Using Jython:
  ```
  AdminTask.deleteWSNTopicDocument(newTopicDoc)
  ```
- Using Jacl:
  ```
  $AdminTask deleteWSNTopicDocument $newTopicDoc
  ```

listWSNTopicDocuments command

A topic namespace can optionally have topic namespace documents applied to it that define the structure of the topics that are permitted within the namespace. Use the listWSNTopicDocuments command to list the topic namespace documents in the configuration of the target WS-Notification topic namespace that match the specified input parameters.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('WSNotificationCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command lists all the topic namespace documents in the configuration of the target WS-Notification topic namespace that match the specified input parameters. This command can be used to obtain a reference to one or more topic namespace documents that have already been created in the configuration in order to work with the topic namespace document further, for example to delete the definition.

Target object

WSNTopicNamespace documents that match the requested pattern.

Required parameters

None.

Conditional parameters

None.

Optional parameters

-url
The web address that was used to load the XML document.

Examples

Obtain a reference to the first topic namespace document defined against the `newTopicNamespace` object.

- Using Jython:

```
wsnDocList = AdminTask.listWSNTopicDocuments(newTopicNamespace)
wsnTopicDoc = wsnDocList.split("\n")[0].rstrip()
```

- Using Jacl:

```
set wsnDocList [$AdminTask listWSNTopicDocuments $newTopicNamespace]
set wsnTopicDoc [ lindex $wsnDocList 0 ]
```

Obtain a reference to the first topic namespace document defined against the `newTopicNamespace` object with a given URL.

- Using Jython:

```
wsnDocList = AdminTask.listWSNTopicDocuments(newTopicNamespace,
 ["-url", "http://www.example.org/instance_doc1.xml"])
wsnTopicDoc = wsnDocList.split("\n")[0].rstrip()
```

- Using Jacl:

```
set wsnDocList [$AdminTask listWSNTopicDocuments $newTopicNamespace
{-url http://www.example.org/instance_doc1.xml}]
set wsnDoc [ lindex $wsnDocList 0 ]
```

showWSNTopicDocument command

A topic namespace can optionally have topic namespace documents applied to it that define the structure of the topics that are permitted within the namespace. Use the showWSNTopicDocument command to show the contents of a WS-Notification topic namespace document.

You can show the contents of a WS-Notification topic namespace document by using the wsadmin tool as described in this topic, or by using the administrative console as described in “Showing the contents of a WS-Notification topic namespace document” on page 3015.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('WSNotificationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command shows the XML contents of a WS-Notification topic namespace document. There are two patterns for use of this command:

- The required topic namespace document is determined by the target topic namespace document.
- The required topic namespace document is determined by a combination of the target WS-Notification topic namespace, and the **url** provided as a parameter.

Target object

There are two choices for the target type of this command:

- WSNTopicDocument (explicitly nominates the topic namespace document to be shown).
- WSNTopicNamespace (determines the required WS-Notification topic namespace; must be used in combination with the **url** parameter).

Required parameters

None.

Conditional parameters

-url
The web address that was used to load the XML document. This parameter must be specified if the target type is WSNTopicNamespace, and must not be specified if a WSNTopicDocument target is supplied.

Optional parameters

None.

Examples

Show the contents of the topic namespace document `newTopicDoc` created in the example from topic "Applying a WS-Notification topic namespace document by using the wsadmin tool":

- Using Jython:

```
AdminTask.showWSNTopicDocument(newTopicDoc)
```

- Using Jacl:

```
$AdminTask showWSNTopicDocument $newTopicDoc
```

Show the contents of the topic namespace document `newTopicDoc` created in the example from topic "Applying a WS-Notification topic namespace document by using the wsadmin tool", by using the WSNTopicNamespace target pattern:

- Using Jython:

```
AdminTask.showWSNTopicDocument(newTopicNamespace,
 ["-url", "http://www.example.org/instance_doc1.xml"])
```

- Using Jacl:

```
$AdminTask showWSNTopicDocument $newTopicNamespace
{ -url http://www.example.org/instance_doc1.xml }
```

getWSN_SIBWSInboundService command

Use the getWSN_SIBWSInboundService command to retrieve a reference to an inbound service that is associated with a Version 6.1 WS-Notification service.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WSNotificationCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

This command retrieves a reference to a specified service integration bus inbound service associated with a Version 6.1 WS-Notification service. Only use this command with Version 6.1 WS-Notification services. There are no bus-enabled inbound services associated with a Version 7.0 WS-Notification service.

Target object

WSNService

Required parameters

-type

The type of inbound service to retrieve. Valid options are:

- BROKER (notification broker)
- SUB_MGR (subscription manager)
- PUB_REG_MGR (publisher registration manager)

Conditional parameters

None.

Optional parameters

None.

Example

Retrieve a reference to the notification broker inbound service from the Version 6.1 WS-Notification service `newService` created in the example from topic “Creating a new WS-Notification service by using the wsadmin tool”:

```
brokerInboundService = AdminTask.getWSN_SIBWSInboundService(newService, ["-type", "BROKER"] )
```

getWSN_SIBWSInboundPort command

Use the getWSN_SIBWSInboundPort command to retrieve a reference to an inbound port associated with a Version 6.1 WS-Notification service point.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WSNotificationCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

This command retrieves a reference to a specified service integration bus inbound port associated with a Version 6.1 WS-Notification service point. Only use this command with Version 6.1 WS-Notification services. There are no bus-enabled inbound ports associated with a Version 7.0 WS-Notification service point..

Target object

WSNServicePoint

Required parameters

-type
The type of service integration bus inbound port to retrieve. Valid options are:

- BROKER (notification broker)
- SUB_MGR (subscription manager)
- PUB_REG_MGR (publisher registration manager)

Conditional parameters

None.

Optional parameters

None.

Example

Retrieve a reference to the subscription manager service integration bus inbound port from the Version 6.1 WS-Notification service point `newServicePoint` created in the example from topic “Creating a new WS-Notification service point by using the wsadmin tool”:

```
subManInboundPort = AdminTask.getWSN_SIBWSInboundPort(newServicePoint, ["-type", "SUB_MGR"] )
```

createJAXWSHandler command

Use the createJAXWSHandler command to create a new Java API for XML-based Web Services (JAX-WS) handler configuration so that the handler can be used, as part of a handler list, with Version 7.0 WS-Notification services.

You can create a new JAX-WS handler configuration by using the wsadmin tool as described in this topic, or by using the administrative console as described in “Creating a new JAX-WS handler configuration” on page 3019.

This task assumes that you have already created your handler. You can do this by using IBM Rational Application Developer or a similar tool. You must also make the handler class available to the server or cluster that hosts the WS-Notification service points (for inbound invocation handling) or WS-Notification services (for outbound invocation handling) that you want to monitor, as detailed in “Loading JAX-WS handler classes” on page 3018.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('WSNotificationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

A Java API for XML-based Web Services (JAX-WS) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. This command creates a new JAX-WS handler configuration so that the handler can be used, as part of a handler list, with Version 7.0 WS-Notification services.

The configuration object associates a unique name (the **name** parameter) with a Java class (the **className** parameter) that refers to the JAX-WS handler implementation.

Target Object

A cell scope object.

Required parameters

-name
The name of the JAX-WS handler configuration object.

This name must be unique at cell scope, and it must obey the following syntax rules:

- It must not start with "." (a period).
- It must not start or end with a space.
- It must not contain any of the following characters: `\ / , # $ @ : ; " * ? < > | = + & % '`

-className
The name of the JAX-WS handler class that this configuration object represents. This name must be a fully qualified java class name. For example com.ibm.jaxws.handler.TestHandler.

Note: You can configure multiple instances of a handler by creating each instance with a different handler name, and pointing to the same handler class.

Conditional parameters

None.

Optional parameters

-description
A description of the JAX-WS handler.

Example

Create the configuration for a particular JAX-WS handler class:

- Using Jython:

```
targetCell = AdminConfig.list('Cell')
JAXWSHandler = AdminTask.createJAXWSHandler(targetCell,
["-name", "handler1", "-className", "handlerClass", "-description", "desc"])
```

- Using Jacl:

```
$AdminTask createJAXWSHandler targetCell
{-name handler1 -className handlerClass -description desc}
```

modifyJAXWSHandler command

Use the modifyJAXWSHandler command to modify a Java API for XML-based Web Services (JAX-WS) handler configuration for a handler that is used, as part of a handler list, with Version 7.0 WS-Notification services.

You can modify a JAX-WS handler configuration by using the wsadmin tool as described in this topic, or by using the administrative console as described in “Modifying an existing JAX-WS handler configuration” on page 3020.

If you modify a handler class but do not change the class name, you do not have to modify the handler configuration as described in this topic. You just have to stop then restart the servers or clusters that host the services or service points that this handler monitors.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('WSNotificationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

A Java API for XML-based Web Services (JAX-WS) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. This command modifies a JAX-WS handler configuration that can be used, as part of a handler list, with Version 7.0 WS-Notification services.

The configuration object associates a unique name (the **name** parameter) with a Java class (the **className** parameter) that refers to the JAX-WS handler implementation.

Target Object

A JAX-WS handler configuration object.

Required parameters

-name
The name of the JAX-WS handler configuration object.

This name must be unique at cell scope, and it must obey the following syntax rules:

- It must not start with "." (a period).
- It must not start or end with a space.
- It must not contain any of the following characters: \ / , # $ @ : ; " * ? < > | = + & % '

Note: When you change a handler name, the system looks up all objects that refer to it and updates the name.

-className

The name of the JAX-WS handler class that this configuration object represents. This name must be a fully qualified java class name. For example com.ibm.jaxws.handler.TestHandler.

If you change the class name, you must also make the new handler class available to the server or cluster that hosts the WS-Notification service points (for inbound invocation handling) or WS-Notification services (for outbound invocation handling) that you want to monitor, as detailed in "Loading JAX-WS handler classes" on page 3018.

Note: You can configure multiple instances of a handler by creating each instance with a different handler name, and pointing to the same handler class.

Conditional parameters

None.

Optional parameters

-description

A description of the JAX-WS handler.

Example

Modify the configuration for a particular JAX-WS handler class:

- Using Jython:

```
AdminTask.modifyJAXWSHandler(JAXWSHandler,
["-name", "newHandler1", "-className", "newHandlerClass",
 "-description", "newDesc"] )
```

- Using Jacl:

```
$AdminTask modifyJAXWSHandler JAXWSHandler
{-name newHandler1 -className newHandlerClass
 -description newDesc}
```

deleteJAXWSHandler command

Use the deleteJAXWSHandler command to delete the configuration for a Java API for XML-based Web Services (JAX-WS) handler that is configured for use, as part of a handler list, with Version 7.0 WS-Notification services.

You can delete a JAX-WS handler configuration by using the wsadmin tool as described in this topic, or by using the administrative console as described in "Deleting JAX-WS handler configurations" on page 3021.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('WSNotificationCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

A Java API for XML-based Web Services (JAX-WS) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. This command deletes the specified JAX-WS handler configuration that enables the handler to be used (as part of a handler list) with Version 7.0 WS-Notification services.

When you remove a handler that is currently used by one or more web services on a service integration bus, the system removes the handler from the handler lists for each associated web service.

Target object

The JAX-WS handler configuration object that is to be deleted.

Parameters

None.

Example

Delete the JAX-WS handler configuration object `JAXWSHandler`.

- Using Jython:
  `AdminTask.deleteJAXWSHandler(JAXWSHandler)`
- Using Jacl:

```
$AdminTask deleteJAXWSHandler JAXWSHandler
```

listJAXWSHandlers command

Use the listJAXWSHandlers command to list the Java API for XML-based Web Services (JAX-WS) handlers that are configured for use, as part of a handler list, with Version 7.0 WS-Notification services.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('WSNotificationCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

Purpose

A Java API for XML-based Web Services (JAX-WS) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. This command lists all the JAX-WS handlers, for a given cell, that are configured for use, as part of a handler list, with Version 7.0 WS-Notification services.

Target Object

A cell scope object.

Parameters

None.

Example

List the JAX-WS Handler configuration objects for a given cell:

- Using Jython:

```
targetCell = AdminConfig.list('Cell')
AdminTask.listJAXWSHandlers(targetCell)
```

- Using Jacl:

```
$AdminTask listJAXWSHandlers targetCell
```

showJAXWSHandler command

Use the showJAXWSHandler command to show the properties of a Java API for XML-based Web Services (JAX-WS) handler that is configured for use (as part of a handler list) with Version 7.0 WS-Notification services.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WSNotificationCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

A Java API for XML-based Web Services (JAX-WS) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. This command shows the properties of the specified JAX-WS handler configuration that enables the handler to be used (as part of a handler list) with Version 7.0 WS-Notification services.

Target object

A JAX-WS handler configuration object.

Parameters

None.

Example

Show the properties of the JAX-WS handler configuration object `JAXWSHandler`.

- Using Jython:

  ```
  AdminTask.showJAXWSHandler(JAXWSHandler)
  ```

- Using Jacl:

```
$AdminTask showJAXWSHandler JAXWSHandler
```

createJAXWSHandlerList command

Use the createJAXWSHandlerList command to create a Java API for XML-based Web Services (JAX-WS) handler list for use with Version 7.0 WS-Notification services.

You can create a new JAX-WS handler list by using the wsadmin tool as described in this topic, or by using the administrative console as described in “Creating a new JAX-WS handler list” on page 3022.

You can only add previously-configured handlers to a handler list. To configure a handler, see the “createJAXWSHandler command” on page 3086.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('WSNotificationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

A Java API for XML-based Web Services (JAX-WS) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. To enable handlers to undertake more complex operations, you chain them together into handler lists. The approach taken in WebSphere Application Server is to assign handler lists (rather than individual handlers) to WS-Notification service points (for inbound invocation handling) or WS-Notification services (for outbound invocation handling).

Target Object

A cell scope object.

Required parameters

-name
The name of the JAX-WS handler list.

This name must be unique at cell scope, and it must obey the following syntax rules:

- It must not start with "." (a period).
- It must not start or end with a space.
- It must not contain any of the following characters: \ / , # $ @ : ; " * ? < > | = + & % '

For example `TestList`.

Conditional parameters

None.

Optional parameters

-description
A description of the JAX-WS handler list.

-handlers
The list of JAX-WS handler names to be added to this list.

Each handler name supplied must exist as a JAX-WS handler object at cell scope. Handlers are applied in the sequence in which they appear in the handler list.

Example

Create the configuration for a particular JAX-WS handler list class:

- Using Jython:

```
targetCell = AdminConfig.list('Cell')
JAXWSHandlerList = AdminTask.createJAXWSHandlerList(targetCell,
'[-name handlerList1 -description desc -handlers [[handler1] [handler2]]]')
```

- Using Jacl:

```
$AdminTask createJAXWSHandlerList targetCell
{-name handlerList1 -description desc -handlers {{handler1}{handler2}} }
```

modifyJAXWSHandlerList command

Use the modifyJAXWSHandlerList command to modify the configuration details for a Java API for XML-based Web Services (JAX-WS) handler list that has been configured for use with Version 7.0 WS-Notification services.

You can modify a JAX-WS handler list by using the wsadmin tool as described in this topic, or by using the administrative console as described in "Modifying an existing JAX-WS handler list" on page 3023.

You can only add previously-configured handlers to a handler list. To configure a handler, see the "createJAXWSHandler command" on page 3086.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WSNotificationCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

A Java API for XML-based Web Services (JAX-WS) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. To enable handlers to undertake more complex operations, you chain them together into handler lists. The approach taken in WebSphere Application Server is to assign handler lists (rather than individual handlers) to WS-Notification service points (for inbound invocation handling) or WS-Notification services (for outbound invocation handling).

Target Object

A JAX-WS handler list object.

Required parameters

-name
The name of the JAX-WS handler list.

This name must be unique at cell scope, and it must obey the following syntax rules:

- It must not start with "." (a period).
- It must not start or end with a space.
- It must not contain any of the following characters: \ / , # $ @ : ; " * ? < > | = + & % '

When you change a handler list name, the system looks up all objects that refer to it and updates the name.

Conditional parameters

None.

Optional parameters

-description
A description of the JAX-WS handler list.

-handlers
The list of JAX-WS handler names to be added to this list.

Each handler name supplied must exist as a JAX-WS handler object at cell scope. Handlers are applied in the sequence in which they appear in the handler list.

Example

Modify the configuration for a particular JAX-WS handler list class:

- Using Jython:

```
JAXWSHandlerList = AdminTask.modifyJAXWSHandlerList(JAXWSHandlerList,
'[-name newHandlerList1 -description newDesc -handlers [[handler1] [handler2]]]')
```

- Using Jacl:

```
$AdminTask modifyJAXWSHandlerList JAXWSHandlerList
{-name handlerList1 -description newDesc -handlers {{handler1}{handler2}} }
```

deleteJAXWSHandlerList command

Use the deleteJAXWSHandlerList command to delete the configuration for a Java API for XML-based Web Services (JAX-WS) handler list that is configured for use with Version 7.0 WS-Notification services.

You can delete a JAX-WS handler list by using the wsadmin tool as described in this topic, or by using the administrative console as described in “Deleting JAX-WS handler lists” on page 3025.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('WSNotificationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

A Java API for XML-based Web Services (JAX-WS) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. This command deletes the specified JAX-WS handler list.

When you remove a handler that is currently used by one or more web services on a service integration bus, the system removes the handler from the handler lists for each associated web service.

Target object

The JAX-WS handler list object that is to be deleted.

Parameters

None.

Example

Delete the JAX-WS handler list object `JAXWSHandlerList`:

- Using Jython:

  ```
  AdminTask.deleteJAXWSHandlerList(JAXWSHandlerList)
  ```

- Using Jacl:

```
$AdminTask deleteJAXWSHandlerList JAXWSHandlerList
```

listJAXWSHandlerLists command

Use the listJAXWSHandlerLists command to list the Java API for XML-based Web Services (JAX-WS) handler lists that are configured, for a given cell, for use with Version 7.0 WS-Notification services.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('WSNotificationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Purpose

A Java API for XML-based Web Services (JAX-WS) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. To enable handlers to undertake more complex operations, you chain them together into handler lists. This command lists all the JAX-WS handler lists for a given cell.

Target Object

A cell scope object.

Parameters

None.

Example

List the JAX-WS handler lists for a given cell:

- Using Jython:

  ```
  targetCell = AdminConfig.list('Cell')
  AdminTask.listJAXWSHandlerLists(targetCell)
  ```

- Using Jacl:

```
$AdminTask listJAXWSHandlerLists targetCell
```

showJAXWSHandlerList command

Use the showJAXWSHandlerList command to show the properties of a Java API for XML-based Web Services (JAX-WS) handler list that is configured for use with Version 7.0 WS-Notification services.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available WS-Notification commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WSNotificationCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

A Java API for XML-based Web Services (JAX-WS) handler is a Java class that performs a range of handling tasks. For example: logging messages, or transforming their contents, or terminating an incoming request. To enable handlers to undertake more complex operations, you chain them together into handler lists. This command shows the properties of the specified JAX-WS handler list.

Target object

A JAX-WS handler list object.

Parameters

None.

Example

Show the properties of the JAX-WS handler list `JAXWSHandlerList`:

- Using Jython:

```
AdminTask.showJAXWSHandlerList(JAXWSHandlerList)
```

- Using Jacl:

```
$AdminTask showJAXWSHandlerList JAXWSHandlerList
```

WS-Notification roles and goals

This topics lists a set of computing roles that members of your organization might perform, and explains how you can use WS-Notification to help meet the goals of each role.

For a general description of each of the following roles, see WebSphere Application Server roles and goals.

Enterprise architect

IT environments are currently evolving towards the following concepts:

- Service Oriented Architecture (SOA)
- Enterprise Service Bus (ESB)

The goal of the enterprise architect might be to guide their organization towards appropriate utilization of these concepts to maximize the efficiency and responsiveness of the business as a whole.

WS-Notification enables publish and subscribe communication patterns (such as a stock ticker) to be exposed by using web services in an SOA environment. This is done through open standards, enabling straightforward replacement of the service implementation. It promotes easy exchange of data between suppliers and customers through use of standard web service operations and prevents vendor lock-in or adoption of proprietary standards.

WebSphere Application Server also allows WS-Notification to be used as an on- or off-ramp to an ESB, providing seamless interchange of data between different types of client connected to the bus.

Solution architect

The main goal of the solution architect is to design a solution that supports the specification set by the enterprise architect. This might include providing an environment in which web service applications can participate in publish and subscribe messaging patterns. This participation might also include the requirement to be able to exchange event notifications between web service clients and other clients of the enterprise service bus.

To create a design, the solution architect completes the following broad steps:

- Learn about the support provided for WS-Notification in WebSphere Application Server.
- Select a hardware and software product combination for the enterprise that supports the WS-Notification standards.
- Design a server topology to host the applications, in accordance with the particular WS-Notification topologies that are to be implemented.

System administrator

For the specific steps that the system administrator performs to help implement common WS-Notification tasks, see the following topics:

- “Using a script to get up and running quickly with WS-Notification” on page 2964.
- “Configuring a WS-Notification service for use only by WS-Notification applications” on page 2968.
- “Providing access for WS-Notification applications to an existing bus topic space” on page 2969.
- “Securing WS-Notification” on page 2970.
- “Configuring JAX-WS handlers” on page 2972.
- “Applying a JAX-WS handler list to a WS-Notification service” on page 2973.
- “Configuring a Version 7.0 WS-Notification service with Web service QoS” on page 2974.
- “Configuring WS-Notification for reliable notification” on page 2976.
- “Migrating a Version 6.1 WS-Notification configuration from WebSphere Application Server Version 6.1 to Version 7.0 or later” on page 2977.
- “Preparing a migrated Version 6.1 WS-Notification configuration for reliable notification” on page 2978.
- “Interacting at run time with WS-Notification” on page 2982.
- “Publishing the WSDL files for a WS-Notification application to a compressed file” on page 2984.

Application developer

If the solution architect specifies a requirement to insert event notifications into the system (that is publish messages) or receive event notifications from the system as a result of creating a subscription containing an interest profile, then the application developer can use WS-Notification to meet this requirement.

There are various patterns of producing and consuming application defined by WS-Notification that are available for use by the application developer, depending upon the exact requirements of the application in question. These options are explored in the following common WS-Notification tasks:

- Writing a WS-Notification application that exposes a web service endpoint.
- Writing a WS-Notification application that does not expose a web service endpoint.

See also Developing applications that use WS-Notification and Filtering the message content of publications.

Chapter 33. Administering web services - Policy (WS-Policy)

WS-Policy is an interoperability standard that is used to describe and communicate the policies of a web service so that service providers can export policy requirements in a standard format. Clients can combine the service provider requirements with their own capabilities to establish the policies required for a specific interaction. This product conforms to the WS-Policy specification, so that policy information can be exchanged and received in accordance with the WS-Policy standard.

Web services are self-contained, modular applications that can be described, published, located, and invoked over a network. They implement a services oriented architecture (SOA), which supports the connecting or sharing of resources and data in a very flexible and standardized manner. Services are described and organized to support their dynamic, automated discovery and reuse.

Using WS-Policy to exchange policies in a standard format

WS-Policy is an interoperability standard that is used to describe and communicate the policies of a web service so that service providers can export policy requirements in a standard format. Clients can combine the service provider requirements with their own capabilities to establish the policies required for a specific interaction. WebSphere Application Server conforms to the WS-Policy specification, so that policy information can be exchanged and received in accordance with the WS-Policy standard.

About this task

For more information about using WS-Policy, see the following topics.

Procedure

- Configure a service provider to share its policy configuration
- Configure the client policy to use a service provider policy
- Configure the client policy to use a service provider policy from a registry
- Configure a service provider to share its policy configuration by using wsadmin scripting
- Configure the client policy based on a service provider policy by using wsadmin scripting
- Configure security for a WS-MetadataExchange request

Configuring a service provider to share its policy configuration

A WebSphere Application Server service provider can share its policy configuration in published Web Services Description Language (WSDL), or WSDL that is obtained by using an HTTP GET request or the Web Services Metadata Exchange (WS-MetadataExchange) GetMetadata request.

Before you begin

You have developed a web services service provider that contains all the necessary artifacts and deployed your web services application into your application server instance. You have attached the policy sets and managed the associated bindings.

For a list of WS-Policy assertion specifications and WS-Policy domains that are supported, see the topic about learning about WS-Policy.

About this task

You can make the policy configuration of a Java API for XML-Based Web Services (JAX-WS) service endpoint available to share in the following ways:

- Include the policy configuration of the service provider in the WSDL. The WSDL is then available to publish, or to obtain by using an HTTP GET request.

- Enable the Web Services Metadata Exchange (WS-MetadataExchange) protocol so that the policy configuration of the service provider is included in the WSDL and is available to a WS-MetadataExchange GetMetadata request. An advantage of using the WS-MetadataExchange protocol is that you can apply message-level security to WS-MetadataExchange GetMetadata requests by using a suitable system policy set.

If the service provider application uses multipart WSDL, all the WSDL must be local to the web service application. For more information about multipart WSDL, see the topic about WSDL.

You must configure a service provider to share its policy configuration because by default the policy configuration is not available in its WSDL. You can configure the service provider to include the policy configuration in its WSDL, to use WS-MetadataExchange so that the policy configuration is available, or both. This topic describes how to configure a service provider to share its policy configuration by using the administrative console. You can also configure a service provider to share its policy configuration by using wsadmin commands or Rational Application Developer tools.

You can configure a service provider to share its policy configuration at application or service level. The policy configuration that is represented by the policy sets attached to any lower levels will also be shared. Policy sets that are attached at lower levels override the policy set configuration attached at a higher level.

Procedure

1. From the navigation pane of the administrative console, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***service_provider_application_instance*** > **[Web services properties] Service provider policy sets and bindings**.
2. In the row for the application or service where the provider policy that you want to share is attached, click the link in the Policy sharing column. The link is either **Enabled** or **Disabled**. The Policy Sharing pane is displayed.
3. To include the policy configuration of the service provider in its WSDL so that it can be either published or obtained by using an HTTP GET request, select **Exported WSDL**.
4. To enable WS-MetadataExchange and make the policy configuration of the service provider available to a WS-MetadataExchange GetMetada request, select **WS-MetadataExchange request**.
5. Optional: If you select **WS-MetadataExchange request** and you want to use message-level security, select **Attach a system policy set to the WS-MetadataExchange**, then select a suitable policy set and binding from the drop-down lists. See “Configuring security for a WS-MetadataExchange request” on page 3115.
6. Click **OK** and save your changes to the master configuration.

Results

The policy configuration of the service provider is available to its clients. The WSDL of the service provider contains the current policy configuration in WS-PolicyAttachments format so that it is available to other clients, service registries, or services that support the Web Services Policy (WS-Policy) specification. The link in the Policy Sharing column on the Service provider policy sets and bindings pane changes to **Enabled**.

If the policy configuration cannot be shared, an error that describes the problem is written to the service provider error log, and the following policy is attached to the WSDL of the service provider:

```
<wsp:Policy>
<wsp:ExactlyOne>
</wsp:ExactlyOne>
</wsp:Policy>
```

This policy notifies the client that there is no acceptable policy configuration for the service. Other aspects of the WSDL are unaffected.

A service provider might not be able to share its policy configuration because the configuration cannot be expressed in the standard WS-PolicyAttachments format. One reason might be because multiple incompatible policies are defined for a particular attach point. Another reason might be because there is not enough binding information to generate the standard policy. Policy configuration might include bootstrap policy, for example, the policy to access a WS-Trust service, so the bootstrap policy must also be expressed in WS-PolicyAttachments format.

Configuring a service provider to share its policy configuration using wsadmin scripting

A WebSphere Application Server service provider can share its policy configuration in published Web Services Description Language (WSDL), or WSDL that is obtained by using an HTTP GET request or the Web Services Metadata Exchange (WS-MetadataExchange) GetMetadata request.

Before you begin

You have developed a web services service provider that contains all the necessary artifacts and deployed your web services application into your application server instance. You have attached the policy sets and managed the associated bindings.

For a list of WS-Policy assertion specifications and WS-Policy domains that are supported, see the topic about learning about WS-Policy.

About this task

You can make the policy configuration of a Java API for XML-Based Web Services (JAX-WS) service endpoint available to share in the following ways:

- Include the policy configuration of the service provider in the WSDL. The WSDL is then available to publish, or to obtain by using an HTTP GET request.
- Enable the Web Services Metadata Exchange (WS-MetadataExchange) protocol so that the policy configuration of the service provider is included in the WSDL and is available to a WS-MetadataExchange GetMetadata request. An advantage of using the WS-MetadataExchange protocol is that you can apply message-level security to WS-MetadataExchange GetMetadata requests by using a suitable system policy set.

If the service provider application uses multipart WSDL, all the WSDL must be local to the web service application. For more information about multipart WSDL, see the topic about WSDL.

You must configure a service provider to share its policy configuration because by default the policy configuration is not available in its WSDL. You can configure the service provider to include the policy configuration in its WSDL, to use WS-MetadataExchange so that the policy configuration is available, or both. This topic describes how to configure a service provider to share its policy configuration by using wsadmin commands. You can also use the administrative console or Rational Application Developer tools.

You can configure a service provider to share its policy configuration at application or service level. The policy configuration that is represented by the policy sets attached to any lower levels will also be shared. Policy sets that are attached at lower levels override the policy set configuration attached at a higher level.

Procedure

1. Start the wsadmin scripting client if it is not already running.
2. Use the SetProviderPolicySharingInfo command. For example:

```
AdminTask.setProviderPolicySharingInfo('[-applicationName WebServiceProviderApplication
-resource WebService:/WebServiceProvider.war:{http://example_path/}Service1
-sharePolicyMethods [httpGet ]]')
```

3. Save your changes to the master configuration.

   To save your configuration changes, enter the following command:

```
AdminConfig.save()
```

Results

The policy configuration of the service provider is available to its clients. The WSDL of the service provider contains the current policy configuration in WS-PolicyAttachments format so that it is available to other clients, service registries, or services that support the Web Services Policy (WS-Policy) specification.

If the policy configuration cannot be shared, an error that describes the problem is written to the service provider error log, and the following policy is attached to the WSDL of the service provider:

```
<wsp:Policy>
<wsp:ExactlyOne>
</wsp:ExactlyOne>
</wsp:Policy>
```

This policy notifies the client that there is no acceptable policy configuration for the service. Other aspects of the WSDL are unaffected.

A service provider might not be able to share its policy configuration because the configuration cannot be expressed in the standard WS-PolicyAttachments format. One reason might be because multiple incompatible policies are defined for a particular attach point. Another reason might be because there is not enough binding information to generate the standard policy. Policy configuration might include bootstrap policy, for example, the policy to access a WS-Trust service, so the bootstrap policy must also be expressed in WS-PolicyAttachments format.

What to do next

Optionally, you can publish the WSDL files.

setProviderPolicySharingInfo command:

Use the setProviderPolicySharingInfo command to set how an application or service that is a web service provider can share its policy configuration with other clients, service registries, or services that support the WS-Policy specification. You can set or remove this information about how a provider policy is shared.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available policy set management administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('PolicySetManagement')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the setProviderPolicySharingInfo command to set how an application, or a service in an application, shares its policy configuration with clients, service registries, or services that support the WS-Policy specification. The policy configuration is shared in WS-PolicyAttachments format.

The policy configuration of the resource can be shared with clients through a WS-MetadataExchange request, through Web Services Description Language (WSDL) exported by a ?WSDL HTTP Get request, or through both methods.

Target object

None.

Required parameters

-applicationName
The name of the application for which you want to set how the provider policy is shared. (String)

-resource
The name of the resource for which you want to set how the provider policy is shared. For all resources in an application, specify `WebService:/`. For a service in an application, specify `WebService:/`*`module`*`:{`*`namespace`*`}`*`service_name`*. Endpoints or operations inherit the settings of the parent application or service. (String)

Optional parameters

-sharePolicyMethods
Specifies how the policy configuration of the resource can be shared. (String array)

Enter either or both of the following values:

httpGet
The resource can share its policy configuration through WSDL that is obtained by a `?WSDL` HTTP Get request.

wsMex
The resource can share its policy configuration through a WS-MetadataExchange request.

-wsMexProperties
Specifies that message-level security is required for WS-MetadataExchange requests and specifies the settings that provide the message-level security. (Properties)

Enter the following values, following each value with the setting that you require for that value:

wsMexPolicySetName
The name of the system policy set that specifies message-level security when the resource shares its policy configuration through a WS-MetadataExchange request. Specify a system policy set that contains only WS-Security policies, only WS-Addressing policies, or both. The default policy set is SystemWSSecurityDefault.

wsMexPolicySetBinding
The name of the general binding for the policy set attachment when the resource shares its policy configuration through a WS-MetadataExchange request. Specify a general binding that is scoped to the global domain, or scoped to the security domain of this service. If you do not specify this property, the default binding is used.

This parameter is valid only when you specify wsMex for the **sharePolicyMethods** parameter.

-remove
Specifies whether the information about how the provider policy is shared is removed from the resource. (Boolean)

This parameter takes the following values:

true The information about how the provider policy is shared is removed from the resource.

false This value is the default. The information about how the provider policy is shared is not removed from the resource.

Examples

The following example removes the information about how the provider policy is shared from the WSSampleServices application:

```
AdminTask.setProviderPolicySharingInfo('[-applicationName WSSampleServices
-resource WebService:/ -remove true]')
```

The following example enables policy sharing, using WSDL exported by a `?WSDL` HTTP Get request, for the EchoService service in the WSSampleServices application:

```
AdminTask.setProviderPolicySharingInfo('[-applicationName WSSampleServices
-resource WebService:/WSSampleServicesSei.war:{http://example_path/}EchoService
-sharePolicyMethods [httpGet ]]')
```

The following example enables policy sharing, using a WS-MetadataExchange request with message-level security, for the WSSampleServices application. Message level security is provided by the SystemWSSecurityDefault policy set and the “Provider sample” general binding.

```
AdminTask.setProviderPolicySharingInfo('[-applicationName WSSampleServices
-resource WebService:/ -sharePolicyMethods [wsMex ]
-wsMexProperties [ [wsMexPolicySetName [SystemWSSecurityDefault]]
[wsMexPolicySetBinding [Provider sample]] ]]')
```

getProviderPolicySharingInfo command:

Use the getProviderPolicySharingInfo command to find out whether an application or service that is a web service provider can share its policy configuration, and list the properties that apply to sharing that configuration.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available policy set management administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('PolicySetManagement')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the getProviderPolicySharingInfo command to find out how a web services application, or a service in a Web services application, shares its policy configuration with clients, service registries, or services that support the WS-Policy specification. The policy configuration is shared in WS-PolicyAttachments format.

The command returns properties that show whether the policy configuration of the resource can be shared with clients through a WS-MetadataExchange request or through Web Services Description Language (WSDL) that is obtained by a `?WSDL` HTTP Get request.

Target object

None.

Required parameters

-applicationName
The name of the application for which you want to find out how it shares its policy configuration. The application must be a service provider. (String)

Optional parameters

-resource
The name of the resource for which you want to find out how it shares its policy configuration. If you specify this parameter, only the properties for that resource are returned. To retrieve information for the application, specify `WebService:/`. Alternatively, you can specify a service, endpoint or operation. However, policy sets are attached only at the application or service level, so the properties returned for an endpoint or operation are the settings that are inherited from the service. (String)

Return value

Returns a list of properties that include the resource name and that show whether the policy configuration of the resource can be shared. The following properties can be returned:

wsMexPolicySetName
The name of the policy set that specifies message-level security when the resource shares its policy configuration through a WS-MetadataExchange request. This property is returned if the value of the **sharePolicyMethods** property is wsMex and a policy set to provide message-level security was specified.

wsMexPolicySetBinding
The name of the binding that is applied when the resource shares its policy configuration through a WS-MetadataExchange request. This property is returned if the value of the **sharePolicyMethods** property is wsMex and a binding to provide message-level security was specified.

resource
The resource that you specified.

directSetting
How the properties apply to the resource. Valid values for this property are:

true
The properties apply directly to the resource.

false
The properties are inherited from the parent application or service.

sharePolicyMethods
How the policy configuration of the resource can be shared. Valid values for this property are:

httpGet
The resource shares its policy configuration through an HTTP Get request.

wsMex
The resource shares its policy configuration through a WS-MetadataExchange request.

Example

The following command displays the policy sharing configuration properties for the EchoService service in the WSSampleServices application. The provider is configured to share its policy through an HTTP Get request, and a WS-MetadataExchange request with message-level security. Message-level security for the WS-MetadataExchange request is provided by using the SystemWSSecurityDefault policy set and the "Provider sample" general binding.

```
AdminTask.getProviderPolicySharingInfo(['-applicationName', 'WSSampleServices',
'-resource', 'WebService:/SampleServicesSei.war:{http://example_path/}EchoService'])
.
.
[ [wsMexPolicySetName SystemWSSecurityDefault] [wsMexPolicySetBinding [Provider sample]]
[resource WebService:/SampleServicesSei.war:{http://example_path/}EchoService/]
[directSetting true] [sharePolicyMethods [httpGet wsMex]] ]
```

Policy sharing settings

Use this pane to view and change whether the policy configuration of a web services service provider is shared. You can configure the service provider to include the policy configuration in its Web Services Description Language (WSDL) so that it can be accessed using an HTTP Get request, or published. You can also make the policy configuration available to a Web Services Metadata Exchange (WS-MetadataExchange) request.

To view this administrative console page for an application or service, complete the following steps. The application must be a web services service provider.

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***service_provider_application_name*** > **[Web Services Properties] Service provider policy sets and bindings**.
2. Select the link in the Policy Sharing column for the application or service you require. The link is available if the application or service has a policy set attached.

To view this administrative console page for a service, complete the following steps.

1. Click **Services** > **Service providers** > ***service_name***.
2. Select the link in the Policy Sharing column for the service. The link is available if the service has a policy set attached.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Exported WSDL:

Select **Exported WSDL** to include the policy configuration of the service provider in the WSDL. The policy configuration is in WS-PolicyAttachments format in the WSDL so that it is then available to other clients, service registries, or services that support the Web Services Policy (WS-Policy) specification. The policy configuration will be available in published WSDL, or a client can use an HTTP Get request that is targeted at the target URL followed by `?WSDL` to obtain the provider policy.

WS-MetadataExchange request:

Select **WS-MetadataExchange** to make the policy configuration of the service provider available to a WS-MetadataExchange GetMetadata request. The policy configuration is in WS-PolicyAttachments format

in the WSDL so that it is then available to other clients, service registries or services that support the Web Services Policy (WS-Policy) specification and the WS-MetadataExchange GetMetadata request.

When **WS-MetadataExchange** is selected, the **Attach a system policy set to the WS-MetadataExchange** option is available.

Attach a system policy set to the WS-MetadataExchange:

Select **Attach a system policy set to the WS-MetadataExchange** to set message-level security for the WS-MetadataExchange request. By default, this option is not selected and the transport policy of the application is used. This option is available only when **WS-MetadataExchange** is selected.

When **Attach a system policy set to the WS-MetadataExchange** is selected, the **Policy set** and **Binding** lists are available.

Policy set:

Select the policy set you require from the list to provide message-level security for the WS-MetadataExchange request. You can select from system policy sets that contain only WS-Security policies, only WS-Addressing policies, or both. The default policy set is SystemWSSecurityDefault.

System policy sets are used for system messages that are not business-related, for example, messages that apply qualities of service (QoS), including the messages that are defined in the WS-MetadataExchange protocol.

Note that any transport policy of the application is always used.

This option is available only when **Attach a system policy set to the WS-MetadataExchange** is selected.

Binding:

Select the binding you require from the list to provide message-level security for the WS-MetadataExchange request. You can select from general bindings that are scoped to the global domain, or scoped to the security domain of this service.

This option is available only when **Attach a system policy set to the WS-MetadataExchange** is selected.

Configuring the client policy to use a service provider policy

An application that is a web service client can obtain the policy configuration of a web service provider and use this information to establish a policy configuration that is acceptable to both the client and the service provider.

Before you begin

You have developed a web service client that contains all the necessary artifacts, and deployed your web services application into your application server instance. If you require them, you have attached the policy sets and managed the associated bindings.

The service provider must publish its policy in its Web Services Description Language (WSDL) and that policy must contain its policy configuration at run time in WS-PolicyAttachments format. The client must be able to support those provider policies.

For a list of WS-Policy assertion specifications and WS-Policy domains that are supported, see the WS-Policy topic.

About this task

You can administer the client to configure itself dynamically at run time, based on the policy of the service provider in the standard WS-PolicyAttachments format. You can administer the client to apply dynamically the provider policy at the application or service or service reference level. By default, endpoints and operations inherit their policy configuration from the relevant service. However, it is possible to configure a service reference to override the service, in which case the endpoints and operations inherit their policy configuration from the service reference.

If the provider policy uses multipart WSDL, you can use an HTTP GET request to obtain the policy of the provider, but you cannot use the WS-MetadataExchange protocol. For more information about multipart WSDL, see the topic about WSDL.

Policy intersection is the comparison of a client policy and a provider policy to determine whether they are compatible, and the calculation of a new policy, known as the effective policy, that complies with both their requirements and capabilities.

This topic describes how to configure the client policy to use a service provider policy by using the administrative console. You can also configure the client policy to use a service provider policy by using wsadmin commands.

Procedure

1. From the navigation panel of the administrative console, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***service_client_application_instance*** > **[Web services properties] Service client policy sets and bindings**.
2. In the row for the application or service where you want to apply the policy, click the link in the Policies Applied column. The Policies Applied panel is displayed.
3. Select one of the following options from the drop-down list:
   - Provider policy only. Configure the client based solely on the policy of the service provider. This option is available when a client policy set is not attached.
   - Client and provider policy. Configure the client based on both the client policy set and the policy of the service provider. This option is available when a client policy set is attached.

   The other options in the list do not apply to this task.
4. Use the radio buttons to select which method to employ to obtain the provider policy: an HTTP GET request (see step 5) or a WS-MetadataExchange request (see step 6).
5. Optional: To obtain the provider policy by using an HTTP GET request, click **HTTP GET request**. By default, the HTTP GET request is targeted at the URL for the service endpoint followed by `?WSDL`. For example:

```
http://myhost:9080/WSSampleSei/EchoService?WSDL
```

   When the policy set attach point is at the application level you cannot change this value.
   a. Optional: If you are applying a policy to a service and the provider policy is located at the service endpoint, ensure that **Use the default request target** is selected.
   b. Optional: If you are applying a policy to a service and the provider policy is not located at the service endpoint, click **Specify request target**, then enter the URL for the location of the provider policy in the field. For example, you might change the target of the HTTP GET request if the provider policy is located in a repository.
   c. Optional: If you select **HTTP GET request** as the method to be used to obtain the provider policy and if you select **Specify request target** and you want to configure transport-level security, select **Attach a system policy set to the HTTP GET request**, then select a suitable policy set and binding from the drop-down lists. Select the policy set you require from the Policy set list to provide transport-level security for the HTTP GET request. Select from system policy sets that contain solely HTTP transport policies, solely SSL transport policies, or both; the policy set cannot contain

other policy types. Select the binding you require from the Binding list for the HTTP GET request. You can select from general bindings that are scoped to the global domain or scoped to the security domain of this service.

6. Optional: To obtain the provider policy by using a Web Services Metadata Exchange (WS-MetadataExchange) GetMetadata request, click **WS-MetadataExchange request**.
   a. Optional: If you select **WS-MetadataExchange request** and want to use message-level security, select **Attach a system policy set to the WS-MetadataExchange request**, then select a suitable policy set and binding from the drop-down lists. See “Configuring security for a WS-MetadataExchange request” on page 3115.
7. Click **OK**.
8. Save your changes to the master configuration.

Results

The web application client-side policy is calculated when it is required at run time, based either on the policy of the service provider, or on the client policy set and the policy of the service provider, depending on which option you selected. This calculated policy is known as the “effective policy” and is cached as a runtime configuration. The effective policy is used for subsequent outbound web service requests to the endpoint or operation for which the dynamic policy calculation was performed. The policy set configuration of the client does not change.

The provider policy that the client holds for a service is refreshed the first time that the web service is invoked after the application is loaded. After that, the provider policy is refreshed when the application restarts, or if the application explicitly invokes a refresh. When the provider policy is refreshed, the effective policy is recalculated.

Configuring the client policy to use a service provider policy by using wsadmin scripting

An application that is a web service client can obtain the policy configuration of a web service provider and use this information to establish a policy configuration that is acceptable to both the client and the service provider.

Before you begin

You have developed a web service client that contains all the necessary artifacts, and deployed your web services application into your application server instance. If you require them, you have attached the policy sets and managed the associated bindings.

The service provider must publish its policy in its Web Services Description Language (WSDL) and that policy must contain its policy configuration at run time in WS-PolicyAttachments format. The client must be able to support those provider policies.

For a list of WS-Policy assertion specifications and WS-Policy domains that are supported, see the WS-Policy topic.

About this task

You can administer the client to configure itself dynamically at run time, based on the policy of the service provider in the standard WS-PolicyAttachments format. You can administer the client to dynamically apply the provider policy at the application or service or service reference level.

Note: If you specify client dynamic policy control at the service reference level, you must use the new name-value paired list format of the resource string. If you are not specifying client dynamic policy control at service reference level, you can use either format.

Table 270. How to specify policy control at different levels of the application. For each applicable level of the application, the table lists the relevant string format command and name-value pair format command needed to specify policy control and summarizes the associated behavior.

Level	String format	Name-value pair list format (NEW)	Behavior
Type	"WebService:/"	"type=WebService:/"	Indicates all artifacts in the application
Service	"WebService:/*myModule*:{*namespace*}*myService*"	"type=WebService:/,module=*myModule*,service={*namespace*}*myService*"	Indicates all artifacts within the web service
Endpoint (under this service)	"WebService:/*myModule*:{*namespace*}*myService*/*endpointA*"	"type=WebService:/ ,module=*myModule*,service={*namespace*}*myService*,endpoint=*endpointA*"	Indicates all operations for this endpoint (under the service)
Operation (under this service)	"WebService:/*myModule*:{*namespace*}*myService*/*endpointA*/*operation1*"	"type=WebService:/ ,module=*myModule*,service={*namespace*}*myService*,endpoint=*endpointA*, operation=*operation1*"	Indicates a specific single operation (under the service)
Service reference	[Not possible]	"type=WebService:/ ,module=*myModule*,service={*namespace*}*myService*,serviceRef=*myServiceRef*"	Indicates all artifacts within the web service reference
Endpoint (under this service reference)	[Not possible]	"type=WebService:/ ,module=*myModule*,service={*namespace*}*myService*,serviceRef=*myServiceRef*, endpoint=*endpointA*"	Indicates all operations for this endpoint (under the service reference)
Operation (under this service reference)	[Not possible]	"type=WebService:/ ,module=*myModule*,service={*namespace*}*myService*,serviceRef=*myServiceRef*, endpoint=*endpointA*,operation=*operation1*"	Indicates a specific single operation (under the service reference)

If the provider policy uses multipart WSDL, you can use an HTTP GET request to obtain the policy of the provider, but you cannot use the WS-MetadataExchange protocol. For more information about multipart WSDL, see the topic about WSDL.

Policy intersection is the comparison of a client policy and a provider policy to determine whether they are compatible, and the calculation of a new policy, known as the effective policy, that complies with both their requirements and capabilities.

This topic describes how to configure the client policy to use a service provider policy by using wsadmin commands. You can also configure the client policy to use a service provider policy by using the administrative console.

Procedure

1. Start the wsadmin scripting client if it is not already running.
2. Use the SetClientDynamicPolicyControl command. For example:

```
AdminTask.setClientDynamicPolicyControl('[-applicationName WebServiceClientApplication
-resource WebService:/ClientApplication.war:{http://example_path/}Service1
-acquireProviderPolicyMethod [httpGet ]
-httpGetProperties [httpGetTargetURI http://example_path]]')
```

3. Save your changes to the master configuration.

   To save your configuration changes, enter the following command:

```
AdminConfig.save()
```

Results

The web application client-side policy is calculated when it is required at run time, based either on the policy of the service provider, or on the client policy set and the policy of the service provider, depending on which option you selected. This calculated policy is known as the “effective policy” and is cached as a runtime configuration. The effective policy is used for subsequent outbound web service requests to the endpoint or operation for which the dynamic policy calculation was performed. The policy set configuration of the client does not change.

The provider policy that the client holds for a service is refreshed the first time that the web service is invoked after the application is loaded. After that, the provider policy is refreshed when the application restarts, or if the application explicitly invokes a refresh. When the provider policy is refreshed, the effective policy is recalculated.

Configuring the client policy to use a service provider policy from a registry

An application that is a web service client can obtain the policy configuration of a web service provider from a registry, such as WebSphere Service Registry and Repository (WSRR), and use this information to establish a policy configuration that is acceptable to both the client and the service provider.

Before you begin

You have developed a web service client that contains all the necessary artifacts, and deployed your web services application into your application server instance. If you require them, you have attached the policy sets and managed the associated bindings.

The Web Services Description Language (WSDL) for the policy of the service provider, and its corresponding policies and policy attachments, are stored in a registry such as WSRR. That policy must contain its policy configuration in WS-PolicyAttachments format. The client must be able to support those provider policies.

The registry must support the use of HTTP GET requests to publish WSDL that contains WS-Policy attachments, for example WSRR Version 6.2 or later.

For a list of WS-Policy assertion specifications and WS-Policy domains that are supported, see the WS-Policy topic.

About this task

You can administer the client to configure itself dynamically at run time, based on the policy of a service provider that is held in a registry. You can administer the client at the service or service reference level to dynamically apply the provider policy that it obtains from a registry. By default, endpoints and operations inherit their policy configuration from the relevant service. However, it is possible to configure a service reference to override the service, in which case the endpoints and operations inherit their policy configuration from the service reference. You cannot administer the client to apply dynamically the provider policy that it obtains from a registry at the application level.

You can configure the client policy to use a service provider policy that is stored in a registry by using the administrative console. You can also configure the client policy to use a service provider policy that is stored in a registry by using wsadmin commands.

Procedure

1. From the navigation pane of the administrative console, click **Applications** > **Application Types** > **WebSphere enterprise applications**.
2. Click the web service client application that you want to configure.
3. Click **[Web services properties] Service client policy sets and bindings**.
4. In the row for the service where you want to apply the policy, click the link in the Policies Applied column. You cannot apply the policy at application level. The Policies Applied pane is displayed.
5. Select one of the following options from the drop-down list:
   - Provider policy only. Configure the client based solely on the policy of the service provider. This option is available when a client policy set is not attached.
   - Client and provider policy. Configure the client based on both the client policy set and the policy of the service provider. This option is available when a client policy set is attached.

   The other options in the list do not apply to this task.
6. Click **HTTP GET request**.
7. Click **Specify request target**, then enter the URL for the location of the provider policy in the field, that is, the address in the repository for the WSDL and policy. For information about using WSRR to

retrieve a WSDL document with embedded policies, and therefore obtain the required URL, see the WSRR documentation. The following example shows a typical URL:

```
https://www.wsrr.host/WSRR/6.2/PolicyService/
WSDL?bsrURI=3b9b493b-278f-4f64.ba3f.dabd30da3f7e
```

8. Click **OK**.
9. Optional: If there is a secure connection that uses the Secure Sockets Layer (SSL) protocol between the client and the registry, ensure that trust is established between the application server and the registry server. To access the registry, the client uses the SSL transport policy that is part of its service-level application policy. For example, for WSRR, you can enter the URL for the WSRR server in a browser window. If the WSRR server is not already trusted, a message is displayed stating that the security certificate is not trusted. To establish trust, use the following steps:
   a. Retrieve and store the X509 certificate from the WSRR server. Use the options on the message to view details of the certificate and save those details to a file, using distinguished encoding rules (DER) encoded binary format.
   b. Find out the key store that the client uses, that is, the key store that is shown by the SSL security transport bindings of the client application policy set. See Configuring the SSL transport policy. For example, the key store might be the default trust store for the node.
   c. Add the signer certificate that you saved in step a. to the key store that the client uses. See "Adding a signer certificate to a keystore" on page 1824.
10. Optional: To access the registry, the client uses the transport policy that is part of its service-level application policy. If the registry requires authentication using the HTTP protocol, configure a valid user name and password as part of the application-level transport policy binding configuration. It is advisable to secure any authorization credentials, because they are used for interactions with both the web service endpoint and the registry.
    a. Ensure that the client has a policy set that contains the HTTP transport policy attached to the application or service level. See the relevant steps in "Managing policy sets and bindings for service clients at the application level using the administrative console" on page 2656.
    b. Configure the HTTP transport client bindings for the binding named Client sample and enter the user name and password that the registry requires to authenticate outbound service requests. See the relevant steps in "Configuring the HTTP transport policy" on page 2720.
11. Save your changes to the master configuration.

Results

The web application client-side policy is calculated when it is required at run time, based either on the policy of the service provider, or on the client policy set and the policy of the service provider, depending on which option you selected. This calculated policy is known as the "effective policy" and is cached as a runtime configuration. The effective policy is used for subsequent outbound web service requests to the endpoint or operation for which the dynamic policy calculation was performed. The policy set configuration of the client does not change.

The provider policy that the client holds for a service is refreshed the first time that the web service is invoked after the application is loaded. After that, the provider policy is refreshed when the application restarts, or if the application explicitly invokes a refresh. When the provider policy is refreshed, the effective policy is recalculated.

Policies applied settings

Use this panel to view and change whether the policy configuration of a WebSphere Application Server service client is configured dynamically, based on the policies supported by its service provider. You can view or change how the client obtains the policy of the service provider; the client can use an HTTP GET request or a Web Services Metadata Exchange (WS-MetadataExchange) request. You can specify a policy set and binding to provide message-level security for WS-MetadataExchange requests or to specify HTTP transport and SSL transport configuration for HTTP GET requests.

To view this administrative console page for an application or service, complete the following steps. The application must be a web services service client.

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***service_client_application_name*** > **[Web Services Properties] Service client policy sets and bindings**.
2. Select the link in the **Policies Applied** column for the application or service you require.

To view this administrative console page for a service, complete the following steps:

1. Click **Services** > **Service clients** > ***service_name***.
2. Select the link in the **Policies Applied** column for the service. The link is available if the service or the parent application has a policy set attached.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Apply the following policies:

Specifies whether the client policy is based on the policy of the service provider, and how that policy is used.

Select from the following options:

- Client policy only. Configure the client based solely on the client policy set. Do not use the policy of the service provider. This option is available when a client policy set is attached to the resource.
- Client and provider policy. Configure the client based on both the client policy set and the policy of the service provider. This option is available when a client policy set is attached to the resource.
- Inherit application attachment. Inherit the setting of the parent application. This option is available for a service when a client policy set is not attached to the service. If there is a policy set attached to the parent application, the inherited properties are displayed on this panel, but you cannot change them. If there is no policy set attached to the parent application, when you return to the Service clients policy sets and bindings panel, the Policies applied column shows a value of **None**.
- Provider policy only. Configure the client based solely on the policy of the service provider. This option is available when a client policy set is not attached to the resource.

HTTP GET request:

Click **HTTP GET request** to obtain the policy of the service provider by using an HTTP GET request. The policy configuration must be in WS-PolicyAttachments format in the WSDL of the service provider.

This option is available when **Apply the following policies** is set to Client and provider policy or Provider policy only.

By default, the HTTP GET request is targeted at the URL for each service endpoint followed by ?WSDL.

Use the default request target:

When you apply a policy to a service, click **Use the default request target** to target the HTTP GET request at the URL for each service endpoint followed by ?WSDL.

If the attach point is for the service, then you can either select this default request target or you can choose to specify an alternative request target using the **Specify request target** option.

If the attach point is for the application then the default request target will be used.

Specify request target:

When you apply a policy to a service, click **Specify request target** to change the target for acquiring provider policy using an HTTP GET request. Enter the URL for the location of the provider policy in the field.

This option is available when **HTTP GET request** is selected and you apply a policy to a service.

When you apply a policy to an application, this option is not available.

Attach a system policy set to the HTTP GET request:

Select **Attach a system policy set to the HTTP GET request** to set HTTP transport and SSL transport configuration for the HTTP GET request. This option is available when **HTTP GET request** is selected as the method to be used to obtain the provider policy and when **Specify request target** is selected and completed.

If you do not specify a policy set you will inherit the HTTP transport and SSL transport configuration from the application.

Policy set (for the HTTP GET request):

Select the policy set you require from the list to provide HTTP transport and SSL transport configuration for the HTTP GET request. Select from system policy sets that contain solely HTTP transport policies, solely SSL transport policies, or both; the policy set cannot contain other policy types.

This option is available when **Attach a system policy set to the HTTP GET request** is selected and the **Specify request target** is selected and completed.

Binding (for the HTTP GET request):

Select the binding you require from the list for the HTTP GET request. You can select from **Global Default Bindings** or **General client/provider policy set bindings**, which are specific to the individual service.

This option is available when **Attach a system policy set to the HTTP GET request** is selected and the **Specify request target** is selected and completed.

The value of **Default** will result in the Global Default Binding being used.

WS-MetadataExchange request:

Click **WS-MetadataExchange** to obtain the policy of the service provider by using a WS-MetadataExchange GetMetadata request. The policy configuration must be in WS-PolicyAttachments format in the WSDL of the service provider.

This option is available when **Apply the following policies** is set to Client and provider policy or Provider policy only.

Attach a system policy set to the WS-MetadataExchange request:

Select **Attach a system policy set to the WS-MetadataExchange request** to set message-level security for the WS-MetadataExchange request. By default, this option is not selected and the transport policy of the application is used. This option is available when **WS-MetadataExchange request** is selected.

When **Attach a system policy set to the WS-MetadataExchange request** is selected, the **Policy set** and **Binding** lists are available. If you select **Attach a system policy set to the WS-MetadataExchange request**, you must also select a policy set and a binding.

Policy set (for the WS-MetadataExchange request):

Select the policy set you require from the list to provide message-level security for the WS-MetadataExchange request. You can select from system policy sets that contain only WS-Security policies, only WS-Addressing policies, or both. The default policy set is SystemWSSecurityDefault.

System policy sets are used for system messages that are not business-related, for example, messages that apply qualities of service (QoS), including the messages that are defined in the WS-MetadataExchange protocol.

Note that any transport policy of the application is always used.

This option is available when **Attach a system policy set to the WS-MetadataExchange** is selected.

Binding (for the WS-MetadataExchange request):

Select the binding you require from the list to provide message level security for the WS-MetadataExchange request. You can select from **Global Default Bindings** or **General client/provider policy set bindings**, which are specific to the individual service.

This option is available when **Attach a system policy set to the WS-MetadataExchange** is selected.

The value of **Default** will result in the Global Default Binding being used.

Configuring security for a WS-MetadataExchange request

You can configure message-level security for a Web Services Metadata Exchange (WS-MetadataExchange) GetMetadata request by specifying a suitable policy set and binding. You do this when you configure a web service provider to share its policies or a web service client to obtain the policies of a service provider.

Before you begin

For a service provider, you have completed the procedure to configure a service provider to share its policy configuration, up to and including the step to enable WS-MetadataExchange.

For a service client, you have completed the procedure to configure the client policy to use a service provider policy, up to and including the step to use WS-MetadataExchange.

About this task

By default, the WS-MetadataExchange GetMetadata request uses the transport-level security configuration of the application. You might want to apply message-level security if transport-level security is not available on the application endpoint, or if transport-level security is not adequate for your requirements. An advantage of message-level security is that it provides end-to-end security, which is especially important for the exchange of security metadata.

You can configure security for a WS-MetadataExchange request by using the administrative console. You can also configure security for a WS-MetadataExchange request by using wsadmin commands.

Procedure

1. For a service provider, in the Policy Sharing panel on the administrative console, select **Attach a system policy set to the WS-MetadataExchange**. For a service client, in the Policies Applied panel on the administrative console, select **Attach a system policy set to the WS-MetadataExchange**.
2. Select a system policy set to provide message-level security from the Policy set list. You can select from system policy sets that contain only WS-Security policies, only WS-Addressing policies, or both. The default policy set is SystemWSSecurityDefault. If the policy sets that are listed are not suitable for your requirements, create your own system policy set, then return to this procedure.
3. Select a general binding for the policy set attachment from the Binding list. You can select from general bindings that are scoped to the global domain, or the security domain of this service. If the bindings that are listed are not suitable for your requirements, create your own general binding, then return to this procedure.
4. Click **OK**.
5. Save your changes to the master configuration.

Results

Message-level security is applied to the WS-MetadataExchange GetMetadata request.

Chapter 34. Administering web services - Reliable messaging (WS-ReliableMessaging)

To configure a web service application to use WS-ReliableMessaging, you attach a policy set that contains a WS-ReliableMessaging policy type. This policy type offers a range of qualities of service: managed persistent, managed non-persistent, or unmanaged non-persistent.

Administering reliable web services

To configure a web service application to use WS-ReliableMessaging, you attach a policy set that contains a WS-ReliableMessaging policy type. This policy type offers a range of qualities of service: managed persistent, managed non-persistent, or unmanaged non-persistent.

About this task

WS-ReliableMessaging is an interoperability standard for the reliable transmission of messages between two endpoints. To administer WS-ReliableMessaging for an application, you take the following broad actions:

1. Attach a reliable messaging policy set (either a default policy set or one that you have created) to an aspect of your application (that is, application level or web service level). Policy sets define the reliability level (quality of service) and other configuration options that you want to apply to your reliable messaging application.
2. Define the bindings for each attachment to a policy set that specifies a managed quality of service. That is, choose the service integration bus and messaging engine to use to maintain the state for the managed persistent and managed non-persistent qualities of service.

At any stage, you can set a property that configures endpoints to only support clients that use reliable messaging. This setting is reflected by WS-Policy if engaged.

If your WS-ReliableMessaging application runs inside the web container and uses a managed quality of service, you can also use WS-ReliableMessaging to provide transactional recoverable messaging.

Procedure

- Configure a WS-ReliableMessaging policy set.

  You can do this using the administrative console or using the wsadmin tool. You can also configure WS-SecureConversation to work with WS-ReliableMessaging.
- Attach and bind a WS-ReliableMessaging policy set to a web service application

  You can do this using the administrative console or using the wsadmin tool.
- Configure endpoints to only support clients that use reliable messaging.
- Provide transactional recoverable messaging through WS-ReliableMessaging.

Configuring a WS-ReliableMessaging policy set by using the administrative console

To configure a web service application to use WS-ReliableMessaging, you attach a policy set that contains a WS-ReliableMessaging policy type. This policy type offers a range of qualities of service: managed persistent, managed non-persistent, or unmanaged non-persistent. Use the administrative console to configure a policy set for reliable messaging.

Before you begin

You can configure a reliable messaging policy set by using the administrative console as described in this task, or you can configure a reliable messaging policy set by using the wsadmin tool.

The following default policy sets work with WS-ReliableMessaging applications:

- WS-I RSP
- WS-I RSP ND
- LTPA WS-I RSP
- Username WS-I RSP
- WSReliableMessaging 1_0
- WSReliableMessaging default
- WSReliableMessaging persistent

For more information, see “WS-ReliableMessaging default policy sets” on page 2671.

If you can use any of these default policy sets without needing to modify their configuration, you need not complete this task. You are ready to attach and bind the default policy set to your application.

At any stage - that is, before or after you have built your reliable web service application, or configured your policy sets - you can set a property that configures endpoints to only support clients that use reliable messaging. This setting is reflected by WS-Policy if engaged.

About this task

To configure a reliable messaging policy set by using the administrative console, complete the following steps:

Procedure

1. Create a policy set. You can create a new policy set, or copy and rename an existing policy set - either one that you have previously created, or one of the WS-ReliableMessaging default policy sets.
2. Check that your policy set includes the policy types **WS-ReliableMessaging** and **WS-Addressing**. Add these policy types if necessary. These policy types contain the configuration options that support WS-ReliableMessaging. WS-Addressing provides the asynchronous request and reply capabilities for WS-ReliableMessaging, and is also required for WS-ReliableMessaging Version 1.1 synchronous messaging.

   Notes:

   - If you want to use secure conversation and reliable messaging policies in the same policy set, the secure conversation bindings must be configured to require that the reliable messaging headers are signed. The reliable secure profile default policy sets (WS-I RSP and WS-I RSP ND) are specifically designed and configured to use secure conversation and reliable messaging in the same policy set. If you use a copy of one of the reliable secure profile default policy sets (WS-I RSP and WS-I RSP ND), no further configuration of the secure conversation bindings is required. Otherwise, see “Configuring WS-SecureConversation to work with WS-ReliableMessaging” on page 3121.
   - WS-ReliableMessaging Version 1.1 messaging requires WS-Addressing to be mandatory. If you use a policy set that includes WS-ReliableMessaging and WS-Addressing policies, and the WS-Addressing policy is configured as optional, then WebSphere Application Server overrides the WS-Addressing setting and automatically enables WS-Addressing.
3. Configure the **WS-ReliableMessaging** policy type attributes. For the WS-ReliableMessaging policy you can configure the version of the WS-ReliableMessaging standard that you want to use, the order in which messages are delivered, and the required quality of service (the reliability level) for message delivery.

   Note: In WebSphere Application Server Version 6.1, you could also configure whether or not to use the WS-MakeConnection protocol. This configuration option has now been removed from the

administrative console panel, because the product now automatically determines whether WS-MakeConnection is used, based on the following criteria:

- Whether you are using WS-ReliableMessaging Version 1.0 or Version 1.1.
- Whether the requester supports WS-MakeConnection.
- Whether the message exchange protocol is synchronous or asynchronous.

4. If required, configure the **WS-Addressing** policy type attributes. For example, the default WS-Addressing policy messaging style is **Synchronous and asynchronous**, which specifies that there is no restriction on the targeting of response messages. However if you enable policy sharing, the WS-Policy framework determines which style to use, and has a preference for the synchronous request-response pattern. Because the WS-Policy framework takes precedence, reliable messages are sent in a synchronous request-response pattern even if your client invokes the service asynchronously. To enforce asynchronous messaging, set the WS-Addressing policy messaging style to asynchronous only.
5. Save your changes to the master configuration.

What to do next

You are now ready to attach your application to the policy set and define the bindings that you want to use.

Configuring a WS-ReliableMessaging policy set by using the wsadmin tool

To configure a web service application to use WS-ReliableMessaging, you attach a policy set that contains a WS-ReliableMessaging policy type. This policy type offers a range of qualities of service: managed persistent, managed non-persistent, or unmanaged non-persistent. Use command scripts to configure a policy set for reliable messaging.

Before you begin

You can configure a reliable messaging policy set by using the wsadmin tool as described in this task, or you can configure a reliable messaging policy set by using the administrative console.

The following default policy sets work with WS-ReliableMessaging applications:

- WS-I RSP
- WS-I RSP ND
- LTPA WS-I RSP
- Username WS-I RSP
- WSReliableMessaging 1_0
- WSReliableMessaging default
- WSReliableMessaging persistent

For more information, see “WS-ReliableMessaging default policy sets” on page 2671.

If you can use any of these default policy sets without needing to modify their configuration, you need not complete this task. You are ready to attach your application to the default policy set and define the bindings that you want to use.

At any stage - that is, before or after you have built your reliable web service application, or configured your policy sets - you can set a property that configures endpoints to only support clients that use reliable messaging. This setting is reflected by WS-Policy if engaged.

About this task

To configure a reliable messaging policy set by using the wsadmin tool, complete the following steps:

Procedure

1. Create a policy set. Use the createPolicySet command to create a new policy set, or the copyPolicySet command to copy and rename an existing policy set - either one that you have previously created, or one of the two “WS-ReliableMessaging default policy sets” on page 2671. For more information, see Creating and copying policy sets by using the wsadmin tool.
2. If the policy set does not include both the policy types WSReliableMessaging and WSAddressing, add these policy types by using the addPolicyType command as described in Creating and copying policy sets by using the wsadmin tool. For example:

```
AdminTask.addPolicyType('[-policySet PolicySet1 -policyType WSReliableMessaging]')
AdminTask.addPolicyType('[-policySet PolicySet1 -policyType WSAddressing]')
```

   These policy types contain the configuration options that support WS-ReliableMessaging. WS-Addressing provides the asynchronous request and reply capabilities for WS-ReliableMessaging, and is also required for WS-ReliableMessaging Version 1.1 synchronous messaging.

   Notes:

   - If you want to use secure conversation and reliable messaging policies in the same policy set, the secure conversation bindings must be configured to require that the reliable messaging headers are signed. The reliable secure profile default policy sets (WS-I RSP and WS-I RSP ND) are specifically designed and configured to use secure conversation and reliable messaging in the same policy set. If you use a copy of one of the reliable secure profile default policy sets (WS-I RSP and WS-I RSP ND), no further configuration of the secure conversation bindings is required. Otherwise, see “Configuring WS-SecureConversation to work with WS-ReliableMessaging” on page 3121.
   - WS-ReliableMessaging Version 1.1 messaging requires WS-Addressing to be mandatory. If you use a policy set that includes WS-ReliableMessaging and WS-Addressing policies, and the WS-Addressing policy is configured as optional, then WebSphere Application Server overrides the WS-Addressing setting and automatically enables WS-Addressing.

3. Configure the **WS-ReliableMessaging** policy type attributes.

   For the WS-ReliableMessaging policy you can configure the version of the WS-ReliableMessaging standard that you want to use, the order in which messages are delivered, and the required quality of service (the reliability level) for message delivery. For detailed information about these configurable attributes, see “WS-ReliableMessaging settings” on page 2716.

   Use the setPolicyType command to configure these attributes. For example:

```
AdminTask.setPolicyType('-policySet PolicySet1 -policyType WSReliableMessaging -attributes "[[inOrderDelivery false][specLevel 1.0]
[enabled true][qualityOfService managedPersistent][type WSReliableMessaging]]" -replace'
```

4. If required, configure the **WS-Addressing** policy type attributes. For example, the default WS-Addressing policy messaging style is **Synchronous and asynchronous**, which specifies that there is no restriction on the targeting of response messages. However if you enable policy sharing, the WS-Policy framework determines which style to use, and has a preference for the synchronous request-response pattern. Because the WS-Policy framework takes precedence, reliable messages are sent in a synchronous request-response pattern even if your client invokes the service asynchronously. To enforce asynchronous messaging, set the WS-Addressing policy messaging style to asynchronous only.

   Use the setPolicyType command to configure these attributes. For example:

```
AdminTask.setPolicyType('[-policySet PolicySet1 -policyType WSAddressing
-attributes "[[wsaMode WSA_ASYNC]]"]')
```

   For detailed information about these configurable attributes, see “WS-Addressing policy settings” on page 2719.

5. Save your changes to the master configuration.

   To save your configuration changes, enter the following command:

```
AdminConfig.save()
```

What to do next

You are now ready to attach your application to the default policy set and define the bindings that you want to use.

Configuring WS-SecureConversation to work with WS-ReliableMessaging

Configure secure conversation to expect the reliable messaging headers to be signed, and to ensure that the scoping security context token does not expire before reliable messaging recovers and resends persistent messages.

Procedure

- "Configure secure conversation to expect the reliable messaging headers to be signed"
- "Configure secure conversation to increase the timeout setting for the scoping security context token"

Configure secure conversation to expect the reliable messaging headers to be signed:
About this task

Although secure conversation allows message headers to remain unsigned, the reliable messaging policy requires the reliable messaging headers to be signed. If you want to use secure conversation and reliable messaging policies in the same policy set, the secure conversation bindings must be configured to require that the reliable messaging headers are signed. To achieve this, complete one of the following steps:

Procedure

- Create your policy set from a copy of one of the reliable secure profile default policy sets (WS-I RSP and WS-I RSP ND). These policy sets contain instances of the secure conversation and reliable messaging policies that are configured to work together.
- Create your policy set from a copy of the secure conversation policy set:
  1. Add the reliable messaging policy to your copy of the secure conversation policy set.
  2. Specify in the secure conversation bindings that the reliable messaging headers must be signed. For more information about how to do this, see "Defining and managing policy set bindings" on page 2680.
  3. Save your changes to the master configuration.

  Note: The reliable secure profile default policy sets (WS-I RSP and WS-I RSP ND) are specifically designed and configured to use secure conversation and reliable messaging in the same policy set. Only create your policy set from a copy of the secure conversation policy set if you have a clear business need to do so. Otherwise, always use a copy of one of the reliable secure profile default policy sets (WS-I RSP and WS-I RSP ND).

Configure secure conversation to increase the timeout setting for the scoping security context token:
About this task

When you use a persistent WS-I RSP policy set, which includes WS-SecureConversation, if the scoping security context token is expired when the server is restarted then WS-ReliableMessaging cannot resend its messages and system messages are written to the log file stating that the reliable messaging sequence was not secured using the correct security token.

To ensure that the scoping security context token does not expire before WS-ReliableMessaging can recover and resend its messages, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Services** > **Security cache**. The Security cache detail form is displayed.

2. Set the **Time token is in cache after timeout** property to a value of at least 120 minutes. This value specifies the length of time to keep tokens after they expire. By default, this is 10 minutes. These expired tokens can be used for reliable messaging recovery.
3. In the navigation pane, click **Services** > **Trust service** > **Token providers**. In the content pane, select a security context token. The Security Context Token detail form is displayed.
4. Set the following values for the security context token:
   a. Check that the **Time in cache after expiration** property is set to a value of at least 120 minutes.
   b. Check that the **Token timeout** property is set to a value of at least 120 minutes.
   c. Select the **Allow renewal after timeout** check box.
5. Save your changes to the master configuration.

Attaching and binding a WS-ReliableMessaging policy set to a web service application by using the administrative console

To configure a web service application to use WS-ReliableMessaging, you attach a policy set that contains a WS-ReliableMessaging policy type. This policy type offers a range of qualities of service: managed persistent, managed non-persistent, or unmanaged non-persistent. Use the administrative console to attach the policy set to your application, and (for managed qualities of service) define bindings to a service integration bus and messaging engine.

Before you begin

You can attach a WS-ReliableMessaging policy set and define bindings by using the administrative console as described in this task, or you can attach and bind a WS-ReliableMessaging policy set by using the wsadmin tool.

This task assumes that you have already developed and installed the web service application to which you want to attach a policy set.

The following default policy sets work with WS-ReliableMessaging applications:

- WS-I RSP
- WS-I RSP ND
- LTPA WS-I RSP
- Username WS-I RSP
- WSReliableMessaging 1_0
- WSReliableMessaging default
- WSReliableMessaging persistent

For more information, see “WS-ReliableMessaging default policy sets” on page 2671.

If you can use any of these default policy sets, or you have configured your own reliable messaging policy set, then you are ready to complete this task.

About this task

Use this task to complete the following broad actions:

1. Attach a reliable messaging policy set (either a default policy set or one that you have created) to an aspect of your application (that is, application level or web service level). Policy sets define the reliability level (quality of service) and other configuration options that you want to apply to your reliable messaging application.
2. Define the bindings for each attachment to a policy set that specifies a managed quality of service. That is, choose the service integration bus and messaging engine to use to maintain the state for the managed persistent and managed non-persistent qualities of service.

To attach a WS-ReliableMessaging policy set and define bindings by using the administrative console, complete the following steps:

Procedure

1. Attach a policy set to your reliable messaging application at either application level or service level..

   Note:

   - You can attach one policy set at each level.
   - You can only apply a WS-ReliableMessaging policy at application level or service level.
   - If you apply reliable messaging at service level, then all services must use the same WS-ReliableMessaging policy and bindings values.
   - You can attach any policy set at operation level. For a policy set that includes the WS-ReliableMessaging policy, attachment at the operation level configures the other components of the policy set (for example WS-Security and WS-Addressing) but any WS-ReliableMessaging configuration at operation level is ignored.

2. If your chosen policy set specifies a managed quality of service, define bindings to a service integration bus and messaging engine.

   If the policy set instance specifies managed non-persistent or managed persistent quality of service, choose the service integration bus and messaging engine that is to manage the WS-ReliableMessaging state. Use the "WS-ReliableMessaging policy binding" on page 2718 panel to select or create the service integration bus and messaging engine that you want to use.

   Note: When many applications use the same messaging engine, it can impact performance. Factors to consider include the number of applications that are already binding to the messaging engine, the CPU utilization, and the message throughput. To improve performance for a single server configuration, create a new messaging engine to bind to your application.

   To define the default WS-ReliableMessaging policy binding for provider and client policy set attachments within WebSphere Application Server Version 6.1 applications, and for attachments to service applications that are deployed to a Version 6.1 server, navigate to **Services** > **Policy sets** > **Default policy set bindings** > **Version 6.1 default policy set bindings** > **WS-ReliableMessaging**.

   To define the bindings for a WebSphere Application Server Version 7.0 or later provider or client policy set, navigate to **Services** > **Policy sets** > **General provider policy set bindings** > ***provider_policy_set_binding_name*** > **WS-ReliableMessaging** or **Services** > **Policy sets** > **General client policy set bindings** > ***client_policy_set_binding_name*** > **WS-ReliableMessaging**

   To define the bindings for an application that you have attached to a service provider policy set, navigate to **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **[Web Service Properties] Service provider policy sets and bindings** and follow the instructions given in "Managing policy sets and bindings for service providers at the application level using the administrative console" on page 2634.

   To define the bindings for an application that you have attached to a service client policy set, navigate to **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **[Web Service Properties] Service client policy sets and bindings** and follow the instructions given in "Managing policy sets and bindings for service clients at the application level using the administrative console" on page 2656.

   WS-Notification note: If the application that you have attached to a service client policy set is a Version 7.0 WS-Notification service client, you can instead use the context-specific version of the "Service client policy sets and bindings" panel that can be reached through either of the following paths:

   - **Service integration** > **WS-Notification** > **Services** > ***service_name*** > **[Additional properties] Outbound request policy sets and bindings**
   - **Service integration** > **Buses** > ***bus_name*** > **[Services] WS-Notification services** > ***service_name*** > **[Additional properties] Outbound request policy sets and bindings**

If you want to configure policy set and binding details for a single Version 7.0 WS-Notification service client, rather than for all clients for the service, you can instead use the following panel:

- **Services** > **Service clients** > ***ws-notification_service_client_name***

This panel also gives you links to the associated service integration bus and WS-Notification service.

3. Save your changes to the master configuration.

Attaching and binding a WS-ReliableMessaging policy set to a web service application by using the wsadmin tool

To configure a web service application to use WS-ReliableMessaging, you attach a policy set that contains a WS-ReliableMessaging policy type. This policy type offers a range of qualities of service: managed persistent, managed non-persistent, or unmanaged non-persistent. Use the wsadmin tool to attach the policy set to your application, and (for managed qualities of service) to define bindings to a service integration bus and messaging engine.

Before you begin

You can attach a WS-ReliableMessaging policy set and define bindings by using the wsadmin tool as described in this task, or you can attach and bind a WS-ReliableMessaging policy set by using the administrative console.

This task assumes that you have already developed and installed the web service application to which you want to attach a policy set.

The following default policy sets work with WS-ReliableMessaging applications:

- WS-I RSP
- WS-I RSP ND
- LTPA WS-I RSP
- Username WS-I RSP
- WSReliableMessaging 1_0
- WSReliableMessaging default
- WSReliableMessaging persistent

For more information, see “WS-ReliableMessaging default policy sets” on page 2671.

If you can use any of these default policy sets, or you have configured your own reliable messaging policy set, then you are ready to complete this task.

About this task

Use this task to complete the following broad actions:

1. Attach a reliable messaging policy set (either a default policy set or one that you have created) to an aspect of your application (that is, application level or web service level). Policy sets define the reliability level (quality of service) and other configuration options that you want to apply to your reliable messaging application.
2. Define the bindings for each attachment to a policy set that specifies a managed quality of service. That is, choose the service integration bus and messaging engine to use to maintain the state for the managed persistent and managed non-persistent qualities of service.

To attach a WS-ReliableMessaging policy set and define bindings by using the wsadmin tool, complete the following steps:

Procedure

1. Attach a policy set to your reliable messaging application at either application level or service level.

Use the createPolicySetAttachment command as described in Creating policy set attachments by using the wsadmin tool. Set the **-policySet** parameter to the name of the reliable messaging policy set that you want to use. For example: WS-I RSP ND

Note:

- You can attach one policy set at each level.
- You can only apply a WS-ReliableMessaging policy at application level or service level.
- If you apply reliable messaging at service level, then all services must use the same WS-ReliableMessaging policy and bindings values.
- You can attach any policy set at operation level. For a policy set that includes the WS-ReliableMessaging policy, attachment at the operation level configures the other components of the policy set (for example WS-Security and WS-Addressing) but any WS-ReliableMessaging configuration at operation level is ignored.

This command returns an attachment ID number. If your chosen policy set specifies a managed quality of service, make a note of this number. In the next step you use it to define the binding.

2. If your chosen policy set specifies a managed quality of service, define bindings to a service integration bus and messaging engine.

   If the policy set instance specifies managed non-persistent or managed persistent quality of service, choose the service integration bus and messaging engine that is to manage the WS-ReliableMessaging state. Use the setBinding command as described in Creating policy set attachments using the wsadmin tool. Set the **-policyType** parameter to WSReliableMessaging. Set the bus name and the messaging engine name by using the following syntax for the **-attributes** parameter:

```
-attributes "[[busName ReliableMessagingBus]
             [messagingEngineName messaging_engine_name]]"
```

   The messaging engine name is in the format *nodeName.serverName-busName* for a messaging engine on a single server, or *clusterName.nnn-busName* for a messaging engine in a cluster.

   Note: When many applications use the same messaging engine, it can impact performance. Factors to consider include the number of applications that are already binding to the messaging engine, the CPU utilization, and the message throughput. To improve performance for a single server configuration, create a new messaging engine to bind to your application.

3. Save your changes to the master configuration.

   To save your configuration changes, enter the following command:

```
AdminConfig.save()
```

Configuring endpoints to only support clients that use WS-ReliableMessaging

By default, when a WS-ReliableMessaging enabled policy set is attached to an endpoint, the server supports clients that use reliable messaging and clients that do not use reliable messaging. In this version of the product, you can configure endpoints to only support clients that use reliable messaging.

About this task

You configure endpoints to only support clients that use reliable messaging by setting a property in either of the following ways:

- Set a property when packaging the application.
- Set a property as a JVM argument for the server.

This setting is reflected by WS-Policy if engaged. For information about how to engage WS-Policy, see “Using WS-Policy to exchange policies in a standard format” on page 3099.

Procedure

- When packaging the application, configure endpoints to only support clients that use reliable messaging by setting the **strictlyEnforceWSRM** property in the META-INF/MANIFEST.MF of a WAR file or EJB module.
- Using a JVM argument for the server, configure endpoints to only support clients that use reliable messaging by defining the Java virtual machine custom property **com.ibm.ws.websvcs.rm.strictlyEnforceWSRM** on the server. For more information, see Configuring the JVM.

Providing transactional recoverable messaging through WS-ReliableMessaging

If your WS-ReliableMessaging application runs inside the web container and uses a managed quality of service, you can use WS-ReliableMessaging to provide transactional recoverable messaging.

About this task

The WS-ReliableMessaging transactional model is as follows:

- On the web service requester side, the transaction is between the application and the local managed store.
- The WS-ReliableMessaging protocol delivers the message to the web service provider side, where a different transaction is used between the second managed store and the application being dispatched.

For the outbound (requestor) case on a one-way message send, if the **enableTransactionalOneWay** property is set to true, then the send is performed under any transactional context currently held by the application thread. (Note that transactions are not supported under an outbound two-way message exchange).

For the inbound (provider) case, if the **inOrderDelivery** property is set to true, then an inbound message is dispatched to the application under a transaction. For an inbound two-way message exchange, the response is also generated under that transaction and is not sent until that transaction has committed.

Note:

WS-ReliableMessaging transactions do not use the WS-AtomicTransactions protocol. The relationship between these two protocols is as follows:

- WS-AtomicTransactions and WS-ReliableMessaging are mutually exclusive when WS-ReliableMessaging is being used, with a managed store, to provide transactional recoverable messaging.
- If WS-ReliableMessaging is configured to use an in-memory store, then there are cases where a WS-AtomicTransaction can be flowed between the reliable messaging source and the reliable messaging destination for two-way invocations. In this situation, WS-ReliableMessaging only protects against network failures, not against server failure.

For more information, see WS-AtomicTransactions.

To provide transactional recoverable messaging through WS-ReliableMessaging, work through the steps described in Adding assured delivery to web services through WS-ReliableMessaging and also complete the following additional steps:

Procedure

- To enable transactional messaging for outbound (requester) one-way message sends, when you develop your JAX-WS web service application set the **enableTransactionalOneWay** property to Boolean.TRUE (or the string true) in the jaxWS request context map.

- To enable transactional messaging for inbound (provider) one-way and two-way message exchanges, when you configure your WS-ReliableMessaging policy either use the administrative console to select the option **Deliver messages in the order that they were sent** or use the wsadmin tool to set the **inOrderDelivery** property to true.

WS-ReliableMessaging - administrative console panels

Links to topics that describe the contents of the administrative console panels that you can use to configure and operate WS-ReliableMessaging. Each topic gives details of the purpose and use of a panel, the administrative console navigation path to the panel, and the values that you can set in each field of the panel.

Configuration panels

- "WS-ReliableMessaging settings" on page 2716
- "WS-ReliableMessaging policy binding" on page 2718

Runtime panels

This set of panels is available at any of the following scopes within the administrative console:

Cell: **Services** > **Reliable messaging state**

Application server:
Servers > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Additional Properties] Reliable messaging state**

Enterprise application:
Applications > **Enterprise Applications** > ***application_name*** > **[Web Services Properties] Reliable messaging state**

Bus: **Service integration** > **Buses** > ***bus_name*** > **[Services] Reliable messaging state**

Messaging engine:
Service integration > **Buses** > ***bus_name*** > **[Topology] Messaging engines** > ***messaging_engine_name*** > **[Additional Properties] Reliable messaging state**

At each of the previous scopes, the navigation structure is as follows:

- "Reliable messaging state settings" on page 3130
  - "Message store collection" on page 3130
  - "Inbound sequence collection" on page 3136
    - "Inbound sequences settings" on page 3138
      - "Acknowledgement state collection" on page 3140
      - "Inbound message collection" on page 3139
        - "Message settings" on page 3135
    - "Export messages settings" on page 3140
  - "Outbound sequence collection" on page 3131
    - "Outbound sequences settings" on page 3133
      - "Outbound message collection" on page 3135
        - "Message settings" on page 3135
    - "Export messages settings" on page 3140

WS-ReliableMessaging settings

For the WS-ReliableMessaging policy you can configure the version of the WS-ReliableMessaging standard that you want to use, the order in which messages are delivered, and the required quality of service (the reliability level) for message delivery. The product can enforce these policies on inbound messages and applies them to outbound messages.

To view this page in the console, click the following path: **Services** > **Policy sets** > **Application policy sets** > ***policy_set_name*** > **WS-ReliableMessaging**.

With WebSphere Application Server, you can use WS-ReliableMessaging with Java API for XML-Based Web Services (JAX-WS) web services applications that use a SOAP over HTTP binding. Select the WS-ReliableMessaging specification to use for reliable transmission of your messages.
WS-ReliableMessaging Version 1.1 is the default value. Select the WS-ReliableMessaging specification to use for reliable transmission of your messages. WS-ReliableMessaging Version 1.1 is the default value. Details of the supported WS-ReliableMessaging specifications are available at the following web addresses:

- The WS-ReliableMessaging specification Version 1.0, February 2005.
- The OASIS WS-ReliableMessaging specification Version 1.1, February 2007.

Note: If you plan to invoke a .NET-based web service, you must select WS-ReliableMessaging Version 1.0.

Do not edit the policies associated with the provided default policy sets. If you have to modify the reliable messaging policy settings, use a copy of a default policy set or create a new policy set.

At any stage - that is, before or after you have built your reliable web service application, or configured your policy sets - you can set a property that configures endpoints to only support clients that use reliable messaging. This setting is reflected by WS-Policy if engaged.

Standard:

Deliver messages in the order that they were sent:

Select this option if the sender of a request has to receive a response before it sends the next request.

If you enable in-order delivery, you must also ensure that the requester application polls for the messages in the order in which it is to receive them. For more information, see “Configuring the WS-ReliableMessaging policy” on page 2714.

Specifying in-order delivery also marginally increases reliability if you are using the managed persistent quality of service.

Quality of Service: Select one of the following qualities of service:

Unmanaged non-persistent - Tolerates network and remote system failures
You can configure web service applications to use WS-ReliableMessaging with a default in-memory store. This quality of service requires minimal configuration. However it is non-transactional and, although it allows for the resending of messages that are lost in the network, if a server becomes unavailable you will lose messages. The default is Unmanaged Non-Persistent.

Managed non-persistent - Tolerates system, network, and remote system failures, but state is discarded after messaging engine restart
This in-memory quality of service option uses a messaging engine to manage the sequence state, and messages are written to disk if memory is low. This quality of service allows for the re-sending of messages that are lost in the network, and can also recover from server failure. However, state is discarded after a messaging engine restart so in this case you will lose messages.

Managed persistent - Tolerates system, network, and remote system failures
This quality of service for asynchronous web service invocations is recoverable. This option also uses a messaging engine and message store to manage the sequence state. Messages are persisted at the web service requester server and at the web service provider server, and are recoverable if the server becomes unavailable. Messages that have not been successfully transmitted when a server becomes unavailable can continue to be transmitted after the server restarts.

Note:

- All three qualities of service are supported when applications are deployed to the application server. Thin client and client container applications use the first option only.
- For the unmanaged non-persistent quality of service, the messages are stored only in memory. For both of the managed qualities of service, the messages are managed by a messaging engine and stored in a message store. You specify a binding to a bus and messaging engine on the "WS-ReliableMessaging policy binding" on page 2718 form. If your chosen quality of service is Unmanaged Non-Persistent, which does not use a binding to a messaging engine, then any binding that you specify is ignored.

WS-ReliableMessaging policy binding

To configure a web service application to use WS-ReliableMessaging, you attach a policy set that contains a WS-ReliableMessaging policy type. This policy type offers a range of qualities of service: managed persistent, managed non-persistent, or unmanaged non-persistent. The managed qualities of service, managed persistent and managed non-persistent, are supported by the service integration bus. Use this page to select the bus and messaging engine to use for the reliable messaging protocol state.

To view this page in the console, click one of the following paths:

- **Services** > **Policy sets** > **Default policy set bindings** > **Version 6.1 default policy set bindings** > **WS-ReliableMessaging** (This is the default binding for client and provider policy set attachments within WebSphere Application Server Version 6.1 applications, and attachments to service applications that are deployed to a Version 6.1 server.)
- **Services** > **Policy sets** > **General provider policy set bindings** > ***provider_policy_set_binding_name*** > **WS-ReliableMessaging** (This binding is used for the specified provider policy set.)
- **Services** > **Policy sets** > **General client policy set bindings** > ***client_policy_set_binding_name*** > **WS-ReliableMessaging** (This binding is used for the specified client policy set.)

Note:

- You only have to specify a binding to a bus and messaging engine if you are using a managed quality of service. If your chosen quality of service is Unmanaged Non-Persistent, any binding that you specify is ignored. The quality of service is defined on the "WS-ReliableMessaging settings" on page 2716 form for your chosen policy set. For more information, see "Configuring the WS-ReliableMessaging policy" on page 2714.
- When many applications use the same messaging engine, it can impact performance. Factors to consider include the number of applications that are already binding to the messaging engine, the CPU utilization, and the message throughput. To improve performance for a single server configuration, create a new messaging engine to bind to your application.

Bus name:

Specifies a list of available service integration buses in the cell. Use the list to select a bus, or click **Manage buses, bus members, and messaging engines** to add a new bus. The bus that you add is selected for this binding configuration when you return to this panel.

Messaging engine:

Specifies a list of each bus member for the selected bus. Use the list to select a bus member, or click **Manage buses, bus members, and messaging engines** to add a new bus member. The bus member that you add is selected for this binding configuration when you return to this panel.

Reliable messaging state settings

This page provides an overview of the WS-ReliableMessaging runtime state. Use this page to manage reliable messaging at run time.

To view this page in the console, click one of the paths to this panel. For example **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Additional Properties] Reliable messaging state**.

The WS-ReliableMessaging runtime panels are available at many different scopes within the administrative console. For more information, see “WS-ReliableMessaging - administrative console panels” on page 3127.

Runtime tab: Runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

Reliable messaging state

Select the aspect of WS-ReliableMessaging for which you want to view runtime information.

The following icons are displayed here and on several other reliable messaging runtime panels:

	**OK**	Everything here, and (if there is a link) in all runtime panels below this link, is running normally.
	**Warning**	Something here, or (if there is a link) in one of the runtime panels below this link, is in an unusual state and you might have to take some action to resolve it. For example, the system might be awaiting a response from an endpoint. In this case, either the response will be received (in which case you need take no action and the runtime information will be updated to "OK") or the reliable messaging destination has stopped acknowledging messages (in which case you have to take some action to resolve the failed sequence).
	**Error**	There is a definite error that you must take some action to resolve, either here or (if there is a link) in one of the runtime panels below this link.

Note that for troubleshooting purposes you only have to follow links to the sub-panels if states other than "OK" are displayed.

Message stores
This page displays the collection of reliable messaging storage managers for the current scope.

Inbound sequences
This page displays the collection of inbound sequences for the current scope. Each inbound sequence is used to receive messages that have been transmitted reliably.

Outbound sequences
This page displays the collection of outbound sequences for the current scope. Outbound sequences are used to transmit messages reliably from the local application to the remote endpoint. Each sequence has a unique identifier.

Message store collection

This page displays the collection of reliable messaging storage managers for the current scope.

To view this page in the console, click one of the paths to this panel. For example **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Additional Properties] Reliable messaging state** > **Runtime** > **Message store**.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

The WS-ReliableMessaging runtime panels are available at many different scopes within the administrative console. For more information, see “WS-ReliableMessaging - administrative console panels” on page 3127.

The following icons are displayed here and on several other reliable messaging runtime panels:

	**OK**	Everything here, and (if there is a link) in all runtime panels below this link, is running normally.
	**Warning**	Something here, or (if there is a link) in one of the runtime panels below this link, is in an unusual state and you might have to take some action to resolve it. For example, the system might be awaiting a response from an endpoint. In this case, either the response will be received (in which case you need take no action and the runtime information will be updated to "OK") or the reliable messaging destination has stopped acknowledging messages (in which case you have to take some action to resolve the failed sequence).
	**Error**	There is a definite error that you must take some action to resolve, either here or (if there is a link) in one of the runtime panels below this link.

Note that for troubleshooting purposes you only have to follow links to the sub-panels if states other than "OK" are displayed.

Message store type
For the managed qualities of service, the messages are written to a messaging engine. For the unmanaged non-persistent quality of service, the messages are stored in memory.

Description
The quality of service being used and the application name.

Details
For in-memory stores the only possible value is "Running". For messages stored by a messaging engine, the possible values are "Running" or "Messaging engine not contactable", probably because the messaging engine is not running.

Status
The "OK" icon indicates that the message store is running. If the messaging engine is not contactable, the "Error" icon is displayed.

Outbound sequence collection

This page displays the collection of outbound sequences for the current scope. Outbound sequences are used to transmit messages reliably from the local application to the remote endpoint. Each sequence has a unique identifier.

To view this page in the console, click one of the paths to this panel. For example **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Additional Properties] Reliable messaging state** > **Runtime** > **Outbound sequences**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

The WS-ReliableMessaging runtime panels are available at many different scopes within the administrative console. For more information, see “WS-ReliableMessaging - administrative console panels” on page 3127.

The following icons are displayed here and on several other reliable messaging runtime panels:

	**OK**	Everything here, and (if there is a link) in all runtime panels below this link, is running normally.
	**Warning**	Something here, or (if there is a link) in one of the runtime panels below this link, is in an unusual state and you might have to take some action to resolve it. For example, the system might be awaiting a response from an endpoint. In this case, either the response will be received (in which case you need take no action and the runtime information will be updated to "OK") or the reliable messaging destination has stopped acknowledging messages (in which case you have to take some action to resolve the failed sequence).
	**Error**	There is a definite error that you must take some action to resolve, either here or (if there is a link) in one of the runtime panels below this link.

Note that for troubleshooting purposes you only have to follow links to the sub-panels if states other than "OK" are displayed.

Note:

You might see more sequences than you expect, due to sequence reallocation. If a sequence is reallocated, the original and new sequences are both visible.

Sequence identifier
This URI is the unique identifier for the sequence.

Associated application
The application that created the sequence.

Target endpoint URI
The destination to which messages are transmitted.

Message depth
The count of messages, held by the reliable messaging layer, that have not yet been transferred.

Messages sent
The total count of messages sent by the application for this sequence.

Details
The current state of the sequence. "Establishing" indicates that the sequence is awaiting a CreateSequenceResponse message from the reliable messaging destination; "Active" indicates that the sequence has been established; "Cannot contact the remote endpoint" indicates that the sequence has been established but the reliable messaging destination has stopped acknowledging messages; "Sequence closing" indicates that the sequence is closing and will accept no new messages; "Sequence closed" indicates that the sequence has been closed and will accept no new messages; "Sequence terminating" indicates that the sequence is terminating and will accept no new messages; "The inbound side has lost state in a terminate" indicates that the sequence has terminated with unacknowledged messages outstanding; "The sequence has timed out" indicates that the sequence has timed out.

Status
The icon indicates "OK", "Warning" or "Error" as previously described on this page. A more precise indication of the sequence state is given in the "Details" column.

Buttons

Export unsent messages	Export the messages from the selected sequences to compressed files. If you select any sequences that have no messages to export, a warning or error message is displayed.

Close sequence	Close the selected sequences and send a CloseSequence message to indicate that the sequence is complete and will not be sending any further messages. The *close* protocol does not delete the resources for the sequence, so you can still access any undispatched or unsent messages. If you are using Version 1.0 of the WS-ReliableMessaging specification (which does not support this option) an error message is displayed. For more information about the reliable messaging *close* protocol, see WS-ReliableMessaging: supported specifications and standards.
Terminate sequence	Close the selected sequences and send a TerminateSequence message to indicate that the sequence is complete and will not be sending any further messages. The *terminate* protocol deletes all resources for the sequence. For more information about the reliable messaging *terminate* protocol, see WS-ReliableMessaging: supported specifications and standards. **Attention:** Terminate sequences only if necessary. Refer to the description of the **Delete sequence** button for more information.
Delete sequence	Delete the selected sequences and all their messages, without sending a TerminateSequence message. **Attention:** Delete or terminate sequences only if necessary. If you delete or terminate an active sequence, the resulting messaging behavior is unpredictable and can cause loss of messages. If you are not sure whether you can safely delete or terminate a sequence, do not delete or terminate it; the system automatically deletes sequences that have been inactive for 12 hours.

Outbound sequences settings

This page displays the collection of outbound sequences for the current scope. Outbound sequences are used to transmit messages reliably from the local application to the remote endpoint. Each sequence has a unique identifier.

To view this page in the console, click one of the paths to this panel. For example **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Additional Properties] Reliable messaging state** > **Runtime** > **Outbound sequences** > ***outbound_sequence_name***.

The WS-ReliableMessaging runtime panels are available at many different scopes within the administrative console. For more information, see “WS-ReliableMessaging - administrative console panels” on page 3127.

Runtime tab: Runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General properties

Sequence identifier

This URI is the unique identifier for the sequence.

Required No
Data type Text

Runtime identifier
The identifier that is used within the application server runtime environment.

Required No
Data type Text

Associated application
The application that created the sequence.

Required No
Data type Text

WS-Addressing namespace
The WS-Addressing namespace that is associated with the sequence.

Required No
Data type Text

WS-ReliableMessaging namespace
The namespace that is defined by the version of the WS-ReliableMessaging specification used by the sequence.

Required No
Data type Text

Target endpoint URI
The destination to which messages are transmitted.

Required No
Data type Text

Reply to address
The WS-Addressing replyTo address that is used for WS-ReliableMessaging protocol messages.

Required No
Data type Text

Acknowledgement address
The address used for WS-ReliableMessaging acknowledgements.

Required No
Data type Text

Message depth
The count of messages, held by the reliable messaging layer, that have not yet been transferred.

Required No
Data type Text

Messages sent
The total count of messages sent by the application for this sequence.

Required	No
Data type	Text

Outbound message collection

The messages on the outbound sequence.

To view this page in the console, click one of the paths to this panel. For example **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Additional Properties] Reliable messaging state** > **Runtime** > **Outbound sequences** > ***outbound_sequence_name*** > **[Additional properties] Messages**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

The WS-ReliableMessaging runtime panels are available at many different scopes within the administrative console. For more information, see “WS-ReliableMessaging - administrative console panels” on page 3127.

Message number
The index number of the message in the sequence.

State The two possible states are "Sendable" (indicating that it is expected to be sent soon) and "Awaiting sequence initialization".

Buttons

Refresh	Refresh the list of items.
Delete	Delete the selected items.

Message settings

The details of an individual message.

The WS-ReliableMessaging runtime panels are available at many different scopes within the administrative console. For more information, see “WS-ReliableMessaging - administrative console panels” on page 3127. At each scope, this panel is available for both inbound and outbound sequences. For example:

- **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Additional Properties] Reliable messaging state** > **Runtime** > **Inbound sequences** > ***inbound_sequence_name*** > **[Additional properties] Messages** > ***message_number***
- **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Additional Properties] Reliable messaging state** > **Runtime** > **Outbound sequences** > ***outbound_sequence_name*** > **[Additional properties] Messages** > ***message_number***

Runtime tab: Runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General properties

Message number
The index number of the message in the sequence.

Required	No
Data type	Text

Message contents
The contents of the message.

Required	No
Data type	Custom

Inbound sequence collection

This page displays the collection of inbound sequences for the current scope. Each inbound sequence is used to receive messages that have been transmitted reliably.

To view this page in the console, click one of the paths to this panel. For example **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Additional Properties] Reliable messaging state** > **Runtime** > **Inbound sequences**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

The WS-ReliableMessaging runtime panels are available at many different scopes within the administrative console. For more information, see “WS-ReliableMessaging - administrative console panels” on page 3127.

The following icons are displayed here and on several other reliable messaging runtime panels:

	**OK**	Everything here, and (if there is a link) in all runtime panels below this link, is running normally.
	**Warning**	Something here, or (if there is a link) in one of the runtime panels below this link, is in an unusual state and you might have to take some action to resolve it. For example, the system might be awaiting a response from an endpoint. In this case, either the response will be received (in which case you need take no action and the runtime information will be updated to "OK") or the reliable messaging destination has stopped acknowledging messages (in which case you have to take some action to resolve the failed sequence).
	**Error**	There is a definite error that you must take some action to resolve, either here or (if there is a link) in one of the runtime panels below this link.

Note that for troubleshooting purposes you only have to follow links to the sub-panels if states other than "OK" are displayed.

Note:

You might see more sequences than you expect, due to sequence reallocation. If a sequence is reallocated, the original and new sequences are both visible.

Sequence identifier
This URI is the unique identifier for the sequence.

Associated application
The application that is receiving messages from the sequence.

Message depth
The count of messages, held by the reliable messaging layer, that have not yet been transferred.

Messages received
The total count of application messages received for the sequence since its creation.

Details
The current state of the sequence. "Connected" indicates that the sequence has been established; "Awaiting redelivery of a missing msg." indicates that there is a gap in the sequence; "Closed" indicates that the sequence has been closed; "Failed due to missing message" indicates that the sequence terminated with a gap in the sequence.

Status
The icon indicates "OK", "Warning" or "Error" as previously described on this page. A more precise indication of the sequence state is given in the "Details" column.

Buttons

Dispatch messages to application	Dispatch the messages on the selected sequences to the associated applications.
Export undispatched messages	Export the messages from the selected sequences to compressed files. If you select any sequences that have no messages to export, a warning or error message is displayed.
Close sequence	Close the selected sequences and send a CloseSequence message to indicate that the sequence is complete and will not be sending any further messages. The *close* protocol does not delete the resources for the sequence, so you can still access any undispatched or unsent messages. If you are using Version 1.0 of the WS-ReliableMessaging specification (which does not support this option) an error message is displayed. For more information about the reliable messaging *close* protocol, see WS-ReliableMessaging: supported specifications and standards.
Terminate sequence	Close the selected sequences and send a TerminateSequence message to indicate that the sequence is complete and will not be sending any further messages. The *terminate* protocol deletes all resources for the sequence. For more information about the reliable messaging *terminate* protocol, see WS-ReliableMessaging: supported specifications and standards. **Attention:** Terminate sequences only if necessary. Refer to the description of the **Delete sequence** button for more information.

Delete sequence and messages	Delete the selected sequences and all their messages. Use this in cases where the remote endpoint is unable to respond to any reliable messaging protocol messages, and therefore the sequence cannot be closed or terminated. **Attention:** Delete or terminate sequences only if necessary. If you delete or terminate an active sequence, the resulting messaging behavior is unpredictable and can cause loss of messages. If you are not sure whether you can safely delete or terminate a sequence, do not delete or terminate it; the system automatically deletes sequences that have been inactive for 12 hours.

Inbound sequences settings

This page displays the collection of inbound sequences for the current scope. Each inbound sequence is used to receive messages that have been transmitted reliably.

To view this page in the console, click one of the paths to this panel. For example **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Additional Properties] Reliable messaging state** > **Runtime** > **Inbound sequences** > ***inbound_sequence_name***.

The WS-ReliableMessaging runtime panels are available at many different scopes within the administrative console. For more information, see “WS-ReliableMessaging - administrative console panels” on page 3127.

Runtime tab: Runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General properties

Sequence identifier

This URI is the unique identifier for the sequence.

Required	No
Data type	Text

Associated application

The application that is receiving messages from the sequence.

Required	No
Data type	Text

WS-Addressing namespace

The WS-Addressing namespace that is associated with the sequence.

Required	No
Data type	Text

WS-ReliableMessaging namespace

The namespace that is defined by the version of the WS-ReliableMessaging specification used by the sequence.

Required	No

Data type Text

Target endpoint URI
The destination to which messages are transmitted.

Required No
Data type Text

Reply to address
The WS-Addressing replyTo address that is used for WS-ReliableMessaging protocol messages.

Required No
Data type Text

Acknowledgement address
The address used for WS-ReliableMessaging acknowledgements.

Required No
Data type Text

Message depth
The count of messages, held by the reliable messaging layer, that have not yet been transferred.

Required No
Data type Text

Highest inbound message number
The highest message number that has been received within the sequence.

Required No
Data type Text

In-order delivery
When this parameter is true, messages are dispatched to the application in the order that they were assigned to the sequence.

Required No
Data type Text

Inbound message collection
The messages on the inbound sequence.

To view this page in the console, click one of the paths to this panel. For example **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Additional Properties] Reliable messaging state** > **Runtime** > **Inbound sequences** > ***inbound_sequence_name*** > **[Additional properties] Messages**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

The WS-ReliableMessaging runtime panels are available at many different scopes within the administrative console. For more information, see “WS-ReliableMessaging - administrative console panels” on page 3127.

Message number
The index number of the message in the sequence.

State The only possible state is "Awaiting dispatch to application".

Buttons

Refresh	Refresh the list of items.
Delete	Delete the selected items.

Acknowledgement state collection
The ranges of message sequence numbers received from the WS-ReliableMessaging source. If more than one range is displayed, this indicates a gap in the messages received. If "In-order delivery" is selected for the sequence manager, messages with a sequence number greater than the lowest gap cannot be delivered to the application until the gap is closed.

To view this page in the console, click one of the paths to this panel. For example **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Additional Properties] Reliable messaging state** > **Runtime** > **Inbound sequences** > ***inbound_sequence_name*** > **[Additional properties] Ack state**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

The WS-ReliableMessaging runtime panels are available at many different scopes within the administrative console. For more information, see “WS-ReliableMessaging - administrative console panels” on page 3127.

Low end of range
The message number for the lowest numbered message in this range.

High end of range
The message number for the highest numbered message in this range.

Buttons

Refresh	Refresh the list of items.

Export messages settings
Export the messages from the selected sequences to ZIP files.

The WS-ReliableMessaging runtime panels are available at many different scopes within the administrative console. For more information, see “WS-ReliableMessaging - administrative console panels” on page 3127. At each scope, this panel is available for both inbound and outbound sequences. For example:

- **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Additional Properties] Reliable messaging state** > **Runtime** > **Inbound sequences** > **[Button bar] Export undispatched messages**

- **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Additional Properties] Reliable messaging state** > **Runtime** > **Outbound sequences** > **[Button bar] Export unsent messages**

General properties

Export messages
A list of the exported messages ZIP files that have been created. To save these ZIP files to your file system, click each file individually then use your web browser "save file" option.

WS-Notification Service client settings

Use this page to manage policy sets and bindings or to access additional information for this WS-Notification service client.

To view this page in the console, click the following path:

Services > **Service clients** > ***ws-notification_service_client_name***

This page shows the policy set and binding configuration information for a single Version 7.0 WS-Notification service client (that is, a service client using the JAX-WS rather than a JAX-RPC WS-Notification implementation), and also gives you links to the associated service integration bus and WS-Notification service.

Note: The same policy set and binding configuration information can also be viewed and modified through the “Service client policy sets and bindings” page, which gives an upper-level view of all service clients associated with a particular WS-Notification service. Through the “Service client policy sets and bindings” page, you can assign a policy set or binding to a specific service client, or to all clients for the service. To view the “Service client policy sets and bindings” page for a given WS-Notification service, click one of the following paths:

- **Service integration** > **WS-Notification** > **Services** > ***service_name*** > **[Additional properties] Outbound request policy sets and bindings**
- **Service integration** > **Buses** > ***bus_name*** > **[Services] WS-Notification services** > ***service_name*** > **[Additional properties] Outbound request policy sets and bindings**

Configuration tab: Configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Service client
Specifies the name of the service client that is displayed.

Additional Properties

Service integration bus
The system integration bus hosting this WS-Notification service web service client.

WS-Notification service
The WS-Notification service hosting this client.

Policy Set Attachments

This section allows you to attach a policy set to the WS-Notification service client. You can complete the attachment by providing system-specific configuration when you assign the appropriate binding.

For more information about the policy set attachment options, see “Service client settings” on page 2646.

Note: For WS-Notification service clients, policy set attachments are not supported at the endpoint (port) or operation level. Therefore, endpoints or operations are not selectable, and they are shown as inheriting any policy set or binding that is attached to the service client.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

About policy set bindings

In this version of the product there are two types of bindings, application-specific bindings and general bindings.

Application specific binding

You can create application-specific bindings only at a policy set attachment point. These bindings are specific to and constrained to the characteristics of the defined policy. Application specific bindings are capable of providing configuration for advanced policy requirements, such as multiple signatures; however, these bindings are only reusable within an application. Furthermore, application-specific bindings have very limited reuse across policy sets.

When you create an application-specific binding for a policy set attachment, the binding begins in a completely unconfigured state. You must add each policy, such as WS-Security or HTTP transport, that you want to override the default binding and fully configure the bindings for each policy that you have added. For WS-Security policy, some high level configuration attributes such as TokenConsumer, TokenGenerator, SigningInfo, or EncryptionInfo might be obtained from the default bindings if they are not configured in the application-specific bindings.

For service providers, you can only create application-specific bindings by selecting **Assign Binding > New Application Specific Binding** for service provider resources that have an attached policy set. See service providers policy sets and bindings collection. Similarly, for service clients, you can only create application-specific bindings by selecting **Assign Binding > New Application Specific Binding** for service client resources that have an attached policy set. See service client policy set and bindings collection.

General bindings

These bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust service attachments. Though general bindings are highly reusable, they are however not able to provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings:

- General provider policy set bindings
- General client policy set bindings

You can create general provider policy set bindings by accessing **Services > Policy sets > General provider policy set bindings** > **New** in the general provider policy sets panel or by accessing **Services > Policy sets > General client policy set bindings** > **New** in the general client policy set and bindings panel. See “Defining and managing service client or provider bindings” on page 2685. General provider policy set bindings might also be used for trust service attachments.

Buttons

Attach Client Policy Set	View a list of policy sets available for attachment to the selected WS-Notification service client. To attach the policy set to the selected service client, select a policy set from the drop-down list. To close the list, click **Attach Client Policy Set**.
Detach Client Policy Set	Detach a policy set from a selected WS-Notification service client. After the policy set is detached, if there is no policy set attached at the upper level (that is, at the level of the WS-Notification service), the Attached Client Policy Set column displays `None` and the Binding column displays `Not Applicable`. If there is a policy set attached at the level of the WS-Notification service, the Attached Client Policy Set column displays *`policy_set_name`*`(inherited)` for all endpoints and operations. Similarly, for endpoints and operations, the binding name is displayed with `(inherited)` after it.
Assign Binding	Select from a list of available bindings for the selected policy set attachment. All the bindings are listed along with the following options: • Default • New Application Specific Binding For more information about these options, see “Service client settings” on page 2646. To close the drop-down list, click Assign Binding.

Chapter 35. Administering web services - RESTful services

You can use Java™ API for RESTful Web Services (JAX-RS) to develop services that follow Representational State Transfer (REST) principles. RESTful services are based on manipulating resources. Resources can contain static or dynamically updated data. By identifying the resources in your application, you can make the service more useful and easier to develop.

Planning JAX-RS web applications

Planning to use JAX-RS to enable RESTful services

By using the Java API for RESTful Web Services (JAX-RS) API, application developers can quickly develop RESTful applications. When planning to use JAX-RS to enable RESTful services, consider how to best implement the capabilities and characteristics of a RESTful application with JAX-RS.

Before you begin

Read the overview of JAX-RS information to learn about REST services and the advantages of using JAX-RS to build RESTful services.

About this task

JAX-RS is a programming model that provides a mechanism for developing services that follow Representational State Transfer (REST) principles. Using JAX-RS, development of RESTful services is simplified.

JAX-RS is a Java API for developing REST applications quickly. While JAX-RS provides a faster way for developing web applications than servlets, the primary goal of JAX-RS is to build RESTful services. JAX-RS 1.0 defines a server-side component API to build REST applications. IBM JAX-RS provides an implementation of the JAX-RS (JSR 311) specification.

By using JAX-RS technology, REST applications are simpler to develop, simpler to consume, and simpler to scale when compared to other types of distributed systems. Many popular and widely used Internet services have successfully provided RESTful APIs to their applications. Third parties have used various REST APIs to build their own businesses and applications.

Due to the simple consumption of RESTful services, you can write clients in many languages on different platforms. Most languages require no third-party libraries as long as there is a method to use an HTTP connection. Because of the pervasiveness of web browsers, the most prevalent clients are typically web browsers. For example, many Web 2.0 properties use a JavaScript framework such as Dojo toolkit for developing a client in a browser in conjunction with a RESTful server-side application that provides the data for the client.

Procedure

1. Review existing business and middleware applications in your environment to determine which services you want to implement as REST services.
2. Define the resources in your RESTful applications.
3. Determine the URL patterns, operations, and media type formats to use for each resource.
   a. Define the URI patterns for resources in RESTful applications.
   b. Define the client capabilities for RESTful applications using HTTP methods .
   c. Define the HTTP headers and response codes for RESTful applications using HTTP methods.

Results

You have a design plan for using JAX-RS to implementing REST services.

Defining the resources in RESTful applications

You can use Java API for RESTful Web Services (JAX-RS) to develop services that follow Representational State Transfer (REST) principles. RESTful services are based on manipulating resources. Resources can contain static or dynamically updated data. By identifying the resources in your application, you can make the service more useful and easier to develop.

Before you begin

After you have identified the application that you want to expose as a RESTFUL service, you must first define the resources for your RESTful application. When defining the resources for your application, consider the type of data do you want to expose. Perhaps you already have a relational database that contains information that you want to expose to users using REST technology. Do you already have a set of Java classes defined for accessing that data?

For example, consider the case of an application defined to support a book store. This application currently has a database with several tables that define the various items in the collection of books and the inventory of each book. In this example, there are a number of ways to represent the data in the database in a RESTful application. One approach is to consider each table as an individual resource, so that each of the verbs in the RESTful request maps to the actions that the database supports on that table such as select, insert, update, delete. This example is a simple approach to creating a RESTful application. This approach using the book store example is also used in the documentation that describes defining URL patterns for resources, resource methods, HTTP headers and response codes, media types, and parameters for request representations to resources

In support of this database for the book store application, there might already be existing code that is responsible for accessing the database and retrieving the data from each table. Even though the rows in each of the tables logically represents each resource, the accessor classes are used to define the resources. The implementing JAX-RS applications documentation provides more details on how these classes are incorporated into your JAX-RS application.

Alternately, you might have more static content that does not reside in a database that you want to distribute as resources. Whether it is a collection of documents in various formats or a resource-based facade for other remote systems, using JAX-RS, you can distribute content from multiple sources.

About this task

Resources are the basic building block of a RESTful service. Examples of a resource from an online book store application include a book, an order from a store, and a collection of users.

Resources are addressable by URLs and HTTP methods can perform operations on resources. Resources can have multiple representations using different formats such as XML and JSON. You can use HTTP headers and parameters to pass additional information that is relevant to the request and response.

With JAX-RS, you can annotate existing or new Plain Old Java objects (POJO) with JAX-RS specific annotations. JAX-RS annotated resource classes and the annotated methods are invoked depending on the URI patterns. You can use the annotated resource classes after these resource classes are added to the list of resources returned by the overridden methods in the JAX-RS application class.

Procedure

1. Identify the types of resources in the application.
2. (optional) Identify existing Java classes that you can use as resource classes.

3. Create new Java classes for resources that do not have an existing Java class.

Results

You have defined the content that you want to expose as a collection of resources in your application.

What to do next

Based on the resources that you have defined, read about defining URL patterns for resources, resource methods, HTTP headers and response codes, media types, and parameters for request representations to resources to learn more about additional steps you can take to define the resources for your JAX-RS application.

Defining the URI patterns for resources in RESTful applications

Representational State Transfer (REST) services are based on manipulating resources. Resources for RESTful services are addressable, and URLs are the primary way of achieving addressability in REST.

Before you begin

Identify the resources in the application that you want to expose as a RESTful service.

About this task

URLs are used to specify the location of a resource. Interaction between the server and client is based on issuing HTTP operations to URLs. Defining URL patterns is important because URLs often have a long lifetime so that clients can directly address a resource long after the resource is initially discovered.

URLs are typically used when you enter addresses to web browsers, such as `http://www.ibm.com/` or `http://www.example.com/bookstore/books/ISBN123`. Although URLs are not required to be understandable by users, RESTful services that provide logical URLs in understandable patterns enable client application developers to work efficiently.

RESTful clients use URLs to manipulate resources. Each resource must have its own unique URL. Some URL patterns have a collection path with a unique identifier appended. For example, you can use `http://www.example.com/bookstore/books` as the collection resource URL, `http://www.example.com/bookstore/books/ISBN123` as a unique book resource URL, and you can use `http://www.example.com/bookstore/books/ISBN123/authors` to retrieve a collection resource describing `ISBN123` authors.

The application developer must carefully consider the granularity of URLs because it can affect usage of the application and performance. For example, you can include the author information of a book as part of the book resource or you can define the author information as a unique resource with its own URL that is referenced in the book resource. Depending on the reuse of resources, it might be more efficient to define a separate resource for the author information that is referenced in a hyperlink of the book resource for cases when the author writes a different book.

After an initial URL is given to a client, subsequent related requests are discoverable by parsing the current resource. In the book example, a GET request to `http://www.example.com/bookstore/books/` retrieves a list of book URLs that can include `http://www.example.com/bookstore/books/ISBN123`.

Because systems rely on resources being available, URLs typically have longevity. Because HTTP has built-in status codes for redirection, such as the 301 moved permanently code and the 307 temporarily redirected code, users and clients with caches often reuse previously discovered URLs first. You can additionally consider including a version identifier in the URL pattern, such as `http://www.example.com/bookstore/v2/books/ISBN123`. Like the planning involved to define an interface using Java code, be sure to carefully choose your URL patterns because of expected longevity.

In Java API for RESTful Web Services (JAX-RS), you must add @Path annotations to the Java class files or the Java methods to define the relative URL of the resource. You can use JAX-RS subresource locators and subresource methods to define resources. Use parameters, such as the path parameter or matrix parameter, in the URL to identify the resource.

The value in the @Path annotation defines the relative part of the full URL to your resource. The base URL is derived from the domain, port, application module context root, and any URL pattern mappings in the web.xml file of the application module. For example, if the domain is `www.example.com`, the port is `9060`, the module context root is `example`, the servlet URL pattern is `store/*`, and the value of the @Path annotation is `/bookstore/books`. The full URL is: `http://www.example.com:9060/example/store/bookstore/books`.

Procedure

1. Identify the types of resources in the application. Suppose that you have two types of resources, a BooksCollection and an individual Book object which have the following class definitions:

```
public class BooksCollection {
    public BooksCollection() {
        /* no argument constructor */
    }

}

public class Book {
    public Book(String ISBN) {
        /* This constructor has an argument that will be annotated with a JAX-RS annotation.
         See the JAX-RS specification for information on valid constructors. */
    }
}
```

   As defined in the JAX-RS specification, by default, resource instances are created per request. For the JAX-RS runtime environment to create a resource instance, you must have either a constructor with no argument or a constructor with only JAX-RS annotated parameters present.

2. Add a @javax.ws.rs.Path annotation to each resource class. For each @javax.ws.rs.Path annotation, set the value as the part of the URL after the base URL of the application.

```
/*
 * BooksCollection.java
 * This Java class represents the books collection URL at /bookstore/books.
 */
@javax.ws.rs.Path("/bookstore/books/")
public class BooksCollection {

}
```

   After completing the application, you can use the resource by visiting `http://<host_name>:<port>/<context_root>/<servlet_path>/bookstore/books`. For this URL, specify the context root value as the part of the URL after the context module. Specify the servlet path as any URL patterns in the web.xml file, if it exists.

3. (optional) Determine if a resource needs to use part of the URL as a parameter. If a resource needs to use part of the URL as a parameter, such as an identifier, you can use the @javax.ws.rs.Path annotation with a regular expression. You can then add a @javax.ws.rs.PathParam annotation in either the resource constructor or the resource method.

```
/*
 * Book.java represents individual books.
  */
@javax.ws.rs.Path("/bookstore/books/{bookID}")
public class Book {
   public Book(@javax.ws.rs.PathParam("bookID") String ISBN) {

   }
}
```

   When an HTTP request is made to `http://<host_name>:<port>/<context_root>/<servlet_path>/bookstore/books/ISBN_number`, a Book instance is created with *ISBN_number* passed in to the ISBN parameter of the constructor.

For more information about other possible parameters, read about defining parameters for requests to resources in RESTful applications.

4. Create the javax.ws.rs.core.Application subclass to define to the JAX-RS runtime environment which classes are part of the JAX-RS application. The resource classes are returned in the getClasses() method; for example:

```
public class BookApplication extends javax.ws.rs.core.Application {
    public Set<Class<?>> getClasses() {
        Set<Class<?>> classes = new HashSet<Class<?>>();
        classes.add(BooksCollection.class);
        classes.add(Book.class);
        return classes;
    }
}
```

By defining the javax.ws.rs.core.Application subclass, classes returned from its methods are registered to the JAX-RS runtime environment. When configuring the web.xml file, you must specify the javax.ws.rs.core.Application subclass as a parameter to the servlet or filter. For more information, read about configuring the web.xml file for JAX-RS applications.

Results

You have created a URL to identify your resources for your RESTful service. By considering issues with URL patterns early in the application design, the RESTful service increases its usability and value over an extended time.

What to do next

The resource at the defined URL exists. However, the resource does not yet have any methods to handle HTTP method actions such as GET, POST, PUT, or DELETE. See the defining resource methods for RESTful applications to learn more about defining capabilities of resources using supported HTTP methods.

Defining resource methods for RESTful applications

Individual resources can define their capabilities using supported HTTP methods. In Representational State Transfer (REST) services, the supported methods are GET, PUT, DELETE, and POST. All operations are typically conducted by using one of the predefined HTTP methods with a resource.

Before you begin

Understand the predefined HTTP methods and their known attributes. Some HTTP methods are meant to be safe, meaning that issuing the request does not change the resource, or idempotent, meaning that multiple invocations of the operation do not change the result. While HTTP methods are defined to have certain attributes, the service implementation follows the definitions. See the HTTP method definitions information to learn more about the common set of methods for HTTP.

About this task

Clients use HTTP methods to perform certain operations. Unlike other distributed systems where unique interfaces are defined by each system, RESTful systems based on HTTP mainly rely on predefined methods. The four most common methods are GET, PUT, DELETE, and POST. Resources are not required to permit all HTTP methods for all clients.

The HTTP GET method retrieves a resource representation. It is safe and idempotent. Repeated GET requests do not change any resources.

The HTTP PUT method is often used to update resources or to create a new entity at a known URL. When a resource must be updated or created, an HTTP PUT method is issued at the resource URL with the new resource data as the request entity, also known as the message body. The HTTP PUT method is

idempotent so multiple identical PUT requests with the same entity to the same URL yields the same result as if only one PUT request was issued. This method assumes that no other relevant requests were made.

The HTTP DELETE method removes a resource at a given URL. It is also idempotent.

The HTTP POST method is often used when creating a resource in a collection when the final resource URL is not known. For instance, an administrator issues a POST request to a `/users` collection resource that creates a user with a unique ID such as `1234567890`. The unique ID is then used as part of the URL path to describe the new user resource, such as `/users/1234567790`. It is not safe and is not idempotent. In this case, the multiple POST requests to the `/users` collection can continue creating a new unique ID and adding this new ID to the users collection even if the user has the same information.

Because most RESTful services use well-known HTTP methods that provide expected results, you can more easily create clients. RESTful service developers can take advantage of the expected behaviors of HTTP methods. Resource methods can also use parameters, such as path parameters, query parameters, or matrix parameters to identify the resource. Read about defining the use of parameters for request representations to resources to learn more.

(optional) If you have a sub-resource method and a sub-resource locator method that have an `@Path` annotation with the same value in the same resource class, the sub-resource locator is not considered when determining the method to invoke by default. This is in compliance with the JAX-RS specification.

Use the `wink.searchPolicyContinuedSearch` property with a value of `true` to modify this behavior. This results in sub-resource locators being used if no sub-resource methods match the request.

To enable the property, include a properties file in the `WEB-INF` directory of the module that has the `wink.searchPolicyContinuedSearch` property and value specified. In the `web.xml` file of the application module, include an `init-param` element with the `propertiesLocation` value for the `param-name` element. The `param-value` element specifies the location of the properties file, for example, `WEB-INF/my_wink.properties`.

The following example illustrates the `web.xml` file:

```
<servlet>
    ...
    ...
    <init-param>
        <param-name>propertiesLocation</param-name>
        <param-value>/WEB-INF/my_wink.properties</param-value>
    </init-param>
</servlet>
```

The following example illustrates the `WEB-INF/my_wink.properties` properties file:

```
wink.searchPolicyContinuedSearch=true
```

Procedure

1. Identify the types of resources in the application.

   For each resource class, identify an existing method or create a method that you want to invoke for each supported HTTP method. Methods that respond to HTTP requests are also known as resource methods. For each resource method in the resource class, annotate the Java method with a single JAX-RS HTTP method annotation such as @javax.ws.rs.GET, @javax.ws.rs.POST, @javax.ws.rs.DELETE or @javax.ws.rs.PUT. For example, if an HTTP GET method is supported by the BooksCollection class, then you can create and annotate a method like the following snippet:

```
@javax.ws.rs.Path("/bookstore/books/")
public class BooksCollection {
    @javax.ws.rs.GET
    public String getBooksCollection() {
        String str = /* Construct a String representation of the resource. */
        return str;
    }
}
```

When issuing an HTTP GET request to `http://<host_name>:<port>/<context_root>/<servlet_path>/bookstore/books` URL using a web browser or another HTTP client, the previous getBooksCollection() method is invoked.

2. Ensure that the resource supports the required HTTP methods.

   Each resource typically has multiple resource methods; for example:

```
@javax.ws.rs.Path("/bookstore/books/{bookID}")
public class Book {
    /* This is a database key. */
    private String ISBN;

    public Book(@javax.ws.rs.PathParam("bookID") String ISBN) {
        this.ISBN = ISBN;
    }

    @javax.ws.rs.GET
    public String retrieveSpecificBookInformation() {
        /* This code retrieves a book resource based on the ISBN key. */
    }

    @javax.ws.rs.PUT
    public String updateBookInformation(String updatedBookInfo) {
        /* This code updates the book resource based on ISBN key and the entity (message body) sent
         in the request that is stored in updatedBookInfo. */
    }

    @javax.ws.rs.DELETE
    public void removeBook() {
        /* This code deletes a book resource based on ISBN key. */
    }
}
```

   When issuing an HTTP GET request to the `http://<host_name>:<port>/<context_root>/<servlet_path>/bookstore/books/<isbn_number>` URL using a web browser or another HTTP client, the retrieveSpecificBookInformation() method is invoked. Sending an HTTP PUT request to the same URL invokes the updateBookInformation method and any content in the request message body is passed as the value of the `updatedBookInfo` object. Finally, sending an HTTP DELETE request to the same URL invokes the removeBook() method.

   Note: According to the JAX-RS specification, you must not put multiple HTTP method annotations, such as @javax.ws.rs.POST or @javax.ws.rs.PUT on the same resource method Because HTTP methods have uniquely defined semantics, do not use a resource method for multiple HTTP methods.

Results

You have defined valid operations for the resources.

Defining the HTTP headers and response codes for RESTful applications

HTTP headers and status codes are useful to help intermediary and client programs understand information about requests and responses for applications. HTTP headers contain metadata information. HTTP status codes provide status information about the response.

Before you begin

See the HTTP 1.1 specification to become familiar with HTTP headers and HTTP status codes.

About this task

HTTP headers contain metadata information such as security authentication information, the user agent that is used, and cache control metadata. Standard HTTP headers are defined in the HTTP specification; however, you can use custom HTTP headers, if necessary.

You can read HTTP headers from the request and set the headers in the response. There are a set of common request and response headers, but there are also unique request and unique response headers. JAX-RS provides the HttpHeaders injectable interface and the @HeaderParam parameter annotation for reading HTTP headers. If a javax.ws.rs.core.Response object is returned from a resource method, you can set HTTP headers on the response. Also, you can set HTTP headers when an entity is written using the MessageBodyWriter interface.

You can set HTTP response status codes to help client programs understand the response. While responses can contain an error code in XML or other format, client programs can quickly and more easily understand an HTTP response status code. The HTTP specification defines several status codes that are typically understood by clients.

Procedure

- To read a specific request header, add a @javax.ws.rs.HeaderParam annotated parameter.

```
@javax.ws.rs.Path("/bookstore/books/{bookID}")
public class Book {
    @javax.ws.rs.GET
    public String retrieveSpecificBookInformation(@javax.ws.rs.HeaderParam("User-Agent") String theUserAgent) {
        /* The book ID was sent in a HTTP request header with the name "bookID". */
    }
}
```

- To read any request header, use the @javax.ws.rs.core.Context javax.ws.rs.core.HttpHeaders injected object.

```
@javax.ws.rs.Path("/bookstore/books/{bookID}")
public class Book {
    @javax.ws.rs.GET
    public String retrieveSpecificBookInformation(@javax.ws.rs.core.Context HttpHeaders requestHeaders) {
        /* Call methods on "requestHeaders" to get any request header sent by the client. */
        List<String> bookIdValues = requestHeaders.getRequestHeader("User-Agent");
    }
}
```

- To set a response status code or header, return a javax.ws.rs.core.Response object and build the response with the appropriate status code and headers.

```
@javax.ws.rs.Path("/bookstore/books/{bookID}") public class Book {
    @javax.ws.rs.GET public javax.ws.rs.core.Response retrieveSpecificBookInformation() {
        return Response.status(200).header("responseHeaderName", "responseHeaderValue").header("anotherResponseHeaderName", "foo").build();
    }
}
```

Results

You have used HTTP headers to read request headers and set response status codes and headers for JAX-RS web applications.

Defining media types for resources in RESTful applications

Resources are represented by multiple formats. XML, JavaScript Object Notation (JSON), Atom, binary formats such as PNG, JPEG, GIF, plain text, and proprietary formats are used to represent resources. Representational State Transfer (REST) provides the flexibility to represent a single resource in multiple formats.

Before you begin

Define the resources in the JAX-RS web application.

About this task

Resources have representations. A resource representation is the content in the HTTP message that is sent to, or returned from the resource using the URI. Each representation that a resource supports has a corresponding media type. For example, if a resource is going to return content formatted as XML, you can use `application/xml` as the associated media type in the HTTP message.

Depending on the requirements of your application, resources can return representations in a preferred single format or in multiple formats. For example, resources that are accessed using JavaScript clients might prefer JSON representations because JSON is easy to consume.

JAX-RS provides @Consumes and @Produces annotations to declare the media types that are acceptable for a resource method to read and write.

JAX-RS also maps Java types to and from resource representations using entity providers. A `MessageBodyReader` entity provider reads a request entity and deserializes the request entity into a Java type. A `MessageBodyWriter` entity provider serializes from a Java type into a response entity.

Table 271. Standard entity providers and basic Java types. This table includes the standard entity providers and basic Java types that are included in the JAX-RS runtime environment, along with the corresponding supported content types.

Java type	MessageBodyReader	MessageBodyWriter	Supported Content types
byte[]	X	X	*/*
java.io.InputStream	X	X	*/*
java.io.Reader	X	X	*/*
java.lang.String	X	X	*/*
java.io.File	X	X	*/*
javax.activation.DataSource	X	X	*/*
javax.xml.transform.Source	X	X	text/xml, application/xml, application/*+xml
javax.ws.rs.core.MultivaluedMap	X	X	application/x-www-form-urlencoded
JAXB types	X	X	text/xml, application/xml, application/*+xml
javax.ws.rs.core.StreamingOutput		X	*/*

If a `String` value is used as the request entity parameter, the `MessageBodyReader` entity provider deserializes the request body into a new `String`. If a JAXB type is used as the return type on a resource method, the MessageBodyWriter serializes the Java Architecture for XML Binding (JAXB) object into a response body.

If you need a custom mapping from a Java type to a specific representation, see the information for using an application-defined entity provider.

If your client can handle multiple formats and you want the server to determine the best resource representation to return, read about using content negotiation in JAX-RS applications to serve multiple content types.

The specifications for XML, JSON, and Atom provide details regarding the formats of resource representations for applications. See the specifications to learn more about the formats of resource representations.

Procedure

1. Determine the resource representation format such as XML, JSON, or ATOM to use for either the request or the response.
2. Add the @Consumes and @Produces annotations appropriately to the resource method.
3. If the resource needs to read the content of the request, add a request entity parameter to the resource method. The request entity parameter is a single Java parameter on the method that does not have an annotation.

4. If the resource method returns content in the response, return a Java object that is writable by a JAX-RS entity provider. This Java object is mapped to the response entity in the HTTP response. The returned object must be a JAX-RS supported Java type or wrapped in a javax.ws.rs.core.Response or javax.ws.rs.core.GenericEntity type.

Results

You have mapped the request entities to the resource method entity parameter and any response objects that are returned are mapped to the response entity for the resource representation.

Example

The following example illustrates defining XML as the resource representation for a RESTful bookstore application.

1. Identify the resource methods that you want to read the request entity or return a response entity.

   In the retrieveSpecificBookInformation method example that follows, there is no request entity that is read. However, there is a response object that is returned. This object wraps a JAXB object that contains the entity information. Adding the @Produces annotation on the resource method with a media type of `application/xml` indicates that the resource method always returns an XML representation with a media type of `application/xml`.

   Clients that have an Accept HTTP request header value compatible with the `application/xml` media type invoke the method correctly.

   Clients that do not have an Accept HTTP header value compatible with the `application/xml` media type automatically receive a `406 Not Acceptable` response status which indicates that the server cannot produce an acceptable response.

   The following example identifies the resource methods that read the request entity or return a response entity:

```
/*
 * Book.java
 * This class represents individual books. The @Produces annotation specifies a media type of application/xml.
 */
@Path("/bookstore/books/{bookID}")
public class Book {
  @GET
  @Produces("application/xml")
  public javax.ws.rs.core.Response retrieveSpecificBookInformation(@PathParam("bookID") String theBookID,
   @Context javax.ws.rs.core.HttpHeaders headers) {
   /* ... */
   return
    Response.ok(/* JAXB object to represent response body entity */).expires(/* Expires response header value*/).header("CustomHeaderName", "CustomHeaderValue").build();
   }
   @PUT
   public String updateBookInformation(@PathParam("bookID") String theBookID, String theRequestEntity,
    @javax.ws.rs.HeaderParam("Content-Length") String contentLengthHeader) { /* ... */ }

   @DELETE
   public void removeBook(@PathParam("bookID") String theBookID) { /* ... */ }
}
```

2. Identify the resource methods that need to consume the request information.

   In the following snippet, the PUT method on the book resource accepts the request entity content if a media type of `text/plain` is sent, as defined in the @Consumes annotation. This method returns content with a `text/plain` representation as specified in the @Produces annotations.

   If a client does not send a message with a Content-Type value of `text/plain`, then the PUT resource method is not invoked. If `Content-Type: application/xml` is sent in the HTTP request headers, the `updateBookInformation` Java method is not be called.

   The DELETE method neither reads a request entity nor returns a response entity; therefore, it does not require either an @Consumes or an @Produces annotation.

   The following example identifies the resource methods that consume the request information:

```
/*
 * Book.java
 * This class represents represent individual books with custom headers.
 */
@Path("/bookstore/books/{bookID}")
public class Book {
  @GET
  @Produces("application/xml")
  public javax.ws.rs.core.Response retrieveSpecificBookInformation(@PathParam("bookID") String theBookID, @Context javax.ws.rs.core.HttpHeaders headers) {
```

```
    /* ... */
    return Response.ok(/* JAXB object to represent response body entity */).expires(/* Expires response header value).header("CustomHeaderName", "CustomHeaderValue").build();
  }
  @PUT
  @Consumes("text/plain")
  @Produces("text/plain")
  public String updateBookInformation(@PathParam("bookID") String theBookID, String theRequestEntity, @javax.ws.rs.HeaderParam("Content-Length") String contentLengthHeader) {
    /* ... */
    String responseEntity = /* a plain text representation */;
    return responseEntity;
  }

  @DELETE
  public void removeBook(@PathParam("bookID") String theBookID) { /* ... */ }
}
```

What to do next

See the JAX-RS specification for a list of all the standard media formats that are supported for representations.

Advanced users might consider defining custom mappings of Java types to representations or using content negotiation for clients to negotiate preferred resource representations. To learn more about these options, see the using custom defined entity formats information or the serving multiple content types with content negotiation information.

Defining parameters for request representations to resources in RESTful applications

Parameters are used to pass and add additional information to a request. You can use parameters as part of the URL or in the headers. Path parameters, matrix parameters, query parameters, header parameters, and cookie parameters are useful for passing in additional information to a request.

About this task

Multiple parameters types exist. Java API for RESTful Web Services (JAX-RS) enables easy access to all the types of parameters using annotated injected parameters.

You can use any basic Java primitive type including java.lang.String as parameters, as well as Java types with a constructor that uses a single String or a valueOf(String) static method. Additionally, you can use `List`, `SortedSet`, and `Set` interfaces where the generic type is one of the previously mentioned types, such as a Set when a parameter can have multiple values. If you need to parse requests, then use String as the parameter type to enable you to complete basic inspection and customization of error path responses.

JAX-RS provides the following annotations to use on resource method parameters to specify that the resource method can be invoked with correct parameter values.

javax.ws.rs.PathParam annotation

Path parameters are part of the URL. For example, the URL can include `/collection/{item}`, where `{item}` is a path parameter that identifies the item in the collection. Because path parameters are part of the URL, they are essential in identifying the request.

If parts of the URL are parameters, you can use a @javax.ws.rs.PathParam annotated parameter; for example:

```
@javax.ws.rs.Path("/bookstore/books/{bookId}")
public class BooksCollection {
    @javax.ws.rs.GET
    public String getSpecificBookInfo(@javax.ws.rs.PathParam("bookId") String theBookId) {
        /* theBookId would contain the next path segment after /bookstore/books/  */
    }
}
```

In this example, requests to `/bookstore/books/12345` assigns the value of `12345` to the `theBookId` variable.

javax.ws.rs.MatrixParam annotation

Matrix parameters are part of the URL. For example, if the URL includes the path segment, `/collection;itemID=itemIDValue`, the matrix parameter name is `itemID` and `itemIDValue` is the value.

You can read matrix parameters with a @javax.ws.rs.MatrixParam annotated parameter; for example:

```
@javax.ws.rs.Path("/bookstore/books")
public class BooksCollection {
    @javax.ws.rs.GET
    public String getBookCollectionInfo(@javax.ws.rs.MatrixParam("page") int page, @javax.ws.rs.MatrixParam("filter") String filter) {
        /* This statement uses the page and filter parameters. */
    }
}
```

In this example, requests to`/bookstore/books;page=25;filter=test` invoke the `getBookCollectionInfo` parameter so that the value for the `page` variable is set to `25` and the value for `filter` variable is set to `test`.

javax.ws.rs.QueryParam annotation

Query parameters are appended to the URL after a "?" with name-value pairs. For instance, if the URL is `http://example.com/collection?itemID=itemIDValue`, the query parameter name is `itemID` and `itemIDValue` is the value. Query parameters are often used when filtering or paging through HTTP GET requests.

You can read query parameters with a @javax.ws.rs.QueryParam annotated parameter; for example:

```
@javax.ws.rs.Path("/bookstore/books")
public class BooksCollection {
    @javax.ws.rs.GET
    public String getBookCollectionInfo(@javax.ws.rs.QueryParam("page") int page, @javax.ws.rs.QueryParam("filter") String filter) {
        /* This statement uses the page and filter parameters. */
    }
}
```

In this example, requests to`/bookstore/books;page=25;filter=test` invoke the `getBookCollectionInfo` parameter so that the value for the `page` variable is set to `25` and the value for `filter` variable is set to `test`.

javax.ws.rs.HeaderParam annotation

Header parameters are HTTP headers. While there are pre-defined HTTP headers, you can also use custom headers. Headers often contain control metadata information for the client, intermediary, or server.

If a HTTP request header must be read, use the @javax.ws.rs.HeaderParam annotation; for example:

```
@javax.ws.rs.Path("/bookstore/books/")
public class BooksCollection {
    @javax.ws.rs.GET
    public String getBookCollectionInfo(@javax.ws.rs.HeaderParam("Range") String rangeValue) {
        /* The rangeValue variable contains the value of the HTTP request header "Range" */
    }
}
```

In this example, requests to `/bookstore/books/` with a `Range` HTTP request header value of `bytes=0-499` invokes the method with `bytes=0-499` as the value for the `rangeValue` variable.

javax.ws.rs.CookieParam annotation

Cookie parameters are special HTTP headers. While cookies are associated with storing session identification or stateful data that is not accepted as RESTful, cookies can contain stateless information.

If an HTTP cookie is sent, such as `mycustomid=customvalue123`, you can retrieve the value of the `mycustomid` variable using the following example:

```
@javax.ws.rs.Path("/bookstore/books/")
public class BooksCollection {
    @javax.ws.rs.GET
```

```
    public String getBookCollectionInfo(@javax.ws.rs.CookieParam("mycustomid") String mycustomid) {
        /* The cookie value is passed to the mycustomid variable. */
    }
}
```

javax.ws.rs.FormParam annotation

Form parameters are used when submitting a HTML form from a browser with a media type of `application/x-www-form-urlencoded`. The form parameters and values are encoded in the request message body in the form like the following: `firstParameter=firstValue &secondParameter=secondValue`. The javax.ws.rs.FormParam annotation enables easy access to individual form parameter values.

If a form is submitted and the entity value is `firstName=Bob&lastName=Smith`, you can retrieve the values of the form parameters using the following example:

```
@javax.ws.rs.Path("/customer")
public class Custommer {
    @javax.ws.rs.POST
    public String postCustomerInfo(@javax.ws.rs.FormParam("firstName") String firstName, @javax.ws.rs.FormParam("lastName") String lastName) {
        /* firstName would be "Bob" and secondName would be "Smith" */
    }
}
```

Note: You can either use a single unannotated parameter to represent the message body or use multiple FormParam annotated parameters, but not both. Because the FormParam requires the request message body to be read and the message body is represented as a byte stream, the message body cannot be read again. The following code is not valid:

```
@javax.ws.rs.Path("/bookstore/books")
public class BooksCollection {
    @javax.ws.rs.POST
    public String postSpecificBookInfo(@javax.ws.rs.FormParam("bookId") String theBookId, String theRequestEntity) {
        /* This code is invalid.  Can only use FormParam or a request entity parameter like "String theRequestEntity" and not both */
    }
}
```

Choose one of the following ways to define variables to read parameters.

Procedure

- Add a parameter to the resource method by using an appropriate JAX-RS parameter annotation on the method to identify the type of parameter. You can read multiple types of parameters from a request; for example:

```
@javax.ws.rs.Path("/bookstore/books/")
public class BooksCollection {
    @javax.ws.rs.GET
    public String getBookCollectionInfo(@javax.ws.rs.QueryParam("page") int page, @javax.ws.rs.QueryParam("filter") String filter) {
        /* This statement uses the page and filter parameters. */
    }
}
```

  Issuing an HTTP GET request using a web browser or other HTTP client, such as `http://<host_name>:<port>/<context_root>/<servlet_path>/bookstore/books?page=10&filter=FilterValue`, invokes the getBookCollectionInfo() method with the page set to 10 and filter set to `FilterValue`.

- Add the parameter annotation on the fields, JavaBeans properties, and constructor arguments; for example:

```
@javax.ws.rs.Path("/bookstore/books/")
public class BooksCollection {
    @javax.ws.rs.QueryParam("page") int page;

    String filter;

    @javax.ws.rs.QueryParam("filter")
    public void setFilter(String filter) {
        this.filter = filter;
    }

    @javax.ws.rs.GET
    public String getBookCollectionInfo() {
        /* This statement uses the page and filter parameters. */
    }
}
```

Issuing an HTTP GET request using a web browser or other HTTP client, such as `http://<host_name>:<port>/<context_root>/<servlet_path>/bookstore/books?page=10&filter=FilterValue`, also invokes the getBookCollectionInfo() method with the page set to 10 and filter set to `FilterValue`.

Results

Your resource methods are defined so that they can be invoked with appropriate parameter values.

Example

Defining exception mappers for resource exceptions and errors

Java API for RESTful Web Services (JAX-RS) applications can produce exceptions and errors. The default behavior is to use the exception handling functionality of application container such as JavaServer Pages (JSP) error pages. However, you can customize the error handling and send specific responses back when an exception or error occurs.

About this task

JAX-RS resource methods, like any Java method, can throw checked and unchecked exceptions. By default, an unchecked runtime exception or error occurs in the container again. A checked exception is wrapped in a `ServletException` for resources running in the web container. Therefore, a developer can use error handling facilities such as JSP error pages to handle exceptions thrown from a JAX-RS application.

JAX-RS introduced the exception, `javax.ws.rs.WebApplicationException`. A developer can specify a specific error class name or `javax.ws.rs.core.Response` object when creating a `WebApplicationException`. When the `WebApplicationException` is thrown, the information included in the exception by way of a status class name or Response object is used to serialize a response.

If you cannot throw the exception, `WebApplicationException`, in your code and you cannot use the error handling facilities in the web container, but you want to use a custom error response, then you can create a customized JAX-RS `javax.ws.rs.ext.ExceptionMapper` class to map exceptions to HTTP error responses.

The following procedure illustrates how to write a custom `ExceptionMapper` class.

Procedure

1. Create a class that implements the `javax.ws.rs.ext.ExceptionMapper` class and annotate the class with the `javax.ws.rs.ext.Provider` annotation. This step assumes that your JAX-RS resource can throw the exception, `MyCustomException`, in its methods. The following example illustrates a simple `ExceptionMapper` class:

```
import javax.ws.rs.core.Response;
import javax.ws.rs.ext.ExceptionMapper;
import javax.ws.rs.ext.Provider;

@Provider
public class CustomExceptionMapper implements ExceptionMapper<MyCustomException> {

    public Response toResponse(MyCustomException exception) {
        return null;
    }

}
```

2. In the `toResponse(MyCustomException)` method, return a `Response` object that contains the customized error response. The following example illustrates a customized `ExceptionMapper.toResponse(MyCustomException)` method:

```
@Provider
public class CustomExceptionMapper implements ExceptionMapper<MyCustomException> {

    public Response toResponse(MyCustomException exception) {
        return Response.status(500).entity("Unfortunately, the application cannot
```

```
            process your request at this time.").type("text/plain").build();
    }

}
```

You can have additional code where you log an error, inspect the exception thrown, or use more complex logic.

3. Package the compiled custom `ExceptionMapper` class with your web application project. If you rely on the annotation scanning capabilities to find all of your JAX-RS classes in your web application, no additional steps are required. However, if you return all of the relevant JAX-RS resource classes and providers in a JAX-RS application subclass method, then you must also add the custom `ExceptionMapper` class to the returned set. The following example illustrates a preexisting `javax.ws.rs.core.Application` subclass:

```
import java.util.HashSet;
import java.util.Set;

import javax.ws.rs.core.Application;

public class MyApplication extends Application {

    @Override
    public Set<Class<?>> getClasses() {
        Set<Class<?>> classes = new HashSet<Class<?>>();
        classes.add(CustomExceptionMapper.class);
        /* add your additional JAX-RS classes here */
        return classes;
    }
}
```

When exceptions occur in your JAX-RS resource methods, you can customize the HTTP error response so that a user cannot see a stack trace or potentially confidential data. Use an `ExceptionMapper` or the exception handling functionality in the web container to give more helpful responses if the application is not behaving correctly.

Results

You have written a custom `ExceptionMapper` to handle exceptions in your JAX-RS web application.

Deploying JAX-RS web applications

After you assemble your Java API for RESTful Web Services (JAX-RS) web application, you can deploy the web application archive (WAR) package or the enterprise archive (EAR) package onto the application server.

Before you begin

To deploy a JAX-RS web application, you need a WAR package or EAR package that is configured and enabled for RESTful services.

About this task

Every web application must have a context root for the web application to deploy successfully. A context root for each Web module is defined in the application deployment descriptor during application assembly or during application deployment. The context root is combined with the defined servlet mapping from the WAR file to compose the full URL that users type to access the servlet. The context root for each deployed web application must be unique on the server. The context root can also be empty. For instance, if a Web application used a context root of `sample/application/`, the web application request URL begins with `http://<hostname>:<port>/sample/application/`.

The URL pattern of a servlet is appended to the context root of the Web application. For example, if the context root is `sample/application/` and the servlet URL mapping is `rest/api/*`, the base URI for the JAX-RS web application is `http://<hostname>:<port>/sample/application/rest/api`.

Procedure

Deploy the JAX-RS web application WAR package or EAR package onto the application server. Read about installing enterprise application files to learn more about deploying web applications.

Results

The JAX-RS web application is deployed and ready for your business use.

Deployment of a Java API for RESTful Web Services (JAX-RS) web application is successful if you can access the application by typing a Uniform Resource Locator (URL) in a browser or if you can access the application by following a link. If you cannot access your application, follow these steps to eliminate some common errors that can occur during deployment.

Note:

Use the following tips to resolve common errors during deployment of JAX-RS web applications.

An HTTP 404 Not Found error message is sent back to the client in the server response.

To resolve this problem, take the following actions:

- Verify that the root resource classes are annotated with a @javax.ws.rs.Path annotation and that value in the annotation is correct. Root resource classes without a @Path annotation are not registered with the JAX-RS runtime. To learn more, see the defining the URI patterns for resources in RESTful applications information.
- Verify that the root resource class is added to the set of classes returned from the getClasses() method for the subclasses of the javax.ws.rs.core.Application class. Classes not registered in the subclasses of the javax.ws.rs.core.Application class are not recognized by the JAX-RS runtime environment. To learn more, see the defining the URI patterns for resources in RESTful applications information.
- Verify that the web.xml configuration is correct with the expected URL patterns. For additional details, see the configuring the web.xml file for JAX-RS servlets and filters information.
- Verify that the URL that is being used is correct and includes the context root. If you are using a servlet, the servlet URL pattern is a part of the final URL. Using a filter might be more suitable in your web application. For additional details, see the configuring the web.xml file for JAX-RS servlets and filters information.

An HTTP 406 Not Acceptable error message is automatically being sent back to the client in the server response.

To resolve this problem, take the following actions:

- Verify that the Accept HTTP request header in the incoming request is correct. To learn more, see the Implementing content negotiation based on HTTP headers information.
- Verify that the @javax.ws.rs.Produces value on the resource method or resource class is compatible with the incoming Accept HTTP request header. To learn more, see the defining media types for resources in RESTful applications.

An HTTP 415 Unsupported Media Type error message is automatically being sent back to the client in the server response.

To resolve this problem, take the following actions:

- Verify that that the Content-Type HTTP request header in the incoming request is correct and is being sent. To learn more, see the defining media types for resources in RESTful applications.
- Verify that the @javax.ws.rs.Consumes value on the resource method or resource class is compatible with the incoming Content-Type HTTP request header.

An HTTP 204 No Content response status is automatically being sent back to the client in the server response.

To resolve this problem, take the following action:

- If the object returned from a resource method is a null value, then a 204 No Content status response code is sent back from the server runtime automatically.

For information about known problems and their resolution, see the IBM Support page.

IBM Support has documents that can save you time gathering information needed to resolve this problem.

Chapter 36. Administering web services - Security (WS-Security)

The Web Services Security specification defines core facilities for protecting the integrity and confidentiality of a message, and provides mechanisms for associating security-related claims with a message.

Deploying applications that use SAML

After SAML policy sets and bindings have been configured, and SAML tokens created, the SAML token information can be sent from the original login server to other servers using the SAML propagation feature. You can also extract SAML attributes from an existing SAML token and then create additional tokens using the extracted attributes.

About this task

Use the SAML propagation feature of WebSphere Application Server to send SAML token information based on the original login to other servers using a SAML token. Four propagation methods are provided. You can propagate the original SAML token, the SAML token identity and attributes, the WSCredential and WSPrincipal information, or a pre-existing SAML token inserted in the RequestContext.

When SAML is installed on a WebSphere server, you can create SAML attributes using the SAML runtime API. The SAML attributes are added to a CredentialConfig object, which is used to generate a SAML token. The API also provides a function that extracts SAML attributes from an existing SAML token and processes the attributes.

The following topics provide more information about deploying SAML applications.

Propagating SAML tokens

You can use various SAML token propagation methods to include SAML tokens in outbound web services messages.

About this task

A web services client can include two types of tokens in outbound web services messages:

- Original SAML tokens the client received from inbound web services messages.
- New self-issued SAML tokens.

New SAML tokens can be generated using attributes from the original SAML tokens, or using attributes from the WSPrincipal user name in the RunAs Subject. The web services policy configuration determines which SAML tokens will be propagated. You can override the policy configuration by programmatically inserting SAML tokens that you want to propagate into the Axis2 RequestContext object.

Four propagation methods are enabled. This table summarizes the propagation methods and the associated binding options:

Table 272. Propagation methods and associated binding options. Use propagation to include SAML tokens in web services messages.

SAML token propagation method	Binding option	Implementation details
Propagate the original SAML token.	The tokenRequest binding option is set to the value, `propagation`.	Sends the original SAML token from the server where the token was received to other servers using WS-Security.

Table 272. Propagation methods and associated binding options (continued). Use propagation to include SAML tokens in web services messages.

SAML token propagation method	Binding option	Implementation details
Propagate the user security name, unique security name, group IDs, and security realm name.	The tokenRequest binding option is set to the value, `issueByWSCredential`.	Overrides the default system implementation. The self-issued SAML token contains user security name, user unique security name, group IDs, and security realm name that are specified by the WSCredential object in user security context.
Propagate the SAML token identity and attributes.	No binding option is set.	Default system implementation. The server self-generates a new SAML token containing the original SAML attributes, Authentication method, and NameIdentifier or SAML NameID, and sends the new self-generated SAML token to downstream servers using WS-Security. The new SAML token issuer name, issuer signing certificate, and lifetime are determined by the SAML provider configuration properties.
Propagate the WSPrincipal.	The tokenRequest binding option is set to the value, `issueByWSPrincipal`.	Overrides the default system implementation. The self-issued SAML token contains WSPrincipal information in the RunAs subject. The information is stored as NameIdentity or NameID without copying anything from the original SAML token, even if the token exists in the subject.
Programmatically propagate a pre-existing SAML token.	Insert the SAML token that you want to propagate into the RequestContext using the property, `com.ibm.wsspi.wssecurity.core.token.config.WSSConstants.`*`SAMLTOKEN_IN_MESSAGECONTEXT`*.	Overrides all other existing binding options.

Procedure

1. Propagate the original SAML token by setting the tokenRequest binding option to the value, `propagation`, in the bindings.xml file, as shown in the steps. This method sends the original SAML token to other servers using WS-Security. In order for the propagation to succeed, there must be a valid SAML token in the RunAs subject. The server extracts the SAML token from the RunAs subject in the current security context and validates the following conditions. If any of these conditions are invalid, the WS-Security runtime environment does not propagate the SAML token, and the propagation request fails.
   - The SAML token has not expired, and the expiration time is within the time window of the notOnOrAfter value.
   - The ConfirmationMethod setting in the SAML token is the same as the confirmationMethod binding option defined in the token generator configuration.
   - The token ValueType in the SAML token matches the ValueType in the token generator configuration.

   Perform these steps to set the correct value for the tokenRequest binding option. This procedure assumes that a web services client application named JaxWSServicesSamples is deployed, and that the Saml Bearer Client sample binding is attached.
   a. Click **Applications > Application types > WebSphere enterprise Applications > *JaxWSServicesSamples* > Service client policy sets and bindings > *Saml Bearer Client sample* > WS-Security > Authentication and protection**.
   b. Click **gen_saml11token** in the Authentication tokens table.
   c. Click **Callback handler**.
   d. Add the custom property `tokenRequest` and set the property value to `propagation`.
2. To propagate the SAML token identity and attributes using a self-issuing SAML token, modify the outbound tokenGenerator in the bindings.xml file. This method sends the original SAML attributes, NameIdentifier or NameID, and authentication method from the original SAML token to other servers using WS-Security. If there is no SAML token in the subject, the server uses the WSPrincipal, stored as NameIdentifier or NameID, to create a self-issued SAML token. This propagation method is the default system implementation. In this method, the binding option is not set.

The following limitations apply to the bindings.xml file when you are using this propagation method:

- Do not set the tokenRequest binding option in the bindings.xml file.
- Do not set the stsURI binding option in the bindings.xml file, or set the option to this value: `www.websphere.ibm.com/SAML/Issuer/Self`.

3. To propagate the WSPrincipal, modify the bindings.xml file as shown in the steps. Set the tokenRequest binding option to the value, `issueByPrincipal`, in the bindings.xml file. Using this method, the self-issued SAML token is always based on the WSPrincipal even if there is a SAML token in the subject. The new SAML token contains the WSPrincipal user name as the NameId or NameIdentifier. The token does not contain any other attributes in the WSPrincipal or WSCredential objects.

   The following limitation applies to the bindings.xml file when you are using this propagation method:

   - Do not set the stsURI binding option in the bindings.xml file, or set the option to the value, `www.websphere.ibm.com/SAML/Issuer/Self`.

   Perform these steps to set the correct value for the tokenRequest binding option. This procedure assumes that a web services client application named JaxWSServicesSamples is deployed, and that the Saml Bearer Client sample binding is attached.

   a. Click **Applications > Application types > WebSphere enterprise Applications > *JaxWSServicesSamples* > Service client policy sets and bindings > *Saml Bearer Client sample* > WS-Security > Authentication and protection**.

   b. Click **gen_saml11token** in the Authentication tokens table.

   c. Click **Callback handler**.

   d. Add the custom property `tokenRequest` and set the property value to `issueByPrincipal`.

4. To propagate a pre-existing SAML token by inserting SAMLToken in the RequestContext, follow these steps. Use this method to send a SAML token that you created to downstream servers using WS-Security. The propagation is automatically triggered if the WS-Security runtime detects a SAML token in the RequestContext. The pre-existing token overrides any other existing binding options. To use this propagation method, save the existing SAML token in the RequestContext by specifying `com.ibm.wsspi.wssecurity.core.token.config.WSSConstants.`*`SAMLTOKEN_IN_MESSAGECONTEXT`* as the key, as shown in the steps.

   a. Generate a SAML token using the method `SAMLToken samlToken = <token type>`, for example:

```
SAMLToken samlToken = samlFactory.newSAMLToken(cred, reqData, samlIssuerCfg);
```

   b. Save the SAMLToken to the RequestContext, for example:

```
Map requestContext = ((BindingProvider)port).getRequestContext();
   requestContext.put("com.ibm.wsspi.wssecurity.core.token.config.WSSConstants.SAMLTOKEN_IN_MESSAGECONTEXT", samlToken );
```

   This propagation option can co-exist with the other propagation methods, and overrides the other methods. If the SAML token in the RequestContext is expired, or the token expiration time is less than current time plus the cache cushion, the WS-Security runtime environment ignores the SAML token, and uses one of the other three propagation methods that is configured in the bindings.xml file. To avoid using the other three propagation methods, add the following binding option to the custom properties under callback handler in the TokenGenerator configuration: `failOverToTokenRequest = false`.

5. To propagate a user's group memberships, unique security name, and realm name contained in the `com.ibm.websphere.security.cred.WSCredential` object, modify the `bindings.xml` file as shown in the steps. Set the `tokenRequest` binding option to the value, `issueByWSCredential`, in the `bindings.xml` file. Using this method, the self-issued SAML token is always based on the `WSCredential` even if there is a SAML token in the subject.

   The new SAML 1.1 token contains the following assertions:

   - The `NameIdentifier` element contains the `SecurityName` value from `WSCredential` with the `NameQualifier` element set to the realm name from `WSCredential`. The `SecurityName` is obtained by calling the `WSCredential.getSecurityName()` method. The realm name is obtained by calling the `WSCredential.getRealmName()` method.

- All attributes have an AttributeNamespace set to com.ibm.websphere.security.cred.WSCredential as the value.
- The GroupIds attribute contains all group names that a user belongs to. The group names are obtained by calling the WSCredential.getGroupIds() method.
- The UniqueSecurityName attribute contains the unique security name, which is obtained by calling the WSCredential.getUniqueSecurityName() method.
- Optionally, you can assert the realm name from WSCredential by adding the includeRealmName=true custom property in the callback handler.

The new SAML 2.0 token contains the following assertions:

- The NameID element contains the SecurityName value from WSCredential with the NameQualifier element set to the realm name from WSCredential. The SecurityName is obtained by calling the WSCredential.getSecurityName() method. The realm name is obtained by calling the WSCredential.getRealmName() method.
- All attributes have a NameFormat set to com.ibm.websphere.security.cred.WSCredential as the value.
- The GroupIds attribute contains all group names that a user belongs to. The group names are obtained by calling the WSCredential.getGroupIds() method.
- The UniqueSecurityName attribute contains the unique security name, which is obtained by calling the WSCredential.getUniqueSecurityName() method.
- Optionally, you can assert the realm name from WSCredential by adding the includeRealmName=true custom property in the callback handler.

The following limitation applies to the bindings.xml file when you use the propagation method:

- Do not set the stsURI binding option in the bindings.xml file.

Perform these steps to set the correct value for the tokenRequest binding option. This procedure assumes that a Web services client application named JaxWSServicesSamples is deployed, and that the Saml Bearer Client sample binding is attached.

a. Click **Applications > Application types > WebSphere enterprise Applications > *JaxWSServicesSamples* > Service client policy sets and bindings > *Saml Bearer Client sample* > WS-Security > Authentication and protection.**
b. Click **gen_saml11token** in the Authentication tokens table.
c. Click **Callback handler**.
d. Add the tokenRequest custom property and set the property value to issueByWSCredential.

The following example illustrates the NameIdentifier and Attribute statement from a self-issued SAML 1.1 assertion based on WSCredential.

```
<saml:AttributeStatement>
    <saml:Subject>
        <saml:NameIdentifier NameQualifier="ldap.acme.com:9080">uid=alice,dc=acme,dc=com</saml:NameIdentifier>
        <saml:SubjectConfirmation>
            <saml:ConfirmationMethod>urn:oasis:names:tc:SAML:1.0:cm:bearer</saml:ConfirmationMethod>
        </saml:SubjectConfirmation>
    </saml:Subject>
    <saml:Attribute AttributeName="UniqueSecurityName" AttributeNamespace="com.ibm.websphere.security.cred.WSCredential">
        <saml:AttributeValue>uid=alice,dc=acme,dc=com</saml:AttributeValue>
    </saml:Attribute>
    <saml:Attribute AttributeName="GroupIds" AttributeNamespace="com.ibm.websphere.security.cred.WSCredential">
        <saml:AttributeValue>cn=development,dc=acme,dc=com</saml:AttributeValue>
        <saml:AttributeValue>cn=deployment,dc=acme,dc=com</saml:AttributeValue>
        <saml:AttributeValue>cn=test,dc=acme,dc=com</saml:AttributeValue>
    </saml:Attribute>
</saml:AttributeStatement>
```

The following example illustrates the NameID and Attribute statement from a self-issued SAML 2.0 assertion based on WSCredential.

```
<saml2:AttributeStatement>
    <saml2:Attribute Name="UniqueSecurityName"
           NameFormat="com.ibm.websphere.security.cred.WSCredential">
        <saml2:AttributeValue>uid=alice,dc=acme,dc=com</saml2:AttributeValue>
```

```
    <saml2:Attribute>
    <saml2:Attribute AttributeName="GroupIds"
           NameFormat="com.ibm.websphere.security.cred.WSCredential">
        <saml2:AttributeValue>cn=development,dc=acme,dc=com</saml2:AttributeValue>
        <saml2:AttributeValue>cn=deployment,dc=acme,dc=com</saml2:AttributeValue>
        <saml2:AttributeValue>cn=test,dc=acme,dc=com</saml2:AttributeValue>
    </saml2:Attribute>
</saml2:AttributeStatement>

<saml2:NameID NameQualifier="ldap.acme.com:9060">alice</saml2:NameID>
```

Creating SAML attributes in SAML tokens

Using the SAML runtime API, you can create SAML tokens containing SAML attributes. You can also extract the SAML attributes from an existing SAML token.

About this task

When WebSphere Application Server Version 7.0.0.7 and later is installed, you can create SAML attributes using the SAML token library APIs. The SAML attributes are added to a CredentialConfig object, which is used to generate a SAML token. The API also provides a function that extracts SAML attributes from an existing SAML token and processes the attributes.

To create a SAML token containing SAML attributes, perform the following steps:

Procedure

1. Initialize a com.ibm.wsspi.wssecurity.saml.data.SAMLAttribute object. This creates a SAML attribute based on an address, for example:

```
SAMLAttribute sattribute =
         new SAMLAttribute("urn:oid:2.5.4.20", //Name
       new String[] {" any address"}, //Attribute Values
       null,  /*XML Attributes empty on this example*/
       "urn:oasis:names:tc:SAML:2.0:profiles:attribute:X500", //NameSpace
       "urn:oasis:names:tc:SAML:2.0:attrname-format:uri",  //format
       "Address");
```

2. Use the SAMLTokenFactory to create a CredentialConfig object containing a SAML attribute. This method requires the Java security permisson wssapi.SAMLTokenFactory.newCredentialConfig.
   a. Create a com.ibm.wsspi.wssecurity.saml.config.CredentialConfig object and set a valid principal name.
   b. Create a SAML attribute.
   c. Create a list of SAML attributes and add the SAML attribute to the list.
   d. Add the SAML attribute list to the CredentialConfig object.

   See the following example:

```
SAMLTokenFactory samlFactory =
  SAMLTokenFactory.getInstance("http://docs.oasis-open.org/wss/oasis-wss-saml-token-profile-1.1#SAMLV2.0");//samlTokenType

CredentialConfig credentialConfig = samlFactory.newCredentialConfig();
credentialConfig.setRequesterNameID("any name");

SAMLAttribute sattribute =
         new SAMLAttribute("urn:oid:2.5.4.20", //Name
       new String[] {" any address"}, //Attribute Values
       null,  /*XML Attributes empty on this example*/
       "urn:oasis:names:tc:SAML:2.0:profiles:attribute:X500", //NameSpace
       "urn:oasis:names:tc:SAML:2.0:attrname-format:uri",  //format
       "Address");

ArrayList<SAMLAttribute> al = new ArrayList<SAMLAttribute>();
al.add(sattribute);
credentialConfig.setSAMLAttributes(al);
```

3. Specifying the CredentialConfig as a parameter, use the com.ibm.websphere.wssecurity.wssapi.token.SAMLTokenFactory newSAMLToken method to create a SAML token containing the attributes. This step assumes that a RequesterConfig `reqData` object and a ProviderConfig `samlIssuerCfg` object have already been created. For more information on these objects, read about RequesterConfig and ProviderConfig.

a. Obtain an instance of the SAMLTokenFactory.

b. Create a SAML token using the newSAMLToken method from the SAMLTokenFactory, for example:

```
SAMLTokenFactory samlFactory =
  SAMLTokenFactory.getInstance("http://docs.oasis-open.org/wss/oasis-wss-saml-token-profile-1.1#SAMLV1.1");

SAMLToken aSamlToken = samlFactory.newSAMLToken(credentialConfig, reqData, samlIssuerCfg);
```

4. Optional: Extract SAML attributes from an existing SAML token. This step is useful to extract the SAML attributes from a received SAML token. You can use this step when a SAML assertion is received and the attributes contained in the assertion need to be processed.

   a. Invoke the getSAMLAttributes() method with the token as a parameter to obtain a list of the SAML attributes in the token. This method requires the Java security permission wssapi.SAMLToken.getSAMLAttributes.

   b. Apply an iterator to the list.

   c. Iterate through the list and perform any additional processing required for your application.

   See the following example:

```
List<SAMLAttribute> aList = aSAMLToken.getSAMLAttributes();
java.util.Iterator<SAMLAttribute> i = aList.iterator();

while(i.hasNext()){

   SAMLAttribute anAttribute = i.next();

   //do something with namespace
   String namespace = anAttribute.getAttributeNamespace();

   //do something with name
   String name = anAttribute.getName();

   //do something with friendly name
   String friendlyName = anAttribute.getFriendlyName();

   //process sring attribute values
   String[] stringAttributeValues = anAttribute.getStringAttributeValue();

   //process XML attribute values
   XMLStructure[] xmlAttributeValues = (XMLStructure[]) anAttribute.getXMLAttributeValue();

   }
```

SAML user attributes

A SAML assertion can contain user attributes relating to the principal of the SAML token. A SAML assertion can contain multiple user attributes.

You can include user attributes in the token to communicate the address of the person who is the SAML assertion principal. This example shows a SAML assertion containing a user attribute:

```
<saml:AttributeStatement>
  <saml:Attribute  xmlns:x500=
      "urn:oasis:names:tc:SAML:2.0:profiles:attribute:X500"
    NameFormat=
      "urn:oasis:names:tc:SAML:2.0:attrname-format:uri"
    Name="urn:oid:2.5.4.20"
    FriendlyName="Address">
          <saml:AttributeValue xsi:type="xs:string">
                      11111 Parker Lane, Austin, Texas, 78758
          </saml:AttributeValue>
  </saml:Attribute>
</saml:AttributeStatement>
```

This table describes the parameters used in the assertion:

Parameter	Description
NameFormat	Specifies how the attribute is interpreted.
Name	Indicates the formal name of the attribute.

Parameter	Description
FriendlyName	Provides a user-friendly name for an attribute when the Name parameter is cryptic.
AttributeValue	The value of the user attribute. The value can be a string, or a complex XML type.

Establishing security context for web services clients using SAML security tokens

WebSphere Application Server supports two policy set caller binding configuration options to establish client security context using SAML security tokens in web services SOAP request messages. The two configuration options are mapping SAML tokens to a user entry in a local user repository and, asserting SAML tokens based on a trust relationship.

Before you begin

This task assumes that you are familiar with WebSphere Application Server SAML technology.

About this task

This task describes setting the WebSphere Application Server policy set caller binding configuration option to establish client security context using SAML security tokens in web services SOAP request messages. You can either map SAML tokens to a user entry in a local user repository or assert SAML tokens based on a trust relationship. The second configuration option does not require accessing the local user repository. Instead, the WS-Security runtime environment populates the client security context entirely using the contents of SAML security tokens. This process is based on a trust relationship to the SAML token issuer. If a SAML tokens specifies the sender-vouches subject confirmation method. the process is based on a trust relationship to the message sender.

Procedure

1. Configure a policy set caller binding and select the SAML token type to represent a web services client request.
   a. Click **WebSphere enterprise applications** > ***application_name*** > **Service provider policy sets and bindings** > ***binding_name*** > **WS-Security** > **Callers**.
   b. Click **New** to create the caller configuration.
   c. Specify a **Name**, such as `caller`.
   d. Enter a value for the **Caller identity local part**. For example, `http://docs.oasis-open.org/wss/oasis-wss-saml-token-profile-1.1#SAMLV2.0`, which must match the local part of the `CustomToken` element in the attached WS-Security policy.
   e. Click **Apply** and **Save**.
2. Optional: Map SAML security tokens to a user entry in a local user repository. Mapping to a user entry is the default behavior when you configure a caller binding without specifying a configuration option. Alternatively and optionally, you can select this configuration option explicitly using the following steps:
   a. On the caller binding configuration page, add a Callback handler: `com.ibm.websphere.wssecurity.callbackhandler.SAMLIdAssertionCallbackHandler`.
   b. Add a Callback handler custom property, `crossDomainIdAssertion`, and set its value to `false`.
3. Optional: Assert SAML security tokens based on trust relationship.
   a. On the caller binding configuration page, add a Callback handler: `com.ibm.websphere.wssecurity.callbackhandler.SAMLIdAssertionCallbackHandler`.
   b. Add a Callback handler custom property, `crossDomainIdAssertion`, and set its value to `true`.

Note: In WebSphere Application Server Version 7.0 Fix Pack 7 and later releases, the WS-Security runtime environment takes a SAML token Issuer name to represent the foreign security realm name. WS-Security takes the `NameID` element in the case of SAML 2.0 security tokens or the `NameIdentifier` element in the case of SAML 1.1 security tokens to represent user security name. Alternatively, you can explicitly specify which SAML token attribute to use to represent user security name. Moreover, you can also specify which SAML token attribute to use to represent user group membership. Read about SAML assertions across WebSphere Application Server security domains for a detailed discussion of the SAML token assertion trust model and binding configuration.

Version 8 supports propagating select security context data in SAML tokens. You must set a `tokenRequest` custom property with an `issueByWSCredential` property value in the WS-Security binding configuration of the web services client. Read about propagating SAML tokens for a detailed description of this binding option. When the `crossDomainIdAssertion` property is set to `true` in Version 8, WS-Security checks whether a SAML token contains a SAML Attribute `UniqueSecurityName` with a `NameFormat` element with a value of `com.ibm.websphere.security.cred.WSCredential`. If found, WS-Security uses the `NameQualifier` attribute value of the `NameID` element or `NameIdentifier` element to represent the user security realm name. WS-Security also uses the `UniqueSecurityName` attribute value and the `GroupIds` attribute value to represent a unique user name and group membership. This default behavior is different between Version 7 and Version 8 of the product. You can add a `CallbackHandler` property, `IssuerNameForRealm`, and set its value to `true` to configure Version 8 to preserve the Version 7 behavior. Alternatively, you can add a `CallbackHandler` property, `NameQualifierForRealm`, and set its value to `true` to configure Version 8 to always use the `NameQualifier` attribute to represent the user security realm name.

Results

You have configured a web service to establish a client security context using the SAML security token in the web services SOAP request messages.

Example

The following example illustrates the `NameIdentifier` and `Attribute` elements from a self-issued SAML 1.1 assertion based on `WSCredential`:

```
<saml:AttributeStatement>
    <saml:Subject>
        <saml:NameIdentifier NameQualifier="ldap.example.com:9080">uid=alice,dc=example,dc=com</saml:NameIdentifier>
        <saml:SubjectConfirmation>
            <saml:ConfirmationMethod>urn:oasis:names:tc:SAML:1.0:cm:bearer</saml:ConfirmationMethod>
        </saml:SubjectConfirmation>
    </saml:Subject>
    <saml:Attribute AttributeName="UniqueSecurityName" AttributeNamespace="com.ibm.websphere.security.cred.WSCredential">
        <saml:AttributeValue>uid=alice,dc=example,dc=com</saml:AttributeValue>
    </saml:Attribute>
    <saml:Attribute AttributeName="GroupIds" AttributeNamespace="com.ibm.websphere.security.cred.WSCredential">
        <saml:AttributeValue>cn=development,dc=example,dc=com</saml:AttributeValue>
        <saml:AttributeValue>cn=deployment,dc=example,dc=com</saml:AttributeValue>
        <saml:AttributeValue>cn=test,dc=example,dc=com</saml:AttributeValue>
    </saml:Attribute>
</saml:AttributeStatement>
```

The following example illustrates the `NameID` and `Attribute` elements from a self-issued SAML 2.0 assertion based on `WSCredential`:

```
<saml2:AttributeStatement>
    <saml2:Attribute Name="UniqueSecurityName" NameFormat="com.ibm.websphere.security.cred.WSCredential" />
    <saml2:AttributeValue>uid=alice,dc=example,dc=com</saml2:AttributeValue>
    <saml2:Attribute>
        <saml2:Attribute AttributeName="GroupIds" NameFormat="com.ibm.websphere.security.cred.WSCredential" />
        <saml2:AttributeValue>cn=development,dc=example,dc=com</saml2:AttributeValue>
        <saml2:AttributeValue>cn=deployment,dc=example,dc=com</saml2:AttributeValue>
        <saml2:AttributeValue>cn=test,dc=example,dc=com</saml2:AttributeValue>
```

```
    </saml2:Attribute>
<saml2:AttributeStatement>

<saml2:NameID NameQualifier="ldap.example.com:9060">alice</saml2:NameID>
```

Administering Web Services Security

To secure web services, you must consider a broad set of security requirements, including authentication, authorization, privacy, trust, integrity, confidentiality, secure communications channels, delegation, and auditing across a spectrum of application and business topologies. You can choose to configure Web Services Security for the application level, the server level or the cell level, depending upon your environment and security needs.

Configuring HTTP outbound transport level security with the administrative console

You can configure HTTP outbound transport level security with the administrative console.

Before you begin

This task is one of several ways that you can configure the HTTP outbound transport level security for a web service acting as a client to another web service server. You can also configure the HTTP outbound transport level security with an assembly tool or by using the Java properties. If you do not configure the HTTP outbound transport level security, the web services runtime defers to the Web Services for Java Platform, Enterprise Edition (Java EE) security runtime in the WebSphere product for an effective Secure Sockets Layer (SSL) configuration. If there is no SSL configuration with the Java EE security runtime in the WebSphere product, the Java Secure Socket Extension (JSSE) system properties are used.

About this task

If you choose to configure the HTTP outbound transport level security with the administrative console or an assembly tool, the Web Services Security binding information is modified. You can use the administrative console to configure the web services client security bindings if you have deployed or installed the web services application into WebSphere Application Server. If you have not installed the web services application, you can configure the HTTP SSL configuration with an assembly tool. This task assumes that you have deployed the web services application into the WebSphere product. See the deploying web services applications onto application servers information to learn more about deploying web services.

If you configure the HTTP outbound transport level security using the standard Java properties for JSSE, the properties are configured as system properties. The configuration specified in the binding takes precedence over the Java properties. However, the configurations that are specified by the Java EE security programming model , or that are associated the Dynamic selection , have higher precedence.

See the secure communications using Secure Sockets Layer information to learn more implementing transport level security.

Configure the HTTP outbound transport level security with the following steps provided in this task section.

Procedure

1. Open the administrative console.
2. Click **Applications** > **Enterprise Applications** > *application_instance* > **Manage Modules** > *module_instance* . Under Web Services Security Properties, click **Web Services: Client security bindings**.
3. Under the heading, HTTP SSL Configuration, click **Edit** to access the HTTP SSL configuration panel. Select the **Centrally-managed** radio button so that the system runtime chooses the SSL configuration

that is based on the current context. Select the **Specific to this Web service port** radio button if you want to choose the SSL configuration in the HTTP SSL configuration drop down box.

Results

You have configured the HTTP outbound transport level security for a web service acting as a client to another web service with the administrative console.

HTTP SSL Configuration collection

Use this page to configure transport-level Secure Sockets Layer (SSL) security. You can use this configuration when a web service is a client to another web service.

You can use transport-level security to enable HTTP SSL (or HTTPS). Transport-level security can be enabled or disabled independently from message-level security. Because transport-level security provides minimal security, use message-level security when security is essential to the web service application.

To view this administrative console page, complete the following steps:

1. Click **Applications > Application Types > WebSphere enterprise applications >** ***application_name*** .
2. Click **Manage modules >** ***URI_file_name*** **> Web Services: Client Security Bindings** .
3. Under HTTP SSL Configuration, click **Edit**.

This administrative console page applies only to Java API for XML-based RPC (JAX-RPC) applications.

SSL configuration: Select the **Centrally-managed** radio button so that the system runtime chooses the SSL configuration that is based on the current context. Select the **Specific to this web service port** radio button if you want to choose the SSL configuration in the **HTTP SSL configuration** drop down box.

HTTP SSL configuration: The **HTTP SSL configuration** drop down box lists the SSL configurations used with the HTTP transport for a port. Use this drop down box if you want to select the SSL configuration rather than using the SSL configuration that the runtime automatically selects. To use the drop down box, select the **Specific to the web service port** radio button that is located in the **SSL configuration** field. After you select the radio button, you can click the drop down box to view and select an SSL configuration.

Configuring HTTP outbound transport level security using Java properties

You can configure the HTTP outbound transport level security for a web service using Java properties.

Before you begin

This task is one of three ways that you can configure HTTP outbound transport-level security for a web service that is acting as a client to another web service. You can also configure the HTTP outbound transport level security with the administrative console or an assembly tool. However, you can also use this task to configure the HTTP outbound transport-level security for a web service client.

About this task

If you choose to configure the HTTP outbound transport-level security with the administrative console or an assembly tool, the Web Services Security binding information is modified.

If you configure the HTTP outbound transport-level security using Java properties, the properties are configured as system properties. However, the configuration specified in the binding takes precedence over the Java properties.

You can configure the HTTP outbound transport-level security using WebSphere SSL properties or JSSE SSL properties. However, the WebSphere SSL properties take precedence over the JSSE SSL properties.

Configure the HTTP outbound transport-level security with the following steps provided in this task section.

Procedure

1. Create a property file that includes the following properties:

```
com.ibm.ssl.protocol
com.ibm.ssl.keyStoreType
com.ibm.ssl.keyStore
com.ibm.ssl.keyStorePassword
com.ibm.ssl.trustStoreType
com.ibm.ssl.trustStore
com.ibm.ssl.trustStorePassword
```

2. Set the `com.ibm.webservices.sslConfigURL` Java system property to the absolute path of the created property file. If no WebSphere SSL properties are defined, the JSSE SSL properties are used. Set the JSSE SSL properties as JVM custom properties. See Secure transports with JSSE and JCE programming interfaces for more information about setting the JSSE SSL properties.

Results

You have configured the HTTP outbound transport-level security for a web service acting as a client to another web service.

Configuring HTTP basic authentication for JAX-RPC web services with the administrative console

You can configure HTTP basic authentication for Java API for XML-based RPC (JAX-RPC) web services with the administrative console.

Before you begin

This task is one of three ways that you can configure HTTP basic authentication. You can also configure HTTP basic authentication with an assembly tool or by modifying the HTTP properties programmatically.

If you choose to configure HTTP basic authentication with the administrative console or an assembly tool, the Web Services Security binding information is modified. You can use the administrative console to configure HTTP basic authentication if you have deployed or installed the web services application into WebSphere Application Server. If you have not installed the web services application, then you can configure the security bindings with an assembly tool. This task assumes that you have deployed the web services application into the WebSphere product. To learn more about deploying web services, see the deploying Web services applications onto application servers information.

If you configure HTTP basic authentication programmatically, the properties are configured in the Stub or Call instance. The values set programmatically take precedence over the values defined in the binding.

About this task

The HTTP basic authentication that is discussed in this topic is orthogonal to WS-Security and is distinct from basic authentication that WS-Security supports. WS-Security supports basic authentication token, not HTTP basic authentication.

Configure HTTP basic authentication with the following steps provided in this task section.

Procedure

Open the administrative console.

1. Click **Applications** > **Enterprise Applications** > *application_instance* > **Manage Modules** > *module_instance* > **Web services: Client security bindings**.
2. Click **HTTP Basic Authentication** to access the HTTP basic authentication panel. Enter the values in the HTTP Basic Authentication panel.

Results

You have configured the HTTP basic authentication.

HTTP basic authentication collection

Use this page to specify a user name and password for transport-level basic authentication security for this port. You can use this configuration when a web service is a client to another web service.

You can use transport-level security to enable basic authentication. Transport-level security can be enabled or disabled independently from message-level security. Because transport-level security provides minimal security, use message-level security when security is essential to the web service application.

To view this administrative console page, complete the following steps:

1. Click **Applications > Application Types > WebSphere enterprise applications > *application_name*** .
2. Click **Manage modules > *URI_file_name* > Web Services: Client Security Bindings** .
3. Under HTTP basic authentication, click **Edit**.

This administrative console page applies only to Java API for XML-based RPC (JAX-RPC) applications.

Basic authentication ID:

The user name for the HTTP basic authentication for this port is set in this field.

Use the Basic authentication ID field to specify the user name for the HTTP basic authentication for this port.

Basic authentication password:

The password for the HTTP basic authentication for this port is set in this field.

Use the Basic authentication password field to specify the password for the HTTP basic authentication for this port.

Configuring custom properties to secure web services

You can configure name-value pairs of data, where the name is a property key and the value is a string value that you can use to set internal system configuration properties. Defining a new property enables you to configure a setting beyond that which is available through options in the administrative console.

About this task

The Web Services Security custom properties topic provides the following information about each custom property:

- Provides a detailed description of the property
- States the type of data that is needed to set the property
- Provides a list of possible values
- Lists the default value

Important: Custom properties that you set for the default consumer or default generator bindings take precedence over general custom properties that you set as additional properties. However, custom bindings take precedence over default bindings.

The following steps explain how to set custom properties to secure Web services:

Procedure

- Set custom properties for Java API for XML-based RPC (JAX-RPC) applications. You can set custom properties to secure Web services for JAX-RPC applications in multiple locations within the administrative console. You can set these custom properties for the default consumer, default generator, or both bindings. Also, you can set custom properties as general additional properties. Collectively, the default consumer bindings, the default generator bindings, and the additional properties are referred to as the *default bindings*.
  - **Custom bindings**
    1. Expand **Applications > Application Types**.
    2. Click **WebSphere enterprise applications** > *application_name*.
    3. Under Modules, click **Manage Modules** > *module_name*.
    4. Under Web Services Security Properties, click **Web services: Server security bindings** or **Web services: Client security bindings** > **Edit custom**.
  - **Default consumer bindings**
    1. Expand **Servers > Server types**.
    2. Click **WebSphere applications servers >** *server_name*.
    3. Under Security, click **JAX-WS and JAX-RPC security runtime**.
    4. Under JAX-RPC Default Consumer Bindings, click **Properties**.
  - **Default generator bindings**
    1. Expand **Servers > Server types**.
    2. Click **WebSphere applications servers >** *server_name*.
    3. Under Security, click **JAX-WS and JAX-RPC security runtime**.
    4. Under JAX-RPC Default Generator Bindings, click **Properties**.
  - **Additional properties**
    1. Expand **Servers > Server types**.
    2. Click **WebSphere applications servers >** *server_name*.
    3. Under Security, click **JAX-WS and JAX-RPC security runtime**.
    4. Under Custom properties, click **Custom properties**.

Order of precedence for custom properties with JAX-RPC applications: Custom properties that you set in the WS-Security extension and custom bindings take precedence over custom properties that you set in the default bindings. Custom properties that you set in the WS-Security bindings take precedence over custom properties that you set in the WS-Security extension. Custom properties that you set in the generator or sender and consumer or receiver

bindings take precedence over custom properties that you set in the additional properties.

- Set custom properties for Java API for XML-Based Web Services (JAX-WS) applications. You can set custom properties to secure web services for JAX-WS applications in multiple locations within the administrative console. You can set these custom properties in the custom bindings for an application, in the WS-Security default bindings, or for inbound and outbound messages.
  - **Custom bindings for an application**
    1. Expand **Services > Service clients** or **Services > Service providers**.
    2. Click *service_name* > *binding_name*.
    3. Click **WS-Security**.
    4. Under the Main message security policy bindings heading, click **Custom properties**.
  - **WS-Security default bindings**
    1. Expand **Services > Policy sets** .
    2. Click **General provider policy set bindings** or **General client policy set bindings** > *binding_name* > **WS-Security**.
    3. Under Main Message Security Policy Bindings, click **Custom properties**.
  - **Inbound and outbound custom properties**
    1. Expand **Services > Policy sets**.
    2. Click **Default policy set bindings**.
    3. Under the Policy heading, click **WS-Security**.
    4. Under the Main message security policy bindings heading, click **Custom properties**.

    For more information, see the Inbound and outbound custom properties topic.

  Alternatively, you can set these properties as parameters or inbound binding properties for your JAX-WS application using wsadmin scripting. The following WS-Security policy type property names are used in the setBinding function:
  - application.parameters
  - application.securityinboundbindingconfig.properties
  - application.securityoutboundbindingconfig.properties

  Note: Custom properties for policy set bindings can not be set using the Web Services Security API. The custom properties must be set using the administrative console.

Web services security custom properties

You can configure name-value pairs of data, where the name is a property key and the value is a string value that you can use to set internal system configuration properties. Defining a new property enables you to configure a setting beyond that which is available through options in the administrative console.

Custom properties for Web Services Security can be set in various levels of the application server and for JAX-RPC versus JAX-WS applications. The following list of custom properties provides information on where the custom property is set and how it is used. You can define the following custom properties:

- "Callback handler custom properties for generic security token login modules" on page 3177
- "com.ibm.ws.wssecurity.createSTR" on page 3181
- "com.ibm.wsspi.wssecurity.Caller.assertionLoginConfig" on page 3182
- "com.ibm.wsspi.wssecurity.config.disableWSSIfApplicationSecurityDisabled" on page 3182
- "com.ibm.wsspi.wssecurity.config.gen.checkCacheUsernameTokens" on page 3183
- "com.ibm.wsspi.wssecurity.config.request.setMustUnderstand and com.ibm.wsspi.wssecurity.config.response.forceMustUnderstandEqualsOne" on page 3183

- “com.ibm.wsspi.wssecurity.consumer.timestampRequired” on page 3184
- “com.ibm.wsspi.wssecurity.dsig.inclusiveNamespaces” on page 3185
- “com.ibm.wsspi.wssecurity.token.forwardable” on page 3185
- “com.ibm.wsspi.wssecurity.token.username.addNonce and com.ibm.wsspi.wssecurity.token.username.addTimestamp” on page 3186
- “com.ibm.wsspi.wssecurity.token.username.password.forwardable” on page 3186
- “com.ibm.wsspi.wssecurity.token.username.verifyNonce and com.ibm.wsspi.wssecurity.token.username.verifyTimestamp” on page 3186
- “com.ibm.wsspi.wssecurity.token.UsernameToken.disableUserRegistryCheck” on page 3186
- “com.ibm.wsspi.wssecurity.tokenGenerator.ltpav1.pre.v7” on page 3187

Callback handler custom properties for generic security token login modules

When you configure a generic security token login module, you can specify configuration properties to control how the token is generated or consumed. To configure these custom properties for the callback handler in the administrative console, complete the following steps:

1. Expand **Applications** > **Application Types** and click **WebSphere enterprise applications**.
2. Select an application that contains web services. The application must contain a service provider or a service client.
3. Under the **Web Services Properties** heading, click **Service provider policy sets and bindings** or **Service client policy sets and bindings**.
4. Select a binding. You must have previously attached a policy set and assigned an application-specific binding.
5. Click **WS-Security** in the Policies table.
6. Under the **Main Message Security Policy Bindings** heading, click **Authentication and protection**.
7. Under the **Authentication tokens** heading, click the name of the authentication token.

   Note: You can use the token, which is processed by the generic security token login module, for authentication only. You cannot use the token as a protection token.
8. Under the **Additional Bindings** heading, click **Callback handler**.
9. Under the **Custom Properties** heading, enter the name and value pairs.

The following tables list the custom properties for the callback handler.

Table 273. Callback handler custom properties for both token generator and token consumer bindings.. This table contains the custom property name, its values, and a short description.

Name	Values	Description
`clockSkew`	This custom property does not have a default value.	Use this custom property to specify, in minutes, an adjustment to the times in the self-issued SAML token that the SAMLGenerateLoginModule creates. The clockSkew custom property is set on the Callback handler of the SAML token generator that uses the SAMLGenerateLoginModule class. The value specified for this custom property must be numeric and is specified in minutes. When a value is specified for this custom property, the following time adjustments are made in the self-issued SAML token that the SAMLGenerateLoginModule creates: • The new NotBefore time setting equals the initial NotBefore time setting, minus the amount of time specified for the clockSkew custom property. • The new NotAfter time setting equals the initial NotAfter time setting, plus the amount of time specified for the clockSkew custom property.
`stsURI`	This custom property does not have a default value.	Use this custom property to specify the Security Token Service (STS) address. This custom property is required for the token consumer. However, this custom property is optional for the token generator if the requested token exists in the RunAs Subject and its verification is not required.
`wstrustClientBinding`	This custom property does not have a default value.	Use this custom property to specify the binding name for the WS-Trust client.
`wstrustClientBindingScope`	You can specify an `application` or `domain` value.	Use this custom property to specify the type of bindings that are used for the WS-Trust client. The following conditions apply: • If you specify the `domain` value, general bindings are used. • If you specify the `application` value, custom bindings are used. • If you do not specify a value and application bindings exist, those application bindings are used. • If you do not specify a value and general bindings exist, those general bindings are used. • If neither application or general bindings exist, the default bindings are used. This custom property is optional.
`wstrustClientPolicy`	This custom property does not have a default value.	Use this custom property to specify the policy set name for the WS-Trust client.
`wstrustClientSoapVersion`	You can specify a `1.1` or `1.2` value.	Use this custom property to specify the SOAP message version that the trust client uses to generate the SOAP message. The SOAP message is sent to the Security Token Service (STS). If you do not define this custom property, the generic security token login module uses the SOAP version of the application when it generates the SOAP message for the trust client request. The default value corresponds to the SOAP version that is used by the application client. This custom property is optional.

Table 273. Callback handler custom properties for both token generator and token consumer bindings. (continued). This table contains the custom property name, its values, and a short description.

Name	Values	Description
wstrustClientWSTNamespace	Specify one of the following values: **Trust Version 1.3 (Default)** Specify 1.3 to use Trust Version 1.3 (Default):http://docs.oasis-open.org/ws-sx/ws-trust/200512 **Trust Version 1.2** Specify 1.2 to use Trust Version 1.2:http://schemas.xmlsoap.org/ws/2005/02/trust	Use this custom property to specify which trust client namespace the generic security token login modules uses when it makes the WS-Trust request.
wstrustValidateClientBinding	By default, the value for this custom property is the same value that is specified for the wstrustClientBinding custom property.	Use this custom property to specify the bindings that are used by the WS-Trust Validate request. If you do not specify this custom property, the WS-Trust Validate request uses the same bindings that are used by WS-Trust Issue, which are defined by the wstrustClientBinding custom property.
wstrustValidateClientPolicy	By default, the value for this custom property is the same value that is specified for the wstrustClientPolicy custom property.	Use this custom property to specify the policy sets to use with the WS-Trust Validate request. If you do not specify a value for this custom property, WS-Trust Validate uses the same policy set as WS-Trust Issue, which is defined by the required wstrustClientPolicy custom property.
wstrustIssuer	You can use any string value.	Use this custom property to specify the issuer for the request token. This custom property is optional
wstrustValidateTargetOption	The default value is the WS-Trust Base element extension. You can specify a token value or a base value, which is also the default value.	Use this custom property to specify whether the WS-Trust client passes the validation token to the WS-Trust Security Token Service using the ValidateTarget or the Base element extension. The following conditions apply: • If you do not specify a value for this custom property, the token is wrapped in the Base element extension within the RequestedSecurityToken element. • If you specify the token value, the token is wrapped in the ValidateTarget element within the RequestedSecurityToken element.

Table 274. Callback handler custom properties for token generator bindings only.. This table contains the custom property name, its values, and a short description.

Name	Value	Description
`useRunAsSubject`	You can use a `True` or `False` value. By default, a `True` value is used. This value for this custom property is case sensitive.	Use this custom property to specify whether the generic security token login modules use the token from the RunAs Subject for the outgoing request. By default, the login module uses the validated tokens in the RunAs Subject first. The following conditions apply: • If you set this custom property to a `false` value, the generic security token login module does not use WS-Trust Validate to exchange the token for the outbound request. Instead, it uses WS-Trust Issue to request a token. • If you do not specify this custom property, the generic security token login module attempts to use a token from the RunAs Subject and WS-Trust Validate to exchange the token. • If a token does not exist in the RunAs Subject, the generic security token login module uses WS-Trust Issue and is protected by the trust client policy sets.
`useRunAsSubjectOnly`	You can use a `True` or `False` value. By default, a `False` value is used. This value for this custom property is case sensitive.	Use this custom property to disable or enable WS-Trust Issue in the generic security token login module. If you set this custom property to a `true` value, the generic security token login module uses the token from the RunAs Subject and WS-Trust Validate to exchange the tokens. The generic security token login module does not use WS-Trust Issue to request a token even if WS-Trust Validate fails or it does not find a matching token in the RunAs Subject.
`useToken`	You can use any string value of the ValueType value for the security token.	When you use a security token in a RunAs Subject to validate and exchange tokens for an outbound request, you can use this custom property to specify which token ValueType value in the RunAs Subject to validate and exchange for the requested token. For example, you might have a token with a ValueType value of *Token_1* in the RunAs Subject. However, the ValueType value of *Token_2* is the required token. You can set this custom property to *Token_1* . If you do not define this custom property, the validation token is the token from the RunAs Subject that has the same ValueType value as the required token. This custom property is optional.

Table 274. Callback handler custom properties for token generator bindings only. (continued). This table contains the custom property name, its values, and a short description.

Name	Value	Description
validateUseToken	You can use a True or False value. By default, a True value is used. This value for this custom property is case sensitive.	Use this custom property to specify whether the token generator uses WS-Trust Validate to validate the token from the RunAs Subject. By default, the generic security token login module validates a token from the RunAs Subject against the Security Token Service (STS) before sending the token in the SOAP message to the service provider. If you set this custom property value to false and the generic security token login module finds a matching token from the RunAs Subject, the login module does not invoke WS-Trust Validate to validate the matching token. Instead, it sends the matching token to the downstream service provider without validation.
wstrustIncludeTokenType	You can use a True or False value. By default, a True value is used. This value for this custom property is case sensitive.	Use this custom property to specify whether the WS-Trust RequestedSecurityToken token includes the requested token ValueType value. If you do not specify this custom property, the generic security token login modules includes the requested token type in the WS-Trust RequestedSecurityToken token. This custom property is optional.

Table 275. Callback handler custom properties for token consumer bindings only.. This table contains the custom property name, its values, and a short description.

Name	Value	Description
exchangedTokenType	The valid value for this custom property is the string ValueType value for the token that is supported by the system default login modules.	Use this custom property to specify the new token with the defined ValueType value, which the trust service must return after successful validation. If you do not specify a value for the custom property, the generic security token login module accepts whichever token the trust service returns. This custom property is optional.

com.ibm.ws.wssecurity.createSTR

The com.ibm.ws.wssecurity.createSTR property creates a security token reference to the security token in the SOAP security header when you specify a True value.

You can set this property to True, the com.ibm.ws.wssecurity.createSTR property creates a security token reference to the security token in the SOAP security header. Set this custom property to True when the following conditions exist:

- The referencing mechanism for the token signature is the STR Dereference Transform, http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform
- The SignedParts element for the WS-Security policy contains an XPath value that represents the SecurityTokenReference.

Data type	String
Values	True, False
Default	False

The value for this property is case-insensitive.

com.ibm.wsspi.wssecurity.Caller.assertionLoginConfig

The com.ibm.wsspi.wssecurity.Caller.assertionLoginConfig property, which is configured on the caller part, specifies the name of the JAAS login configuration that is used by Web Services Security to obtain WebSphere Application Server authorization credentials. You must configure this property using an assembly tool such as the Rational Application Developer. For more information, see the "Configuring the caller in consumer security constraints" topic for Rational Application Developer. Within this topic, this custom property is set when you configure identity assertion.

Use this property with WS-Security V1.0 JAX-RPC applications only.

Data type	String
Default	system.DEFAULT

com.ibm.wsspi.wssecurity.config.disableWSSIfApplicationSecurityDisabled

When you set the com.ibm.wsspi.wssecurity.config.disableWSSIfApplicationSecurityDisabled custom property to `true`, Web Services Security does not enforce the configured WS-Security constraints if application security is disabled on the application server. You can use this custom property to debug services in a non-secure environment without needing to remove security constraints from web services applications.

Note: Use this custom property for diagnosis purposes only. Do not use it in a production environment.

Data type	String
Values	true, false
Defaultfalse	false

You can set this custom property as an inbound custom property or an inbound and outbound custom property for the policy set bindings. Complete the following steps in the administrative console to set the custom property:

1. Expand **Services** > **Policy sets**.
2. Click **General provider policy set bindings** or **General client policy set bindings**.
3. Click the *binding_name*.
4. Under the Policy heading, click **WS-Security** > **Custom properties**.

You can also set this custom property as a parameter or as an inbound binding property on your application using wsadmin tooling. The following WS-Security policy-type property names are used in setBinding:

- application.parameters
- application.securityinboundbinding config.properties

com.ibm.wsspi.wssecurity.config.gen.checkCacheUsernameTokens

The com.ibm.wsspi.wssecurity.config.gen.checkCacheUsernameTokens custom property specifies whether to cache UsernameTokens all of the time, which is the default behavior, or cache them as determined by a set of rules. You can configure this custom property for the token generator or as an additional property.

When the com.ibm.wsspi.wssecurity.config.gen.checkCacheUsernameTokens custom property is set to false, UsernameTokens are always cached on client threads. When you set this custom property to true, the web services security run time determines whether UsernameTokens are cached based on the following rules:

- Never cache UsernameTokens if the application is running on an application server.
- Cache UsernameTokens if the token generator for the UsernameToken has the following callback handler configured: com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler.

This custom property applies to the JAX-RPC run time only. Use an assembly tool, such as Rational Application Developer, to set the custom property within the encrypted message part bindings.

Data type	String
Values	true, false
Default	false

com.ibm.wsspi.wssecurity.config.request.setMustUnderstand and com.ibm.wsspi.wssecurity.config.response.forceMustUnderstandEqualsOne

In WebSphere Application Server prior to Version 6.1x, the mustUnderstand=1 attribute in the `<wsse:Security>` tag in the SOAP header on the request from the web services client was hardcoded. It was not possible to configure the mustUnderstand attribute in the SOAP Web Services Security header. In an update to the product, an administrator can configure the attribute using outbound generator custom properties.

You can configure the following outbound generator custom properties for Web Services Security:

com.ibm.wsspi.wssecurity.config.request.setMustUnderstand custom property

The `com.ibm.wsspi.wssecurity.config.request.setMustUnderstand` custom property specifies the mustUnderstand setting in outbound consumer requests. If the value of the property is set to zero (0), no, or false, then the mustUnderstand attribute is not set in the WS-Security header within outbound consumer requests.

Data type	String
Value	Zero (0), no, false
Default	true

In SOAP messages, the default value for the mustUnderstand attribute is zero (0). According to the SOAP specification, if the intended value for the attribute is zero, then the attribute must not be present in the message.

com.ibm.wsspi.wssecurity.config.response.forceMustUnderstandEqualsOne custom property

The `com.ibm.wsspi.wssecurity.config.response.forceMustUnderstandEqualsOne` custom property specifies that the provider should always respond with a `mustUnderstand="1"` attribute in the SOAP security header. If the value is set to one (1), yes, or true, the provider responds with the `mustUnderstand="1"` attribute in the WS-Security header. The default value of the attribute is false.

Data type	String
Value	One (1), yes, or true
Default	false

By default, the response contains the same mustUnderstand attribute as the request. For example, if the inbound request has mustUnderstand="1", the response also includes mustUnderstand="1". If the request does not have a mustUnderstand attribute, the response does not include a mustUnderstand attribute.

For JAX-RPC applications, you can specify both properties in the following locations within the administrative console:

- Click **Servers** > **Server Types** > **WebSphere application servers** > ***server name***. Under Security, click **JAX-WS and JAX-RPC security runtime**. Under JAX-RPC Default Generator Bindings, click **Properties**.
- Click **Servers** > **Server Types** > **WebSphere application servers** > ***server name*** . Under Security, click **JAX-WS and JAX-RPC security runtime**. Under Custom properties, click **Custom properties**.

If you are using an assembly tool with a JAX-RPC WS-Security version 1.0 application, you can set the `com.ibm.wsspi.wssecurity.config.request.setMustUnderstand` custom property on the security request generator extension or binding. You can set the `com.ibm.wsspi.wssecurity.config.response.forceMustUnderstandEqualsOne` custom property on the response generator extension or binding. A setting in the binding takes precedence over a setting in the extension.

If using an assembly tool with a JAX-RPC WS-Security specification draft 13–level application, you can set the `com.ibm.wsspi.wssecurity.config.request.setMustUnderstand` custom property as a parameter on the port qualified name binding. You can set the `com.ibm.wsspi.wssecurity.config.response.forceMustUnderstandEqualsOne` custom property as a parameter on the port component binding.

If using a JAX-WS application , you can set the custom properties as outbound binding properties or parameters on the application using wsadmin scripts. The following property names are used:

- `application.parameters`
- `application.securityoutboundbindingconfig.properties`

However, properties values in the `application.securityoutboundbindingconfig.properties` properties take precedence over properties in application parameters. The follow example shows how to use Jython wsadmin commands to obtain the ID of the policy set attachment for a consumer, then set the `com.ibm.wsspi.wssecurity.config.request.setMustUnderstand` property to false in the outbound binding configuration:

```
AdminTask.getPolicySetAttachments([-applicationName
HelloSvcClientEAR -attachmentType client])

AdminTask.setBinding([-policyType WSSecurity -bindingLocation "[
[application HelloSvcClientEAR] [attachmentId 1490] ]"
-attributes "[[application.securityoutboundbindingconfig.properties_999.name
com.ibm.wsspi.wssecurity.config.request.setMustUnderstand]
[application.securityoutboundbindingconfig.properties_999.value
false]]" -attachmentType client])
```

com.ibm.wsspi.wssecurity.consumer.timestampRequired

The com.ibm.wsspi.wssecurity.consumer.timestampRequired property specifies whether Timestamp is not expected in the security header for the response when the **Include timestamp in security header** setting is selected for the WS-Security policy.

The JAX-WS WS-Security runtime is updated to comply with the OASIS WS-SecurityPolicy 1.2 specification Timestamp Required requirement. If you want to configure an application to not require an inbound time stamp when an outbound time stamp is configured you can add the com.ibm.wsspi.wssecurity.consumer.timestampRequired custom property to your Web Services Security

settings and set that property to `false`. When this property is set to `false`, even if the **Include timestamp in security header** is selected as a setting for the WS-Security policy, a Timestamp is not expected in the security header for a response.

The default value for this property is true.

gotcha: On the custom properties panel, you can set this property as either an inbound or an inbound/outbound custom property. It is not valid as an outbound custom property.

Data type	Boolean
Default	true

com.ibm.wsspi.wssecurity.dsig.inclusiveNamespaces

This custom property, which applies to both the JAX-RPC and JAX-WS applications, specifies whether to disable the inclusive namespace prefix list for XML digital signatures. WebSphere Application Server, by default, includes the prefix in the digital signature for Web Services Security. You can set this custom property to false if you do not want inclusive namespaces set as an element. Some implementations of Web Services Security cannot handle this prefix list. If you experience a signature validation failure when a signed SOAP message is sent and you are using another vendor in your environment, check with your service provider for a possible fix to their implementation before you disable this property.

For JAX-RPC applications, you can set the custom property in the administrative console in the signing information or as a web services security custom property in additional properties or in the default or custom generator bindings. For more information, see the additional properties and generator sections of the Configuring custom properties to secure web services topic. To add the custom property to the signing information, complete the following steps:

1. Click **Applications** > **Enterprise Applications** > ***application_name***.
2. Click **Manage Modules** > ***module_name***.
3. Under Web Services Security Properties, click **Web services: Client security bindings** or **Web services: Server security bindings**.
4. Under Request generator (sender) binding or Response generator (sender) binding, click **Edit custom**.
5. Under Required properties, click **Signing information** > ***signing_information_name*** > **Properties**.
6. Specify the custom property and its value.

For JAX-WS applications, you can configure this custom property in the outbound signing information. To configure the custom property, complete the following steps:

1. Click **Services** > **Service clients** or **Services** > **Service providers**.
2. Click the ***service_name*** > ***binding_name***.
3. Under Policy, click **WS-Security**
4. Under Message Security Policy Bindings, click **Authentication and protection**
5. Under either Request message signature and encryption protection or Response message signature and encryption protection, click the *signature_message_part_reference*. When you click the *signature_message_part_reference* name, you are accessing the configuration for the signed message part binding.
6. Specify the custom property and its value.

com.ibm.wsspi.wssecurity.token.forwardable

When configuring SecurityToken consumer bindings for the JAX-WS programming model, use this custom property to specify whether the receiving token is propagated to other servers. If you specify a value of `true` for this property, you enable this token for propagating to other servers. If you specify a value of

`false` for this property, the token is not propagated to other servers. The default value is `true`, and the value is not case sensitive.

com.ibm.wsspi.wssecurity.token.username.addNonce and com.ibm.wsspi.wssecurity.token.username.addTimestamp

When configuring a username token for the JAX-WS programming model, to protect against replay attacks it is strongly recommended that you add custom properties, com.ibm.wsspi.wssecurity.token.username.addNonce and com.ibm.wsspi.wssecurity.token.username.addTimestamp, to the callback handler configuration for token generation. These custom properties enable and verify the nonce and timestamp for message authentication. The value of the properties must be set to `true`.

com.ibm.wsspi.wssecurity.token.username.password.forwardable

When configuring UsernameToken consumer bindings for the JAX-WS programming model, use this custom property to specify whether the password is propagated along with the UsernameToken to other servers during UsernameToken propagation. If you specify a value of `true` for this property, the password is preserved during propagation. If you specify a value of `false` for this property,the password must be removed prior to UsernameToken propagation. The default value is `true`, and the value is not case sensitive.

com.ibm.wsspi.wssecurity.token.username.verifyNonce and com.ibm.wsspi.wssecurity.token.username.verifyTimestamp

When configuring a username token for the JAX-WS programming model, to protect against replay attacks it is strongly recommended that you add custom properties, com.ibm.wsspi.wssecurity.token.username.verifyNonce and com.ibm.wsspi.wssecurity.token.username.verifyTimestamp, to the callback handler configuration for the token consumer. These custom properties enable and verify the nonce and timestamp for message authentication. The value of the properties must be set to `true`.

com.ibm.wsspi.wssecurity.token.UsernameToken.disableUserRegistryCheck

This propery allows the user registry check to be skipped for identity tokens. This means that the user name associated with the identity token in an identity assertion scenario can pass through the UNTConsumeLoginModule without generating a registry error. Typically an identity token must not contain a password, and there might, or might not be a trust token. For example there might be a blind trust.

This property does not affect any UsernameToken that contains a password. If you need to bypass the registry check for a UsernameToken that contains a password, the UNTConsumeLoginModule that is provided with the product cannot be used. The following WS-Security custom property is added to the UNTConsumeLoginModule to allow the user registry check to be skipped for identity tokens:

When the property is set to true, the UNTConsumeLoginModule does not validate the inbound UsernameToken if, and only if, the UsernameToken does not contain a password.

Valid values for this property are true and false. The default value is false.

To configure this property, in the administrative console:

1. Expand **Services** > **Policy sets**.
2. Click **General provider policy set bindings** or **General client policy set bindings**.
3. Click the binding name.
4. Under the Policy heading, click **WS-Security** > **Authentication and Protection** > ***tokenName*** > **Callback Handler**.

5. Add this property and its value in the Custom Properties **Name** and **Value** fields.

com.ibm.wsspi.wssecurity.tokenGenerator.ltpav1.pre.v7

Web services security supports both LTPA (Version 1) and LTPA Version 2 (LTPA2) tokens. The LTPA2 token, which is more secure than Version 1, is supported by the JAX-WS run time only. You can set the **Enforce token version** interoperability option on the token generator to determine whether an LTPA (Version 1) or an LTPA2 token is retrieved when a request message is received. However, if you want to force the run time to use LTPA (Version 1) tokens only, you can set the com.ibm.wsspi.wssecurity.tokenGenerator.ltpav1.pre.v7 custom property to true

To enable this custom property, complete the following steps in the administrative console:

1. Locate the binding that you want to configure.
2. Click the WS-Security policy in the Policies table.
3. Click the Authentication and protection link in the security policy bindings section.
4. Click the token generator that you want to configure.
5. Specify com.ibm.wsspi.wssecurity.tokenGenerator.ltpav1.pre.v7 to true in the Custom properties section.

The following table explains how combinations of this custom property and the **Enforce token version** interoperability option affect the runtime.

Table 276. LTPA interoperability. Table of the com.ibm.wsspi.wssecurity.tokenGenerator.ltpav1.pre.v7 custom property and **Enforce token version** *interoperability option values.*

com.ibm.wsspi.wssecurity.tokenGenerator.ltpav1.pre.v7 custom property value	**Enforce token version value**	**Result**
false	Disabled	The run time can use both LTPA (Version 1) and LTPA2 tokens.
not specified, which implies a false value	Disabled	The run time can use both LTPA (Version 1) and LTPA2 tokens.
true	Disabled	The run time can use LTPA (Version 1) tokens only.
true	Enabled	The run time can use LTPA (Version 1) tokens only.

For more information, see the documentation about enabling or disabling single sign-on interoperability mode for the LTPA token.

Administering message-level security for JAX-WS web services

Web Services Security standards and profiles describe how to provide security and protection for SOAP messages that are exchanged in a web services environment. Using JAX-WS, development of web services and clients is simplified with greater platform independence for Java applications through the use of dynamic proxies and Java annotations.

Auditing the Web Services Security runtime

Security auditing provides tracking and archiving of auditable events for the web services runtime operations. When security auditing is enabled for web services, the event generator utility collects and logs signing, encryption, security, authentication, and delegation events in audit event records. You can analyze the audit event records to identify possible security breaches or potential weaknesses in the security configuration of your environment.

The audit security subsystem must be enabled for WebSphere Application Server before the event generator can collect auditing records for the Web Services Security runtime. The recording of auditable security events is achieved by enabled the security auditing subsystem. For more information about enabling security auditing, read the topic "Enabling the security auditing subsystem."

Web Services Security auditing is enabled for the JAX-WS runtime only. Several auditing events can occur when a SOAP message is received. Auditing data is collected during various Web Services Security runtime operations, such as validating the digital signature of a SOAP message, decrypting the message, or checking the message security header. The auditing data is stored and managed by the event generator, and stored in audit logs for later analysis.

Auditable events for web services include:

Signing

As the digital signature in each SOAP message part is validated, a SECURITY_SIGNING event is sent to the event generator, along with an outcome, which can be SUCCESS or ERROR. Reason codes, either VALID_SIGNATURE or INVALID_SIGNATURE, are also sent. The integrity of the message is audited, also with a SECURITY_SIGNING event, with the outcome of SUCCESS or DENIED. Reason codes are INTEGRITY or INTEGRITY_BAD. The following table summarizes the signing events:

Table 277. Signing audit events. Use the signing audit event records to identify possible security breaches or weaknesses in the security configuration.

Event type	Possible outcomes	Reason codes
SECURITY_SIGNING (digital signature)	SUCCESS ERROR	VALID_SIGNATURE INVALID_SIGNATURE
SECURITY_SIGNING (integrity)	SUCCESS DENIED	INTEGRITY INTEGRITY_BAD

If the SECURITY_SIGNING event outcome is DENIED, and the reason code is INTEGRITY_BAD, this means that at least one message part, which must be signed by the security policy, failed signature validation. If the SECURITY_SIGNING event outcome is ERROR, and the reason code is INVALID_SIGNATURE, this means that the digital signature validation failed. This could lead to an INTEGRITY_BAD reason code in the audit record, depending on whether the digital signature is required by the security policy.

Encryption

Encryption auditing is performed in two parts: first, the encrypted parts of the SOAP message are processed, then the confidentiality of the message is audited. To audit each encrypted part of the message, a SECURITY_ENCRYPTION event is sent. An event record is created only if the outcome of the event is ERROR, meaning that an exception is encountered. The reason code is DECRYPTION_ERROR. Next, the confidentiality of the message is checked with another SECURITY_ENCRYPTION event, which has possible outcomes of SUCCESS or DENIED. Reason codes for this event are CONFIDENTIALITY or CONFIDENTIALITY_BAD. The following table summarizes the encryption events:

Table 278. Encryption audit events. Use the encryption audit event records to identify possible security breaches or weaknesses in the security configuration.

Event type	Possible outcomes	Reason codes
SECURITY_ENCRYPTION (encrypted message parts)	ERROR	DECRYPTION_ERROR
SECURITY_ENCRYPTION (confidentiality)	SUCCESS DENIED	CONFIDENTIALITY CONFIDENTIALITY_BAD

If the SECURITY_ENCRYPTION event outcome is DENIED and the reason code is CONFIDENTIALITY_BAD, this means that at least one message part, which is required to be encrypted, is not correctly encrypted. A DECRYPTION_ERROR in the audit record could lead to a CONFIDENTIALITY_BAD reason code, depending on whether message encryption is required.

Time stamp

For each SOAP message, the time stamp is audited when a SECURITY_RESOURCE_ACCESS event is sent to the event generator. The possible outcomes of this event are SUCCESS or DENIED. Reason codes are TIMESTAMP or TIMESTAMP_BAD. The following table summarizes the time stamp events:

Table 279. Time stamp audit event. Use the time stamp audit event record to identify possible security breaches or weaknesses in the security configuration.

Event type	Possible outcome	Reason code
SECURITY_RESOURCE_ACCESS	SUCCESS DENIED	TIMESTAMP TIMESTAMP_BAD

Security header

The security header is audited to make sure it is not missing from the SOAP message. A SECURITY_RESOURCE_ACCESS event is sent, and if the header is missing, the outcome is DENIED, with the reason code SECURITY_HEADER_MISSING. The following table summarizes the security header event:

Table 280. Security header audit event. Use the security audit event record to identify possible security breaches or weaknesses in the security configuration.

Event type	Possible outcome	Reason code
SECURITY_RESOURCE_ACCESS	DENIED	SECURITY_HEADER_MISSING

Authentication

The security token used to authenticate a message is audited to determine if authentication is successful, and information about the authentication type, provider name and provider status are saved in the audit event record. The token ID is also recorded, along with information that is specific to the token type, such as username or keystore. Sensitive information such as the token itself, or the token password, is not recorded in the audit event record. Information recorded for each token type is described in the following table:

Table 281. Token information recorded in audit event record. Use the authentication audit event records to identify possible security breaches or weaknesses in the security configuration.

Token type	Recorded information
Username token	Username Password (null or not-null) Token ID
LTPA	Principal Expiration Token ID
LTPAPropagate	Principal Expiration Token ID
SecureConversation	UUID Instance UUID Token ID
DerivedKey	Reference ID Token ID
Kerberos	Principal SPN pSHA1 Token ID
X509	Certificate Subject Issuer Keystore Token ID TrustAny
PKP Path (public key infrastructure)	Certificate Subject Issuer Keystore Token ID TrustAny

Table 281. Token information recorded in audit event record (continued). Use the authentication audit event records to identify possible security breaches or weaknesses in the security configuration.

Token type	Recorded information
PKCS7 (Public Key Cryptography Standards)	Certificate Subject Issuer Keystore Token ID TrustAny
SAML token	Principal SAML Token Issuer Name Confirmation Method

Message authentication is audited using a SECURITY_AUTHN event. Possible outcomes of the event are SUCCESS, DENIED or FAILURE. Reason codes are AUTHN_SUCCESS, AUTHN_LOGIN_EXCEPTION or AUTHN_PRIVILEDGE_ACTION_EXCEPTION. The following table summarizes the authentication events:

Table 282. Authentication audit event. Use the authentication audit event records to identify possible security breaches or weaknesses in the security configuration.

Event type	Possible outcomes	Reason codes
SECURITY_AUTHN	SUCCESS DENIED FAILURE	AUTHN_SUCCESS AUTHN_LOGIN_EXCEPTION AUTHN_PRIVILEDGE_ACTION_EXCEPTION

Delegation

Authentication of a SOAP message can be delegated, and the delegation function is audited using a SECURITY_AUTHN_DELEGATION event. This event is sent when the client identity is propogated or when delegation involves the use of a special identity. In the Web Services Security runtime, auditing events are recorded only when the delegation type is set to Identity Assertion. Possible outcomes are SUCCESS or DENIED, with reason codes AUTHN_SUCCESS or AUTHN_DENIED. Additional information, such as delegation type, role name and identity name, is collected and stored in the audit event record. The following table summarizes the delegation events:

Table 283. Delegation audit event. Use the delegation audit event record to identify possible security breaches or weaknesses in the security configuration.

Event type	Possible outcomes	Reason codes
SECURITY_AUTHN_DELEGATION	SUCCESS DENIED	AUTHN_SUCCESS AUTHN_DENIED

Validation

As part of the generic security token login module support, a Security Token Service can validate a token using a WS-Trust Validate request. This validation operation can return a token in exchange for a token that is being validated. The information that is exchanged is located in the documentation on auditing for a generic security token. The following table shows the token exchange information that is recorded.

Table 284. Token exchange. Use the token exchange information to trace the token exchange process.

Event	Description
TokenSentForExchangeId	This information identifies the token that is sent for validation and is exchanged.
TokenSentForExchangeType	This information identifies the type of the token that is sent for validation and is exchanged.
ExchangedTokenId	This information identifies the token that is received in exchange during the validation request.
ExchangedTokenType	This information identifies the type of the token that is received in exchange during the validation request.

If the token is validated without a token exchange, only the Token ID is recorded.

Securing web services using policy sets

Policy sets are assertions about how services are defined. They are used to simplify the quality of service configuration for web services.

About this task

Policy sets combine configuration settings, including those for transport and message level configuration, such as WS-Addressing, WS-ReliableMessaging, and WS-Security. There are two main types of policy sets; application policy sets and system policy sets. Application policy sets are used for business-related assertions. These assertions are related to the business operations that are defined in the Web Services Description Language (WSDL) file. System policy sets, on the other hand, are used for non-business-related system messages. These messages are not related to the business operations that are defined in the WSDL, but instead refer to messages that are defined in other specifications which apply qualities of service (QoS). Such QoS are the request security token (RST) messages that are defined in WS-Trust, or create sequence messages that are defined in WS-Reliable Messaging metadata exchange messages of the WS-MetadataExchange.

Note: You can use policy sets only with Java™ API for XML-Based Web Services (JAX-WS) applications. You cannot use policy sets with Java API for XML-based RPC (JAX-RPC) applications.

Policies are defined based on a quality of service. Policy definition is typically based on WS-Policy standard language, for example, the WS-Security policy is based on the current WS-SecurityPolicy from the Organization for the Advancement of Structured Information Standards (OASIS) standards.

Policy sets do not include environment or platform-specific information, such as keys for signing, keystore information, or persistent store information. This type of information is defined in the binding. A policy set attachment defines how a policy set is attached to service resources and bindings. The attachment definition is outside the policy set definition and is defined as meta-data associated with application data.

To secure JAX-WS web services with message-level security using policy sets, follow these steps:

Procedure

1. Select, create, or copy and modify a policy set to specify the message-level protection required. The policy specifies what protection will be applied, for example, what message parts to sign or encrypt and the token types and algorithms to use.
   - Select one of the web services policy sets.
   - Create, copy, modify, import, export or delete a policy set. For more information, read about managing policy sets using the administrative console
2. Attach the policy set to the application.
3. Create or select the policy set bindings to be used. The bindings are then attached to the application along with the policy set. The bindings used can either be general bindings that can be shared among applications or application specific bindings. For more information, read about defining and managing policy set bindings.
4. If WS-SecureConversation is being used, specify the trust service system policy sets and bindings on the application server.

Example: Configuring the message-level WS-Security policy set and bindings:

This example shows how to configure the message-level WS-Security policy set and bindings to send a Username token in a JAX-WS request, and to encrypt the Username token using asymmetric encryption.

Before you begin

Make a copy of the **Username WSSecurity** default policy set and give it a unique name. This example illustrates how to modify a copy of the default policy set. For more information, read about copying default policy set and bindings settings.

About this task

By default, the Username WSSecurity policy set signs the WS-Addressing headers and body in the request and the response, and encrypts the body and signature in the request and the response. However, in this example, the goal is to encrypt only the Username token in the request from the client to the service, but not to encrypt any part of the response from the service to the client. In addition, no part of the request or the response will be signed. Therefore, the policy set must be modified to remove several message protection parts. You must also configure the client and server bindings.

First, configure the policy set by modifying your copy of the Username WSSecurity default policy set.

Procedure

1. From the administrative console, click **Services > Policy sets > Application policy sets > *policy_set_name***. In the Policy set settings panel, you can specify information about the policy set, such as the description.
2. Remove the following message protection parts: request:app_signparts, response:app_signparts and response:app_encparts.
   a. Click **Application policy sets > *policy_set_name* > WS-Security > Main policy > Response message part protection**.
   b. Click on **app_encparts** in the Encrypted parts box, then click the **Delete** button.
   c. Click on **app_signparts** in the Signed parts box, then click the **Delete** button.
   d. Click **Application policy sets > *policy_set_name* > WS-Security > Main policy > Request message part protection**.
   e. Click on **app_signparts** in the Signed parts box, then click the **Delete** button.
3. Update the protection part specified for request:app_encparts. By default, this message protection part encrypts the body and signature elements, and must be modified to encrypt the Username token.
   a. Click **Application policy sets > *policy_set_name* > WS-Security > Main policy > Request message part protection > Encrypted part - app_encparts > Edit**.
   b. Delete the existing elements in the Elements in part panel, then add two XPath expressions for encrypting the Username token.

      Expression 1:

```
/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
        and local-name()='Envelope']/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
        and local-name()='Header']/*[namespace-uri()='http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-secext-1.0.xsd'
        and local-name()='Security']/*[namespace-uri()='http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-secext-1.0.xsd'
        and local-name()='UsernameToken']
```

      Expression 2:

```
/*[namespace-uri()='http://www.w3.org/2003/05/soap-envelope'
        and local-name()='Envelope']/*[namespace-uri()='http://www.w3.org/2003/05/soap-envelope'
        and local-name()='Header']/*[namespace-uri()='http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-secext-1.0.xsd'
        and local-name()='Security']/*[namespace-uri()='http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-secext-1.0.xsd'
        and local-name()='UsernameToken']
```

What to do next

The second part of the process is to configure the client and server bindings.

gotcha: When working with the client binding, be careful when choosing the protection token that you want to edit. The names of the tokens are represented from the perspective of the protector. For instance, on a client, even though the word recipient is in its name, the

AsymmetricBindingRecipientEncryptionToken0 is a generator. The best way to make sure that you are choosing the correct token is to look at the Usage column in the Protection tokens table.

1. Configure the client binding, as follows:
   a. Attach the policy to a service resource and create a new binding for that resource that includes the WSSecurity policy.
   b. Click on **WSSecurity** in the new binding to display the main WSSecurity binding panel. For example, click **Enterprise applications > WSSampleServiceSei > Service client policy sets and bindings > *binding_name* > WS-Security**.
   c. Click **Authentication and protection**.
   d. Under Protection tokens, click **AsymmetricBindingRecipientEncryptionToken0** (the Asymmetric encryption generator).
   e. Click **Apply**.
   f. Click **Callback handler**.
   g. Select **Custom** from the Keystore menu.
   h. Click **Custom keystore configuration**.
   i. Enter the keystore path. For example: `${USER_INSTALL_ROOT}/etc/ws-security/samples/enc-receiver.jceks`.
   j. Select **JCEKS** for the Type.
   k. Enter the password in the Password and Confirm password fields. For example, **storepass**.
   l. Enter a Key Name. For example, **CN=Bob, O=IBM, C=US**.
   m. Enter a Key Alias. For example, **bob**.
   n. Click **OK**.
   o. Click **OK** again.
   p. Click **OK** one more time to return to the **Enterprise Applications > WSSampleServicesSei > Service client policy sets and bindings > *binding_name* > WS-Security > Authentication and protection** panel.
   q. The status of AsymmetricBindingRecipientEncryptionToken0 should display as **Configured**.
2. Modify the encrypted parts settings for the client binding, as follows:
   a. Click **request:app_encparts** under Request message signature and encryption protection.
   b. Enter a Name. For example, **MyEncPart**.
   c. Click **New** under Key information.
   d. Fill in a Name. For example, **MyEncKeyInfo**.
   e. Click **OK**.
   f. Select **MyEncKeyInfo** (or the name that you specified for the encrypted part) from the Available box and click **Add**. MyEncKeyInfo appears in the **Assigned** box.
   g. Click **OK** to return to the **Enterprise Applications > WSSampleServicesSei > Service client policy sets and bindings > *binding_name* > WS-Security > Authentication and protection** panel.
   h. The status of request:app_encparts should display as **Configured**.
3. Configure the Username token settings in the client binding, as follows:
   a. Click **request:myUserNameToken** under Authentication tokens.
   b. Click **Apply**.
   c. Click **Callback handler**.
   d. Specify the User name. For example, **LDAPSunuser6**.
   e. Specify the password, and confirm the password.
   f. Click **OK**.
   g. Under **Custom properties**, click **New** to add the properties for enabling nonce and timestamp.

h. Enter the property name `com.ibm.wsspi.wssecurity.token.username.addNonce` to enable nonce, and the property value `true`.

i. Enter the property name `com.ibm.wsspi.wssecurity.token.username.addTimestamp` to enable timestamp, and the property value `true`.

j. Click **OK** again.

k. The status of request:myUserNameToken should now display as **Configured**.

l. Click **Save** to save your client bindings.

4. Configure the server binding, as follows:

a. Attach the policy to a service resource and create a new binding for that resource that includes the WSSecurity policy.

b. Click on **WSSecurity** in the new binding to display the main WSSecurity binding panel. For example, click **Enterprise Applications > WSSampleServiceSei > Service client policy sets and bindings > *binding_name* > WS-Security**.

c. Click **Authentication and protection**.

d. Under Protection tokens, click AsymmetricBindingRecipientEncryptionToken0 (the Asymmetric encryption consumer)

e. Click **Apply**.

f. Click **Callback handler**.

g. Select **Custom** from the Keystore menu.

h. Click **Custom keystore configuration**.

i. Enter the keystore path. For example: `${USER_INSTALL_ROOT}/etc/ws-security/samples/enc-receiver.jceks`.

j. Select **JCEKS** for the Type.

k. Enter the password in the Password and Confirm password fields. For example, **storepass**.

l. Enter a Key Name. For example, **CN=Bob, O=IBM, C=US**.

m. Enter a Key Alias. For example, **bob**.

n. Enter the password for the keypass in the Password and Confirm password fields.

o. Click **OK**.

p. Click **OK** again.

q. Click **OK** one more time to get return to the **Enterprise Applications > WSSampleServicesSei > Service client policy sets and bindings > *binding_name* > WS-Security > Authentication and protection** panel.

r. The status of AsymmetricBindingRecipientEncryptionToken0 should display as **Configured**.

5. Modify the encrypted parts settings for the server binding, as follows:

a. Click **request:app_encparts** under Request message signature and encryption protection.

b. Enter a Name. For example, **MyEncPart**.

c. Click **New** under Key information.

d. Fill in a Name. For example, **MyEncKeyInfo**.

e. Click **OK**.

f. Select **MyEncKeyInfo** (or the name that you specified for the encrypted part) from the Available box and click **Add**. MyEncKeyInfo appears in the **Assigned** box.

g. Click **OK** to return to the **Enterprise Applications > WSSampleServicesSei > Service client policy sets and bindings > *binding_name* > WS-Security > Authentication and protection** panel.

h. The status of request:app_encparts should display as **Configured**.

6. Configure the Username token settings in the server binding, as follows:

a. Click **request:myUserNameToken** under Authentication tokens.

b. Click **Apply**.
c. Click **Callback handler**.
d. Click **OK**.
e. Under **Custom properties**, click **New** to add the properties for verifying nonce and timestamp.
f. Enter the property name `com.ibm.wsspi.wssecurity.token.username.verifyNonce` to verify nonce, and the property value `true`.
g. Enter the property name `com.ibm.wsspi.wssecurity.token.username.verifyTimestamp` to verify timestamp, and the property value `true`.
h. Click **OK** again.
i. The status of request:myUserNameToken should display as **Configured**.
j. Click **Save** to save the server bindings.

Configuring the username and password for WS-Security Username or LTPA token authentication

When using the Username WSSecurity default policy set, you must configure the username and password for username token authentication separately from the security settings defined in the bindings.

About this task

When you install a JAX-WS application and attach the default Username WSSecurity default policy set, the next step is to configure the general provider sample binding for the JAX-WS provider, and the general client sample binding for the JAX-WS client. However, the binding file for the default client sample binding does not include a username or password for token authentication. Since the username and password is not available from the target deployed system, you must specify a valid username and password in your environment using the administrative console.

Procedure

1. Log in to the administrative console, then click **Services** > **Policy sets** > **General client policy set bindings**.
2. Click **Client sample** to edit the binding.
3. Click **WS-Security**.

   Add basic authentication information, such as username and password, to the general client sample bindings for any policy set that uses a Username token or LTPA token, including:
   - Username SecureConversation
   - Username WS-I RSP
   - LTPA SecureConversation
   - LTPA WS-I RSP
   - LTPA WSSecurity default
4. Click **Authentication and protection**.
5. In the Authentication tokens table, click **gen_signunametoken** to edit the username token settings.
6. Click **Callback handler** in the Additional Bindings section.
7. Enter the appropriate username and password information for your environment in the **User name** and **Password** fields.
8. Enter the password a second time in the **Confirm Password** field, then click **Apply**.
9. Repeat steps 5 through 8 for the gen_signltpatoken LTPA token generator.

Results

Note: This administrative console panel applies only to Java™ API for XML Web Services (JAX-WS) web services.

Securing requests to the trust service using system policy sets

WebSphere Application Server provides message-level protection for its security token service, known as the WebSphere Application Server trust service. For the trust service, you must use a special class of policy sets known as system policy sets.

Before you begin

You can secure requests to the trust service by using two different configuration methods:

- Use the administrative console to define and attach a system policy set and binding to a trust service operation that is associated with an endpoint.
- Use the wsadmin tool, which supports the Jython and Jacl scripting languages, to configure system policy sets for the trust service. You can manage the policies for the Quality of Service (QoS) by creating policy sets and managing associated policies.

About this task

For WebSphere Application Server trust service security, you must configure the system policy sets, the bindings, the trust service attachments, and the security cache.

Perform the following high-level steps. The order of the tasks is not important but all high-level required steps must be performed to complete the trust configuration.

Procedure

1. Define a new system policy set or manage existing system policy sets. To manage system policy sets, you can perform the following tasks:
   a. Define the system policy set and binding. The system policy set can be a new or existing policy set. If you create a new system policy set, you must specify and configure the policy types. A default binding configuration is associated with each policy type.
   b. Modify the system policy set, as needed.

      Other optional policy set-related tasks that you can perform include:

      - Add, edit, or remove policy set attachments.
      - Edit, enable, disable or remove policy types
      - Create a system policy set by selecting and copying an existing system policy set. When copying an existing system policy set, you also specify whether to move the existing attachments to this new system policy set.
      - Delete system policy sets. You cannot delete pre-configured system policy sets that are provided by WebSphere Application Server by default.
      - Archive a system policy set by selecting and exporting an existing system policy set. When exporting an existing system policy set, you create a .zip archive file. The .zip file for exporting the policy set is provided for downloading. For example, if you have a policy set named ABC_ps and you want to export and move the archive file from ServerA to ServerB, first use the export function to create the .zip file. Then, manually transfer the archive file to ServerB.
2. Create and manage explicit attachments. You can perform the following trust service attachment tasks:
   a. Attach the system policy set and assign a binding to an endpoint. For an endpoint, you can create explicit attachments for each of the four trust service operations to the respective Trust Service Defaults policy sets and bindings. After you have created these initial attachments, you can view and further modify existing policy set and binding configurations.
   b. Modify existing policy set attachment and binding configurations, as needed.. The system policy set can be a new or existing policy set. If you create a new system policy set, you must specify and configure the policy types. A default binding configuration is associated with each policy type.

      The system policy set that is attached to issue and renew must correspond to the client and endpoint's bootstrap policy set and the system policy set attached to validate and cancel must

correspond to the client and endpoint's application policy set. The bootstrap policy set for the endpoint service is only required if the endpoint service makes issue and renew requests to the trust service.

Other optional attachment-related tasks that you can perform include:

- Change the system policy set and binding configurations.
- Create custom system policy sets and bindings.
- Attach each of the four default trust service operations to a system policy set and binding.
- Attach each of the four trust service operations associated with a specific endpoint to a system policy set and binding.
- Specify that the selected trust service operations for an endpoint inherit the respective default trust service policy set and binding.
- Assign the Default binding or a custom binding configuration to the selected policy set attachment.
- Update the trust service runtime configuration.

3. Manage the security context token provider that the trust service provides. You can perform the following trust service token provider tasks:
   a. Modify the configuration of the Security Context Token provider, as needed..

      Other optional token provider-related tasks that you can perform include:

      - Update the trust service runtime configuration for any token provider configuration changes.
4. Manage the trust service default token provider and any endpoints that have an explicitly assigned token (rather than inheriting from the default). Targets are endpoints that are assigned a specific token provider. You can perform the following trust service target tasks:
   a. Create a new trust service target by explicitly assigning a service endpoint URL to the default token provider.. Performing this task creates an explicit assignment to the default trust service token provider, the Security Context Token. All other endpoints inherit the trust service default token provider.
   b. Configure a target. WebSphere Application Server defines one default supported token provider, the Security Context Token. Other tasks that you can perform for existing targets include:
      - Modifying one or more endpoints that have a security context token provider explicitly assigned.
      - Changing the token provider for an endpoint from inherited to explicitly assigned. Therefore, the token provider for the endpoint does not change as the default trust service token provider changes.
      - Changing the token provider for an endpoint from explicitly assigned to inherited. Therefore, the token provider for the endpoint is the default trust service token provider and changes as the default changes.
      - Updating the trust service runtime configuration.
5. Configure the security cache. You can change the behavior of client-side security caching.
6. Update the trust service runtime configuration. You must update the runtime configuration whenever one or all of the following trust-related items are created or changed:
   - Trust service attachments
   - Token providers
   - Targets

Results

After the configurations are completed and the trust service runtime configuration has been updated, you have used the administrative console to secure requests to the trust service by using system policy sets.

Enabling secure conversation:

Use secure conversation to secure web services application messages.

Before you begin

Applications that contain web services must have been deployed.

About this task

The Organization for the Advancement of Structured Information Standards (OASIS) Web Services Secure Conversation (WS-SecureConversation) draft specification describes ways to establish a secure session between the initiator and recipient of SOAP messages. The WS-SecureConversation draft specification also defines how to use the OASIS Web Services Trust (WS-Trust) protocol to establish a security context token (SCT). For complete information, see the OASIS Web Services Secure Conversation specification.

WebSphere Application Server supports the ability of an endpoint to issue a security context token for WS-SecureConversation, and thereby provides a secure session between the initiator and recipient of SOAP messages.

The following figure describes the flow that is required to establish a secured context and to use session-based security.

Figure 45. Displaying the flow between the client and the web service and security token service

In the WS-SecureConversation specification, a security context is represented by the <wsc:SecurityContextToken> security token. The following example represents the assertion syntax for a <wsc:SecurityContextToken> element.

```
<wsc:SecurityContextToken wsu:Id="..." ...>
    <wsc:Identifier>...</wsc:Identifier>
    <wsc:Instance>...</wsc:Instance>
    ...
</wsc:SecurityContextToken>
```

The security context token does not support references to it by using key identifiers or key names. All references must either use an ID (to a wsu:Id attribute) or a <wsse:Reference> to the <wsc:Identifier> element.

WebSphere Application Server provides these pre-configured secure conversation-related polices:

- The **SecureConveration** policy set follows the WS-SecureConversation and WS-Security specifications and provides a policy set with secure conversation enabled and using keys derived from security context token for signing and encrypting the application messages.
- The **Username SecureConversation** policy set follows the WS-SecureConversation and WS-Security specifications and adds authentication using the Username token.
- The **LTPA SecureConversation** policy follows the WS-SecureConversation and WS-Security specifications and provides authentication using the Lightweight Third Party Authentication (LTPA) tokens.

In this example, the default SecureConversation policy set, and the default WS-Security binding and TrustServiceSecurityDefault binding are used to achieve the task of enabling secure conversation. The default SecureConversation policy set has both the application policy (symmetricBinding) and the bootstrap policy (asymmetricBinding). The application policy is used to secure application messages and the bootstrap policy is used to secure the RequestSecurityToken (RST) messages.

A trust service that issues a security context token is configured with the TrustServiceSecurityDefault system policy and the TrustServiceSecurityDefault binding. The trust policy is responsible for securing RequestSecurityTokenResponse (RSTR) messages. If the bootstrap policy is modified, the trust policy has to be modified to match both of the configurations.

Note: The following steps are to be used only in development and test environments.

The Web Services Security (WS-Security) default bindings that are used here contain sample key files and must be customized before use in a production. For the production environment, use of custom bindings is advised. Also note that, if the profile is created by using the choice of **Create the server using the development template**, you can skip steps 2 and 3.

To configure secure conversation, configure the policy set, and add a policy assertion to the policy, complete the following steps:

Procedure

1. Make a copy of a default secure conversation policy so you can customize the policy set for your own environment.
   a. Launch the administrative console, and click **Services** > **Policy sets** > **Application policy sets**.
   b. Select the check box next to an existing policy set that follows the WS-SecureConversation specifications. For example, you might click the check box next to **SecureConversation**. This policy set is one of the pre-configured secure conversation-related application policy sets that is listed in the table. The SecureConversation policy set has a bootstrap policy to match the default policy set for the trust service to issue and renew tokens.
   c. Click **Copy**.
   d. Enter a unique name for the new copy of the SecureConversation application policy set. For example: CopyOfSCPolicySet
   e. Optional: Change the description, as needed, for your customized version of this policy set.
2. Attach the policy set and binding to the application.
   a. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application name***.
   b. Click either **Service provider policy sets and bindings** or **Service client policy sets and bindings** to attach resources to the CopyOfSCPolicySet policy set. The general binding is assigned automatically as the default.
   c. You can use the **Attach Policy Set** and **Assign Binding** menu lists to select a different policy set or binding.

Results

After completing these steps, you have configured secure conversation.

What to do next

Next, review the example scenario about how to establish a security context token to secure a secure conversation.

Web Services Secure Conversation:

Web Services Secure Conversation (WS-SecureConversation) provides a secured session for long running message exchanges and leveraging of the symmetric cryptographic algorithm.

WS-SecureConversation provides session-based security. Session-based security optimizes long message exchanges, as symmetric cryptography can be used to sign and encrypt the message. Typically, symmetric

cryptographic algorithm is less CPU intensive than the asymmetric cryptography. Symmetric cryptographic algorithms should provide better performance and throughput when compared to the asymmetric cryptographic algorithms.

The symmetric cryptographic algorithm also provides a means to secure other session-based protocol and exchange patterns, such as Web Services Reliable Messaging (WS-ReliableMessaging).

Security context token for secure conversation

The Web Services Security specification defines the basic mechanisms for providing secure messaging. The Web Services Trust (WS-Trust) specification defines extensions to Web Services Security that provide ways to establish and broker trust relationships between two parties. The WS-Trust protocol defines the syntax of the request that can be sent to a security token service and the corresponding or subsequent response of the security token service. The security token service provided with WebSphere Application Server is called the *trust service*.

Using the WS-Trust protocol, a party can request the trust service issue a security context token (SCT). Then, this token can be used to establish a secure conversation (WS-SecureConversation). The request for a security token is sent to an application endpoint. The request is intercepted by the WebSphere Application Server and routed to the trust service.

A policy can be defined as the default for all trust issue operations, renew operations, validate operations, or cancel operations. Additionally, a policy can be attached to a specific URL and operation pair.

WS-SecureConversation defines extensions to allow security context establishment and sharing, and session key derivation, which allows contexts to be established and, potentially, more efficient keys, or new key material, to be exchanged. The WebSphere Application Server support for WS-Trust and WS-SecureConversation focuses on the issuing, renewing, validating, and cancelling of the security context token for secure conversation.

Policy set and bootstrap policy

In addition to describing these functions, the OASIS WS-SecureConversation draft submission describes multiple methods of establishing a secure session between the initiator and the recipient of the SOAP messages.

The bootstrap security policy is the security policy for the initiating party to acquire the security token for secure conversation from the trust service by using a token-issuing WS-Trust or WS-SecureConversation protocol message. The policy set configuration consists of the security policy for communication with the application service, and the bootstrap policy for communication with the trust service.

If sharing of a policy configuration (using WS-Policy) containing the secure conversation bootstrap policy fails, it may be because the bootstrap request and response policies differ. The message part protection for the bootstrap policy must be the same for both request and response bootstrap messages, because a single policy is published for both request and response.

What is supported for Web Services Secure Conversation

The following list highlights some of the key functions that are supported in WebSphere Application Server. The list is not exhaustive.

- A security context token (SCT) established between the initiating party and the recipient party.
- The WS-SecureConversation operations that are supported on the security context token (SCT), such as Issue token, Renew token, and Cancel token. Validate token is supported using WS-Trust protocol.
- A derived key (explicit and implied)

What is not supported for Web Services Secure Conversation

The following list highlights some of the key functions that are not supported in WebSphere Application Server. The list is not exhaustive.

- WS-SecureConversation does not support establishing a security context through the security context token that is created by an external security token service (trust component). However, WebSphere Application Server supports an internal security token service.
- WebSphere Application Server does not support establishing a security context through the security context token that is created by one of the communicating parties and propagated with a message.
- WebSphere Application Server does not support amending a security context token.
- WebSphere Application Server does not support a client creating the security context token.
- WebSphere Application Server provides no support for exchange and negotiation.

Secure conversation scenarios

The following scenarios describe the WS-SecureConversation functions that WebSphere Application Server supports:

- WS-SecureConversation

  This scenario is based on establishing a security context token with the recipient and using the derived key to sign and encrypt the message. It describes how to establish a security context by using session-based security. Session-based security is where the flow of the initiator establishes the security context token by using the WS-SecureConversation protocol with the recipient.
- WS-SecureConversation with WS-ReliableMessaging

  This scenario is a composite scenario that includes functions that are required for the composition scenario of Web Services Reliable Messaging (WS-ReliableMessaging), WS-SecureConversation, and WS-Trust. This scenario describes how to use WS-SecureConversation with WS-ReliableMessaging where the flow is similar to the previous scenario, but which is from the secure conversation prospective. However, the main difference is that the WS-ReliableMessaging sequence is secured with the security context token and scopes the WS-ReliableMessaging sequence to the security context token. This description focuses on the message exchanges that are using the security context token in the overall flow.

Scoping of Web Services Secure Conversation:

Web Services Secure Conversation supports two scoping mechanisms: the default and the Java API for XML Web Services (JAX-WS) client service level.

Review the following information about the two scoping mechanisms to ensure the proper scoping of secure conversation and policy set for WebSphere Application Server.

Default

The default scope is based on a cluster, an application, a module, and a target service endpoint. For a client running in a thin client environment, it is considered to be a single application, cluster, and module.

In this scoping mode, all the instances of the JAX-WS client within a particular application, cluster, and module to the same target service endpoint share the same secure conversation. For example, in the following figure, the two client instances (Client 1 and Client 2) are in the same module. Client 1 and Client 2 share the same secured conversation with Service 1. The other two client instances (Client 3 and Client 4), which are in a different module than Clients 1 and 2 and which share a secured conversation with each other but not with Clients 1 and 2.

JAX-WS client service level

Scope at the JAX-WS client service level is enabled by specifying a property in the token generator binding configuration of the Secure Conversation Token (SCT)in the client application request (application outbound). The binding is located in the META-INF of the deployed application.

For example, if the application is `WSSampleClientBeta.ear` and the binding directory is `SecureConversation123binding`, the binding file would be located at:

```
$PROFILE_DIR/config/cells/<cellname>/WSSampleClientBeta.ear/deployments/WSSampleClientBeta
/META-INF/SecureConversation123binding/PolicyTypes/WSSecurity/bindings.xml.
```

An example of the configuration follows:

```
<tokenGenerator name="gen_enctgen"
      classname="com.ibm.ws.wssecurity.wssapi.token.impl.CommonTokenGenerator">
   <valueType localName="http://schemas.xmlsoap.org/ws/2005/02/sc/sct" uri="" />
      <callbackHandler classname="com.ibm.ws.wssecurity.impl.auth.callback.WSTrustCallbackHandler">
         <properties name="com.ibm.ws.wssecurity.sc.SCTScope" value="SERVICE_SCOPE"/>
      </callbackHandler>
         <properties name="com.ibm.ws.wssecurity.sc.dkt.ServiceLabel" value="WSC"/>
         <properties name="com.ibm.ws.wssecurity.sc.dkt.ClientLabel" value="WSC"/>
            <jAASConfig configName="system.wss.generate.sct"/>
</tokenGenerator>
```

The following code example demonstrate the behavior after the property in the token generator binding configuration of the SCT in the client application request (application outbound) is enabled. In this mode, Web Services Secure Conversation is scoped at the JAX-WS client service instance.

```
QName serviceQname = new QName("http://ws.apache.org/axis2", "EchoService");
QName portQname = new QName("http://ws.apache.org/axis2", "EchoServicePort");
String endpointUrl = "http://myhost/......";
Service svc1 = Service.create(serviceQname);
svc1.addPort(portQname, null, endpointUrl);
Dispatch<Source> dispatch = svc1.createDispatch(portQname, Source.class, null);
......
......
Service svc2 = Service.create(serviceQname);
svc2.addPort(portQname, null, endpointUrl);
Dispatch<Source> dispatch = svc2.createDispatch(portQname, Source.class, null);
```

where `svc1` and `svc2` are in two different secure conversations with the target service endpoint.

You can change the scope by using either the administrative console or by using scripting to add a property.

Secure conversation client cache and trust service configuration:

For both distributed and local clients, the WebSphere Application Server secure conversation client cache stores tokens on the client.

WebSphere Application Server supports caching of the security context token for both the distributed client and local client. If the security context token is distributed, a client in the same replication domain uses the same security context token. Distributed caching also supports disk offload to save the security context token to disk for recovery. When the client runs applications using secure conversation, and is part of a cluster setup, then the client can use the distributed cache mechanism to replicate the token data among the cluster members.

To use the administrative console to modify the cache settings, click **Services** > **Security Cache**.

You can configure the cache settings, such as the following.

- Set the time that the token remains in the cache after timeout. The default value is 10 minutes. This value is a time window to renew an expired token.

- Set the renewal interval before the token expires. The default value is 10 minutes, and the minimum value is 3 minutes. Entering a number less than 3 minutes causes an error.

  Important: This setting is critical. This setting represents the maximum roundtrip time for a client to make a request, the transport request to go to the server, the server to process the request, and the transport response (if applicable) back to the client. If the time specified is too small and there is not enough time specified, then the token might expire during the roundtrip, and the client receives a failure response. If the time specified is too large, then performance diminishes.

  If the security context token is renewed too often, it might cause Web Services Secure Conversation (WS-SecureConversation) to fail or even cause an out-of-memory error to occur. It is required that you set the renewal interval before the token expires value for the Secure conversation client cache to a value less than the token timeout value for the security context token. It is also suggested that the token timeout value be at least two times the renewal interval before the token expires value.
- Select the **Enable distributed caching** check box to support distributed clients. You must ensure that the WebSphere Application Server dynamic cache service, and cache replication, are enabled. For more information on enabling the dynamic cache service, refer to the topic Enabling the distributed cache using synchronous update and token recovery.
- Define a custom property, edit, or remove existing custom properties.

The WS-SecureConversation client rejects a security context token that is issued at a future time. If you cannot synchronize the clock between the client machine and service machine, the clock skew could be configured to prevent the rejection of a valid token. The default clock skew is 3 minutes. To modify the default clock skew setting, add the following custom property to the desired minutes:

```
clockSkewToleranceInMinutes
```

Alternatively, use the wsadmin commands to manage secure conversation client cache configurations.

Thin client

For a web service application client running outside WebSphere Application Server, the security context token is cached only in the local Java process. The following system properties can be used to override the default cache setting on the thin client:

com.ibm.wsspi.wssecurity.SC.cache.cushion
: Specifies the time in minutes to renew a security context token to be used with WS-SecureConversation on the client side so that the security context token has enough time to complete the downstream call. The default value is 10 minutes, and the minimum value is 3 minutes.

com.ibm.wsspi.wssecurity.SC.token.clockSkewTolerance
: Specifies the tolerant clock skew time for a token between two machines. The default value is 3 minutes.

WS-Reliable Messaging settings

When WebSphere Application Server applications use policies such as WS-I RSP with managed persistent WS-Reliable Messaging, modify the cache and trust configuration values.

Set the cache configuration time value to 120 minutes.

1. In the WebSphere Application Server administrative console, click **Services** > **Security Cache**.
2. Modify the value of the **Time token is in cache after timeout** field from 10 to 120.
3. Click **Apply**, and then click **Save**.

Increasing the cache time value means that the token remains in the cache for a longer period after token expiration, so that the token is available for renewal. The WS-Reliable Messaging runtime scopes the

CreateSequence message to the security context token. Therefore, it is important to maintain the same security context for the life time of the Reliable Messaging sequence.

Enable distributed caching using the default option, Synchronous update of cluster members, to support distributed clients. For more information, refer to the topic Enabling the distributed cache using synchronous update and token recovery.

Additional recommended changes

Other important configuration changes are also recommended.

- Modify the life time of the Security Context Token by changing the value from the default of 120 minutes, to 600 minutes.
- Modify the Renew after expiration value by changing the value from `false` to `true`.
- Modify settings for the token providers, as follows:
  1. In the administrative console, click on **Services** > **Trust service** > **Token providers**.
  2. Click **Security Context Token**.
  3. Change the value in the **Token timeout** field from 120 to 600.
  4. Click the check box to select **Allow renewal after timeout**.
  5. Click **Apply**, and then click **Save**.

Derived key token:

After establishing the security context and after the secret have been established (authenticated), derived keys can be used to sign and encrypt the SOAP message to provide message level protection. You can then use derived keys for each key that is used in the security context.

You can enable Web Services Secure Conversation (WS-SecureConversation) by using symmetric keys that are derived from the security token for signing and encrypting the application messages.

Using WS-SecureConversation, the initiator can establish a security context token using the Web Services Trust (WS-Trust) protocol with the recipient. A security context token implies or contains a shared secret. Using a common secret, different key derivations can be defined. Then, using the security context token, the <wsc:DerivedKeyToken> token can be used to derive keys from any security token that has a shared secret, key, or key material. This secret can be used for signing or encrypting messages, but it is recommended that derived keys be used for signing and encrypting messages that are associated only with the security context.

Syntax for the <wsc:DerivedKeyToken> element

The <wsc:DerivedKeyToken> element is used to indicate that the key for a specific reference is generated from the function so that explicit security tokens, secrets, or key material need not be exchanged as often. The derived key token does not support references to it using key identifiers or key names. All references must use an ID to a *wsu:Id* attribute or use a URI reference, <wsse:Reference>, to the <wsc:Identifier> element in the security context token.

The syntax for <wsc:DerivedKeyToken> element is as follows:

```
<wsc:DerivedKeyToken wsu:Id="...">
    <wsse:SecurityTokenReference>...</wsse:SecurityTokenReference>
    <wsc:Label>...</wsc:Label>
    <wsc:Nonce>...</wsc:Nonce>
  </wsc:DerivedKeyToken>
```

Derived keys are expressed as security tokens and use different algorithms for deriving keys. The following URI is used to represent the derived key token type:

```
http://docs.oasis-open.org/ws-sx/ws-secureconversation/200512/dk
```

The nonce is processed as a binary octet sequence (the value prior to base64 encoding). The nonce seed is required, and must be generated by one or more of the communicating parties. Use separate nonces and have independently generated keys for signing and encrypting for request and response. New keys should be derived for each message, meaning that a previous nonce should not be reused.

Implied derived key generation

Implied derived keys define a shortcut mechanism for referencing certain types of derived keys. Specifically, an @wsc:Nonce attribute can be added to the security token reference (STR) that is defined in the WS-Security specification. When present, an implied derived key indicates that the key is not in the referenced token but, instead, is a key that is derived from the key or secret of the referenced token. It is recommended that you do not use implied derived Keys in the <wsc:DerivedKeyToken> element.

The following example illustrates a message that is sent using two derived keys, one for signing and one for encrypting:

```
<S11:Envelope xmlns:S11="..." xmlns:wsse="..." xmlns:wsu="..."
    xmlns:xenc="..." xmlns:wsc="..." xmlns:ds="...">
  <S11:Header>
    <wsse:Security>
      <wsc:SecurityContextToken wsu:Id="ctx2">
        <wsc:Identifier>uuid:...UUID2...</wsc:Identifier>
      </wsc:SecurityContextToken>
      <wsc:DerivedKeyToken wsu:Id="dk2">
        <wsse:SecurityTokenReference>
          <wsse:Reference URI="#ctx2"/>
        </wsse:SecurityTokenReference>
        <wsc:Nonce>KJHFRE...</wsc:Nonce>
      </wsc:DerivedKeyToken>
      <xenc:ReferenceList>
        ...
        <ds:KeyInfo>
          <wsse:SecurityTokenReference>
            <wsse:Reference URI="#dk2"/>
          </wsse:SecurityTokenReference>
        </ds:KeyInfo>
          ...
      </xenc:ReferenceList>
      <wsc:SecurityContextToken wsu:Id="ctx1">
        <wsc:Identifier>uuid:...UUID1...</wsc:Identifier>
      </wsc:SecurityContextToken>
      <wsc:DerivedKeyToken wsu:Id="dk1">
        <wsse:SecurityTokenReference>
          <wsse:Reference URI="#ctx1"/>
        </wsse:SecurityTokenReference>
        <wsc:Nonce>KJHFRE...</wsc:Nonce>
      </wsc:DerivedKeyToken>
      <xenc:ReferenceList>
        ...
        <ds:KeyInfo>
          <wsse:SecurityTokenReference>
            <wsse:Reference URI="#dk1"/>
          </wsse:SecurityTokenReference>
        </ds:KeyInfo>
        ...
      </xenc:ReferenceList>
    </wsse:Security>
  ...
  </S11:Header>
  <S11:Body>
    ...
  </S11:Body>
</S11:Envelope>
```

Enabling secure conversation in a mixed cluster environment:

When Web Services Security applications using secure conversation run in a mixed cluster environment, an interoperability property must be set for the WebSphere Application Server Version 8.0 nodes.

About this task

A mixed cluster environment consists of nodes running WebSphere Application Server Version 6.1 Feature Pack for Web Services, and nodes running WebSphere Application Server V7 and later. To run Web Services Security applications utilizing secure conversation in this environment, enable the following

property for the V7.0 and later nodes in the cluster:
com.ibm.ws.wssecurity.distributedcache.PreV70InteropMode.

This property ensures that the method for adding entries in the cache is consistent between the different nodes, and also allows the applications to interoperate. To enable the property, follow these steps:

Procedure

1. In the WebSphere Application Server administrative console, click **Servers** > **Server Types** > **WebSphere application servers**.
2. Click the server name.
3. Under the Security section, click **JAX-WS and JAX-RPC security runtime**.
4. Click **Custom properties**.
5. Click **New**.
6. Enter the property name, `com.ibm.ws.wssecurity.distributedcache.PreV70InteropMode`, in the Property name field. Enter the property value of `true` in the Property value field, then click **OK**.
7. When the Properties panel is refreshed, the com.ibm.ws.wssecurity.distributedcache.PreV70InteropMode property appears in the properties table.
8. Click **Save** to commit the change.
9. Restart the server to load the new property.

Results

Secure conversation is now enabled for Web Services Security applications running in a mixed cluster environment.

Enabling distributed cache and session affinity when using Secure Conversation:

WebSphere Application Server provides message-level protection in a cluster environment. You can use Web Services Secure Conversation (WS-SecureConversation) for message-level protection of Java API for XML Web Services 2.0 (JAX-WS) Web services in a cluster environment.

Before you begin

A web services request that is protected with a Security Context Token (SCT) is routed to one server in a cluster, but that SCT might have been issued or renewed by a different server in the cluster. If the WebSphere Application Server distributed cache is not configured to replicate or does not replicate quickly enough, the server processing the request might not have access to the SCT. The task steps described in this topic need to be performed only if the replication setting for cluster members is set to asynchronous update for the Web Services Security distributed cache.

For more information on cache update settings, read the topic Enabling the distributed cache using synchronous update and token recovery. You can also enable the Web Services Security distributed cache with the default setting, which enables synchronous update of cluster members.

About this task

Perform the following high-level steps to enable distributed cache and session affinity when using secure conversation for message-level protection in a cluster environment.

Procedure

1. Enable the distributed cache for the Security Context Token.
   a. In the administrative console for WebSphere Application Server, click **Services** > **Security cache**.
   b. Select the **Enable distributed caching** check box.

c. Click the radio button to select **Asynchronous update of cluster members**.
d. Click **Apply** and then click **Save** to save the configuration.

2. Create a replication domain. Perform the following steps:
   a. In the Administrative Console, click **Environment** > **Replication domains** > **New**.
   b. Enter a name. For example, `ABCDomain`.
   c. Under Number of replicas, select the **Entire Domain** option.
   d. Click **OK** and then click **Save** to save the configuration.
3. Enable the dynamic cache. Perform the following steps for each server in the cluster:
   a. In the Administrative Console, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **Container Services** > **Dynamic Cache Service**.
   b. Select the **Enable cache replication** option.
   c. Select the replication domain name that you created. For example, `ABCDomain`.
   d. Select the replication type as **Both push and pull**.
   e. Click **OK** and then click **Save** to save the configuration.
4. Optional: Change the distributed cache batch update interval. By default, the distributed cache batch update interval is 1,000 milliseconds. However, you can set this interval to a value that is less than 1,000 milliseconds. To change the value, complete the following steps for each server in the cluster:
   a. In the Administrative Console, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **Java and Process Management** > **Process Definition** > **Java Virtual Machine** > **Custom Properties** > **New**.
   b. Enter the `com.ibm.ws.cache.CacheConfig.batchUpdateInterval` property name.
   c. Enter the property value.
   d. Click **OK** and then click **Save** to save the configuration.
5. Install and configure a web server or proxy server that supports session affinity. The IBM HTTP Server and WebSphere Application Server proxy server support session affinity. In the WebSphere Application Server Information Center, read the topic "Communicating with Web servers." for information on installing and configuring the IBM HTTP Server.
6. Configure the client systems to send the web services requests to the host and port where the web server or proxy server is running. The web server or proxy server then routes the requests to the proper cluster member.
7. On the services that are receiving the web services requests, which are protected by using Web Services Secure Conversation, select the HTTP transport Session enabled policy option. Complete the policy set configuration by following these steps:
   a. Add the HTTP Transport policy to the policy set that is being used by the services.
   b. In the configuration panel for the HTTP Transport policy, select **Session enabled**.
   c. Click **OK** and then click **Save** to save the configuration.
8. On the client systems that are sending the web services requests and are protected by Secure Conversation, enable the HTTP transport Maintain session property. Complete the policy set configuration or set the property programmatically. If you are using a policy set with your configuration, follow these steps:
   a. Add the HTTP Transport policy to the policy set that is being used by the clients.
   b. At the HTTP Transport policy configuration panel, select the **Session enabled** option.
   c. Click **OK** and then click **Save** to save the configuration.

Results

After the configurations are completed, you have enabled the distributed cache and session affinity when using secure conversation in a cluster environment. If the server processing the request does not have access to the SCT, it will fail the request with the error of `Either null SCT or invalid SCT`.

Example

The following example, which is a code snippet, demonstrates how to programmatically set the Maintain session property on the correct JAX-WS object:

```
Map<String> rc = ((BindingProvider) port).getRequestContext();
...
rc.put(BindingProvider.SESSION_MAINTAIN_PROPERTY, Boolean.TRUE);
... </String>
```

Flow for establishing a security context token to secure conversations:

This example scenario describes the flow of how the initiator establishes the security context token (SCT) by using the WS-Trust protocol for session-based security with the recipient. After establishing the security context token, derived keys from the security context token are used to sign and encrypt the SOAP message to provide message-level protection. This examples focuses on the message exchanges using the security context token in the overall flow of the SOAP messages.

The Organization for the Advancement of Structured Information Standards (OASIS) Web Services Secure Conversation (WS-SecureConversation) specification describes ways to establish a secure session between the initiator and recipient of SOAP messages. The WS-SecureConversation specification also defines how to use Web Services Trust (WS-Trust) protocol to establish a security context token. The product supports both Version 1.3, and the draft version, of the WS-SecureConversation specification.

WebSphere Application Server supports the ability of an endpoint to issue a security context token for WS-SecureConversation and thereby provides a secure session between the initiator and recipient of SOAP messages.

The following figure describes the flow that is required to establish a secured context and to use session-based security.

Figure 46. Displaying the flow between the client and the Web service and security token service

Exchanging messages between the initiator and the recipient

The following figure shows how the messages are exchanged between the initiator and the recipient to establish the security context token. The two WS-Trust protocols, RequestSecurityToken (RST) and RequestSecurityTokenResponse (RSTR), are used to request the security context token from the recipient endpoint.

The bootstrap policy is used to secure the RST and validate the RSTR request, which is typically different from the application security policy.

Figure 47. Using WS-Trust protocols RST and RSTR to establish the SCT between the initiator and the recipient

Scenario describing how to use secure conversation

Typically, to use secure conversation, the following steps are involved;

1. The client sends a RequestSecurityToken (RST) trust request for a security context token to an application endpoint with its secret key (entropy and target key size) and requests the target service secret key.

   This request is typically secured with asymmetric Web Service Security that is defined in the bootstrap policy.

2. The RST is processed by the trust service and, if the request is trusted based on the security policy, the trust service returns the security context token with the target service secret key by using a WS-Trust RequestSecurityTokenResponse (RSTR).

   This request is typically secured with asymmetric Web Service Security. The client verifies whether the RSTR can be trusted, based on the bootstrap policy.
3. If the RequestSecurityTokenResponse is trusted, the client secures (signs and encrypts) the subsequent application messages by using the session keys.

   The session keys are derived from secret of the security context token that is obtained from the initial WS-Trust RequestSecurityToken and RequestSecurityTokenResponse messages that are exchanged between the initiator and the recipient.
4. The specification defines an algorithm of how to derive the key based on the initial secret. The target web service calculates the derive key from the metadata contained in the security header of the SOAP message and the initial secret.
5. The target web service uses the derived key to verify and decrypt the message based on the application security policy.
6. The target web service uses the derived key from the secret to sign and encrypt the response based on the application security policy.
7. Repeat of steps 3 through 6 until the message exchange has completed.

Using keys that are derived from the secret of the security context token

After the security context token is established, the application messages are secured with message protection by using keys that are derived from the secret of the security context token. The derived keys are used to secure the application messages by signing and encrypting the application messages. The security context token contains a UUID, which is used as identification of a shared secret. The token UUID can be used in the SOAP message to identify the security context token for the message exchanges. The secret must be kept in memory by the session participants (in this case the initiator and the recipient) and protected. Compromising the secret undermines the secure conversation between the participants.

Figure 48. Securing application messages with keys derived from secret of the security context token

A similar scenario except with Web Services Reliable Messaging (WS-ReliableMessaging) is possible from the WS-SecureConversation prospective. See the example for establishing a security context token to secure reliable messaging.

Flow for establishing a security context token to secure reliable messaging:

This example scenario includes functions that are required for the composite scenario of Web Services Reliable Messaging (WS-ReliableMessaging), WS-SecureConversation, and WS-Trust. The scenario describes how to use WS-SecureConversation with WS-ReliableMessaging, the scenario is described from the WS-SecureConversation perspective.

The flow of this Web Services Reliable Messaging (WS-ReliableMessaging) scenario is very similar to the flow of the WS-SecureConversation scenario, and the exchange of the application messages is very similar to the Secure Conversation scenarios. The main difference in the two example scenarios is that the WS-ReliableMessaging sequence is secured with the security context token and scopes the WS-ReliableMessaging sequence to the security context token.

The following figure describes a summary of the message flows that are required to establish a security context token to secure reliable messaging.

Figure 49. Messages exchange for the SCT and reliable messaging

Scenario

The WS-ReliableMessaging sequence is secured with the security context token and is scoping the WS-ReliableMessaging sequence to the security context token. This scenario focuses on the message exchanges that are using the security context token in the overall flow.

Note: The exact detail of how WS-ReliableMessaging is validating the WS-ReliableMessaging sequence, with respect to the security context token scoping, is not described.

Typically, to use secure conversation and a security context token to secure reliable messaging, the following steps are involved;

- The WS-ReliableMessaging run time calls APIs from the Web Services Security run time to get the UUID of the security context token for the session and also the API for serializing and deserializing the security context token for managed persistent for reliable recovery.

  Because of the security nature of the security context token, the WS-ReliableMessaging protocol makes sure that the serialized security context token in persistent store is protected.
- If there is already a security context token established the UUID of the existing security context token is returned to WS-ReliableMessaging. If there is no security context token already established, the Web Services Security run time initiates a call to the recipient to establish the security context token.

  The latter case is similar to the Secure Conversation scenario.
- After the WS-ReliableMessaging run time acquires the UUID of the security context token, the WS-ReliableMessaging run time scopes the CreateSequence message to the security context token by using the SecurityTokenReference (STR) argument in the CreateSequence message and responds with the CreateSequenceResponse message.

  The exchange of the application messages is very similar to the WS-SecureConversation scenario.
- The WS-ReliableMessaging run time responds with the CreateSequenceResponse message.

  The exchange of the messages is very similar to the exchange in the WS-SecureConversation scenario.
- The WS-ReliableMessaging run time sends a SequenceAcknowledgement message to acknowledge that the message is properly delivered and secured by the security context token.
- Finally, the WS-ReliableMessaging run time sends a TerminateSequence message to terminate the sequence and is secured by the security context token.

Enabling the distributed cache using synchronous update and token recovery:

To support secure conversation in a cluster environment, the distributed cache stores the shared state information. Version 7.0 and later of WebSphere Application Server uses MBeans to improve synchronous update of the cache across the cluster. In addition, persistent token support is provided by storing the token data in a database.

About this task

Synchronous update of shared information in the distributed cache is implemented in the product using an MBean solution. When update of the shared state information across cluster members is required, a synchronous blocking call is issued to replicate the token state changes to all the servers in the cluster. This solution removes the limitations of using session affinity for secure conversation in a cluster environment.

Perform the following high-level steps to enable distributed cache when using secure conversation for message-level protection in a cluster environment.

Procedure

1. In the administrative console for WebSphere Application Server, click **Services** > **Security cache**.
2. Click the check box to select the **Enable distributed cache** setting.
3. The distributed cache setting has three options. The first option is **Synchronous update of cluster members**. This option is selected by default, enabling the runtime to update all the cluster members with token information synchronously. If this is selected, then session affinity does not have to be enabled.

   The second option is **Asynchronous update of cluster members**, which you can select by clicking the corresponding radio button. For this option to work successfully, session affinity must be enabled. For information on enabling session affinity, read the topic Enable distributed cache and session affinity when using Secure Conversation. If Asynchronous update of cluster members is selected, skip steps 4 and 5.

   The third option is **Token recovery support**. To enable this option, click the corresponding radio button, then select a data source (database) from the **Cell level data sources** menu list. To create a data source, click the **Manage data sources** link. If Token recovery support is selected, skip steps 4 and 5.
4. This step is needed only if Synchronous update of cluster members is selected. Create a replication domain, as follows:
   a. In the administrative console, click **Environment > Replication domains > New**.
   b. Enter a name for the domain. For example, **ABCDomain**.
   c. In the Number of replicas section, click the radio button to select the **Entire Domain** option.
   d. Click **OK**, then **Save**, to save the modified configuration.
5. This step is needed only if Synchronous update of cluster members is selected. Enable the dynamic cache by performing the following steps for each server in the cluster:
   a. In the administrative console, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **Container Services** > **Dynamic cache service**.
   b. Select the **Enable cache replication** option.
   c. Select the replication domain name that you created in the previous step. For example, **ABCDomain**.
   d. Under Replication type. select **Both push and pull** from the menu list.
   e. Click **OK**, then click **Save** to save the modified configuration.

   Different clusters should use different replication domains. Likewise, cluster members from the same cluster should use the same replication domain. This ensures that synchronous update of cluster members performed by the Web Services Security runtime, and dynamic replication service updates of cluster members performed by the WebSphere Application Server dynamic cache runtime, are in sync.

Results

When the configuration steps are complete, you have enabled the distributed cache with either the default option, which is synchronous update of cluster members, or with asynchronous cluster update or with token recovery support. The token recovery support option uses a JDBC database to store the token state. This provides failover support for high availability of the token. If the server processing the request does not have access to the secure conversation token, the request fails, producing an error such as "null secure conversation token" or "invalid secure conversation token."

Configuring the token generator and token consumer to use a specific level of WS-SecureConversation:

Use the administrative console to configure the token generator or token consumer to use a specific level of the WS-SecureConversation OASIS specification standard. Select one of the two levels of token types supported: Secure Conversation Token v200502, or Secure Conversation Token v1.3.

About this task

WebSphere Application Server supports two levels of the OASIS standard for WS-SecureConversation including both the submission draft version (February 2005 draft specification) and version 1.3 of the standard, which was approved on March 1, 2007. Using the administrative console, configure the token generator so that the appropriate token type for a specific level of the standard is issued when a security token is requested.

Procedure

1. Log on to the administrative console and navigate to the panel where the token generator is configured by clicking **Services** > **Policy sets** > **General provider policy set bindings** or **General client policy set bindings**.
2. Click on the name of the binding you want to edit.
3. Click the **WS-Security** policy in the Policies table.
4. Click the **Authentication and protection** link in the Main message security policy bindings section.
5. Click **New token** to create a new token generator or consumer, or click an existing token link from the Protection Tokens table.
6. Enter a token name, then use the Token type drop-down menu to select a secure conversation token type.
   - To specify a submission draft token type, select **Secure Conversation Token v200502**.
   - To specify a version 1.3 token type, select **Secure Conversation Token v1.3**.
7. The local name is populated according to the token type you selected, as follows:
   - Local name for the submission draft token type: http://schemas.xmlsoap.org/ws/2005/02/sc/sct
   - Local name for the version 1.3 token type: http://docs.oasis-open.org/ws-sx/ws-secureconversation/200512

   The URI field is also filled in based on the token type.
8. Click to deselect the option **Tolerate Secure Conversation Token v200502** if you want to enforce use of only the version 1.3 tokens. This option specifies whether the provider should handle both Secure Conversation Token version 1.3 and Secure Conversation Token v200502. By default, the provider handles both versions.
9. Click **Apply** to create a secure conversation token of the selected type.

Web Services Secure Conversation standard:

Web Services Secure Conversation (WS-SecureConversation) is a proposed Organization for the Advancement of Structured Information Standards (OASIS) standard that defines mechanisms for establishing and sharing security contexts, and deriving keys from security contexts, to enable a secure conversation.

The base Web Services Security (WS-Security) standard from OASIS defines how to digitally sign and encrypt the SOAP message to provide message level protection. The standard also defines how to attach and reference a security token for digital signature and encryption. However, it does not provide session-based protection when a long series of related messages were exchanged. The WS-Security specification focuses on the *message authentication model*. This approach, while useful in many situations, could be subject to several forms of attack.

The WS-SecureConversation specification introduces the concept of a security context and its usage. The security context token is a new WS-Security token type that represents the security context abstract concept. The token is identified by a URI and consists of negotiated keys as well as other security related properties. The *context authentication model* authenticates a series of messages and, therefore, addresses

these concerns. The context authentication model increases the overall performance and security of the subsequent exchanges, but it requires additional communications when authentication happens prior to normal application exchanges.

Version 1.0 of the OASIS WS-SecureConversation specification defines extensions that build on the Web Services Security (WS-Security) and Web Services Trust (WS-Trust) standards to provide secure communication across one or more messages.

IBM, Microsoft, and other vendors have been working on the WS-SecureConversation specification since 2004. A draft of this document was jointly published in February, 2005. The WS-SecureConversation draft was submitted to the OASIS Web Service Secure Exchange Technical Committee (WS-SX TC), which was formed in December 2005, along with Web Services Trust (WS-Trust) and Web Services Security Policy (WS-SecurityPolicy) drafts in order to begin the standardization process.

A revised Version 1.1 draft version of the WS-SecureConversation specification standard was submitted to OASIS in February 2005 and further defines the extensions in Version 1.0. This specification defines extensions to allow security context establishment and sharing, and session key derivation. These extensions allow contexts to be established and potentially more efficient keys or new key material to be exchanged.

The most recent version of the specification standard is version 1.3, which was approved by the WS-SX TC on March 1, 2007. Key requirements in this level of the specification include derived keys and per-message keys, and extensible security contexts. WebSphere Application Server adds support for version 1.3 of WS-SecureConversation, providing improved error handling using the standard fault codes as defined in the specification.

The Web Services Secure Conversation (WS-SecureConversation) standard is a building block that is used in conjunction with the other web service and application-specific protocols such as Web Services Security and Web Services Trust to accommodate a wide variety of security models and technologies. WS-SecureConversation is built on top of the WS-Security and WS-Trust models to provide secure communication between services. The WS-SecureConversation draft specification describes how to establish a security context token between two parties, and the WS-Trust specification describes how to issue and exchange security tokens.

This WS-SecureConversation draft specification includes extensions to Web Services Security and:

- Describes the security context token.
- Defines how security contexts are established.
- Describes how security contexts are amended, renewed, and cancelled. Amending context is not supported by WebSphere Application Server.
- Specifies how derived keys are computed.
- Specifies how to associate a specific security context with an action, if multiple security contexts exist.

WebSphere Application Server supports the client establishing a secured conversation with the target service endpoint.

WebSphere Application Server supports the OASIS Version 1.1 submission draft, which became available in February 2005. The WebSphere Application Server does not support all of the functions in the submission draft. WebSphere Application Server support of WS-SecureConversation focuses on:

- A security context token that is established between the initiating party and the recipient party.
- The operations that are supported on security context token, such as Issue token, Renew token, and Cancel token.
- The derived key (both explicit and implied)

Secure conversation provided with WebSphere Application Server does not provide support for a security context token (SCT) that is acquired from a third-party trust server, and does not provide support for a security context token that is created by the client.

For information about WS-SecureConversation:

- See the IBM developerWorks website.
- See the schema for this specification: WS-SecureConversation schema
- Refer to the following namespace prefixes that are used for WS-SecureConversation: http://schemas.xmlsoap.org/ws/2005/02/sc and http://docs.oasis-open.org/ws-sx/ws-secureconversation/200512

Trust service:

The security token service that is provided by WebSphere Application Server is called the trust service. The WebSphere Application Server trust service uses the secure messaging mechanisms of Web Services Trust (WS-Trust) to define additional extensions for the issuance, exchange, and validation of security tokens.

Web Services Trust (WS-Trust) is an OASIS standard that enables security token interoperability by defining a request/response protocol. This protocol allows SOAP actors, such as a web services client, to request of some trusted authority that a particular security token be exchanged for another.

WebSphere Application Server is not providing a full security token service that implements all the contents of the WS-Trust draft specification. The WebSphere Application Server support of WS-Trust focuses on establishing a security context token for secure conversation. WebSphere Application Server supports many of the security features described in version 1.3 of the WS-Trust OASIS standard, dated March 19, 2007.

Third party WS-Trust client

WebSphere Application Server does not provide a WS-Trust client implementation. You can choose to use a third-party WS-Trust-enabled client but, if you do, WebSphere Application Server does not support a third-party trust-enabled client. A trust client can facilitate the generation of these soap messages and the processing of the response, but the client is not required.

WebSphere Application Server focuses on the issuing, renewing, and canceling of the security context token for Web Services Secure Conversation (WS-SecureConversation).

The WS-Trust specification must be followed to make requests of the trust service. This specification includes the use of Web Services Addressing (WS-Addressing) headers. The WS-Addressing headers are specified in both the August 2004 or the August 2005 specifications. Per the specification, the SOAP body must consist of a single RequestSecurityToken (RST) element. This element can contain sub-elements as defined in the WS-Trust and WS-SecureConversation specifications.

You can secure the WS-Trust SOAP messages by using the bootstrap policy that is defined in the policy set. The bootstrap security policy is invoked in the process of an initiator establishing communication with an application service. Initial requests to services other than the application service are secured by using the bootstrap policy. These initial requests typically involve one or more requests to a security token service (STS), such as the WebSphere Application Server trust service. An example of a request might be acquiring the security context token necessary for WS-SecureConversation. An *initiator* is the role that initiates the original request and, in most cases, it is the client. The client bootstrap policy set must correspond to the trust service issue and renew attached policy sets for the endpoint. The trust service cancel and validate attached policy sets for the endpoint must correspond to the client's application policy set.

Websphere Application Server provides two ways to secure SOAP messages that are destined for the trust service. One way is to use the bootstrap policy that is defined in the policy set. A second way is to use the Web Services Security API (WSS API). Your application might use the WSS API to acquire the security context token for the programmatic, API-based WS-SecureConversation.

For Secure Conversation, a request from the client to an endpoint service is suspended while a new (second) request is generated and processed by the trust service. The security context token returned with the second request is used to derive keys that secure communications with the service.

High-level trust service functions

The following list includes WS-Trust-related functions that are currently supported in WebSphere Application Server. The list is not exhaustive and it focuses only on the high-level functions.

- The trust service component is embedded into and available on each WebSphere Application Server that processes the WS-Trust protocol messages.
- Communication is accomplished through the RequestSecurityToken (RST), RequestSecurityTokenCollection (RSTC), RequestSecurityTokenResponse (RSTR), and RequestSecurityTokenResponseCollection (RSTRC).

  Note: An RST request can be made to an external security token service (trust service). However, the restriction is that security context token, which is needed for WS-SecureConversation, must be provided by the WebSphere Application Server trust service.
- A security policy for each of the WS-Trust operations (issue, cancel, validate, and renew).
- Pre-configured Security Context Token provider which issues tokens for specific URL.
- Specification of a token provider's token-specific parameters (for example, expiration time).
- A security context token for WS-SecureConversation.
- Caching support for the security context token in both cluster and non-cluster environments. WebSphere Application Server issues security context tokens when requested if the request meets the security requirements. However, WS-SecureConversation provided by WebSphere Application Server only processes security context tokens that are issued by WebSphere Application Server.
- Note that WebSphere Application Server trust service only supports the security context token.
- Trust service supports both the Submission specification (2004/08) and the final specification (2005/08) versions of WS-Addressing.
- Trust service uses a default policy set called TrustServiceSecurityDefault, which includes WS-Security and WS-Addressing and provides default security for the issue and renew operations.
- Trust service uses a second default policy set called TrustServiceSymmetricDefault, which includes WS-Security and WS-Addressing and provides default security for the cancel and validate operations.

Trust service functions that are not supported

The following high-level WS-Trust functions that are not supported in WebSphere Application Server. The list is not exhaustive, and the list focuses only on key functions:

- No negotiation and exchange protocols are supported.
- No other token types are currently supported out of the box; only the security context token is supported.
- No Trust10 specifications from WS-SecurityPolicySet are supported.
- No unsolicited RequestSecurityTokenResponse (RSTR) is supported.
- A Request Security Token (RST) request cannot be issued to an external security token service (STS) to establish a secure conversation; only the embedded trust service is currently supported.
- Policy requests that are contained in the RST are not honored.
- The ability to amend a token (the amend operation) is not supported.

- A dedicated external endpoint for access to the token service is not supported; only the embedded trust service is currently supported.
- The trust services does not support the entropy element that contains an EncryptedKey.
- Delegation and forwarding are not supported.
- The OnBehalfOf element is not supported.
- The Key Exchange Token (KET) binding is not supported.

Trust service operations

WebSphere Application Server specifically supports the ability of the trust service, on behalf of the endpoint, to issue a security context token for WS-SecureConversation. The token-issuing support is currently limited only to the security context token. There is also trust policy management for defining a policy for the trust service to issue, cancel, validate, or renew tokens.

The token service supports the WS-Trust schema namespace. Within this namespace the following actions are supported:

- http://docs.oasis-open.org/ws-sx/ws-trust/200512/RST/Issue
- http://docs.oasis-open.org/ws-sx/ws-trust/200512/RST/Cancel
- http://docs.oasis-open.org/ws-sx/ws-trust/200512/RST/Validate
- http://docs.oasis-open.org/ws-sx/ws-trust/200512/RST/Renew

The token service also supports the WS-SecureConversation schema namespace. Within this namespace the following actions are supported:

- http://docs.oasis-open.org/ws-sx/ws-trust/200512/RST/SCT
- http://docs.oasis-open.org/ws-sx/ws-trust/200512/RST/SCT/Cancel
- http://docs.oasis-open.org/ws-sx/ws-trust/200512/RST/SCT/Renew

An inbound RST for the security context token issue operation must contain an Entropy element. The Entropy element must contain a BinarySecret. The trust services does not support the Entropy element that contains an EncryptedKey.

Note that the trust service does not support unsolicited RSTR actions. In addition, the ability to amend a token is not supported by WebSphere Application Server. Also, see the section titled Trust service functions that are not supported.

Trust policy set-related files

The default trust service policy set for issue and renew is TrustServiceSecurityDefault. You can set up the corresponding policy set and binding for each service endpoint URL.

Security context token:

Web Services Trust (WS-Trust) and Web Services Secure Conversation (WS-SecureConversation) support in the application server provides the ability to issue a security context token (SCT). Requests for a security context token are processed by the security token service.

The security token service for WebSphere Application Server is called the trust service. However, the application server does not provide a full security token service that implements all the contents of the WS-Trust specification.

The secure session is referred to as *secure conversation* because the message protocols that are used are defined by WS-SecureConversation and WS-Trust. WebSphere Application Server supports secure conversation.

To request a security context token, a RequestSecurityToken (RST), which is defined by WS-Trust and WS-SecureConversation protocols, is sent to the service endpoint to which you are setting up a secure conversation. These requests are transparently rerouted to the trust service. The trust service processes the RST and responds with a RequestSecurityTokenResponse (RSTR). This response is returned to the requestor as if it was generated by the endpoint service.

The WebSphere Application Server token provider support is limited to the Security Context Token provider. WS-SecureConversation in the application server focuses on the establishing of the security context token between the initiating party and the recipient party for secure conversation.

WebSphere Application Server includes caching support for the Security Context Token in both cluster and non-cluster environments as well as on both the client and server. WebSphere Application Server also provides trust policy set management for each of the trust service operations: issue, cancel, validate, and renew. Trust system policy sets can be managed for each of these trust operations relative to an explicit service endpoint or the trust service default. The default trust service policy set for a trust operation is enforced when there is not an explicit attachment.

See the information about Web Services Trust for the WS-Trust functions that are supported.

For the security context token, you can:

- Configure the security context token provider for WS-SecureConversation, providing issue, renew and cancel operations.
- Configure the trust service to issue a security context token for access to a specific endpoint service (target).
- Configure the security requirements for access to the trust service and applications. WebSphere Application Server provides pre-configured application policy sets and trust service policy sets to assist with this configuration.
- Define a system policy for each of the four trust service operations: issue, cancel, validate, and renew. These policies are configured for the default or a specific endpoint service. Note that the amend operation is not supported.

The Security Context Token provider does not support the following operations:

- WS-SecureConversation amend
- Negotation to establish Secure Conversation
- WS-Trust key exchange requests
- Client-initiated RequestSecurityTokenResponse (RSTR) and RequestSecurityTokenResponseCollection (RSTRC) requests
- WS-SecurityPolicy trust assertions

Definitions

To better understand security tokens, the following terms are defined:

security token
A security token represents a collection of claims.

security context
A security context is an abstract concept that refers to an established authentication state and negotiated key or keys that can have additional security-related properties. A security context needs to be created and shared by the communicating parties before being used. A security context is shared among the communicating parties for the lifetime of a communications session and a security context token is the wire representation of this abstract security context.

WebSphere Application Server does not support a security context token created by one of the communicating parties and propagated with a messageWebSphere Application Server does not support creating a security context token through negotiation and exchanges.

security context token
A security context token is a wire representation of that security context abstract concept, which allows a context to be named by a URI and to be used with Web Services Security. A secured communication with a security context token between two parties is realized with WS-Trust and WS-SecureConversation.

security token service
A security token service (STS) is a web service that issues security tokens, meaning it makes assertions that are based on evidence that it trusts, to whoever trusts it (or to specific recipients).

Trust service
The trust service is the security token service and supporting code that is provided by Websphere Application Server.

RequestSecurityToken (RST)
A RST is a message sent to a security token service to request a security token.

RequestSecurityToken Response (RSTR)
A RSTR is a response to a request for a security token from a security token service to a requestor after receiving an RST message.

To communicate trust, a service requires proof, such as a signature, to prove knowledge of a security token or set of security tokens. A service itself can generate tokens or it can rely on a separate security token service to issue a security token with its own trust statement. Note that, for some security token formats, communicating trust can just be a re-issuance or a co-signature that forms the basis of trust brokering.

Syntax for the <wsc:SecurityContextToken> element

A security context is shared among the communicating parties for the lifetime of a communications session and a security context token is the wire representation of this abstract security context.

In the WS-SecureConversation specification, a security context is represented by the <wsc:SecurityContextToken> security token. The following URI represents the security context token type that is required to establish a secure conversation.

```
http://docs.oasis-open.org/ws-sx/ws-secureconversation/200512/sct
```

The syntax for <wsc:SecurityContextToken> element is as follows:

```
<wsc:SecurityContextToken wsu:Id="..." ...>
    <wsc:Identifier>...</wsc:Identifier>
    <wsc:Instance>...</wsc:Instance>
    ...
</wsc:SecurityContextToken>
```

The security context token does not support references to it by using key identifiers or key names. All references must use an ID (to a *wsu:Id* attribute) or use a URI reference, <wsse:Reference>, to the <wsc:Identifier> element in the security context token.

RST and RSTR examples to issue a security token

This example shows a RST request to issue a security token. The URI `http://docs.oasis-open.org/ws-sx/ws-secureconversation/200512/sct`, which is used in this example, represents the token type:

```
<wsc:SecurityContextToken>

 </soapenv:Body>
</soapenv:Envelope>
```

For additional information, review the two example scenario topics that discuss establishing the security context token.

System policy sets:

A policy set is a named collection of Quality of Service (QoS) policies. You can use either the administrative console or the wsadmin commands to manage system policy sets. Policy sets can be created, deleted, copied, imported or exported.

A policy set can be shared by multiple resources, such as applications, services, inbound or outbound service endpoints, and operations. Default policy sets are installed using profile augmentation. A policy set can also be imported. A policy set does not have its own bindings. You must attach a policy set to a resource, and then assign a binding to the attachment.

Note: When attempting to connect to a web service from a thin client, verify that the resources that you are specifying are valid before running the updatePolicySetAttachment command. No configuration changes are made if the requested resource does not match a resource in the attachment file for the application.

A client application can dynamically select a policy suite (reference by name from an application-level policy suites list). Options shown in the administrative console list are based on the type of template that is selected to create the policy set. For example, the SecureConversation policy type is made up of policies for both WSSecurity and WSAddressing.

There are two types of policy sets:

- Application policy sets
- System/trust policy sets

WebSphere Application Server provides predefined system policy sets. For example, WebSphere Application Server provides the following system policy sets by default for the security trust service:

- TrustServiceSecurityDefault

  This trust policy set specifies the asymmetric algorithm as well as the public and private keys to provide message security. Message integrity is provided by digitally signing the body, time stamp, and WS-Addressing headers using RSA. Message confidentiality is provided by encrypting the body and signature using RSA. This policy set follows the WS-Security specifications for the issue and renew trust operation requests.
- TrustServiceSymmetricDefault

  This policy set specifies the symmetric algorithm as well as the derived keys to provide message security. Message integrity is provided by digitally signing the body, time stamp, and WS-Addressing headers using HMAC-SHA1. Message confidentiality is provided by encrypting the body and signature using AES. This policy set follows the WS-Security and Secure Conversation specifications for validate and cancel trust operation requests.
- SystemWSSecurityDefault

  This policy set specifies the asymmetric algorithm and both the public and private keys to provide message security. Message integrity is provided by digitally signing the body, time stamp, and WS-Addressing headers using RSA encryption. Message confidentiality is provided by encrypting the body and signature using RSA encryption

You cannot edit default system policy sets. However, you can create your own custom system policy set, which can be edited later. Copy or export a default or existing custom system policy set to create the new custom policy set. System policy sets can also be imported from a predefined location, or from the default repository. Add one or more policies to each policy set. For example, add any of the following existing policies:

- Custom properties
- HTTP transport
- JMS transport
- SSL Transport
- WS-Addressing
- WS-Security

The HTTP transport policy can be used for HTTPS, basic authorization, compression, and binary encoding transport methods.

Web Services Trust standard:

Web Services Trust (WS-Trust) is a proposed Organization for the Advancement of Structured Information Standards (OASIS) standard that enables security token interoperability by defining a request/response protocol. This protocol allows SOAP actors, such as a web services client, to request of some trusted authority that a particular security token be exchanged for another. The trust service, which is provided with WebSphere Application Service, uses the secure messaging mechanisms of WS-Trust to define additional extensions for the issuance, exchange, and validation of security tokens.

WS-Trust defines a request and response protocol for security token exchange. A client sends a RequestSecurityToken (RST) to a security token service. The request includes the security token that the client is asking to be exchanged. The security token service responds back with a RequestSecurityTokenResponse (RSTR) that contains the new token.

In addition to the token exchange, the WS-Trust request/response protocol is general enough to support token *issuance*, where the client presents a claim to the trust service for the service to authorize through the issuance of a corresponding security token. Token *validation* is where the client presents a token to the trust service and asks that its validity be determined.

Also, WS-Trust enables the issuance and dissemination of credentials within different trust domains. To secure a communication between two parties, the two parties must exchange security credentials (either directly or indirectly). Each party must first determine if they can trust the asserted credentials of the other party.

The OASIS WS-Trust specification defines extensions to Web Services Security (WS-Security) for issuing and exchanging security tokens and for providing ways to establish and access the presence of trust relationships. Using these extensions, applications can engage in secure communication, and these extensions are designed to work with the general web services framework. The general web services framework includes the WSDL service descriptions, UDDI businessServices and bindingTemplates, and SOAP messages.

The WebSphere Application Server support of WS-Trust focuses on establishing a security context token for Web Services Secure Conversation (WS-SecureConversation). The WS-Trust support focuses on the four actions for the security context token: issue, renew, validate, and cancel. Also supported for WS-Trust Version 1.3 are collection requests for the same actions: issue, renew, validate and cancel. The major component for WS-Trust that WebSphere Application Server supports is the security token service, which is referred to as the trust service.

Support for submission draft and approved levels of the WS-Trust standard

Version 6.1 and later of WebSphere Application Server supports the WS-Trust 2005 Submission Draft specification (Version 1.1). However, WebSphere Application Server does not provide a full security token service that implements all the contents of the WS-Trust draft specification.

Support for the approved version 1.3 specification, which is dated March 2007, is provided for WebSphere Application Server version 7.0 and later. The Security Context Token (SCT) provider supports the OASIS version 1.3 specifications for WS-Trust and WS-SecureConversation. There is a configuration option that allows support for the two different levels of the WS-Trust standard to co-exist on the same server. This provides interoperability between systems and products that support different specification levels. See the topic Configuring the security context token provider for the trust service using the administrative console for details.

A setting is also provided to specifically disable support for the WS-Trust 2005 Submission Draft specification (Version 1.1) for the Security Context Token provider. For more information about this property, refer to the topic Disabling the draft standard level for the Security Context Token.

Processing a trust service request depends on the specifications referenced in the request. Also, the trust service response is determined by the level of the specification used in the request.

For more information about WS-Trust:

- See the IBM developerWorks website.
- See the schema for the specification: http://docs.oasis-open.org/ws-sx/ws-trust/200512
- Refer to the `wst` namespace prefix that is used for WS-Trust in the Web Services Trust Language (WS-Trust) specification dated March 2007.

Configuring system policy sets using the administrative console:

By defining a custom policy set or defining assertions about how services are defined, you can configure Web Services Security. You can use the administrative console to manage custom policy sets.

Before you begin

A policy set specifies a set of common message policy assertions that can be specified within a policy. For example, a policy set can define general security policy assertions that apply to other protocols, such as Web Services Security (WS-Security), SOAP messages, Web Services Secure Conversation (WS-Secure Conversation) and Web Services Trust (WS-Trust).

There are two main types of policy sets; application policy sets and system policy sets. Application policy sets are used for business-related assertions. These assertions are related to the business operations that are defined in the Web Services Description Language (WSDL) file. System policy sets, on the other hand, are used for non-business-related system messages. These messages are defined in other specifications which apply qualities of service (QoS). Examples of QoS are the request security token (RST) messages that are defined in WS-Trust, the create sequence messages that are defined in WS-Reliable Messaging, and the metadata exchange messages defined by WS-MetadataExchange.

Important: Use system policy sets with the trust service, or Web Services MetadataExhange (WS-MEX). The requestor (client) must utilize Java API for XML-Based Web Services (JAX-WS) only. Requestors which use Java API for XML-based remote procedure calls (JAX-RPC) are incompatible with the policy set QOS.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

About this task

Only custom policy sets can be modified. Default system policy sets are read only and cannot be changed.

Procedure

1. To define system policy sets, click **Services** > **Policy sets** > **System policy sets**.
2. Click one of the following actions to work with the system policy set configurations:

   New To create a system policy set configuration. Enter a unique name for the system policy set configuration in the Name field. For example, you might specify `EcommerceTrustServiceSecurity`.

   Delete To delete an existing configuration. Select the check box next to an existing policy set name, and click **Delete**.

   Copy To copy an existing configuration. Select the check box next to an existing policy set name, and click **Copy**.

   Import
   To import an existing configuration. Select the check box next to an existing policy set name, and click **Import**. For more information, read about importing policy sets using the administrative console.

   Export
   To export an existing configuration. Select the check box next to an existing policy set name, and click **Export**. For more information, read about exporting policy sets using the administrative console.
3. To edit the settings of an existing policy set configuration, click the link for the existing custom system policy set that you want to change. Use the administrative console to modify existing custom policy sets that have been created.
4. Optional: If creating a policy set, enter a short description for the new policy set. Default policy sets can only be viewed. For a custom policy set, edit the brief description of the policy set in the

Description field. This description displays in the list on the System policy sets panel. The description should be meaningful to you and other potential users of this policy set.

5. If creating a new policy set, click **Apply**. The policy set name must be applied before you can add policy types to the new policy set.
6. Optional: If needed, add the policy type information, or change the policy types for an existing system policy set. You can add, delete, enable, or disable policy types for the selected policy set. You can add any valid policy types to the policy set collection. The following are available policy types for system policy sets:
   - HTTP transport - for HTTP transport policies
   - SSL transport - for HTTPS transport policies
   - WS-Addressing - for endpoint addressing policies
   - WS-Security - for secure SOAP messages policies
7. Click **OK** and then click **Save** to save the information directly to the master configuration.

Results

You have provided the basic information to create a system policy set. You can also create a new or update an existing system policy set for the WebSphere Application Server trust service, or Web Services MetadataExhange (WS-MEX), using the wsadmin tool. The wsadmin tool examples are written in the Jython scripting language.

What to do next

After creating a system policy set and adding the policy types, attach the system policy set to a trust service operation for an endpoint, or attach it to one of the trust service default operations.

Defining a new system policy set using the administrative console:

Use policy sets, or assertions, to define system service operations, for your Web Services Security configuration. Whenever you create a new policy set, you must add policy types to the policy set. You can add HTTP Transport, WS-Addressing, WS-Security, and SSL Transport policy types to the system policy set collection.

Before you begin

A policy set specifies a set of common message policy assertions that can be specified within a policy. For example, a policy set can define general security policy assertions that apply to other protocols such as Web Services Security (WS-Security), SOAP messages, Web Services Trust (WS-Trust), and Web Services Secure Conversation (WS-SecureConversation).

Important: Use system policy sets with the trust service only. The requestor (client) must utilize Java API for XML-Based Web Services (JAX-WS) only. Requestors which use Java API for XML-based remote procedure calls (JAX-RPC) are incompatible with the policy set QOS.

About this task

Use the system policy sets to configure access to the WebSphere Application Server trust service. You can create and define a custom system policy set.

Procedure

1. Using the administrative console, click **Services > Policy sets > System policy sets** .
2. To create a system policy set and add a policy type, click **New**.
3. Enter a name for the policy set in the **Name** field. The name must be unique for the new system policy set. For example: EcommerceTrustServiceSecurity

4. Enter a brief description of the policy set in the **Description** field. This description displays in the System Policy Sets collection. The description should be descriptive enough for you and other potential users to identify the policy set.
5. Click **Apply** to apply the name and description information.
6. Click **Add** to add a trust policy by selecting one from the policies listed. The following policies are available to use for system policy sets:
   - HTTP transport - for HTTP transport policies
   - SSL transport - for HTTPS transport policies
   - WS-Addressing - for endpoint addressing policies
   - WS-Security - for secure SOAP messages policies
7. Click **Save** to save directly to the master configuration.

Results

You have provided the basic information to create or modify a policy set. You can also create a new or update an existing policy set for the WebSphere Application Server trust service using the wsadmin tool. The wsadmin tool examples are written in the Jython scripting language.

What to do next

After creating or modifying a system policy set and adding the policy types, attach the policy set to an endpoint operation or attach it to one of the trust service default operations.

System policy set collection:

Use this panel to create and manage policy sets. A policy set is a named collection of policies. System policy sets, or assertions about how services are defined, are used to configure access to the trust service.

There are two main types of policy sets; application policy sets and system policy sets. Application policy sets are used for business-related assertions. These assertions are related to the business operations that are defined in the Web Services Description Language (WSDL) file. System policy sets, on the other hand, are used for non-business-related system messages. These messages are defined in other specifications which apply qualities of service (QoS). Examples of QoS are the request security token (RST) messages that are defined in WS-Trust, the create sequence messages that are defined in WS-Reliable Messaging, and the metadata exchange messages defined by WS-MetadataExchange.

To view this administrative console page, click **Services** > **Policy sets** > **System policy sets**.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Select:

Provides a check box next to the name of an existing system policy set that you want to select for further actions.

To manage existing system policy sets, select the check box for a system policy set and then select one of the following actions:

Actions	Description
Delete	Removes one or more selected system policy sets.

Actions	Description
Copy	Opens a new panel where you can create a copy of the selected existing policy set. Provide a unique name and, optionally, a description for the copied policy set. You must also specify whether to transfer the attachment and binding from the original version to the copy. You can select only one policy set to be copied at one time.
Import	Imports a policy set. This is a menu item with the option of importing a policy set from a default repository or a selected location. You can select and import the default policy sets from the default repository. The default repository for the import function in the administrative console is the directory which contains the default policy sets. The administrative console also displays the default policy sets in a list which includes descriptions, to allow you to select the desired policy set that you want to import.
Export	Opens a new panel where you can export the selected policy set. You can select only one policy set to be exported at one time.

New:

Specifies to create and define a custom system policy set.

Name:

Provides a list of available system policy sets.

This column displays a list of default and custom system policy set names. WebSphere Application Server provides several default system policy sets:

- **TrustServiceSecurityDefault** is a default trust policy set. This trust policy set specifies the asymmetric algorithm as well as the public and private keys to provide message security. Message integrity is provided by digitally signing the body, time stamp, and WS-Addressing headers using RSA. Message confidentiality is provided by encrypting the body and signature using RSA. This policy set follows the WS-Security specifications for the issue and renew trust operation requests.
- **TrustServiceSymmetricDefault** is a default trust policy set. This trust policy set specifies the symmetric algorithm as well as the derived key algorithms to provide message security. Message integrity is provided by digitally signing the body, time stamp, and WS-Addressing headers using HMAC-SHA1. Message confidentiality is provided by encrypting the body and signature using AES. This policy set follows the WS-Security and WS-SecureConversation specifications for the validate and cancel trust operation requests.
- **SystemWSSecurityDefault** is a default system policy set that specifies the asymmetric algorithm and both the public and private keys to provide message security. Message integrity is provided by digitally signing the body, time stamp, and WS-Addressing headers using RSA encryption. Message confidentiality is provided by encrypting the body and signature using RSA encryption.

All custom system policy sets are also displayed in the list. Click the system policy set name to view additional details about the selected policy set.

Data type:	String
Defaults:	TrustServiceSecurityDefault, TrustServiceSymmetricDefault or SystemWSSecurityDefault

Editable:

Provides information as to whether the system policy set can be edited.

This column shows whether the policy set is a user-defined, custom policy set that can be edited or whether the policy set is a default policy set that is not editable. Values displayed in this field are: `Editable` or `Not editable`. You can change the properties for a default, not editable policy set by copying it, and then modifying the properties of the copy. For more information, read about copying default policy set and bindings settings.

Important: Even though a policy set is identified as not editable, it is deletable. For example, you cannot edit information for the default system policy set, but you can delete the policy set.

Data type: String
Default: Not editable

Description:

Provides brief descriptions of the system policy sets that currently exist.

This column provides a brief description of the policy sets that are available. You cannot edit information for the default system policy sets. For custom policy sets that you create, you can create the description when you create the policy set. Or, you can edit any custom policy set and modify the description on the details panel at any time. The description field is optional.

System policy set settings:

Use this panel to create a new system policy set or to edit information about an existing custom system policy set. System policy sets, or assertions about how services are defined, are used to configure access to the trust service.

To view this administrative console page, complete one of the following procedures:

- **Services** > **Policy sets** > **System policy sets** > ***policyset_name***
- **Services** > **Policy sets** > **System policy sets** > **New**

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Important: You can edit the fields on this page only if the policy set is a custom trust policy set. You cannot edit default trust policy sets.

Name:

Specifies the name of the trust policy set.

This field displays the name of the existing custom policy set that you selected. If a new policy set is being created, this field is blank. Enter a policy set name.

Data type: String

Description:

Specifies a brief description of the new or existing custom policy set.

This field provides a brief description for the existing policy set that is displayed in the Name field. If a new policy set is being created, this field is blank. Enter a brief policy set description to help distinguish it from other policy sets. You cannot change the descriptions of the default policy sets.

Data type: String

Policies:

Specifies a collection of trust-related policies.

The Policies section displays a list of pre-configured system-level trust policies. If the system policy set is a default trust policy set, policies cannot be added, deleted, enabled, or disabled. If the system policy set is an existing custom trust policy set, you can change the policies. If you are creating a new custom trust policy set, you can add new policies. You can also delete, enable, or disable any policies that are added.

Select:

Specifies that you want to select an existing policy for further actions.

Click `Add` to display a list of valid policies that you can add to the named trust policy set.

To manage existing system policies, select the check box for a policy and select one of the following actions:

Actions	Description
Delete	Removes one or more policies from the named custom policy set.
Enable	Specifies that the policy is enabled for the policy set and displays `Enabled` in the State column.
Disable	Specifies that the policy is disabled for the policy set. The policy remains in the list but displays `Disabled` in the State column.

Policy:

Specifies the name of the policy.

This column displays one or more of these trust policies:

- **Custom properties** – for custom property policies
- **HTTP transport** – for HTTP transport policies
- **SSL transport** – for HTTPS transport policies
- **WS-Addressing** – for endpoint addressing policies
- **WS-Security** – for secure SOAP messages policies

State:

Specifies an enabled or disabled state for each policy.

This column displays whether the policy is enabled or disabled for each of the policies that are listed in the Policy column. For example, to change the state of the policy from enabled to disabled, select the check box for the policy, and click **Disable**.

Description:

Displays a brief description of the policy.

You can view these descriptions only.

Configuring attachments for the trust service using the administrative console:

You can attach the trust service operations for a service endpoint to a system policy set and binding. Each new endpoint that is specified initially has the following four operations: issue, renew, cancel, and validate. By default, all endpoints inherit the policy set and binding that are attached to the respective trust service operation under Trust Service Defaults. However, you can explicitly attach a different policy set.

Before you begin

First you must define your policy sets and bindings. *Policies* describe the protection or quality of service that is provided (such as message security, transport and so forth). *Bindings* specify some details about how to implement the policy, such as: the path for the keystore file, the class name of the token generator, or the JAAS configuration name.

Important: Use system policy sets with the trust service only. The requestor (client) must utilize Java API for XML-Based Web Services (JAX-WS) only. Requestors which use Java API for XML-based remote procedure calls (JAX-RPC) are incompatible with the policy set QOS.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

About this task

You can attach the trust service operations for a new endpoint to an existing policy set and binding. For each new service endpoint that is specified, four trust service operations (cancel, renew, validate and issue) change from having inherited attachments to being explicitly attached. The four operations are attached to the respective policy set and binding as specified in Trust Service Defaults. Then you can change the attachment to the desired existing policy set and binding.

An endpoint policy set consists of two sections: a bootstrap section and an application section. The system policy set attached to the Issue and renew trust service operations for a specific endpoint must correspond to the bootstrap section of the policy set for that endpoint. The system policy set attached to the Cancel and Validate trust service operations for a specific endpoint must correspond to the application section of the policy set for that endpoint.

This task describes how to manage trust service operations for service endpoint URLs that you want to attach to a system policy set and binding. To complete the configuration of the WebSphere Application Server trust service, you must also complete the following task:

- Create or manage targets. You can create explicit assignments for new service endpoints (targets) or manage endpoints that have a security token explicitly assigned or that inherit the Trust Service Default token.

The sample general bindings that are provided with the product are initially set as the global security (cell) default bindings. The default service provider binding and the default service client bindings are used when no application specific bindings or trust service bindings are assigned to a policy set attachment. For trust service attachments, the default bindings are used when no trust specific bindings are assigned. If you do not want to use the provided Provider sample as the default service provider binding, you can select an existing general provider binding or create a new general provider binding to meet your business needs. Likewise, if you do not want to use the provided Client sample as the default service client binding, you can select an existing general client binding or create a new general client binding. To specify your global security (cell) default bindings, use the administrative console and click **Services** > **Policy sets** > **Default**

policy set bindings. For environments with multiple security domains, you can optionally choose the general provider and general client bindings that you want to use as the default bindings for a domain. For more information about default bindings see the topic Setting default policy set bindings.

Procedure

1. To manage system policy set attachments for trust service operations, click **Services** > **Trust service** > **Trust service attachments**. The list displays all endpoints that have at least one operation with a policy set attached as well as Trust Service Defaults. The list also displays the system policy set and the binding for each operation.
2. Select one or more of the following actions to configure the trust service attachments:

   New Attachment

   Opens a new panel where you can specify the service endpoint URL. For each new service endpoint that is specified, four trust service operations (cancel, renew, validate and issue) change from having inherited attachments to being explicitly attached. The four operations are attached to the respective policy set and binding as specified in Trust Service Defaults. These initial attachments can be changed.

   Attach

   Displays a list of existing system policy sets, including the default trust-related system policy sets, to which each of the four trust service operations for a service endpoint can be attached. First, select the operation (for example, Cancel token) and then click **Attach** to display the list of available system policy sets. Select a default or custom system policy set to attach. When you change the policy set attachment, the binding automatically changes to **Default**. Select the operation and click **Assign Binding** to change the binding.

   The pre-configured system policy sets that you can select include:

   - **TrustServiceSecurityDefault**

     This trust policy set specifies the asymmetric algorithm as well as the public and private keys to provide message security. Message integrity is provided by digitally signing the body, time stamp, and WS-Addressing headers using RSA. Message confidentiality is provided by encrypting the body and signature using RSA. This policy set follows the WS-Security specification for the issue and renew trust operation requests.
   - **TrustServiceSymmetricDefault**

     This trust policy set specifies the symmetric algorithm as well as the derived key algorithms to provide message security. Message integrity is provided by digitally signing the body, time stamp, and WS-Addressing headers using HMAC-SHA1. Message confidentiality is provided by encrypting the body and signature using AES. This policy set follows the WS-Security and WS-SecureConversation specifications for the validate and cancel trust operation requests.
   - **SystemWSSecurityDefault**

     This system policy set specifies the asymmetric algorithm and both the public and private keys to provide message security. Message integrity is provided by digitally signing the body, time stamp, and WS-Addressing headers using RSA encryption. Message confidentiality is provided by encrypting the body and signature using RSA encryption.

   Inherit Operation Defaults

   Sets the operation to inherit the respective trust service default trust service policy set attachment and binding. If you select the attachments to modify and then click **Inherit Operation Defaults**, the explicit attachment for both the policy set and the binding is removed. Thereafter, the operation inherits any change to the default trust service policy set and binding.

   Assign Binding

   Changes the existing binding. You can create and assign a new binding, assign the Default binding, or assign an existing trust service specific binding to each of the selected trust service attachments.

Update Runtime
Updates the trust service runtime with any configuration changes that are made to the trust service attachments, token providers, and targets.

3. Optional: Modify the custom policy set by clicking the name of a custom policy set from the list. Edit the settings for custom policy sets, as needed. Default trust service policy set information can only be viewed.

   You cannot edit the default policy sets: TrustServiceSecurityDefault and TrustServiceSymmetricDefault, or SystemWSSecurityDefault. TrustServiceSecurityDefault is the default for the issue and renew operations. TrustServiceSymmetricDefault is the default for the cancel and validate operations.

   At least one trust service operation for the endpoint service URL must be explicitly attached for the endpoint service URL to be displayed. If an operation is explicitly attached, the system policy set name appears. If no policy set is explicitly attached, the respective default trust service policy set appears, followed by the text `(inherited)`.
4. Optional: Modify the trust service specific binding by clicking the name of a binding from the list, as needed. Edit the settings for the trust service specific binding, as needed. Any modifications to a trust service binding affect all trust service attachments that reference the binding.

   If the resource has a policy set directly attached, either the bindings name appears or `Default` appears.
5. Save your changes before applying the changes to the trust service runtime configuration.
6. Click **Update Runtime** to update the trust service runtime configuration with any data changes for token providers, trust service attachments, and targets. Whether the confirmation window appears depends on whether you select the **Show confirmation for update runtime command** check box. Expand **Preferences** to view the check box.
7. Optional: Confirm or cancel if the confirmation window appears. If you deselected the **Show confirmation for update runtime command** check box, all changes are made immediately without displaying the confirmation window.

Results

You have provided the basic information to create or update a trust service attachment. You have configured trust service operation attachments to system policy sets and bindings.

What to do next

You can also create a new attachment for the WebSphere Application Server trust service using the wsadmin tool. The wsadmin tool examples are written in the Jython scripting language.

Creating a service endpoint attachment using the administrative console:

You can attach the trust service operations for a new service endpoint URL to system policy sets and bindings. The operations for each new endpoint are attached to the Trust Service Default policy sets and bindings. Each new endpoint initially has the following four operations: issue, renew, cancel, and validate.

Before you begin

First you must define your policy sets and their bindings. *Policy sets* describe the protection or quality of service that is provided (such as message security, transport and so forth). *Bindings* specify some details about how to implement the policy set, such as: the path for the keystore file, the class name of the token generator, or the JAAS configuration name.

Important: Only use system policy sets with the trust service. The requestor (client) must utilize only Java API for XML-Based Web Services (JAX-WS). Requestors that use Java API for XML-based remote procedure calls (JAX-RPC) are incompatible with the policy set QOS.

About this task

Attaching the trust service operations for a new endpoint to existing policy sets and bindings requires two steps. After initially attaching the endpoint, the following four operations are configured: issue, renew, cancel, and validate. These four operations explicitly attach to Trust Service Defaults. You can then modify these attachments to existing policy sets and bindings.

This task describes how to create or manage service endpoint URLs that you want to attach to the policy set and binding. To complete the configuration for the WebSphere Application Server trust service, you must also create or manage targets.

If no explicit bindings are attached, WebSphere Application Server uses the cell-level default binding, referred to as Default.

Procedure

1. To view existing trust service attachments, click **Services** > **Trust service** > **Trust service attachments**. Until you create the first attachment, only the default attachments for each operation are displayed.
2. To create an attachment, click **New Attachment**.
3. Enter the service endpoint URL in a valid format. Note that when the URL in the trust service attachment does not match the URL, including matching the case, to which the trust service request is sent, the policy set that is defined in the attachment is not applied. Instead, IBM WebSphere Application Server uses the policy set that is attached to the default for the trust operation.

   For example, where `demo` is the endpoint, you might enter: http://localhost:9080/wssamplebeta/demo
4. Click **Attach** to attach the URL and to return to the Trust service attachments panel. After you click **Attach**, the Trust service attachments panel displays the new service endpoint URL and the initial four operations. The service endpoint URL that you specified is listed in the Trust service attachments collection. These four token operations (cancel, renew, validate and issue) for the specified endpoint are initially attached to Trust Service Defaults.
5. On the Trust service attachments panel, change the policy set or binding attachment, as needed. You can return any operation to its initial state by inheriting Trust Service Defaults.

   Note: Changing the policy set forces the binding to change to Default.
6. Save your changes before applying the changes to the Web Services Security runtime configuration.
7. Click **Update Runtime** to update the Web Services Security runtime configuration with any data changes for token providers, trust service attachments, and targets. Whether the confirmation window appears depends on whether you selected the **Show confirmation for update runtime command** check box. Expand **Preferences** to view the check box.
8. Optional: Confirm or cancel if the confirmation window appears. If you deselected the **Show confirmation for update runtime command** check box, all changes are made immediately without displaying the confirmation window.

Results

You have provided the basic information to create a trust service attachment and to configure a policy set, a binding, and the operation information.

What to do next

You can also create a new attachment for the trust service using the wsadmin tool. The wsadmin tool examples are written in the Jython scripting language.

Next, configure the security context token provider or configure targets to complete the trust service configuration.

Trust service attachments collection:

Use this page to view information about or manage system policy set attachments and bindings. Endpoints with at least one operation directly attached to a policy set are displayed.

This page displays each endpoint that has at least one operation that is directly attached to a system policy set. The operations for other endpoints inherit the trust service default policy set and binding data. You can click **New Attachment** to create explicit attachments for endpoints not displayed, or click **Attach** to change the policy set for an operation. Changing the system policy set for an operation removes the binding data for that operation, and resets that data to the system default binding settings. You can also click **Assign Binding** to create a new binding configuration or change the existing binding configuration for the selected operation.

To view this administrative console page, click **Services > Trust service > Trust service attachments**.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Show confirmation for update runtime command:

Specifies whether to enable or disable the display of the confirmation window before the Web Services Security runtime configuration is updated for supported tokens, targets, and trust service attachments.

Click **Preferences** to expand the information. You can select or clear the **Show confirmation for update runtime command** check box. If you do not select this check box, updates to the security runtime configuration are made without first displaying a confirmation window. If you select the check box, the confirmation window is displayed before updates to the security runtime configuration are made.

Data type: Check box
Default: Enabled (check box is selected)

Retain filter criteria:

Specifies whether to retain the filter criteria.

Click **Preferences** to expand the information. You can select or deselect the **Retain filter criteria** check box. This check box determines whether **Endpoint URL** is used as the filter criteria to reduce the displayed list of endpoints.

Data type: String
Default: All (check box is not selected)

Search terms:

Specifies the search criteria to use to reduce the displayed list of endpoints.

Click **Preferences** to expand the information. Type the search term you want to use in the **Search terms** field. Use the asterisk (*) as a wildcard character for all terms. You can also search for multiple unknown or partial characters within the term. For example, typing the search term `par*` returns `partly`, `participate`, `partial`, and all other terms beginning with the letters `par`.

Data type: String
Default: * (search for all)

Select:

Specifies that you want to select an existing resource, such as an endpoint or an operation, for further actions.

For existing endpoints, select the check box next to an operation, and then select one of the following actions:

Actions	Description
Attach	Displays a list of policy sets that are available to be attached to an endpoint operation (cancel, reset, validate, or issue) or to one of the trust service default operations. Highlight and click the policy set to attach the policy set to the selected operation. You cannot attach a policy set to an endpoint.
Inherit operation defaults	Detaches the currently attached policy set and binding for each selected operation and sets the operation to inherit the trust service default policy set and binding for each operation.
Assign binding	Lists the bindings that are available to select for the policy set to which you want to attach the binding. You can also create a new binding. • Select **Default** to create and assign the system default binding to the selected policy set attachment. When you select this binding the runtime uses the default binding for the server, cell or in the multiple security domain environment to which the service resource is deployed. • Select **New Trust Service Specific Binding** to create a binding that is specific to the policy set and shares the characteristics of the policy set. This type of binding is reusable only for trust service attachments. • Select an existing general binding to assign the binding to the selected policy set attachment. Multiple selection is valid only when all the resources have the same policy set attached.

New attachment:

Specifies that you want to create an explicit policy set attachment.

Click **New Attachment** to access a new panel where you can enter an endpoint URL to create attachments for each of the four endpoint operations of the provided URL. Initially, the attachment consists of the policy set and binding that are listed as the Trust Service Default for that operation.

Data type: Button

Update runtime:

Updates the trust service configuration for any changed attachments, targets, and token information.

If the **Show confirmation for update runtime command** preference is enabled, then a panel is displayed where you can confirm that you want to update the trust service configuration. If the preference is disabled, the trust service configuration is updated immediately without any confirmation.

Data type: Button

Service endpoint URL / Operation:

Displays a list of the trust service default operation attachments and every service endpoint URL that has at least one operation with a policy set attached.

Each endpoint has four operations: issue, cancel, renew, and validate. Each of the operations for all other endpoints inherits the trust service default policy set and binding.

When the URL in the trust service attachment does not match the URL to which the trust service request is sent, the policy set that is defined in the attachment is not applied. Instead, IBM WebSphere Application Server uses the policy set that is attached to the default for the trust operation.

Data type: String
Default: Trust Service Default

Policy set:

Displays the attached or inherited policy set for each operation of all endpoint URLs. Any endpoint URL that is not displayed inherits the trust service default policy set for each operation. Provides a list of default and custom system policy sets that are attached to the service endpoint URL.

The policy set names are displayed in this column for each operation. If the policy set is inherited from the trust service default, rather than being explicitly attached, **inherited** is displayed in parentheses following the policy set name. Because only operations can have a policy set attachment, the Policy Set column for each endpoint URL row displays **Not applicable**.

Click the system policy set name to view or edit the policy set details information. Note that you can view, but not edit, the default policy sets. Default policy sets cannot be changed.

Data type: String
Defaults: TrustServiceSecurityDefault, TrustServiceSymmetricDefault or SystemWSSecurityDefault

Binding:

Displays the binding that is assigned to each policy set attachment for each operation of the listed endpoint URLs. Any endpoint URL that is not displayed inherits the trust service default binding for each of the four operations.

The name of the assigned binding for each policy set attachment is displayed in this column for each operation. If the attachment is inherited from the trust service default, **inherited** is displayed in parentheses following the binding name. If you select **Assign Binding > Default**, the system default binding is applied to the policy set attachment, and the word **Default** is displayed in this column. If the system default binding is inherited, then **inherited** is displayed in parentheses following **Default**.

The system default binding is also assigned when you attach a new policy set to an operation. Because only operations can have policy set attachments, the binding column for each endpoint URL row displays **Not applicable**. Rows that are not directly related to a token and display the trust service default, display the text, **Not applicable**, for the binding. Additionally, rows that are not directly related to a token and display only the service endpoint URL display the text, **Not applicable**, for the binding.

Click the trust service specific binding name to view or edit the binding information. You can view, but not edit, the TrustServiceSecurityDefault, TrustServiceSymmetricDefault or SystemWSSecurityDefault bindings.

Data type: String
Default: TrustServiceSecurityDefault, TrustServiceSymmetricDefault or SystemWSSecurityDefault

Trust service attachments settings:

Use this page to create a new attachment to the current Trust Service Defaults policy set and binding for the four token operations: cancel, issue, renew, and validate.

To view this administrative console page, complete the following procedure:

- Click **Services** > **Trust service** > **Trust service attachments** > **New Attachment** .

Service endpoint URL:

Specifies the service endpoint URL that you want to attach to the policy set and binding for the trust service default operations.

Use this field to specify a service endpoint URL. The URL must be specified in a valid format, such as `http://www.mybusiness.com`.

Note that when the URL in the trust service attachment does not match the URL to which the trust service request is sent, the policy set that is defined in the attachment is not applied. Instead, IBM WebSphere Application Server uses the policy set that is attached to the default for the trust operation.

After you enter the URL and click **Attach**, the custom service endpoint URL is displayed in a list of explicitly attached service endpoint URLs on the Trust service attachments panel. In addition to the new service endpoint URL, the Trust service attachments panel displays a list of the corresponding four operations (cancel, issue, renew and validate).

On the Trust service attachments panel, you can change the Trust Service Default policy set and binding attachments for any of the four operations. These policy sets apply to any URL not displayed, and therefore not explicitly attached to a policy set and binding. Changing the policy set for a URL operation resets a custom binding setting to the default value.

On the Trust service attachments panel, if you want to remove the explicit policy set attachments and binding assignments, select each of the URL operations, and click **Inherit Operation Defaults**. If all four operations are changed to inherit the Trust Service Default policy set and binding, then the URL no longer displays on this panel.

Data type: String (URL format)

Configuring the security context token provider for the trust service using the administrative console:

Configure the WebSphere Application Server trust service to issue a specific security token to the requestor for communication with an endpoint. Use the administrative console to configure the security context token provider that the trust service provides.

Before you begin

WebSphere Application Server provides a trust service. The trust service provides both a security token service and additional WebSphere Application Server trust-related functionality. To configure the trust service, in addition to managing the security context token provider, you must first complete the following tasks:

- Create or manage supported targets. You can create explicit assignments for new service endpoints (targets) or manage endpoints that have the security context token provider explicitly assigned or that inherit the token provider designated as the Trust Service default.
- Create or manage the attachment of token operations for service endpoints to policy sets and bindings.

The order in which you complete these tasks is not important.

About this task

This task describes how to manage the security context token provider and how to define or modify the properties of the security context token provider.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Procedure

1. To manage the security context token provider, click **Services > Trust service > Token providers**.
2. To edit the settings of the security context token provider configuration, click the link for the token provider name. You cannot edit the name, class name, or token type schema URI when modifying the token provider information.
   a. The format of the token type schema Uniform Resource Identifier (URI) is in the standard URI format. For example, for a version 1.3 security context token, the URI is: http://docs.oasis-open.org/ws-sx/ws-secureconversation/200512/sct
   b. Change the amount of time, in minutes, in the **Time in cache after timeout** field that the expired token is kept in cache and where the token can still be renewed. The default value is 120 minutes. This value cannot be less than 10 minutes.
   c. Change the amount of time, in minutes, in the **Token timeout** field that the issued token is valid. The default value is 10 minutes. This value cannot be less than 10 minutes.
   d. Select the **Allow renewal after timeout** check box to enable the renewal of a token after the token has expired. If selected, the amount of time, within which an expired token can still be renewed, is specified in minutes in the **Time in cache after expiration** field.
   e. Select the **Allow postdated tokens** check box to enable postdated tokens. Use postdated tokens to specify whether a client can request a token to become valid at a later time.
   f. Select the **Support Secure Conversation Token v200502** to enable use of the older draft submission specification level of the security context token. The correct URI for this level of the token type schema appears in the field under the check box: http://schemas.xmlsoap.org/ws/2005/02/sc/sct.
   g. Click **New** to define a new custom property or click **Edit** to modify the custom property. Specify these settings using the Custom Properties setting. Custom properties are used to set internal system configuration properties. Custom properties are arbitrary name-value pairs of data, where the name might be a property key or a class implementation, and where the value might be a string or the value might be a true or false value.
   h. If you define a custom property, type a name. Refer to the documentation for the token provider for valid custom property names.
   i. If you define a custom property, type a value. Refer to the documentation for the token provider for the values for a property name.

j. Repeat defining the name and the value for each custom property that you add.
k. Click **OK**. You are returned to the Token providers panel.

3. Save your changes before applying the changes to the Web Services Security runtime configuration.
4. Click **Update Runtime** to update the Web Services Security runtime configuration with any data changes for token providers, trust service attachments, and targets. Whether the confirmation window is displayed depends on whether you select the **Show confirmation for update runtime command** check box. Expand **Preferences** to view the check box.
5. Optional: Confirm or click **Cancel** when the confirmation window appears. If you deselected the **Show confirmation for update runtime command** check box, all changes are made immediately without displaying the confirmation window.

Results

You have completed the required steps to modify the security context token provider configuration and to update the Web Services Security runtime configuration. You can also update the security context token provider configuration for the trust service using the wsadmin tool. The wsadmin tool examples are written in the Jython scripting language.

What to do next

Next, if you have not done so already, you must also configure targets or configure attachments to complete the trust service configuration.

Modifying the security context token provider configuration for the trust service using the administrative console:

WebSphere Application Server provides a pre-configured token, the Security Context Token (SCT). Use the administrative console to modify the configuration of the security context token provider.

Before you begin

WebSphere Application Server provides a trust service. The trust service provides both a security token service and additional WebSphere Application Server trust-related functionality. To configure the trust service, in addition to managing the security context token provider, you must first complete the following tasks:

- Create or manage supported targets. You can create explicit assignments for new service endpoints (targets) or manage endpoints that have a security token provider explicitly assigned or that inherit the token provider designated as the Trust Service default.
- Create or manage the attachment of token operations for service endpoints to policy sets and bindings.

The order in which you complete these tasks is not important.

About this task

This task describes how to configure the security context token provider and how to define the token provider properties.

Procedure

1. To configure the security context token provider, click **Services > Trust services > Token providers**.
2. To change the configuration of the security context token provider, click the link for the token provider name (Security Context Token). For an existing token, the token name, class name and URI are displayed, but are not editable.

3. Optional: Change the amount of time, in minutes, in the **Time in cache after expiration** field that the expired token is kept in cache and where the token can still be renewed. The default value is 120 minutes, and you cannot type a value that is less than 10 minutes.
4. Optional: Change the amount of time, in minutes, in the **Token timeout** field that the issued token is valid. The default value is 120 minutes, and you cannot type a value that is less than 10 minutes.
5. Optional: Select the **Allow renewal after timeout** check box to enable the renewal of a token, after the timeout time has expired. If selected, the amount of time, within which an expired token can still be renewed, is specified in the **Time in cache after expiration** field.
6. Optional: Select the **Allow postdated tokens** check box to enable postdated tokens. Use postdated tokens to specify whether a client can request a token to become valid at a later time.
7. Optional: Select the **Support Secure Conversation Token v200502** check box to enable use of the older draft submission specification level of the security context token. The correct URI for this level of the token type schema appears in the field under the check box: http://schemas.xmlsoap.org/ws/2005/02/sc/sct.
8. Click **New** if you want to define a new custom property. Specify additional configuration using the **Custom Properties** setting. Custom properties are used to set internal system configuration properties. Custom properties are arbitrary name-value pairs of data, where the name might be a property key or a class implementation, and where the value might be a string or Boolean value.
   a. If defining a new custom property, type a name. For example, for a custom property, type: com.ibm.wsspi.wssecurity.trust.keySize
   b. If defining a new custom property, type a value. For example, the following value: 128
   c. Repeat the name and value steps for each new custom property.
9. Click **OK**. You are returned to the Token provider panel.
10. Save your changes before applying the changes to the Web Services Security runtime configuration.
11. On the Token provider panel, click **Update Runtime** to update the Web Services Security runtime configuration with any data changes for token providers, trust service attachments, and targets. Whether the confirmation window is displayed depends on whether you select the **Show confirmation for update runtime command** check box. Expand **Preferences** to view the check box.
12. Optional: Confirm or click **Cancel** when the confirmation window appears. If you deselected the **Show confirmation for update runtime command** check box, all changes are made immediately without displaying the confirmation window.

Results

You have completed the required steps to modify the configuration of the security context token provider and to update the Web Services Security runtime configuration. You can also modify the configuration of the security context token provider for the trust service using the wsadmin tool. The wsadmin tool examples are written in the Jython scripting language.

What to do next

If you have not done so already, you must also configure targets or configure attachments to complete the trust service configuration.

Trust service token custom properties:

WebSphere Application Server trust service provides several custom properties by default to define the default security context token (SCT).

Custom properties are name-value pairs of data that are passed to the token provider during configuration.

The Property name column displays the name of the custom property. The name must match the name of a configuration property or setting that the provider understands and expects. The Property value column displays the configuration setting that is passed to the provider during configuration.

These custom properties are provided by default by WebSphere Application Server, for you to configure when using the **Services > Trust service > Token providers > Security Context Token** page.

algorithm:

The value is AES.

keySize:

The value is 128.

Provider:

The value is IBMJCE.

Disabling the submission draft level for the security context token provider:

Use the administrative console to configure the security context token provider that the trust service provides. Two levels of the token are supported on WebSphere Application Server: the token defined by the WS-Trust February 2005 Submission Draft specification, and the token defined by the OASIS WS-Trust Standard version 1.3. You can disable a setting so that the server will not accept a trust request that specifies the submission draft level of the token.

About this task

Disable the Security Context Token provider support for the submission draft specification using the administrative console.

Procedure

1. Log on to the administrative console and navigate to the Token providers panel by clicking **Services** > **Trust service** > **Token providers**.
2. Click on **Security Context Token**.
3. Click to clear the **Support Secure Conversation Token v200502** check box.
4. Click **Apply** to save the changed setting.

Results

For more information, see the topic Modifying the security context token provider configuration for the trust service using the administrative console.

Trust service token provider settings:

Use this page to modify information for an existing token provider.

To view this administrative console page, complete the following actions:

- **Services** > **Trust service** > **Token providers** > ***token_provider_name***

Name:

Specifies the name of the token provider.

This field displays the unique name of the token provider (for example, `Security Context Token`). You cannot change the name for any existing token provider.

Data type: String

Class name:

Specifies the package and class name of the trust service's Security Context Token provider.

This field displays the configuration class name, including the package information (for example, `com.ibm.ws.wssecurity.trust.server.sts.ext.sct.SCTHandlerFactory`).

You cannot change the class name for any existing token provider.

Data type: String

Token type schema URI:

Specifies the Uniform Resource Identifier (URI) for the token type schema.

This field displays the unique token type schema URI. Use a valid URI format, such as: `http://docs.oasis-open.org/ws-sx/ws-secureconversation/200512/sct`.

You cannot change the schema URI for any existing token provider.

Data type: String

Time in cache after expiration:

Specifies the number of minutes that a token remains in the token cache after the token expires.

This field displays the time, in minutes, that the expired token is kept cached and can still be renewed.

Data type: Integer
Default: 120
Minimum: 10
Maximum: 2147483647

Token timeout:

Specifies the amount of time, in minutes, that the issued token is valid.

This field displays the maximum timeout, in minutes, for a token to be considered valid.

Data type: Integer
Default: 120
Minimum: 10
Maximum: 2147483647

Allow renewal after timeout:

Specifies to enable or disable the renewal of a token.

This check box specifies whether to allow a client to renew an expired token. Note the **Time in cache after expiration** field specifies the amount of time within which an expired token can still be renewed.

Data type:	Check box
Default:	Do not allow (unchecked)

Allow postdated tokens:

Specifies to enable or disable the use of postdated tokens.

This check box specifies whether a client can request a token to become valid at some point in the future.

Data type:	Check box
Default:	Do not allow (unchecked)

Support Secure Conversation Token v200502: This check box specifies whether support for the WS-Trust and WS-Secure Conversation Feb 2005 Submission Draft OASIS specification is enabled. The default URI for the token type schema is provided in the non-editable field below the check box.

Data type:	Check box
Default:	Enabled (checked)

Custom Properties:

Specifies additional configuration settings that the token provider might require.

This table lists custom properties. Use custom properties to set internal system configuration properties.

The Secure Context Token default configuration settings are :

Property Name	Property Value
com.ibm.wsspi.wssecurity.trust.algorithm	AES
com.ibm.wsspi.wssecurity.trust.keySize	128
com.ibm.wsspi.wssecurity.trust.provider	IBMJCE

Select:

Specifies custom properties that you can add to, edit, or delete from the token provider.

Click **New** to add and define a new custom property.

For existing custom properties, first select the check box for the name of the custom property, and click one of the following actions:

Actions	Description
Edit	Specifies whether to modify existing custom properties. This action requires one or more custom properties to be selected.
Delete	Removes the selected existing property from the listing in the Name column. This action requires one or more custom properties to be selected.

Name:

Displays the names of the custom properties that have been defined for the token provider.

This column displays the name of the custom property (for example, `com.ibm.wsspi.wssecurity.trust.keySize`). Custom properties are name-value pairs of data that are passed to the token provider during configuration. The name that you specify must match the name of a configuration property or setting that the provider understands and expects.

Data type: String

Value:

Specifies the value for the custom property.

This column displays the value for the custom property (for example, `true`). Custom properties are name-value pairs of data. The value, which is represented as a string, is a configuration setting that is passed to the provider during configuration.

Data type: String or Boolean

Trust service token providers collection:

Use this page to view information about or manage token providers for the trust service.

To view this administrative console page, click **Services > Trust service > Token providers**.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Show confirmation for update runtime command:

Specifies to enable or disable the display of the confirmation window before the trust service configuration is updated when you click **Update Runtime**.

Click **Preferences** and then select the **Show confirmation for update runtime command** check box. If you select this check box, the confirmation window is displayed before updates to the security trust service configuration are made. If you do not select this check box, clicking **Update Runtime** updates the security trust service configuration without first displaying a confirmation window.

Data type: Check box
Default: Enabled (checked)

Update Runtime:

Updates the trust service configuration for any changed attachments, targets, and token information.

If the **Show confirmation for update runtime command** preference is enabled, then a panel is displayed where you can confirm that you want to update the trust service configuration. If the preference is disabled, updates to the trust service configuration are applied immediately without any confirmation.

Data type: Button

Token Provider Name:

Lists available token providers.

This column displays the names of the pre-configured token providers. The pre-configured token provider is the Security Context Token (SCT). Click a token provider name link to view additional details.

Data type: String
Default: Security Context Token

Token Type Schema URI:

Provides the Uniform Resource Identifier (URI) for the token type schema.

This column displays the URIs of all pre-configured token providers.

Data type: String

Configuring trust service endpoint targets using the administrative console:

The Trust Service manages tokens on behalf of service endpoints. A token provider is either explicitly or implicitly associated with each service endpoint. A specific token can be explicitly assigned to be issued when access to an endpoint is requested. Otherwise, the Trust Service Default token is issued.

Before you begin

The Web Services Secure Conversation specification defines the protocol for a client to establish a secure session with a target service. The security token service that WebSphere Application Server provides, referred to as the trust service, issues only the Security Context Token (SCT). The security context token is used for Web Services Secure Conversation (WS-SecureConversation).

About this task

This task describes how to create new or manage existing assignments of tokens to be issued for endpoint targets. You can create explicit assignments for new service endpoints (targets) or manage existing token assignments.

To complete the configuration for the trust service, you must have performed the following tasks:

- Manage the security context token provider.
- Create or manage service endpoint URLs that you want to attach to the policy set and binding.

The order in which you complete these tasks is not important.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Procedure

1. To configure new and existing trust service endpoint targets, click **Services > Trust service > Targets**. A list of all service endpoints that have a security token provider explicitly defined is displayed. The token provider assigned to the Trust Service Default by default handles requests to issue tokens to access an endpoint.
2. Click one of the following actions to manage a new or existing endpoint target configuration:

New Assignment

Opens a new panel where you can specify a custom service endpoint URL and explicitly assign the token provider, which is specified as the Trust Service Default, to be issued for access to the endpoint.

Change Token

Changes an explicitly assigned token to be issued for the service endpoint to the security context token. Select an endpoint and then click **Change Token**. Select the Security Context Token.

Also, removes the explicit assignment of a token to be issued; therefore, the token that is issued is inherited from the Trust Service Default. Select an endpoint and then click **Change Token**. Click **Inherit Default** to remove a token provider assignment for the selected endpoint and to return the issued token to be the token that is specified as the Trust Service Default. If the token that is issued is inherited, the endpoint is no longer displayed in the list because the token provider is no longer explicitly assigned to the endpoint.

3. Click the token name link for an existing endpoint target to modify the token provider configuration information. You can modify the token type schema URI, or change custom properties.
4. Save your changes before applying the changes to the Web Services Security runtime configuration.
5. Click **Update Runtime** to update the Web Services Security runtime configuration with any data changes for token providers, trust service attachments, and targets. Whether the confirmation window is displayed depends on whether you select the **Show confirmation for update runtime command** check box. Expand **Preferences** to view the check box.
6. Optional: Confirm or click **Cancel** when the confirmation window appears. If you deselected the **Show confirmation for update runtime command** check box, all changes are made immediately without displaying the confirmation window.

Results

When you complete these steps, the service endpoint URL displays in the Targets collection, unless you changed the token to inherit the default value. You can also configure the trust service to issue tokens for individual endpoint targets using the wsadmin tool. The wsadmin tool examples are written in the Jython scripting language.

What to do next

You have completed the required steps to create or manage existing trust service targets, to assign the security token provider to an endpoint target, and to update the Web Services Security runtime configuration. Next, if you have not competed these tasks already, configure the security context token provider or configure attachments to the policy set and binding to complete the trust service configuration.

Assigning a new target for the trust service using the administrative console:

You can associate a security token provider with a service endpoint using the administrative console. After entering the service endpoint URL, the token provider configured as the Trust Service Default is explicitly associated with the service endpoint.

Before you begin

The Web Services Secure Conversation specification defines the protocol for a client to establish a secure session with a target service. The security token service that WebSphere Application Server provides, referred to as the trust service, issues the Security Context Token (SCT). The security context token is required for Web Services Secure Conversation (WS-SecureConversation).

About this task

This task describes how to register a service endpoint (target) with the trust service. Registration of an service endpoint with the trust service initially associates the token provider configured as the Trust Service Default with that service endpoint.

To complete the configuration for the trust service, you must have completed the following tasks:

- Manage the Security Context Token.
- Create or manage service endpoint URLs that you want to attach to the policy set and binding.

The order in which you complete these tasks is not important.

Procedure

1. To configure a custom endpoint target, click **Services > Trust service > Targets > New Assignment**.
2. At the New assignment panel, enter the Universal Resource Locator (URL) for the service endpoint, and click **Assign**. You are returned to the Targets panel where the custom service endpoint URL is displayed in the list. Initially, the token that is explicitly assigned to the custom endpoint is the token that is assigned as the Trust Service Default.
3. At the Targets panel, select the check box for a service endpoint, click **Change Token**, and select one of the following:
   a. Security Context Token (SCT). A security context token is defined by the WS-SecureConversation specification.
   b. **Inherit Default** if you want the token that is issued to be the token assigned as the Trust Service Default. The endpoint is not displayed in the list when the assignment is inherited because the token is no longer explicitly assigned to the endpoint.
4. At the targets panel, click the token name link for an existing endpoint target to modify the token provider configuration information.
5. Save your changes before applying the changes to the Web Services Security runtime configuration.
6. Click **Update Runtime** to update the Web Services Security runtime configuration with any data changes for token providers, trust service attachments, and targets. Whether the confirmation window is displayed depends on whether you select the **Show confirmation for update runtime command** check box. Expand **Preferences** to view the check box.
7. Optional: Confirm or click **Cancel** when the confirmation window appears. If you deselected the **Show confirmation for update runtime command** check box, all changes are made immediately without displaying the confirmation window.

Results

When you complete these steps, service endpoints explicitly associated with a token provider are displayed in the Targets collection. Service endpoints that have been changed to inherit the token provider configured as the Trust Service Default are not displayed. You can also configure the security token service to issue a specific token for access to a target using the wsadmin tool. The wsadmin tool examples are written in the Jython scripting language.

What to do next

You have completed the required steps to create a service endpoint URL, to assign the token to be issued for access to the target, and to update the Web Services Security runtime configuration. Next, if you have not completed these tasks already, configure the Security Context Token provider or configure attachments to the policy set and binding to complete the trust service configuration.

Trust service targets collection:

Use this page to view a list of targets, which are application server service endpoints. You can manage tokens by specifying which token is to be issued when access to a specific endpoint is requested.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

To view this administrative console page, click **Services** > **Trust service** > **Targets**.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Show confirmation for update runtime command:

Specifies to enable or disable the display of the confirmation window before the WebSphere Application Server trust service configuration is updated when you click **Update Runtime**.

Click **Preferences** and then select the **Show confirmation for update runtime command** check box. If you select this check box, the confirmation window is displayed before updates to the trust service configuration are made. If you do not select this check box, clicking Update Runtime updates the trust service configuration without first displaying a confirmation window.

Data type: Check box
Default: Enabled (checked)

Select:

Specifies a check box for the service endpoint Universal Resource Locator (URL) that you want to select for further actions.

For existing endpoints, select the checkbox for the service endpoint and select one of the following actions:

Actions	Description
Change Token	Changes the token that is issued when access to an endpoint is requested. Selecting **Inherit Default** in the Change Token menu causes the following actions to occur: • The security token assignment is removed for the endpoint. • The token assigned as the Trust Service Default is issued for access to the endpoint. • The endpoint is no longer displayed in the list of endpoints that have tokens explicitly assigned. Only endpoints that are explicitly assigned a security token are displayed in the list. Endpoints that inherit the default do not display in the list.

New Assignment:

Defines a new service endpoint.

Initially, each endpoint is explicitly assigned the Trust Service Default token. By default, the pre-configured Security Context Token (SCT) is assigned, but that can be changed.

Data type: Button

Update Runtime:

Updates the trust service configuration for any changed attachments, targets, and token information.

If the **Show confirmation for update runtime command** preference is enabled, then a panel is displayed where you can confirm that you want to update the trust service configuration. If the preference is disabled, updates the trust service configuration immediately without any confirmation.

Data type: Button

Service Endpoint URL:

Specifies the Universal Resource Locator (URL) of the service endpoint for the explicitly assigned token.

This column lists the default service endpoint, Trust Service Default, and any custom service endpoints that have a token that is explicitly assigned to the endpoint, such as: `http://localhost:9080/EcommerceSTS`.

Data type: String
Default: Trust Service Default

Token Name:

Displays the name of the token to be issued when access to the endpoint is requested.

To inherit the default token, select the check box for a custom service endpoint URL, click **Change Token** > **Inherit Default**.

You can change the token type that is explicitly assigned as the Trust Service Default, but the token type cannot be left unassigned. If the token is not explicitly assigned, then the endpoint inherits the token that is assigned as the Trust Service Default token.

Click a token name link to access detailed information about the token. You can modify the token information, except for the token name. It is recommended that you do not modify the class name or the token type schema URI for the default token type, Security Context Token.

Changes to token properties apply to all tokens of this type that are issued for any endpoint.

Data type: String
Default: Security Context Token

Token Type Schema URI:

Specifies the schema Uniform Resource Identifier (URI) for the token type.

This column displays the schema URI for the explicitly assigned token type (for example, Security Context Token) in a valid URI format. The token type schema URI is a property of the token name and describes the version of the specification that is implemented for the security token.

Data type: String
Default value: http://docs.oasis-open.org/ws-sx/ws-secureconversation/200512/sct

Trust service targets settings:

Use this page to specify a custom service endpoint Universal Resource Locator (URL) and to assign a custom token type to the endpoint URL.

To view this administrative console page, click **Services** > **Trust service** > **Targets** > **New Assignment**.

Service endpoint URL:

Specifies the URL for the service endpoint.

Use this field to specify a custom service endpoint URL. The URL must be specified in a valid format, such as `http://localhost:9080/EcommerceSTS`. After you enter the URL and click **Assign**, the endpoint URL is explicitly assigned to the security token that is assigned the Trust Service Default.

The service endpoint URL is added to the list that displays on the Targets panel. Only endpoints that are explicitly assigned a security token are displayed in the list. Endpoints that inherit the default do not display in the list.

By default, the Trust Service Default token is the Security Context Token (SCT).

After clicking **Assign** and returning to the Targets panel, if you want to remove the explicit token assignment (and thereby change the token to be issued back to the default value), select the custom endpoint URL, and click **Inherit Default**. Then the following actions occur:

- The security token assignment is removed for the endpoint.
- The token assigned as the Trust Service Default is issued for access to the endpoint.
- The endpoint is no longer displayed in the list of endpoints that have tokens explicitly assigned.

Data type: String (URL format)

Updating the Web Services Security runtime configuration:

Update Web Services Security runtime configuration with any data changes that you make and save for token providers, trust service attachments, and targets.

Before you begin

Before you update the Web Services Security runtime configuration, make your required data changes for token providers, trust service attachments, and targets. Save your changes before applying the changes to the Web Services Security runtime configuration.

About this task

Whether the confirmation window appears depends on whether the **Show confirmation for update runtime command** check box is selected. Expand **Preferences** from the Token providers panel, the Trust service attachments panel, or the Targets panel to see the **Show confirmation for update runtime command** check box. Preferences are collapsed by default.

- If you select the check box, then the confirmation window is displayed before updates to the security runtime configuration are made. The check box is selected by default.

- If you do not select the check box, then updates to the security runtime configuration are made immediately, without first displaying the confirmation window. The confirmation window does not appear again until you re-select the checkbox located under Preferences.

  Or, instead of deselecting the check box under Preferences, you can select the **Do not show this message again** check box on the Update runtime confirmation panel.

Procedure

1. Perform one of the following tasks:
   - **Services > Trust service > Trust service attachments**
   - **Services > Trust service > Token providers**
   - **Services > Trust service > Targets**
2. Click **Update Runtime**. If you did not select the **Show confirmation for update runtime command** check box, all changes are made immediately without displaying the confirmation window.
3. Optional: Confirm or cancel when the confirmation window appears. If you selected the **Show confirmation for update runtime command** check box, all changes require confirmation and the confirmation window is displayed.

Results

After clicking **Update Runtime**, the configuration changes you made on the Token providers, the Trust service attachments, or the Targets panel are updated for the Web Services Security runtime configuration.

What to do next

You can also manage and administer the trust service using the wsadmin tool. The wsadmin tool examples are written in the Jython scripting language.

After configuring the trust service targets, attachments, and tokens, next configure the secure conversation client cache, if you have not already completed this step.

Web services update runtime settings:

Use this page to confirm that the web services trust service runtime should be updated with the most recent configuration changes.

To view this administrative console page, complete one of the following procedures:

- **Services > Trust service > Trust service attachments**
- **Services > Trust service > Supported tokens**
- **Services > Trust service > Targets**

Make changes to attachments, tokens, or targets, save the changes, and click .**Update Runtime**.

Do not show this message again:

Specifies to enable or disable the confirmation panel before the Web Services Security runtime configuration is updated.

Click **OK** to confirm that you want to make the configuration changes effective immediately for the web services trust service runtime.

Data type:	Check box
Default	Enabled (checked)

Configuring the Web Services Security distributed cache using the administrative console:

You can configure the Web Services Security runtime to use the security distributed cache to store security tokens.

About this task

Web Services Security functions such as secure conversation, trust, and nonce use the distributed cache to store security tokens when the distributed cache is enabled. If the distributed cache option is not selected, then a local cache is used to store the tokens. WebSphere Application Server Version supports distributed caching for the tokens in both cluster and non-cluster environments. In a cluster environment, you can configure the security cache to be distributed. If the cache is distributed, then all servers in the cluster share information about issued tokens.

Procedure

1. To configure the secure conversation client cache, click **Services** > **Security cache**.
2. Change the time in minutes in the **Time token is in cache after timeout** field. The default value is 120 minutes. The minimum allowable time is 10 minutes, meaning you cannot enter a value that is less than 10 minutes. This field specifies the number of minutes that the token is in cache after the token expiration time expires (cache persist period).
3. Change the time in minutes in the **Renewal interval before token timeout** field. The default value and minimum allowable time is 10 minutes. You cannot enter a value that is less than 10 minutes. This field specifies the time period before the token expires when the client attempts to renew the token. This window of time is just before token expires where, if the token is accessed, then the client attempts to renew the token so that a downstream call can complete.

   It is important that this setting be set to a length of time that is longer than the longest possible transaction. This value must include the time it takes to transport to and from the server, the time that is needed by the server to process the request, and the time that is cached by reliable messaging, if appropriate. Setting this value to a length of time that is too small might result in the token expiring in the middle of a transaction and might prevent the transaction from completing.

   If the Security Context Token is renewed too often, it might cause Web Services Secure Conversation (WS-SecureConversation) to fail or even cause an out-of-memory error to occur. It is required that you set the renewal interval before the token expires value for the Secure conversation client cache to a value less than the token timeout value for the Security Context Token. It is also suggested that the token timeout value be at least two times the renewal interval before the token expires value.
4. Select the **Enable distributed caching** check box, if you want to share the tokens across the cluster. When the checkbox is selected to enable distributed caching, choose one of the following settings for updating the caches.
   - Synchronous update of cluster members: performs synchronous update of cache objects on cluster members (default).
   - Asynchronous update of cluster members: performs a non-synchronous update of the cache on cluster members. This setting allows interoperability with cluster members that use the older style of updating as implemented in versions of WebSphere Application Server prior to version 7.0.
   - Token recovery support: assigns a shared data source as the distributed cache.

   If token recovery support is selected as the update method, then you must select a cell level data source using the drop-down list. Token state data is saved in the database defined as the data source. If there are no available data sources in the list, click on Manage data sources to add one or more new data source objects. The data source object supplies an application with connections for accessing the database.
5. To create a new custom property, click **New**. For example, you might add the `cancelActionRST` custom property with a value of `http://schemas.xmlsoap.org/ws/2005/02/trust/RST/SCT/Cancel`.
6. To edit an existing custom property, select the check box for the name of the existing custom property, and then click **Edit**. For example, you might change the name or the value of the cancelActionRST custom property.

7. Click **Apply** to save and apply the changes.

Results

You have provided the basic information to configure the Web Services Security distributed cache. Use either the administrative console or the wsadmin tool to modify the security cache configuration.

What to do next

You can also add or delete custom properties for the trust service using the wsadmin tool. The wsadmin tool examples are written in the Jython scripting language.

Security cache settings:

Use this page to configure the Web Services Secure Conversation (WS-SecureConversation) security local and distributed cache settings using the administrative console.

To view this administrative console page, click **Services** > **Security cache**.

Time token is in cache after timeout:

Sets the time that the token remains in cache after the token times out.

This field specifies the number of minutes for the time the token is in cache after the token expiration time expires (cache persist period). For example, if you specify 30 minutes, the token is kept in cache for this time period after the token expiration time. The default value is 10 minutes, which is the minimum number of minutes that is allowed.

Data type: Integer
Default: 10 (minutes)

Renewal interval before token timeout:

Sets the time period before expiration that the client attempts to renew the token.

This field specifies the period of time, in minutes, before expiration that the client attempts to renew the token. This setting must specify a period of time that is longer than the time for the longest transaction or else the token might expire during the transaction. This time must include time for transport to and from the server, processing by the server, and any time delay that is because of time used for reliable messaging, when applicable. The default value is 10 minutes, which is the minimum number of minutes that is allowed.

If the Security Context Token is renewed too often, it might cause Web Services Secure Conversation (WS-SecureConversation) to fail or even cause an out-of-memory error to occur. It is required that you set the renewal interval before the token expires value for the security cache to a value less than the token timeout value for the Security Context Token. It is also suggested that the token timeout value be at least two times the renewal interval before the token expires value.

Data type: Integer
Default: 10 (minutes)

Enable distributed caching:

Specifies whether distributed caching is enabled or disabled. If distributed caching is enabled, select distributed cache settings.

Use this check box to specify whether to use distributed caching when the server is in a clustered environment and when the tokens are shared across the cluster.

Data type:	Check box
Default:	No distributed caching (unchecked)

When the checkbox is selected to enable distributed caching, choose one of the following settings for updating the caches.

Button	Resulting Action
Synchronous update of cluster members	Performs synchronous update of cache objects on cluster members (default).
Asynchronous update of cluster members	Performs a non-synchronous update of the cache on cluster members. This setting allows interoperability with cluster members that use the older style of updating as implemented in versions of IBM WebSphere Application Server prior to version 7.0.
Token recovery support	Assigns a shared data source as the distributed cache.

If token recovery support is selected as the update method, then you must select a cell level data source using the drop-down list. Token state data is saved in the database defined as the data source. If there are no available data sources in the list, click on **Manage data sources** to add one or more new data source objects. The data source object supplies an application with connections for accessing the database.

Custom Properties:

Specifies additional configuration settings that the secure conversation client might require.

This table lists custom properties. Use custom properties to set internal system configuration properties. This collection is empty until the first custom property is defined.

Data type:	String

Select:

Specifies that you want to select further actions.

Use this check box to select custom properties for further actions. To manage existing custom properties, select the check box beside the name, and then select one of the following actions:

Actions	Description
Edit	Select to modify an existing custom property. This action is not displayed until you have added at least one custom property.
Delete	Select to remove an existing custom property.

Data type:	Check box

New:

Specifies that you want to add and define a new custom property.

Click **New** to define a new custom property.

Data type: Button

Name:

Lists available custom properties.

This column displays the names of the custom properties that you can use with the secure conversation client (for example, `exampleProperty`). Custom properties are name-value pairs of data, where the name is a string representation of a property that is expected by the secure conversation client.

Data type: String

Value:

Lists the values of the custom properties.

This column displays the values of the custom properties (for example, `true`). Custom properties are name-value pairs of data, where the value is a string representation of the property setting.

Data type: String

Configuring the Kerberos token for Web Services Security

Use this topic to configure the Kerberos token for message-level Web Services Security.

Before you begin

Before you can use Kerberos with Web Service Security, you must configure Kerberos in the IBM WebSphere Application Server. You do not need to enable Kerberos as the authentication mechanism. However, the Kerberos configuration file, `krb5.conf` or `krb5.ini`, and the Kerberos keytab file, `krb5.keytab`, are required.

The initial setup and configuration processes to use Kerberos with Web Services Security are identical to the configuration processes for using Kerberos with the security function. Therefore, you must set up and configure Kerberos before continuing with the steps in this topic.

The "Kerberos (KRB5) authentication mechanism support for security" topic provides an overview of the Kerberos functionality and provides the initial steps for setting up and configuring Kerberos for authentication purposes. Within this topic, you must complete the steps in the section "Setting up Kerberos as the authentication mechanism for WebSphere Application Server." Use that topic to configure Kerberos, the service principal, and the keytab files. In addition, that topic provides references to the process for configuring Kerberos as the authentication mechanism using the administrative console or commands. You can also find information on how to setup up Kerberos when the Key Distribution Center (KDC) and the Application Server do not use the same user registry.

About this task

The Kerberos token for JAX-WS applications is configured using policy sets and bindings. The JAX-WS application is attached with a custom policy and the Kerberos token is configured as a message protection token or an authentication token.

The implemented Kerberos functionality for Web Services Security also leverages existing tools and frameworks for the Kerberos token profile configuration for authentication and message protection. The support for Kerberos with Web Services Security in the product is based on the OASIS Web Services Security Kerberos Token Profile 1.1 specification.

To configure Kerberos with Web Service Security, complete the following steps:

Procedure

1. Enable the Kerberos token profile for JAX-WS applications.

   The JAX-WS application is attached with a custom policy that has a Kerberos token, which is configured with a message protection token or an authentication token. For more information, see "Configuring the Kerberos token policy set for JAX-WS applications."
2. Select the customized Kerberos token type. You can define key bindings for request message protection and response message protection. You can use the key type, such as the key identifier or security token reference, for the outbound key information. If you use a derived key, use a security token reference in both the outbound and inbound key information. If you use a Kerberos session key, you can use a security token reference in the outbound key information and a key identifier in the inbound key information for the client bindings. Then, use a key identifier in the outbound key information and a security token reference in the inbound key information for the provider bindings.
3. Select the customized Kerberos token types for the token generator or token consumer.
4. Configure the bindings for Kerberos message protection for JAX-WS applications. For more information, see the "Configuring the bindings for message protection for Kerberos" on page 3261.

What to do next

Using this task, you have configured the Kerberos token for WebSphere Application Server.

Configuring the Kerberos token policy set for JAX-WS applications:

Use this topic to enable the Kerberos token policy set for JAX-WS applications.

Before you begin

Prior to beginning this task, you must specify the Kerberos configuration information for IBM WebSphere Application Server. For more information, see Kerberos (KRB5) authentication mechanism support for security.

The configuration model for the Kerberos token enables you to choose from the following existing WebSphere Application Server frameworks:

- For JAX-RPC applications, the deployment descriptor and bindings are used in the configuration. JAX-RPC application includes the deployment descriptor for a Kerberos custom token, which is configured with authentication tokens.
- For JAX-WS applications, the configuration uses a policy set and bindings. The JAX-WS application is attached by a custom policy with the Kerberos token configured with authentication tokens, message protection tokens, or both.

Note: Fix packs that include updates to the Software Development Kit (SDK) might overwrite unrestricted policy files. Back up unrestricted policy files before you apply a fix pack and reapply these files after the fix pack is applied.

About this task

Complete the following steps to configure the Kerberos token policy set for JAX-WS applications using the administrative console for WebSphere Application Server. In these steps, the Main policy configuation panel references the administrative console panel that is available after you complete the first five steps.

Procedure

1. Expand **Services** > **Policy sets** and click **Application policy sets** > **New** to create a new policy set.
2. Specify a name and a short description for the new policy set and click **Apply**.

3. From the Policies heading, click **Add** and then select the **WS-Security** security policy type.
4. Click **OK** and click **Save** to save the new configuration directly to the master configuration.
5. In the **Policies** field, click **WS-Security** and click **Main policy** on the WS-Security panel to configure the main policy for the Kerberos token policy set.
6. From the Key Symmetry heading, select **Use symmetric tokens** for message protection.
7. Click **Symmetric signature and encryption policies** to configure the Kerberos custom token type or clear the **Message level protection** check box if you are configuring an authentication token only.

   Important: You do not need to configure the request token policy if you are using the Kerberos token for message protection. If you are configuring the authentication token only, proceed to the next step. If you are not configuring the request token policy for the authentication token, skip the next step.
8. On the Main policy configuration panel, configure the policy for the request token if you are configuring the authentication token.
   a. From the Policy Details heading, click **Request token policies**.
   b. Click **Add token type** and select **Custom**.
   c. Specify the name of the custom token in the **Custom token name** field.
   d. Specify the local part value in the **Local part** field. For interoperability with other web services technologies, specify the following local part: `http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ`. If you are not concerned with interoperability issues, you can specify one of the following local name values:
      - `http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ`
      - `http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ1510`
      - `http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ1510`
      - `http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ4120`
      - `http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ4120`

      These alternative values depend on the specification level for the Kerberos AP-REQ token that is generated by the Key Distribution Center (KDC). For more information about when to use these values, see Token type settings.
   e. Do not specify a value for the **Namespace URI** field if you are generating a Kerberos token.
   f. Click **OK** and **Save** to save the configuration directly to the master configuration.

   This step completes the configuration process for configuring the request token policy for the authentication token. You do not need to complete the next two steps. Complete the next steps to configure encryption and symmetric signature policies.
9. Return to the main policy configuration panel for the application policy set and click **Symmetric signature and encryption policies** to configure the encryption and symmetric signature policies.
   a. From the Message Integrity heading, click the **Action** menu list beside the **Token type for signing and validating messages** field and select **Custom**.
   b. From the Message Confidentiality heading, select the **Use same token for confidentiality that is used for integrity** option.
   c. Click **OK** and **Save** to save the configuration changes.
   d. From the Message Integrity heading, click the **Action** menu list beside the **Token type for signing and validating messages** field and select **Edit Selected Type Policy**.
   e. Edit the custom token type for the signature and encryption by specifying the local part for the Kerberos custom token.

For example, specify `http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ` for the local part value. Do not specify a Namespace URI value.

f. Click **OK** and then click the **Save** link to save the configuration changes.

10. Return to the main policy configuration panel for the application policy set and click **Algorithms for symmetric tokens** to configure the symmetric token algorithm.

a. Select the algorithm suite to use for the symmetric tokens from the **Algorithm suite** menu list. Select the Advanced Encryption Standard (AES) algorithms for a Kerberos token that is compliant with RFC-4120.

The symmetric key wrap, or private key cryptography, algorithms include:

- Triple DES key wrap: http://www.w3.org/2001/04/xmlenc#kw-tripledes
- AES key wrap (aes128): http://www.w3.org/2001/04/xmlenc#kw-aes128
- AES key wrap (aes256): http://www.w3.org/2001/04/xmlenc#kw-aes256

Restriction: To use the 256–bit AES encryption algorithm, you must apply the unlimited jurisdiction policy files. To remain in compliance, see Basic Security Profile compliance tips.

Important: Your country of origin might have restrictions on the import, possession, use, or re-export to another country, of encryption software. Before downloading or using the unrestricted policy files, you must check the laws of your country, its regulations, and its policies concerning the import, possession, use, and re-export of encryption software, to determine if it is permitted.

For application server platforms using IBM Developer Kit, Java Technology Edition Version 5, you can obtain unlimited jurisdiction policy files by completing the following steps:

1) Visit the IBM developerWorks: Security Information website.
2) Click **Java 5**.
3) Click **IBM SDK Policy files**.

   The Unrestricted JCE Policy files for SDK 5 website is displayed.
4) Enter your user ID and password or register with IBM to download the policy files. The policy files are downloaded onto your workstation.
5) Re-mount your product HFS as read/only.

For more information on the algorithm suite components, see Algorithms settings.

b. Select either the **Exclusive cannonicalization** or **Inclusive cannonicalization** value for the **Cannonicalization algorithm** menu list. For more information, see XML digital signature.

c. Specify the **XPath 1.0** or **XPathfilter 2.0** version to use from the **XPath version** menu list.

What to do next

Configure the bindings for message protection for Kerberos for JAX-WS applications. For more information, see “Configuring the bindings for message protection for Kerberos.”

Configuring the bindings for message protection for Kerberos:

To set up bindings for message protection with JAX-WS applications, you must create a custom binding. Complete this task to set the bindings for a Kerberos token as defined in the OASIS Web Services Security Specification for Kerberos Token Profile Version 1.1.

Before you begin

You must configure Kerberos for IBM WebSphere Application Server. For more information, see Kerberos (KRB5) authentication mechanism support for security. In addition, you must configure the Kerberos token

policy set for JAX-WS applications. For more information, see Configuring the Kerberos token policy set for JAX-WS applications.

About this task

You can leverage existing frameworks including the policy set and bindings for JAX-WS applications.

You can configure a symmetric protection token or an authentication token. Both symmetric protection token and authentication token configurations use similar configuration data. However, you do not need to configure the authentication token if you intend to use a Kerberos symmetric protection token. For whichever token type you use, configure the token generator and the token consumer as indicated in the following list:

- Symmetric protection token
  - Token generator
  - Token consumer
- Authentication token
  - Token generator
  - Token consumer

Use the administrative console to configure the application-specific bindings to use a Kerberos token in web services message protection.

Procedure

1. Expand **Applications** > **Application Types**.
2. Click **WebSphere enterprise applications** > ***application name*** .
3. From the Web Services Properties heading, click **Service provider policy sets and bindings** to configure the service bindings or click **Service client policy sets and bindings** to configure the client bindings.
4. Select the resource to attach to the Kerberos token policy set and select **Attach Policy Set** > ***policy set name***. To configure the Kerberos token policy set, see “Configuring the Kerberos token policy set for JAX-WS applications” on page 3259.
5. Click **Assign bindings** and select the application-specific binding or select **New Application Specific Binding** to create a new binding. To create a new binding, complete the following actions.
   a. Enter a name for the new binding in the **Binding configuration name** field and optionally enter a description for the binding in the **Description** field.
   b. Click **Add** and select **WS-Security** to specify a new policy set.
   c. Click **Authentication and protection** > **New**.
   d. Optional: Define a symmetric protection token for the token generator.

      Important: If you configure a symmetric protection token for the token generator, you must define a complimentary symmetric protection token for the token consumer.

      1) From the Protection tokens heading, click **New** and select **Token Generator**.
      2) Specify the name of the protection token in the **Name** field.
      3) Select **Custom** from the values in the **Token type** menu list.
      4) Specify the local name value in the **Local name** field.

         For interoperability with other web services technologies, specify the following local name: `http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ`. If you are not concerned with interoperability issues, you can specify one of the following local name values:

         - `http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ`

- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ1510
- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ1510
- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ4120
- http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ4120

These alternative values depend on the specification level for the Kerberos token that is generated by the Key Distribution Center (KDC). For more information about when to use these values, see Protection token settings (generator or consumer).

5) Do not specify a value for the **Namespace URI** field.
6) Select the **wss.generate.KRB5BST** value from the JAAS login menu list.

   If you have previously defined your own Java Authentication and Authorization Service (JAAS) login module, you can select your login module to handle the Kerberos custom token. To define a custom JAAS login module, click **New Application Login** > **New**, specify an alias for the new module, and click **Apply**. For more information, see Login module settings for Java Authentication and Authorization Service.

   Attention: Although the information in the "Login module settings for Java Authentication and Authorization Service" topic refers to security and not Web Services Security, the configuration for a login module for Web Services Security is identical to security.
7) Specify the token generator custom properties for the target service name, host, and realm.

   The combination of the target service name and host values forms the Service Principal Name (SPN), which represents the target Kerberos service principal name. The Kerberos client requests the initial Kerberos AP_REQ token for the SPN. Specify the following custom properties.

Table 285. Target service custom properties. Use these properties to specify the token generator information.

Name	Value	Type
com.ibm.wsspi.wssecurity.krbtoken.targetServiceName	Specify the name of the target service.	Required
com.ibm.wsspi.wssecurity.krbtoken.targetServiceHost	Specify the host name that is associated with the target service in the following format: myhost.mycompany.com	Required
com.ibm.wsspi.wssecurity.krbtoken.targetServiceRealm	Specify the name of the realm that is associated with the target service.	Optional*

* If the targetServiceRealm property is not specified, the default realm name from the Kerberos configuration file is used as the realm name. To use Kerberos token security in a cross or trusted realm environment, you must provide a value for the targetServiceRealm property.

To specify multiple custom property name and value pairs, click **New**.

8) Click **Apply**.
9) From the Additional bindings heading, click **Callback handler**.
10) From the Class Name heading, select the **Use custom** option and specify com.ibm.websphere.wssecurity.callbackhandler.KRBTokenGenerateCallbackHandler in the associated field.
11) From the Basic Authentication heading, specify the appropriate values for the **User name**, **Password**, and **Confirm password** fields.

    The user name specifies the default user ID that is passed to the constructor of the callback handler; for example, kerberosuser.
12) Specify the token generator custom properties for Kerberos client principal name and password to initiate the Kerberos login.

    These custom properties control the prompt and establish the token based on the credential cache. Specify the following custom properties.

Table 286. Kerberos login custom properties. Use this property to specify the token generator information.

Name	Value	Type
com.ibm.wsspi.wssecurity.krbtoken.loginPrompt	Enables the Kerberos login when the value is True. The default value is False.	Optional

To specify multiple custom property name and value pairs, click **New**.

13) Click **Apply** and **OK**.

When you return to the Authentication and protection panel in the next step, a new protection token is defined for the token generator. To edit the configuration for this new token, click its name on the panel.

e. Optional: Return to the Authentication and protection panel to define a symmetric protection token for the token consumer. To return to the Authentication and protection panel, click the **Authentication and protection** link after the messages section of the panel.

Important: If you configure a symmetric protection token for the token consumer, ensure that you have previously defined a complimentary symmetric protection token for the token generator.

1) From the Protection tokens heading, click **New** and select **Token Consumer**.
2) Specify the name of the protection token in the **Name** field.
3) Select **Custom** from the values in the **Token type** menu list.
4) Specify the local name value in the **Local name** field.

   For interoperability with other web services technologies, specify the following local name: `http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ`. If you are not concerned with interoperability issues, you can specify one of the following local name values:

   - `http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ`
   - `http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ1510`
   - `http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ1510`
   - `http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ4120`
   - `http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ4120`

   These alternative values depend on the specification level for the Kerberos token that is generated by the Key Distribution Center (KDC). For more information about when to use these values, see Protection token settings (generator or consumer).
5) Do not specify a value for the **Namespace URI** field.
6) Select the **wss.consume.KRB5BST** value from the JAAS login drop-down menu.

   If you have previously defined your own Java Authentication and Authorization Service (JAAS) login module, you can select this login module to handle the Kerberos custom token. To define a custom JAAS login module, click **New Application Login** > **New**, specify an alias for the new module, and click **Apply**. For more information, see Login module settings for Java Authentication and Authorization Service.

   Attention: Although the information in the Login module settings for Java Authentication and Authorization Service topic refers to security and not Web Services Security, the configuration for a login module for Web Services Security is identical to security.
7) Click **Apply**.
8) From the Additional bindings heading, click **Callback handler**.

9) From the Class Name heading, select the **Use custom** option and specify `com.ibm.websphere.wssecurity.callbackhandler.KRBTokenConsumeCallbackHandler` in the associated field.

10) Click **Apply** and **OK**.

When you return to the Authentication and protection panel in the next step, you will see a new protection token defined for the token consumer. To edit the configuration for this new token, click its name on the panel.

f. Optional: Return to the Authentication and protection panel to define an authentication token configuration for the token generator. To return to the Authentication and protection panel, click the **Authentication and protection** link after the messages section of the panel.

Authentication tokens are sent in messages to prove or assert an identity.

Important: If you configure an authentication token for the token generator, you must define a complimentary authentication token for the token consumer.

1) From the Authentication tokens heading, click **New** and select **Token Generator**.

2) Specify the name of the authentication token in the **Name** field.

3) Select **Custom** from the values in the **Token type** menu list.

4) Specify the local name value in the **Local name** field.

For interoperability with other web services technologies, specify the following local name: `http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ`. If you are not concerned with interoperability issues, you can specify one of the following local name values:

- `http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ`
- `http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ1510`
- `http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ1510`
- `http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ4120`
- `http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ4120`

These alternative values depend on the specification level for the Kerberos token that is generated by the Key Distribution Center (KDC). For more information about when to use these values, see Authentication generator or consumer token settings.

5) Do not specify a value for the **Namespace URI** field.

6) Select the **wss.generate.KRB5BST** value from the JAAS login menu list.

If you have previously defined your own Java Authentication and Authorization Service (JAAS) login module, you can select this login module to handle the Kerberos custom token. To define a custom JAAS login module, click **New Application Login** > **New**, specify an alias for the new module, and click **Apply**. For more information, see Login module settings for Java Authentication and Authorization Service.

Attention: Although the information in the Login module settings for Java Authentication and Authorization Service topic refers to security and not Web Services Security, the configuration for a login module for Web Services Security is identical to security.

7) Specify the token generator custom properties for the target service name, host, and realm.

The combination of the target service name and host values forms the Service Principal Name (SPN), which represents the target Kerberos service principal name. The Kerberos client requests the initial Kerberos AP_REQ token for the SPN. Specify the following custom properties.

Table 287. Target service custom properties. Use these custom properties to specify the token generator information.

Name	Value	Type
com.ibm.wsspi.wssecurity.krbtoken.targetServiceName	Specify the name of the target service.	Required
com.ibm.wsspi.wssecurity.krbtoken.targetServiceHost	Specify the host name that is associated with the target service in the following format: myhost.mycompany.com	Required
com.ibm.wsspi.wssecurity.krbtoken.targetServiceRealm	Specify the name of the realm that is associated with the target service.	Optional

To specify multiple custom property name and value pairs, click **New**.

8) Click **Apply**.
9) From the Additional bindings heading, click **Callback handler**.
10) From the Class Name heading, select the **Use custom** option and specify com.ibm.websphere.wssecurity.callbackhandler.KRBTokenGenerateCallbackHandler in the associated field.
11) From the Basic Authentication heading, specify the appropriate values for the **User name**, **Password**, and **Confirm password** fields.

    The user name specifies the default user ID that is passed to the constructor of the callback handler. For example: kerberosuser
12) Specify the token generator custom properties for Kerberos client principal name and password to initiate the Kerberos login.

    These custom properties control the prompt and establish the token based on the credential cache. Specify the following custom properties name and value pairs.

Table 288. Kerberos login custom properties. Use the custom properties to specify the token generator information.

Name	Value	Type
com.ibm.wsspi.wssecurity.krbtoken.loginPrompt	Enables the Kerberos login when the value is True. The default value is False.	Optional
com.ibm.wsspi.wssecurity.krbtoken.clientRealm	Specify the name of the Kerberos realm associated with the client	Optional*

* The clientRealm property is optional for a single Kerberos realm environment. When implementing Web Services Security in a cross or trusted Kerberos realm environment, you must provide a value for the clientRealm property.

If an application generates or consumes a Kerberos V5 AP_REQ token for each web services request message, set the com.ibm.wsspi.wssecurity.kerberos.attach.apreq custom property to **true** in the token generator and the token consumer bindings for the application

To specify multiple custom property name and value pairs, click **New**.

13) Click **Apply** and **OK**.

When you return to the Authentication and protection panel in the next step, you will see a new authentication token is defined for the token generator. To edit the configuration for this new token, click its name on the panel.

g. Optional: Return to the Authentication and protection panel to define an authentication token configuration for the token consumer. To return to the Authentication and protection panel, click the **Authentication and protection** link after the messages section of the panel.

Important: If you configure an authentication token for the token consumer, ensure that you have previously defined an authentication token for the token generator.

1) From the Authentication tokens heading, click **New** and select **Token Consumer**.
2) Specify the name of the authentication token in the **Name** field.
3) Select **Custom** from the values in the **Token type** menu list.
4) Specify the local name value in the **Local name** field.

For interoperability with other web services technologies, specify the following local name: `http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ`. If you are not concerned with interoperability issues, you can specify one of the following local name values:

- `http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ`
- `http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ1510`
- `http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ1510`
- `http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#Kerberosv5_AP_REQ4120`
- `http://docs.oasis-open.org/wss/oasis-wss-kerberos-token-profile-1.1#GSS_Kerberosv5_AP_REQ4120`

These alternative values depend on the specification level for the Kerberos token that is generated by the Key Distribution Center (KDC). For more information conditions under which to use these values, see the related link for the "Authentication generator or consumer token settings" topic.

5) Do not specify a value for the **Namespace URI** field.
6) Select the **wss.consume.KRB5BST** value from the JAAS login drop-down menu.

   If you have previously defined your own Java Authentication and Authorization Service (JAAS) login module, you can select this login module to handle the Kerberos custom token. To define a custom JAAS login module, click **New Application Login** > **New**, specify an alias for the new module, and click **Apply**. For more information, see Login module settings for Java Authentication and Authorization Service.

   Attention: Although the information in the Login module settings for Java Authentication and Authorization Service topic refers to security and not Web Services Security, the configuration for a login module for Web Services Security is identical to security.
7) Click **Apply**.
8) From the Additional bindings heading, click **Callback handler**.
9) From the Class Name heading, select the **Use custom** option and specify `com.ibm.websphere.wssecurity.callbackhandler.KRBTokenConsumeCallbackHandler` in the associated field.
10) Click **Apply** and **OK**.

When you return to the Authentication and protection panel in the next step, you will see a new authentication token is defined for the token consumer. To edit the configuration for this new token, click its name on the panel.

What to do next

You can optionally define key bindings for the request message protection and response message protection. If you choose to derive a key from the Kerberos token, configure the derived key information when you configure the key information for signature and encryption.

Return to the steps in the Configuring the Kerberos token for Web Services Security topic to ensure you have completed the steps for configuring the Kerberos token.

Updating the system JAAS login with the Kerberos login module:

Update the Kerberos system JAAS login module for JAX-WS applications.

About this task

If the Kerberos authentication mechanism is configured in the WebSphere Application Server security configuration for JAX-WS applications, the JAAS login wss.caller must be updated with the system JAAS login module for Kerberos. The login module is specified as com.ibm.ws.security.auth.kerberos.WSKrb5LoginModule.

There are two methods to update the Kerberos system JAAS login module: using the administrative console, or by running a Jython script.

Procedure

1. Using the administrative console, follow these steps:
   a. Click **Security > Global security > Java Authentication and Authorization Service > System logins**.
   b. Click on **wss.caller**, then click **New** to create a new JAAS login module.
   c. In the **Module class name** field, type `com.ibm.ws.security.auth.kerberos.WSKrb5LoginModule`.
   d. Click **OK**.
   e. In the wss.caller panel, click **Set Order**, then click on **WSKrb5LoginModule**.
   f. Move WSKrb5LoginModule up in the list of modules so that it is after com.ibm.ws.wssecurity.impl.auth.module.WSWSSLoginModule but before com.ibm.ws.security.server.lm.ltpaLoginModule. The order of the modules in the list is important. The finished list of modules should look like this:

```
com.ibm.ws.wssecurity.impl.auth.module.PreCallerLoginModule                      1
com.ibm.ws.wssecurity.impl.auth.module.UNTCallerLoginModule                      2
com.ibm.ws.wssecurity.impl.auth.module.X509CallerLoginModule                     3
com.ibm.ws.wssecurity.impl.auth.module.LTPACallerLoginModule                     4
com.ibm.ws.wssecurity.impl.auth.module.LTPAPropagationCallerLoginModule          5
com.ibm.ws.wssecurity.impl.auth.module.KRBCallerLoginModule                      6
com.ibm.ws.wssecurity.impl.auth.module.WSWSSLoginModule                          7
com.ibm.ws.security.auth.kerberos.WSKrb5LoginModule                           8
com.ibm.ws.security.server.lm.ltpaLoginModule                                    9
com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule                     10
```

   g. Click **OK**, then click **Save** to save the changes.
   h. Restart the server.
2. You can also run a Jython script to update the module. For each cell, run the script **addKrbLoginModuleWSSCaller.py**, located in the *app_server_root*\bin directory, to update the WSKrb5LoginModule login module in the security configuration.
   a. Run the following command, where *app_server_root* is C:\WebSphere\AppServer:

```
wsadmin -conntype NONE -lang jython -f  C:\WebSphere\AppServer\bin\addKrbLoginModuleWSSCaller.py
```

   b. If the script is successful, the following message is displayed:

```
System JAAS login entry wss.caller has been updated.
```

   c. Restart the server.

Configuring Kerberos policy sets and V2 general sample bindings:

Configure the Kerberos policy sets and V2 general sample bindings that are included with WebSphere Application Server Version 7.0.0.1 and later.

Before you begin

In order to use the additional Kerberos policy sets and V2 general sample bindings that are included with the product, you must create a new profile after installing the product. Existing profiles are not automatically updated, and do not contain the Kerberos policy sets and V2 general sample bindings. You can update existing profiles manually using the following steps.

About this task

To update existing profiles, perform the following manual steps. The deployment manager profile and the stand-alone application server profile are the only profiles that you need to update.

Procedure

1. Copy the directories containing the additional Kerberos policy sets from the profile templates directory, *app_server_root*/profileTemplates/default/documents/config/templates/PolicySets, to the profile configuration directory, *profile_root*/config/templates/PolicySets. Each additional Kerberos policy set is contained in a separate directory. The directories are:
   - Kerberos V5 SecureConversation
   - Kerberos V5 WSSecurity default
   - TrustServiceKerberosDefault
2. Unpackage and copy the general bindings, Client sample V2 and Provider sample V2.
   a. Extract the directories and files from the package file *app_server_root*/profileTemplates/default/configArchives/AppSrv.car into a temporary directory.
   b. Copy the general binding directories from the temporary directory <*temp_dir*>/cells/defaultCell/bindings/, to the profile configuration directory for the cell, *profile_root*/config/cells/*<cellName>*/bindings. Each general binding is contained in a separate directory. The directories are:
      - Provider sample V2
      - Client sample V2
3. Restart the server.

Securing messages using SAML

Configure policy sets, bindings, and SAML-specific tokens to secure web services and messages.

About this task

To secure messages using SAML, you can import the SAML default policy sets and modify them to enable SAML function. Because WebSphere Application Server with SAML does not support attaching a policy set directly to a Web services client, you must specify the policy sets and bindings used to enable SAML as custom properties in the web services client binding document.

You can also create a SAML bearer token using the SAML library API. A bearer token contains a bearer assertion, which is used to facilitate web browser single sign-on (SSO). Other SAML set up tasks described in this section include configuring policy sets and bindings for a bearer token, or a holder-of-key token, or to communicate with a Security Token Service (STS).

See the following topics for more information about securing messages using SAML.

Signing SAML tokens at the message level:

Secure SAML tokens at the message level by enabling assertion signing.

Before you begin

Before configuring signing for SAML tokens, you must configure SAML policy sets and bindings to create SAML tokens as authentication supporting tokens, with message level integrity protection. For more information, read about securing messages using SAML. In addition, the attached SAML bindings must be application-specific bindings, not general bindings. The transform algorithm used for signing SAML assertions is different from other signed parts, while only one transform algorithm is used with general bindings.

About this task

To sign SAML assertions, a SOAP message must include a <wsse:SecurityTokenReference> element in the <wsse:Security> header block. The SecurityTokenReference (STR) is referenced by the message signature using a <ds:Reference> element. The security token reference must include a <wsse:KeyIdentifier> element with the ValueType value, http://docs.oasis-open.org/wss/oasis-wss-saml-token-profile-1.1#SAMLID, or http://docs.oasis-open.org/wss/oasis-wss-saml-token-profile-1.0#SAMLAssertionID, specifying the referenced assertion identifier. The <ds:Reference> element must include the URI of the STR-transform algorithm, http://docs.oasis-open.org/wss/2004/01/oasis-200401-wsssoap-message-security-1.0#STR-Transform. Use of STR-transform ensures that the SAML assertion itself is signed, not only the <wsse:SecurityTokenReference> element.

Follow these configuration steps to enable signing SAML tokens at the message level.

Procedure

1. Configure the message parts.
   a. From the administrative console, edit the SAML policy set, then click **WS-Security > Main policy > Request message part protection**.
   b. Select **Integrity protection**.
   c. Click **Add**.
   d. Enter a part name for **Name of part to be signed**; for example, saml_part.
   e. Under **Elements in Part**, click **Add**.
   f. Select **XPath**.
   g. Add two XPath expressions.

```
/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
and local-name()='Envelope']/*[namespace-uri()='http://schemas.xmlsoap.org/soap/envelope/'
and local-name()='Header']/*[namespace-uri()='http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-secext-1.0.xsd'
and local-name()='Security']/*[namespace-uri()='http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-secext-1.0.xsd'
and local-name()='SecurityTokenReference']
```

```
/*[namespace-uri()='http://www.w3.org/2003/05/soap-envelope'
and local-name()='Envelope']/*[namespace-uri()='http://www.w3.org/2003/05/soap-envelope'
and local-name()='Header']/*[namespace-uri()='http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-secext-1.0.xsd'
and local-name()='Security']/*[namespace-uri()='http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-secext-1.0.xsd'
and local-name()='SecurityTokenReference']
```

   h. Click **Apply** and **Save**.
   i. Restart the application.
2. Configure protection and signing for the client.
   a. From the Service client policy set and bindings panel, click **WS-Security > Authentication and protection**.
   b. Under **Request message signature and encryption protection**, select a configured resource. The signature of the resource you select includes the SAML token.
      1) From the **Available** list under Message part reference, select the name of the part to be signed, as created in step 1; for example, saml_part.
      2) Click **Add**.
      3) In the **Assigned** list under Message part reference, highlight the name of the part you added; for example, saml_part.
      4) Click **Edit**.
      5) For the **Transform algorithms** setting, click **New**.
      6) Select **http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform**.
      7) Click **Apply**.
   c. Under Authentication tokens, select and edit the SAML token you want to sign.
      1) Under Custom property, click **New**.

2) Enter `signToken` as the custom property name.

   Note: The custom property is added at the token generator level, although it only applies to the SAML custom token. The property does not apply to other token types.

3) Enter `true` as the value of the custom property.
4) Click **Apply**.

3. Configure protection and signing for the service provider.
   a. From the Service provider policy sets and bindings panel, click **WS-Security > Authentication and protection**.
   b. Under **Request message signature and encryption protection**, select a configured resource. The signature of the resources you select includes the SAML token.
      1) From the **Available** list under Message part reference, select the name of the part to be signed, as created in step 1; for example, saml_part.
      2) Click **Add**.
      3) In the **Assigned** list under Message part reference, highlight the name of the part you added; for example, saml_part.
      4) Click **Edit**.
      5) For the **Transform algorithms** setting, click **New**.
      6) Select **http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform**.
      7) Click **Apply**.

Configuring policy sets and bindings to communicate with STS:

Configure policy sets and binding documents to enable a web services client to request SAML assertions from an external Security Token Service (STS).

Before you begin

This function is enabled in WebSphere Application Server Version 7.0.0.7 and later releases. After installing, you must create a new server profile, or add SAML configuration settings to an existing profile. Read about setting up the SAML configuration for more information.

About this task

WebSphere Application Server with SAML supports web services clients using the Web Services Security policy set and bindings when communicating with an external security token service (STS). In WebSphere Application Server Version 6.1 and later, web services clients use policy set and bindings to communicate with the target web services provider. A web services client uses two sets of policy set attachments: one set of policy set attachments for communicating to the target web services provider; and the other set of policy set attachments for communicating to the STS. Policy sets and bindings that are used when communicating with the target web services provider are attached to the web services client. In contrast, policy sets and bindings that enable STS communication are not directly attached to the web services clients. Instead, policy sets and bindings that enable STS communication are specified as custom properties in the web services client binding document. You can use general bindings or application-specific bindings to communicate with an STS. Using a general binding to access an STS is straightforward; simply specify the general binding name in the custom properties.

The procedure to configure application-specific bindings to access an STS is more involved. The administrative console is designed to manage policy set attachments to communicate with a web service provider. The console is not designed to manage a second set of policy set attachments to communicate to an STS. However, you can use the administrative console to manage a policy set attachment to access an STS, as described in the procedure.

Use the administrative console to attach the policy set that is used to access an STS to a web services client, and then create and modify an application-specific binding. Once the binding configuration is complete, detach the policy set and binding from the web services client. This procedure is necessary because the next step is to attach the policy set and bindings to communicate to the target web services provider. Detached application-specific bindings are not deleted from the file system, so the web services client bindings custom properties can successfully refer to the detached application-specific bindings.

The procedure uses a default application policy set, Username WSHTTPS default, as an example to describe the configuration steps to access the STS. The steps can also be applied to other policy sets. The web services application, JaxWSServicesSamples, is used in the example. JaxWSServicesSamples is not installed by default.

Procedure

1. Import the Username WSHTTPS default policy set. In this example, the Username WSHTTPS default policy is used to demonstrate the procedure, but you can use a different policy set to configure the bindings, if the policy set meets the policy requirements of the external STS.
   a. Click **Services > Policy sets > Application policy sets**.
   b. Click **Import**.
   c. Select **From Default Repository**.
   d. Select the **WSHTTPS default** policy set.
   e. Click **OK** to import the policy set.
2. Attach a policy set for the trust client. Click **Applications > Application types > WebSphere enterprise applications > *JaxWSServicesSamples* > Service client policy sets and bindings**. The steps which pertain to attaching and detaching the policy set, and configuring the trust client binding, are required only if an application-specific binding is used to access the external STS. You can skip these steps, and go to the step that discusses configuring communication with the STS, if you use a general binding to access the external STS.
   a. Select the check box for the web services client resource.
   b. Click **Attach Client Policy Set**.
   c. Select the policy set, **Username WSHTTPS default**.

   This step attaches the policy set to the web services trust client, as you would do to use this policy set for the application client to access the target web services. However, since you plan to use the Username WSHTTPS default policy set to access an external STS instead, the policy set is only temporarily attached to the Web services client. The purpose of this step is to allow you to use the administrative console to create or to modify the client binding document.
3. Configure the trust client binding.
   a. Select the web services client resource again.
   b. In the Service client policy sets and bindings panel, click **Assign Binding**.
   c. Click **New Application Specific Binding** to create an application-specific binding.
   d. Specify a binding configuration name for the new application-specific binding. In this example, the binding name is **SamlTCSample**.
   e. Add the **SSL transport** policy type to the binding. Optionally, you can modify the NodeDefaultSSLSettings settings. Click **Security > SSL certificate and key management > SSL configurations > NodeDefaultSSLSettings**.
4. Optional: You can create an HTTP transport binding using the previous steps if you want to configure a user name and password to add to the HTTP header, or if you want to configure a proxy. If you elect not to create an HTTP transport binding, the web services runtime environment uses the default HTTP transport settings.
5. Add the **WS-Security** policy type to the binding, then modify the authentication settings.

a. Click **Applications > Application types > WebSphere enterprise applications > *JaxWSServicesSamples* > Service client policy sets and bindings > *SamlTCSample* > Add > WS-Security > Authentication and protection > request:uname_token**.
b. Click **Apply**.
c. Select **Callback handler**.
d. Specify a user name and password (and confirm the password) to authenticate the web services client to the external STS.
e. Click **OK** and **Save**.

6. After the binding settings are saved, return to the Service client policy sets and bindings panel to detach the policy set and bindings.
   a. Click **Applications > Application types > WebSphere enterprise applications > *JaxWSServicesSamples* > Service client policy sets and bindings**.
   b. Click the check box for the web services client resource.
   c. Click **Detach client policy set**.

   The application-specific binding configuration you created in the previous steps is not deleted from the file system when the policy set is detached. This means that you can still use the application-specific binding you created to access the STS.
7. Import the SSL certificate from the external STS.
   a. Click **Security > SSL certificate and key management > Manage endpoint security configurations > *server_or_node_endpoint* > Keystores and certificates > NodeDefaultTrustStore > Signer certificates**.
   b. Click **Retrieve from port**.
   c. Specify the host name and port number of the external STS server, and assign an alias to the certificate. Use the SSL STS port.
   d. Click **Retrieve signer information**.
   e. Click **Apply** and **Save** to copy the retrieved certificate to the NodeDefaultTrustStore object.
8. Optional: If further modifications to the wstrustClientBinding configuration are needed, and the wstrustClientBinding property is pointing to an application-specific binding, you must attach the application-specific binding to the web services client before you can complete the modifications. The attachment is temporary. As detailed in the previous steps, you can detach the modified application-specific binding from the web service client after the modification is completed.

Results

After successfully completing the steps, the web services client is ready to send requests to the external STS. To enable this function, the following conditions and settings were activated when you completed the procedure:

- Attach a policy set and bindings that propagate SAML tokens. For example, attach the SAML11 Bearer WSHTTPS default policy set and the Saml Bearer Client sample general binding to the web service client.
- The Username WSHTTPS default policy set and an application-specific binding, SamlTCSample, are referenced in the Saml Bearer Client sample binding, and are set up to access the external STS.
- The external STS SSL certificate has been retrieved and added to the NodeDefaultTrustStore truststore.
- To confirm that you successfully enabled the function, you can configure the trace setting, com.ibm.ws.wssecurity.*=all=enabled. The trace shows that SAML assertions are issued by the external STS, for example:

```

What to do next

Complete the web service client and web service provider configuration. Read about configuring client and provider bindings for the SAML bearer token for more information.

Configuring client and provider bindings for the SAML bearer token:

Configure the client and provider policy set attachments and bindings for the SAML bearer token.

Before you begin

This function is enabled in WebSphere Application Server Version 7.0.0.7 and later releases. After installing, you must create one or more new server profiles, or add SAML configuration settings to an existing profile. For example, in a network deployment environment, there are multiple profiles. Read about

setting up the SAML configuration for more information.

About this task

A SAML bearer token is a SAML token that uses the Bearer subject confirmation method. In a bearer subject confirmation method, a sender of SOAP messages is not required to establish correspondence that binds a SAML token with contents of the containing SOAP message.

WebSphere Application Server with SAML provides numerous default SAML token application policy sets and several general client and provider binding samples. Before you can configure the client and provider bindings for the SAML bearer token, you must import one of these default policy sets: SAML20 Bearer WSHTTPS default, SAML20 Bearer WSSecurity default, SAML11 Bearer WSHTTPS default, or SAML11 Bearer WSSecurity default. The SAML11 policy sets are almost identical to the SAML20 policy sets, except that the SAML20 policy sets support the SAML Version 2.0 token type, while the SAML11 policy sets support the Version 1.1 token type.

A SAML token policy is defined by a CustomToken extension in the application server. To create the CustomToken extension, define the SAML token configuration parameters in terms of custom properties in the client and provider binding document. The Saml Bearer Client sample and the Saml Bearer Provider sample general bindings contain the essential configuration for the custom properties. The client and provider sample bindings contain both SAML11 and SAML20 token type configuration information and therefore can be used with both SAML11 and SAML20 policy sets. Depending on how you plan to implement the SAML tokens, you must modify the property values in the installed binding samples. Examples of the properties and property values are provided in the procedure.

The procedure for modifying the binding sample begins with configuring the web services client policy set attachment, and then modifies the web services provider policy set attachment. The example presented in the procedure uses the sample web services application JaxWSServicesSamples.

Procedure

1. Import two default policy sets: the Username WSHTTPS default policy set, and one of the following bearer policy sets:
   - SAML11 Bearer WSHTTPS default
   - SAML20 Bearer WSHTTPS default
   - SAML20 Bearer WSSecurity default
   - SAML11 Bearer WSSecurity default

   a. Click **Services** > **Policy sets** > **Application policy sets**.
   b. Click **Import**.
   c. Select **From Default Repository**.
   d. Select the two default policy sets.
   e. Click **OK** to import the policy sets.
2. Attach a policy set for the trust client. Click **Applications > Application types > WebSphere enterprise applications > *JaxWSServicesSamples* > Service client policy sets and bindings**. The steps which pertain to attaching and detaching the policy set, and configuring the trust client binding, are required only if an application-specific binding is used to access the external STS. You can skip these steps, and go to the step that discusses configuring communication with the STS, if you use a general binding to access the external STS.
   a. Select the check box for the web services client resource.
   b. Click **Attach Client Policy Set**.
   c. Select the policy set, **Username WSHTTPS default**.

   This step attaches the policy set to the web services trust client, as you would do to use this policy set for the application client to access the target web services. However, since you plan to use the

Username WSHTTPS default policy set to access an external STS instead, the policy set is only temporarily attached to the Web services client. The purpose of this step is to allow you to use the administrative console to create or to modify the client binding document.

3. Configure the trust client binding.
   a. Select the web services client resource again.
   b. In the Service client policy sets and bindings panel, click **Assign Binding**.
   c. Click **New Application Specific Binding** to create an application-specific binding.
   d. Specify a binding configuration name for the new application-specific binding. In this example, the binding name is **SamlTCSample**.
   e. Add the **SSL transport** policy type to the binding. Optionally, you can modify the NodeDefaultSSLSettings settings. Click **Security > SSL certificate and key management > SSL configurations > NodeDefaultSSLSettings**.
4. Add the **WS-Security** policy type to the binding, then modify the authentication settings.
   a. Click **Applications > Application types > WebSphere enterprise applications > *JaxWSServicesSamples* > Service client policy sets and bindings > *SamlTCSample* > Add > WS-Security > Authentication and protection > request:uname_token**.
   b. Click **Apply**.
   c. Select **Callback handler**.
   d. Specify a user name and password (and confirm the password) to authenticate the web services client to the external STS.
   e. Click **OK** and **Save**.
5. After the binding settings are saved, return to the Service client policy sets and bindings panel to detach the policy set and bindings.
   a. Click **Applications > Application types > WebSphere enterprise applications > *JaxWSServicesSamples* > Service client policy sets and bindings**.
   b. Click the check box for the web services client resource.
   c. Click **Detach client policy set**.

   The application-specific binding configuration you created in the previous steps is not deleted from the file system when the policy set is detached. This means that you can still use the application-specific binding you created to access the STS.
6. Configure the STS endpoint URL and the username and password to authenticate to the STS.
   a. Click **Applications** > **Application types** > **WebSphere enterprise applications** > ***JaxWSServicesSamples*** > **Service client policy sets and bindings** > **Saml Bearer Client sample** > **WS-Security** > **Authentication and protection**.
   b. Click **gen_saml11token** in the Authentication tokens table.
   c. Click **Callback handler**.
   d. Modify the **stsURI** property to specify the STS endpoint. For the self-issuer in an intermediate server, this property is not required, or if the property is specified, it is set to `www.websphere.ibm.com/SAML/Issuer/Self`.
   e. Verify that the value of the **confirmationMethod** property is **bearer**, or modify the property value if necessary.
   f. Verify that the value of the **keyType** property is **http://docs.oasis-open.org/ws-sx/ws-trust/200512/Bearer**, or modify the property value if necessary.
   g. Verify that the value of the **wstrustClientPolicy** property is **Username WSHTTPS default**, or modify the property if necessary.
   h. Modify the **wstrustClientBinding** property and change the value to match the application-specific binding created in the previous steps. For this example, the value is **SamlTCSample**.
   i. Optional: To change how the application server searches for the binding, you can specify the **wstrustClientBindingScope** property and set its value to either **application** or **domain**. When the

value is set to domain, the application server searches for the wstrustClientBinding at the file system location that contains general binding documents. When the value is set to application, the application server searches for the wstrustClientBinding at the file system location that contains application-specific binding documents. When the wstrustClientBindingScope property is not specified, the default behavior of the application server is to search for application-specific bindings and then search for general bindings. If the wstrustClientBinding cannot be located, the application server uses the default bindings.

j. Optional: You can modify the default trust client SOAP version, which is the same as the application client. Set the custom property **wstrustClientSoapVersion** to the value `1.1` to change to SOAP Version 1.1, or set the property to the value `1.2` to change to SOAP Version 1.2.

k. Click **Apply** and **Save**.

7. Optional: If further modifications to the wstrustClientBinding configuration are needed, and the wstrustClientBinding property is pointing to an application-specific binding, you must attach the application-specific binding to the web services client before you can complete the modifications. The attachment is temporary. As detailed in the previous steps, you can detach the modified application-specific binding from the web service client after the modification is completed.
8. Import the SSL certificate from the external STS.
   a. Click **Security > SSL certificate and key management > Manage endpoint security configurations > *server_or_node_endpoint* > Keystores and certificates > NodeDefaultTrustStore > Signer certificates**.
   b. Click **Retrieve from port**.
   c. Specify the host name and port number of the external STS server, and assign an alias to the certificate. Use the SSL STS port.
   d. Click **Retrieve signer information**.
   e. Click **Apply** and **Save** to copy the retrieved certificate to the NodeDefaultTrustStore object.
9. Restart the web services client application so that the policy set attachment modifications can take effect.
10. Attach the **SAML11 Bearer WSHTTPS default** policy set to the web services provider.
11. Assign the **Saml Bearer Provider sample** general binding.
12. Click **WebSphere enterprise applications** > ***JaxWSServicesSamples*** > **Service provider policy sets and bindings** > **Saml Bearer Provider sample** > **WS-Security** > **Authentication and protection**.
    a. Click **con_saml11token** in the Authentication tokens table.
    b. Click the **Callback handler** link.
    c. Use this panel to configure the SAML token issuer digital signature validation binding data for authentication to the external STS, as described in the following step.
13. Add the external STS signing certificate to the truststore for the provider. This step is required if the SAML assertions are signed by the STS and the **signatureRequired** custom property is not specified, or has a value of `true`.

    A trust store specifies keystores that contain trusted root certificates that validate the signer certificate of the SAML token. The SAML token consumer uses this keystore to validate the SAML signer certificate of the digital signature.
    a. Set the custom property **trustStoreType** to match the key store type. Supported keys store types include: **jks**, **jceks**, and **pkcs12**.
    b. Set the custom property **trustStorePath** to the key store file location. For example, *app_server_root*`/etc/ws-security/samples/dsig-issuer.jceks`. The file dsig_issuer.jceks is not provided when WebSphere Application Server is installed, so you must create the file.
    c. Set the custom property **trustStorePassword** to the value of the truststore password. The password is stored as a custom property and is encoded by the administrative console.

d. Optional: You can set the custom property **trustedAlias** to a value such as `samlissuer`. If this property is specified, the X.509 certificate represented by the alias is the only STS certificate that is trusted for SAML signature verification. If this custom property is not specified, the web services runtime environment uses the signing certificate inside the SAML assertions to validate the SAML signature and then verifies the certificate against the configured truststore.

e. Optional: You can set the custom property **trustAnySigner** to the value `true` to allow no signer certificate validation. The Trust Any certificate configuration setting is ignored for the purposes of SAML signature validation.

f. Optional: You can set the custom property **signatureRequired** to `false`, which waives digital signature validation. However, a good security practice is to require SAML assertions to be signed and always require issuer digital signature validation.

g. If the SAML assertion is encrypted by the STS with the PublicKey from the recipient, you must configure the private key from the recipient to decrypt the EncryptedAssertion. The following callback handler custom properties must be set to the value described in the table for the recipient to decrypt the SAML assertion:

Custom property	Value
keyStorePath	Keystore location
keyStoreType	Matching keystore type Supported keystore types include: jks, jceks, and pkcs12
keyStorePassword	Password for the keystore
keyAlias	The alias of the public key used for SAML encryption
keyName	The name of the public key used for SAML encryption
keyPassword	The password for the key name

h. Optional: You can configure the recipient to validate either the issuer name or the certificate SubjectDN of the issuer in the SAML assertion, or you can validate both. Create a list of trusted issuer names, or a list of trusted certificate SubjectDNs, or both types of lists. If you create both issuer name and SubjectDN lists, both issuer name and SubjectDN are verified. If the received SAML issuer name or signer SubjectDN is not in the trusted list, SAML validation fails, and an exception is issued. This example shows how to create a list of trusted issuers and trusted SubjectDNs.

For each trusted issuer name, use *trustedIssuer_n* where *n* is a positive integer. For each trusted SubjectDN, use *trustedSubjectDN_n* where *n* is a positive integer. If you create both types of lists, the integer *n* must match in both lists for the same SAML assertion. The integer *n* starts with 1, and increments by 1.

In this example, you trust a SAML assertion with the issuer name `WebSphere/samlissuer`, regardless of the SubjectDN of the signer, so you add the following custom property:

```
<properties value="WebSphere/samlissuer" name="trustedIssuer_1"/>
```

In addition, you trust a SAML assertion issued by `IBM/samlissuer`, when the SubjectDN of the signer is `ou=websphere,o=ibm,c=us`, so you add the following custom properties:

```
<properties value="IBM/samlissuer" name="trustedIssuer_2"/>
<properties value="ou=websphere,o=ibm,c=us" name="trustedSubjectDN_2"/>
```

By default, WebSphere Application Server trusts all SAML issuers when you do not define a `trustedIssuer_n` value. Without knowing this default behavior, you might mistakenly accept SAML assertions that are issued by an unauthorized STS

i. Optional: You can add a list of non-root certificate authority (CA) certificates that can be used to check the signature of the SAML token. To add non-root certificates, add a custom property named `X509PATH_n` where *n* is a non-negative integer as the value for the non-root certificates.

j. Optional: You can add a list of certificate revocation lists (CRLs) that can be used to validate the signature of the SAML token. To add CRLs, add a custom property named `CRLPATH_n` where *n* is a non-negative integer as the value for the CRLs.

k. Click **Apply** and **Save**.

14. Verify that the token is configured as a bearer token.
    a. Verify that the value of the **confirmationMethod** is `Bearer`.
    b. Verify that the value of the **keyType** property value is `http://docs.oasis-open.org/ws-sx/ws-trust/200512/Bearer` or the `bearer` alias. The `wstrustClientWSTNamespace` property determines how the `bearer` alias is interpreted. In this case, it is assumed that it is set to the WS-Trust 1.3 namespace. If it had a value of WS-Trust 1.2, the `bearer` alias carries no meaning, as it is not defined for WS-Trust 1.2.
    c. Click **Apply** and **Save**.
15. Optional: You can configure the caller binding to select a SAML token to represent the requester identity. The Web Services Security runtime environment uses the specified JAAS login configuration to acquire the user security name and group membership data from the user registry using the SAML token NameId or NameIdentifier as the user name.
    a. Click **WebSphere enterprise applications** > ***JaxWSServicesSamples*** > **Service provider policy sets and bindings** > **Saml Bearer Provider sample** > **WS-Security** > **Callers**.
    b. Click **New** to create the caller configuration
    c. Specify a **Name**, such as `caller`.
    d. Enter a value for the **Caller identity local part**. For example, `http://docs.oasis-open.org/wss/oasis-wss-saml-token-profile-1.1#SAMLV1.1`, which is the local part of the CustomToken element in the attached WS-Security policy.
    e. Click **Apply** and **Save**.
16. Restart the web services provider application so that the policy set attachment modifications can take effect.

Results

When you have completed the procedure, the JaxWSServicesSamples web services application is ready to use the SAML Bearer default policy set, the Saml Bearer Client sample, and the Saml Bearer Provider sample general bindings.

Configuring client and provider bindings for the SAML holder-of-key symmetric key token:

Configure the client and provider policy set attachments and bindings for the SAML holder-of-key token. This configuration scenario uses a symmetric key.

Before you begin

This function is enabled in WebSphere Application Server Version 7.0.0.7 and later releases. After installing, you must create one or more new server profiles, or add SAML configuration settings to an existing profile. For example, in a network deployment environment, there are multiple profiles. Read about setting up the SAML configuration for more information.

About this task

WebSphere Application Server with SAML provides numerous default SAML token application policy sets and several general client and provider binding samples. Before you can configure the client and provider bindings for the SAML holder-of-key token, you must import one of these default policy sets: SAML20 HoK Symmetric WSSecurity default or SAML11 HoK Symmetric WSSecurity default. The SAML11 policy sets are almost identical to the SAML20 policy sets, except that SAML20 HoK Symmetic WSSecurity default

policy set supports the SAML Version 2.0 token type, while the SAML11 HoK Symmetric WSSecurity default policy set supports the Version 1.1 token type.

The SAML token policy is defined by a CustomToken extension in the application server. To create the CustomToken extension, define the SAML token configuration parameters in terms of custom properties in the client and provider binding document. The Saml HoK Symmetric Client sample and the Saml HoK Symmetric Provider sample general bindings contain the essential configuration for the custom properties. The client and provider sample bindings contain both SAML11 and SAML20 token type configuration information and therefore can be used with both SAML11 and SAML20 policy sets. Depending on how you plan to implement the SAML tokens, you must modify the property values in the installed binding samples. Examples of the properties and property values are provided in the procedure.

The procedure for modifying the binding sample begins with configuring the web services client policy set attachment, then configuring the web services provider policy set attachment. The example presented in the procedure uses the sample web services application JaxWSServicesSamples.

Procedure

1. Import two default policy sets: SAML20 HoK Symmetric WSSecurity default, and the Username WSHTTPS default.
   a. Click **Services** > **Policy sets** > **Application policy sets**.
   b. Click **Import**.
   c. Select **From Default Repository**.
   d. Select the two default policy sets.
   e. Click **OK** to import the policy sets.

   If you do not want the server to automatically request a SAML token from the Security Token Service (STS) using the WS-Trust client, you can skip steps 2, 3, and 4, and continue to step 5. For example, you can skip steps 2, 3, and 4, if web services act as a client and self-issues a SAML token based on the original SAML token, or the web services client has already acquired a SAML token and cached the SAML token in the RequestContext.
2. Attach a policy set for the trust client. Click **Applications > Application types > WebSphere enterprise applications > *JaxWSServicesSamples* > Service client policy sets and bindings**. The steps which pertain to attaching and detaching the policy set, and configuring the trust client binding, are required only if an application-specific binding is used to access the external STS. You can skip these steps, and go to the step that discusses configuring communication with the STS, if you use a general binding to access the external STS.
   a. Select the check box for the web services client resource.
   b. Click **Attach Client Policy Set**.
   c. Select the policy set, **Username WSHTTPS default**.

   This step attaches the policy set to the web services trust client, as you would do to use this policy set for the application client to access the target web services. However, since you plan to use the Username WSHTTPS default policy set to access an external STS instead, the policy set is only temporarily attached to the Web services client. The purpose of this step is to allow you to use the administrative console to create or to modify the client binding document.
3. Configure the trust client binding.
   a. Select the web services client resource again.
   b. In the Service client policy sets and bindings panel, click **Assign Binding**.
   c. Click **New Application Specific Binding** to create an application-specific binding.
   d. Specify a binding configuration name for the new application-specific binding. In this example, the binding name is **SamlTCSample**.

e. Add the **SSL transport** policy type to the binding. Optionally, you can modify the NodeDefaultSSLSettings settings. Click **Security > SSL certificate and key management > SSL configurations > NodeDefaultSSLSettings**.

4. Add the **WS-Security** policy type to the binding, then modify the authentication settings.
   a. Click **Applications > Application types > WebSphere enterprise applications > *JaxWSServicesSamples* > Service client policy sets and bindings > *SamlTCSample* > Add > WS-Security > Authentication and protection > request:uname_token**.
   b. Click **Apply**.
   c. Select **Callback handler**.
   d. Specify a user name and password (and confirm the password) to authenticate the web services client to the external STS.
   e. Click **OK** and **Save**.
5. After the binding settings are saved, return to the Service client policy sets and bindings panel to detach the policy set and bindings.
   a. Click **Applications > Application types > WebSphere enterprise applications > *JaxWSServicesSamples* > Service client policy sets and bindings**.
   b. Click the check box for the web services client resource.
   c. Click **Detach client policy set**.

   The application-specific binding configuration you created in the previous steps is not deleted from the file system when the policy set is detached. This means that you can still use the application-specific binding you created to access the STS.
6. Download the unrestricted jurisdiction policy file. The SAML20 HoK Symmetric WSSecurity default security policy uses the 256 bit encryption key size, which requires the unrestricted Java Cryptography Extension (JCE) policy file. For more information, read the section Using the unrestricted JCE policy files in the Tuning Web Services Security topic.
7. Attach the SAML20 HoK Symmetric WSSecurity default policy set and assign the Saml HoK Symmetric Client sample binding to the client resource.
   a. Click **Applications** > **Application types** > **WebSphere enterprise applications** > ***JaxWSServicesSamples*** > **Service client policy sets and bindings**.
   b. Select the web services client resource.
   c. Click **Attach Client Policy Set**.
   d. Select the policy set, **SAML20 HoK Symmetric WSSecurity default**.
   e. Select the web services client resource again.
   f. In the Service client policy sets and bindings panel, click **Assign Binding**.
   g. Select the **Saml HoK Symmetric Client sample** general binding.
   h. Click **Save**.
8. Configure the STS endpoint URL and the user name and password to authenticate to the STS.
   a. Click **Applications** > **Application types** > **WebSphere enterprise applications** > ***JaxWSServicesSamples*** > **Service client policy sets and bindings** > **Saml HoK Symmetric Client sample** > **WS-Security** > **Authentication and protection**.
   b. Click **gen_saml20token** in the Protection tokens table.
   c. Click **Callback handler**.
   d. Modify the **stsURI** property and specify the STS endpoint. If you do not use an external STS, and you want the application server to self-issue a holder-of-key assertion with a symmetric key, do not complete this step and go to step 8i.
   e. If necessary, modify the **wstrustClientPolicy** property and change the value to **Username WSHTTPS default**.
   f. Modify the **wstrustClientBinding** property and change the value to match the application-specific binding created in the previous steps. For this example, the value is **SamlTCSample**. This step

attaches the WS-Trust client policy set. You can skip this step if you do not want the server to automatically request a SAML token from the STS using the WS-Trust client.

g. Change the value of the **wstrustClientBindingScope** property, which controls how the application server searches for the binding. Set the property value to either **application** or **domain**. When the value is set to domain, the application server searches for the wstrustClientBinding at the file system location that contains general binding documents. When the value is set to application, the application server searches for the wstrustClientBinding at the file system location that contains application-specific binding documents. When the wstrustClientBindingScope property is not specified, the default behavior of the application server is to search for application-specific bindings and then search for general bindings. If the wstrustClientBinding can not be located, the application server uses the default bindings.

h. Verify that the value of the `confirmationMethod` property is `Holder-of-key`.

i. Verify that the value of the `keyType` property value is `http://docs.oasis-open.org/ws-sx/ws-trust/200512/SymmetricKey` or the `symmetrickey` alias. The `wstrustClientWSTNamespace` property determines how the `symmetrickey` alias is interpreted. In this case it is assumed that it is set to the WS-Trust 1.3 namespace. If it had a value of WS-Trust 1.2, the `symmetrickey` alias is interpreted as `http://schemas.xmlsoap.org/ws/2005/02/trust/SymmetricKey`.

j. Optional: You can modify the default trust client SOAP version, which is the same as the application client. Set the custom property **wstrustClientSoapVersion** to the value `1.1` to change to SOAP Version 1.1, or set the property to the value `1.2` to change to SOAP Version 1.2.

k. Optional: If you are not using an external STS, and you want the application server to self-issue a holder-of-key assertion with a symmetric key, set the custom property **recipientAlias** to the value of the key alias of the target service. Specifying this property protects the symmetric key for the target service. This alias must be a valid key alias that is contained in the configured trust store of the SAML issuer. The TrustStorePath property specifies the location of the trust store file. The TrustStorePath property is defined in the `SAMLIssuerConfig.properties` file for the application server. For example, the location of the `SAMLIssuerConfig.properties` file at the server level on a WebSphere Application server is:

app_server_root`/profiles/$PROFILE/config/cells/$CELLNAME/nodes/$NODENAME/servers/$SERVERNAME/SAMLIssuerConfig.properties`

The location of this file at the cell level on a WebSphere Application server is:

app_server_root`/profiles/$PROFILE/config/cells/$CELLNAME/sts/SAMLIssuerConfig.properties`

l. Click **Apply** and **Save**.

9. Optional: If further modifications to the wstrustClientBinding configuration are needed, and the wstrustClientBinding property is pointing to an application-specific binding, you must attach the application-specific binding to the web services client before you can complete the modifications. The attachment is temporary. As detailed in the previous steps, you can detach the modified application-specific binding from the web service client after the modification is completed.
10. Import the SSL certificate from the external STS.
    a. Click **Security > SSL certificate and key management > Manage endpoint security configurations > *server_or_node_endpoint* > Keystores and certificates > NodeDefaultTrustStore > Signer certificates**.
    b. Click **Retrieve from port**.
    c. Specify the host name and port number of the external STS server, and assign an alias to the certificate. Use the SSL STS port.
    d. Click **Retrieve signer information**.
    e. Click **Apply** and **Save** to copy the retrieved certificate to the NodeDefaultTrustStore object.
11. Restart the web services client application so that the policy set attachment modifications can take effect.
12. Attach the **SAML20 HoK Symmetric WSSecurity default** policy set to the web services provider.
13. Download the unrestricted jurisdiction policy file. The SAML20 HoK Symmetric WSSecurity default security policy uses the 256 bit encryption key size, which requires the unrestricted Java

Cryptography Extension (JCE) policy file. For more information, read the section Using the unrestricted JCE policy files in the Tuning Web Services Security applications topic.

14. Assign the **Saml HoK Symmetric Provider sample** general binding.
15. Click **Applications** > **Application types** > **WebSphere enterprise applications** > ***JaxWSServicesSamples*** > **Service provider policy sets and bindings** > **Saml HoK Symmetric Provider sample** > **WS-Security** > **Authentication and protection**.
    a. Click **con_saml20token** in the Authentication tokens table.
    b. Click the **Callback handler** link.
    c. Use this panel to configure the embedded symmetric key decryption configuration, and the SAML token issuer digital signature validation to the external STS, as described in the following step.
16. Configure the binding data to decrypt the embedded secret key, or the SAML assertion that is protected by the public key from the recipient. The STS must have access to the public key of the recipient. There are two options to configure the keys for decryption:
    - Option 1: Configure the keystore and a private key, as follows:
      a. Verify that the **Keystore name** field has the value `custom`.
      b. Click **Custom keystore configuration** to view and edit the keystore configuration.
      c. Verify that the initial value for the key file is *app_server_root*`/etc/ws-security/samples/enc-service.jceks`.
    - Option 2: Set the custom properties in the callback handler as follows:

Custom property	Value
keyStorePath	Keystore location
keyStoreType	Matching keystore type Supported keystore types include: jks, jceks, and pkcs12
keyStorePassword	Password for the keystore
keyAlias	The alias of the public key used for SAML encryption
keyName	The name of the public key used for SAML encryption
keyPassword	The password for the key name

17. Add the external STS signing certificate to the truststore. This step is required if the SAML assertions are signed by the STS and the **signatureRequired** custom property is not specified, or has a value of **true**. This truststore is configured for the service provider.
    a. Set the custom property **trustStoreType** to match the keystore type. Supported keystore types include: **jks**, **jceks**, and **pkcs12**.
    b. Set the custom property **trustStorePath** to the keystore file location. For example, *app_server_root*`/etc/ws-security/samples/dsig-issuer.jceks`. The file dsig_issuer.jceks is not provided when WebSphere Application Server is installed, so you must create the file.
    c. Set the custom property **trustStorePassword** to the encoded value of the store password. The password is stored as a custom property and is encoded by the administrative console.
    d. Optional: You can set the custom property **trustedAlias** to a value such as `samlissuer`. Do not set the trustedAlias property if the SAML token is signed by different signers, for example, if the STS delegates token requests to different token providers, and each provider signs with a certificate. If this custom property is not specified, the web services runtime environment uses the signing certificate password in the SAML assertions to validate the signature and then verifies the certificate against the configured truststore.
    e. Optional: You can set the custom property **trustAnySigner** to the value `true` to allow no signer certificate validation. The Trust Any certificate configuration setting is ignored for the purposes of SAML signature validation.

f. Optional: You can set the custom property **signatureRequired** to `false`, which waives digital signature validation. However, a good security practice is to require SAML assertions to be signed and always require issuer digital signature validation.

g. Optional: You can configure the recipient to validate either the issuer name or the certificate SubjectDN of the issuer in the SAML assertion, or you can validate both. Create a list of trusted issuer names, or a list of trusted certificate SubjectDNs, or both types of lists. If you create both issuer name and SubjectDN lists, both issuer name and SubjectDN are verified. If the received SAML issuer name or signer SubjectDN is not in the trusted list, SAML validation fails, and an exception is issued. This example shows how to create a list of trusted issuers and trusted SubjectDNs.

   For each trusted issuer name, use *trustedIssuer_n* where *n* is a positive integer. For each trusted SubjectDN, use *trustedSubjectDN_n* where *n* is a positive integer. If you create both types of lists, the integer *n* must match in both lists for the same SAML assertion. The integer *n* starts with 1, and increments by 1.

   In this example, you trust a SAML assertion with the issuer name `WebSphere/samlissuer`, regardless of the SubjectDN of the signer, so you add the following custom property:

```
<properties value="WebSphere/samlissuer" name="trustedIssuer_1"/>
```

   In addition, you trust a SAML assertion issued by `IBM/samlissuer`, when the SubjectDN of the signer is `ou=websphere,o=ibm,c=us`, so you add the following custom properties:

```
<properties value="IBM/samlissuer" name="trustedIssuer_2"/>
<properties value="ou=websphere,o=ibm,c=us" name="trustedSubjectDN_2"/>
```

   By default, WebSphere Application Server trusts all SAML issuers when you do not define a `trustedIssuer_n` value. Without knowing this default behavior, you might mistakenly accept SAML assertions that are issued by an authorized STS

h. Optional: You can add a list of non-root certificate authority (CA) certificates that can be used to check the signature of the SAML token. To add non-root certificates, add a custom property named `X509PATH_n` where *n* is a non-negative integer as the value for the non-root certificates.

i. Optional: You can add a list of certificate revocation lists (CRLs) that can be used to validate the signature of the SAML token. To add CRLs, add a custom property named `CRLPATH_n` where *n* is a non-negative integer as the value for the CRLs.

j. Click **Apply** and **Save**.

18. Optional: You can configure the caller binding to select a SAML token to represent the requester identity. The Web Services Security runtime environment uses the specified JAAS login configuration to acquire the user security name and group membership data from the user registry using the SAML token NameId or NameIdentifier as the user name.

    a. Click **Applications** > **Application types** > **WebSphere enterprise applications** > ***JaxWSServicesSamples*** > **Service provider policy sets and bindings** > **Saml HoK Symmetric Provider sample** > **WS-Security** > **Callers**.

    b. Click **New** to create the caller configuration

    c. Specify a **Name**, such as `caller`.

    d. Enter a value for the **Caller identity local part**. For example, `http://docs.oasis-open.org/wss/oasis-wss-saml-token-profile-1.1#SAMLV2.0`, which is the local part of the CustomToken element in the attached WS-Security policy.

    e. Click **Apply** and **Save**.

19. Restart the web services provider application so that the policy set attachment modifications can take effect.

Results

When you have completed the procedure, the JaxWSServicesSamples web services application is ready to use the SAML20 HoK Symmetric default policy set, the Saml HoK Symmetric Client sample, and the Saml HoK Symmetric Provider sample general bindings.

SAMLIssuerConfig.properties file:

When creating a new SAML token, you can specify configuration properties to control how the token is configured. The configuration properties are stored in a properties file containing name/value pairs. The properties describe provider-side information such as the issuer location, and the keystore and truststore file paths.

Starting with WebSphere Application Server version 8, you can also use the administrative console or the `setSAMLIssuerConfigInBinding` command task to specify a self-issued SAML token's configuration as custom properties in the requester's outbound configuration in the general bindings or in the application-specific bindings. You can also specify a self-issued SAML token's configuration as custom properties of `com.ibm.websphere.wssecurity.wssapi.WSSGenerationContext` objects when programming to Web Services Security (WSS) Application Programming interfaces (APIs). Migrate self-issued SAML token configuration data from the `SAMLIssuerConfig.properties` file to the bindings. Refer to the "Managing self-issue SAML token configuration using wsadmin commands" section for additional information.

The `SAMLIssuerConfig.properties` file usage is deprecated in WebSphere Application Server version 8. Do not specify a `SAMLIssuerConfig.properties` file using a Java System property. The `com.ibm.websphere.wssecurity.wssapi.token.SAMLTokenFactory.newDefaultProviderConfig()` method returns a `com.ibm.wsspi.wssecurity.saml.config.ProviderConfig` object with empty contents when no `SAMLIssuerConfig.properties` file is specified, which is the recommended programming style. Use `ProviderConfig` setter methods to populate its contents.

File Location

A single configuration file, SAMLIssuerConfig.properties, containing the provider-side properties is created and stored on each server. On a WebSphere server, the file is located in the server-level repository, or in the cell-level repository. In an environment that is not based on WebSphere, the file location is defined by a Java system property. The name of this property is `com.ibm.webservices.wssecurity.platform.SAMLIssuerConfigDataPath`.

For example, the location of the file at the server level on a WebSphere server is:

app_server_root`/profiles/$PROFILE/config/cells/$CELLNAME/nodes/$NODENAME/servers/$SERVERNAME/SAMLIssuerConfig.properties`

The location of the file at the cell level on a WebSphere server is:

app_server_root`/profiles/$PROFILE/config/cells/$CELLNAME/sts/SAMLIssuerConfig.properties`

SAML token properties

The following table describes the provider configuration properties.

Table 289. Properties to configure provider information for a new SAML token. Use these properties to control how the token is created.

Property name	Sample property value	Property description
IssuerURI	http://www.websphere.ibm.com/SAML/SelfIssuer	The URI of the issuer.
TimeToLiveMilliseconds	3600000	Amount of time before expiration of the token.
KeyStoreRef	*MyKeyStoreRef*	A reference to a managed keystore from security.xml.
KeyStorePath	*app_server_root*/etc/ws-security/samples/dsig-receiver.ks	The location of the keystore file. **Note:** You must modify this value from the default value to match the path location for your system.
KeyStoreType	JKS	The keystore type.
KeyStorePassword	*password*	The password of the keystore file (the password must be XOR encoded). For more information, read about encoding passwords in files.

Table 289. Properties to configure provider information for a new SAML token (continued). Use these properties to control how the token is created.

Property name	Sample property value	Property description
KeyAlias	*soapprovider*	The alias of the key as defined in the keystore file.
KeyName	CN=SOAPProvider, OU=TRL, O=IBM, ST=Kanagawa, C=JP	The name of the key as defined in the keystore file.
KeyPassword	*password*	The password of the private key as defined in the keystore file (the password must be XOR encoded).
TrustStoreRef	*MyTrustStoreRef*	A reference to a managed keystore from security.xml.
TrustStorePath	*app_server_root*/etc/ws-security/samples/dsig-receiver.ks	The location of the truststore file. **Note:** You must modify this value from the default value to match the path location for your system.
TrustStoreType	JKS	The truststore type.
TrustStorePassword	*password*	The password of the truststore file.
AttributeProvider	*com.mycompany.SAML.AttributeProviderImpl*	Implementation class of attribute provider.
NameIDProvider	*com.mycompany.SAML.NameIDProviderImpl*	Implementation class of name ID provider.

Example

See the following example of a SAML token configuration properties file:

```
IssuerURI=http://www.websphere.ibm.com/SAML/SelfIssuer
TimeToLiveMilliseconds=3600000
KeyStorePath=${USER_INSTALL_ROOT}/etc/ws-security/samples/dsig-receiver.ks
KeyStoreType=JKS
KeyStorePassword={xor}LDotKTot
KeyAlias=soapprovider
KeyName=CN=SOAPProvider, OU=TRL, O=IBM, ST=Kanagawa, C=JP
KeyPassword={xor}LDotKTot
TrustStorePath=${USER_INSTALL_ROOT}/etc/ws-security/samples/dsig-receiver.ks
TrustStoreType=JKS
TrustStorePassword={xor}LDotKTot
```

Configuring client and provider bindings for the SAML sender-vouches token:

Configure the client and provider policy set attachments and bindings for the SAML sender-vouches token, which includes the sender-vouches confirmation method. The sender-vouches confirmation method is used when a server needs to propagate the client identity or behavior of the client.

Before you begin

This function is enabled in WebSphere Application Server Version 7.0.0.9 and later releases. To use the function, you must first install WebSphere Application Server Version 7.0.0.9, which includes SAML sender-vouches support. After installing Version 7.0.0.9, you must create one or more new server profiles, or add SAML configuration settings to an existing profile. For example, in a WebSphere Application Server, Network Deployment environment, there are multiple profiles. Read about setting up the SAML configuration for more information. The sender-vouches token must be protected using either message-level security or HTTPS transport. Therefore, you must determine which type of security you want to use.

About this task

A SAML sender-vouches token is a SAML token that uses the sender-vouches subject confirmation method. A SOAP message sender is required to protect the integrity of SOAP messages and SAML tokens so that a receiver can verify that the message contents and SAML tokens were not modified by unauthorized parties.

WebSphere Application Server with SAML provides numerous default SAML token application policy sets and several general client and provider binding samples. The policy set for the SAML sender-vouches token is similar to the SAML bearer token policy set. The procedure shows how to create a sender-vouches policy set based on the attached SAML bearer token policy set. Before you can configure the client and provider bindings for the SAML sender-vouches token, you must attach SAML bearer token client and provider bindings to the JAX-WS application. For more information about the bearer policy sets, read about configuring client and provider bindings for the SAML bearer token.

You must use application-specific custom bindings instead of general bindings for sender-vouches. Therefore, if you configure sender-vouches policy sets and bindings from attached bearer token policy sets and bindings, you must ensure that the assigned bindings are application-specific bindings.

The procedure for creating the sender-vouches policy set begins with attaching the Web services bearer token policy sets.

Procedure

Complete the associated steps to configure the selected protection method. Follow the first set of steps to protect messages using message-level security, or follow the second set of steps to protect messages using HTTPS transport.

- To protect messages using message-level security, attach the SAML20 Bearer WSSecurity default policy set and configure the associated application-specific bindings.
  1. Attach the SAML20 Bearer WSSecurity default policy set. Refer to steps 1 and 2 in the topic, Configuring client and provider bindings for the SAML bearer token.
  2. Create and configure application-specific bindings for the client and the service provider. Refer to steps 3 to 9 in the topic Configuring client and provider bindings for the SAML bearer token. For the binding names, enter names that include sender-vouches, such as SAML20SenderVouches_Client and SAML20SenderVouches_Service.
  3. The sender of SOAP messages (attesting entity) satisfies the sender-vouches subject confirmation requirement by including a <ds:Signature> element in the corresponding <wsse:Security> header. The initiator key is used to sign the relevant message content and assertions. Modify the sender-vouches bindings to satisfy the vouching requirement.
     a. Refer to the topic, Signing SAML tokens at the message level for information about modifying the sender-vouches bindings.
     b. Edit both the **Client policy set and bindings** and the **Service provider policy sets and bindings**. Click **WS-Security** > **Authentication and protection**.
     c. Click the name of the authentication token that is configured in the attached SAML bearer policy set; for example, **request:SAMLToken20Bearer**.
     d. Click **Callback handler**.
     e. Under Custom Properties, select **confirmationMethod**.
     f. Click **Edit**.
     g. Change the value of the confirmationMethod property to sender-vouches.
     h. Verify that the value of the `keyType` property value is `http://docs.oasis-open.org/ws-sx/ws-trust/200512/Bearer` or the `bearer` alias. The `wstrustClientWSTNamespace` property determines how the `bearer` alias is interpreted. In this case it is assumed that it is set to the WS-Trust 1.3 namespace. If it had a value of WS-Trust 1.2, the `bearer` alias carries no meaning, as it is not defined for WS-Trust 1.2.
- To protect messages using HTTPS transport, attach the SAML20 Bearer WSHHTPS default policy set and configure the associated application-specific bindings.
  1. Attach the SAML20 Bearer WSHHTPS default policy set. Refer to steps 1 and 2 in the topic, Configuring policy sets and bindings to communicate with the Security Token Service (STS).

2. Create and configure application-specific bindings for the client and the service provider. Refer to steps 3 to 5 in the topic, Configuring policy sets and bindings to communicate with STS. For the binding names, enter names that include sender-vouches, such as sslSamlSenderVouches_Client and sslSamlSenderVouches_Service.
3. Set the required SAML SubjectConfirmation method to the sender-vouches method.
   a. Edit both the **Client policy set and bindings** and the **Service provider policy sets and bindings**. Click **WS-Security > Authentication and protection**.
   b. Click the name of the authentication token configured in the attached SAML bearer policy set. For example, **request:SAMLToken20Bearer**.
   c. Click **Callback handler**.
   d. Under Custom Properties, select **confirmationMethod**.
   e. Click **Edit**.
   f. Change the value of the confirmationMethod property to sender-vouches.
   g. Verify that the value of the `keyType` property value is `http://docs.oasis-open.org/ws-sx/ws-trust/200512/Bearer` or the `bearer` alias. The `wstrustClientWSTNamespace` property determines how the `bearer` alias is interpreted. In this case it is assumed that it is set to the WS-Trust 1.3 namespace. If it had a value of WS-Trust 1.2, the `bearer` alias carries no meaning, as it is not defined for WS-Trust 1.2.
4. Use X.509 client certificate authentication over SSL to satisfy the sender-vouches subject confirmation requirement. The configuration steps vary on the SOAP message receiver side depending on whether SSL connections end at the internal HTTP server or at an external HTTP server. An external HTTP server might be a web server, a reverse proxy security server, a proxy server, and so on.

   When client certificate authentication is required, the internal HTTP server accepts a client SSL connection request under one of the following conditions:
   - The X.509 certificate for the client exists in the trust store.
   - The X.509 certificate is issued by a trusted entity or party, which means that the X.509 certificate for the issuer exists in the trust store.
   - If a web services SSL connection ends at an internal HTTP server, complete the following steps:
     a. Click **Security > SSL certificate and key management > Manage endpoint security configurations > *node_name* > SSL configurations**.
     b. Select the resources used in the SSL transport bindings and in the secure transport chain.
     c. Under Additional Properties, click **Quality of protection (QoP) settings**.
     d. Under General Properties, select **Required** from the Client Authentication menu list.
     e. Click **Apply**.
   - If a web services client SSL connection ends at an external HTTP server, complete the following steps:
     a. Regenerate the plug-in. Click **Servers > Web Servers**.
     b. Select the web server, then click **Generate Plug-in**.
     c. Update the HTTP server with the generated plug-in.
     d. Restart the HTTP server.
     e. Enable client certificate authentication from the HTTPS client to your web server. For more information, see the documentation about Secure Sockets Layer (SSL) client certificate authentication.

        The external web server is configured to propagate web services client SSL context data to the application server. Protect the connection between the external web server and the application server to prevent man-in-the-middle attacks.

Managing self-issue SAML token configuration using wsadmin commands:

The SAMLIssuerConfig.properties file usage is deprecated in WebSphere Application Server Version 8. You can use the listSAMLIssuerConfig and updateSAMLIssuerConfig wsadmin command tasks to read and modify the SAMLIssuerConfig.properties cell level and server level configuration files. Starting with WebSphere Application Server Version 8, you should use the administrative console or the setSAMLIssuerConfigInBinding command task to specify a self-issued SAML token's configuration as custom properties in the requester's outbound configuration in the general bindings or in the application-specific bindings. Do not use server level and cell level SAMLIssuerConfig.properties file.

Before you begin

The product provides an alternate way to specify a self-issued SAML token configuration in policy set bindings. Migrate self-issued SAML token configuration data from the SAMLIssuerConfig.properties file to the bindings. Specifying configuration data for creating self-issued SAML tokens in general bindings or application-specific bindings provides management flexibility to specify the configuration at a finer grained scope, in addition to the cell level and the server level. For example you can configure a specific SAML token issuer for a particular web service application, for an arbitrary group of applications, or for a web service application in a security domain.

Note: Self-issued SAML token configuration data that is defined in the bindings takes precedence over data that is defined in the server level or the cell level SAMLIssuerConfig.properties file, in that order. When a self-issued SAML token configuration data is defined in an attached policy set bindings, the Web services security runtime environment will neglect the SAMLIssuerConfig.properties files, both at the server level and at the cell level. So it is important that when you migrate from the SAMLIssuerConfig.properties file to the bindings, you must migrate all the required properties.

About this task

Note: Two command tasks are available to manage the SAMLIssuerConfig.properties file-based SAML issuer configuration. This file can be located at the cell level and the server level. These two tasks are:

- listSAMLIssuerConfig
- updateSAMLIssuerConfig

Procedure

1. Run the wsadmin command task in the interactive mode. The following Jython script illustrates how to run the wsadmin command task in the interactive mode.

```
AdminTask.listSAMLIssuerConfig('[-interactive]')
```

   To select the server level SAML issuer configuration, the *serverName* and *nodeName* parameters are required. If these parameters are missing, then the command task lists the cell level SAML issuer configuration.

2. Use the listSAMLIssuerConfig command task to display the server level SAML issuer configuration.

```
AdminTask.listSAMLIssuerConfig('[-nodeName Node01 -serverName server1]')
```

   You need the “monitor” or above administrative role privilege to execute the listSAMLIssuerConfig command.

3. Use the updateSAMLIssuerConfig command task to update the server level or cell level SAML issuer configuration.

```
AdminTask.updateSAMLIssuerConfig('[-IssuerURI My_Issuer
                                  -TimeToLiveMilliseconds 3600000
                                  -KeyStoreRef "name=myKeyStore managementScope=(cell):Node01Cell:(node):Node01"
                                  -KeyAlias samlissuer
                                  -KeyName "CN=SAMLIssuer, O=Acme, C=US" -KeyPassword *****
                                  -TrustStoreRef "name=myKeyStore managementScope=(cell):Node01Cell:(node):Node01 "]')
```

   If the *serverName* and *nodeName* parameters are not specified, then the task updates the cell level SAML issuer configuration.

You need the “administrator” administrative role privilege to execute the `updateSAMLIssuerConfig` command.

Results

You have created command scripts to automate the process of updating the cell level or the server level `SAMLIssuerConfig.properties` files, or you have created self-issued SAML token configuration data as custom properties in the requester's outbound configuration in the general bindings or in the application-specific bindings.

Example

The following example illustrates how to add or modify self-issued SAML token configuration data in the application-specific bindings:

```
AdminTask.setSAMLIssuerConfigInBinding('[-bindingName SAMLTestAppClientBinding
-bindingLocation [ [application JaxWSServicesSamples] [attachmentId 1904] ]
-com.ibm.wsspi.wssecurity.saml.config.issuer.IssuerURI My_Issuer
-com.ibm.wsspi.wssecurity.saml.config.issuer.TimeToLiveMilliseconds 3600000
-com.ibm.wsspi.wssecurity.saml.config.issuer.KeyStoreRef "name=myKeyStore managementScope=(cell):Node01Cell:(node):Node01 "
-com.ibm.wsspi.wssecurity.saml.config.issuer.KeyAlias samlissuer
-com.ibm.wsspi.wssecurity.saml.config.issuer.KeyName "CN=SAMLIssuer, O=Acme,C=US"
-com.ibm.wsspi.wssecurity.saml.config.issuer.KeyPassword *****
-com.ibm.wsspi.wssecurity.saml.config.issuer.TrustStoreRef "name=myKeyStore managementScope=(cell):Node01Cell:(node):Node01 "]')
```

The following example illustrates how to modify the general bindings:

```
AdminTask.setSAMLIssuerConfigInBinding('[-bindingName "Saml Bearer Client sample"
-bindingScope domain -bindingLocation  -domainName global
-com.ibm.wsspi.wssecurity.saml.config.issuer.IssuerURI My_Issuer
-com.ibm.wsspi.wssecurity.saml.config.issuer.TimeToLiveMilliseconds 3600000
-com.ibm.wsspi.wssecurity.saml.config.issuer.KeyStorePath "profile_root/etc/ws-security/saml/saml-issuer.jceks
-com.ibm.wsspi.wssecurity.saml.config.issuer.KeyStoreType jceks
-com.ibm.wsspi.wssecurity.saml.config.issuer.KeyStorePassword *****
-com.ibm.wsspi.wssecurity.saml.config.issuer.KeyAlias samlissuer
-com.ibm.wsspi.wssecurity.saml.config.issuer.KeyName "CN=SAMLIssuer, O=Acme, C=US"
-com.ibm.wsspi.wssecurity.saml.config.issuer.KeyPassword *****
-com.ibm.wsspi.wssecurity.saml.config.issuer.TrustStorePath "profile_root/profiles/<server_name>/etc/ws-security/saml/saml-issuer.jceks
-com.ibm.wsspi.wssecurity.saml.config.issuer.TrustStoreType jceks
-com.ibm.wsspi.wssecurity.saml.config.issuer.TrustStorePassword *****]')
```

When specifying the application bindings, **bindingLocation** is a required parameter and can be supplied as a properties object. The property names are `application` and `attachmentId`. When specifying the general bindings, **bindingLocation**, which can be null or have empty properties, is required. Additionally, **bindingScope** is required if the scope is not global. Use the **bindingName** parameter to identify the binding location. For more information about **bindingLocation**, **bindingScope**, and **domainName**, refer to the setBinding or getBinding command tasks documentation.

To remove SAML issuer configuration custom properties from the bindings, use the administrative console or the setBinding command task.

Configuring default Web Services Security bindings

WebSphere Application Server provides support for a set of default Web Services Security bindings for applications. A set of bindings is a named object that is associated with a specific policy set and service resource attached to the policy set.

About this task

Bindings contain environment and platform specific information, such as the following types of information:

- Keys used for signature and encryption
- Keystore information
- Authentication information
- Persistent information

In WebSphere Application Server Version 7.0 and later, there are two types of bindings, application specific bindings and general bindings. Typically, bindings are specific to the application or the platform, and they are not shared.

General bindings can be configured to be used across a range of policy sets and can be reused across applications and for trust service attachments. Though general bindings are highly reusable, they are not able to provide configuration for advanced policy requirements, such as multiple signatures. There are two types of general bindings: general provider policy set bindings and general client policy set bindings. The general bindings that are shipped with WebSphere Application Server are initially set as the default bindings, but you can choose a different binding as the default, or change the level of binding that should be used as the default, for example, from cell level binding to server level binding. Default bindings are used when no application specific binding or trust service binding has been assigned to a policy set attachment. For more information, see the topic General JAX-WS default bindings for Web Services Security. For a description of the general sample bindings that are included with WebSphere Application Server, and used with the JAX-WS programming model, read the topic General sample bindings for JAX-WS applications.

To create general bindings:

Procedure

1. Log in to the administrative console and navigate to the general provider policy set and bindings panel, or the general client policy set and bindings panel
   - Click **Services > Policy sets > General provider policy set bindings**.
   - Click **Services > Policy sets > General client policy set bindings**.
2. Click **New**.

Results

Policy set bindings contain platform-specific information, like keystore, authentication information or persistent information, required by a policy set attachment. Each policy set attachment to a service provider or service client must have exactly one binding. When you create a policy set attachment, the general default bindings are used initially. When general bindings are used in association with a policy set attachment, the cell-level general bindings are applied at run time. If application server level bindings exist, the server-level general bindings override the cell-level definition. General bindings specify configuration for both service client and service provider attachments and the general bindings are not tailored to a specific policy set or application. When you define server-level general bindings, the binding begins in a completely unconfigured state. You must add the policy, and then fully configure the bindings for each added policy.

An application specific binding is a named binding that you create. Application specific bindings enable you to provide platform-specific configuration information for specific policy set attachments. When you create an application specific binding, the available binding configuration options are tailored to the definitions in the attached policy set. You can reuse application specific bindings for multiple service resources within an application. For example, if you create a trust service specific binding, that binding can be reused only for trust service attachments. When you create an application specific binding for a policy set attachment, the binding begins in a completely unconfigured state. For each policy, such as WS-Security or HTTP Transport, where you want to override the general binding, you must add the policy, and then fully configure the bindings for each added policy.

Important: Only use the sample default bindings in a testing environment. Do not use sample default bindings in a production environment. Default bindings contain sample key files that must be customized before use in a production environment.

See the topic Defining and managing service client or provider bindings for more information about bindings.

General JAX-WS default bindings for Web Services Security

General bindings are used as the default bindings at the cell level or server level, or for multiple domains, at the domain level. The general bindings that are included with WebSphere Application Server are initially set as the default bindings. However, you can choose a different binding as the default, or change the level of binding that is used as the default, for example, from cell-level binding to server-level binding.

Policy set bindings contain platform-specific information, such as keystore, authentication information or persistent information, required by a policy set attachment. In WebSphere Application Server Version 7.0 and later, there are two types of bindings: application-specific bindings, and general bindings. Both types of bindings are supported for WS-Security policy sets. General bindings can be used as default bindings, and can also be shared across multiple applications and for trust service attachments. There are two types of general bindings: one for service providers and one for service clients. You can define multiple general bindings for the provider and also for the client. However, only one general provider binding and one general client binding can be designated as the default.

Default bindings are used when no application-specific binding or trust service binding has been assigned to a policy set attachment. You can choose the general provider and general client bindings, which are used as the default bindings for the cell. These are the global security settings. Likewise, you can choose the general provider and general client bindings, which are used as the default bindings for a server. For specific information about selecting bindings, see the topic Defining and managing policy set bindings.

In an environment with multiple security domains, you can also choose the general provider and general client bindings, which are used as the default bindings for a domain. If you do not choose a binding to be the default for a server, the default bindings for the domain in which the server resides are used. If you do not choose a binding to be the default for a domain, the default bindings for the cell (global security) are used. You must choose default provider and default client bindings for the cell.

The general bindings that are included with WebSphere Application Server are initially set as the cell default bindings. You cannot delete a binding that has been selected as the default binding for server, a domain, or the cell. Before you delete a binding that is selected as the default, you must select a different default binding, or specify that the defaults for the cell (global security) should be used.

The following default bindings are shipped with the product:

- Provider sample
- Client sample
- Version 6.1 default policy set bindings

  The Version 6.1 bindings are used only if a WebSphere Application Server Version 6.1 Feature Pack for Web Services application is installed within the WebSphere Application Server Version 7.0 and later environment. For more information on these bindings, see the topic Version 6.1 default policy set bindings.

Important: Do not use the provider and client sample bindings that are included with WebSphere Application Server in their current state in a production environment. You must modify these bindings to meet your security needs before using them in a production environment by making a copy of the bindings and then modifying the copy. For example, change the key and keystore settings to ensure security, and modify the binding settings to match your environment.

For a detailed description of the general sample bindings, see the topic General sample bindings for JAX-WS applications.

To define and manage general bindings, in the administrative console click **Services > Policy sets > General provider policy set bindings** or **Services > Policy sets > General client policy set bindings**. To manage bindings for the cell or the domain, click **Services > Policy sets > Default policy set**

bindings. The general service provider and client bindings have independent settings that you can customize to meet the needs of your environment. To learn more about general bindings, read the topic Defining and managing policy set bindings.

In addition to choosing default bindings for the cell (global security), you can also choose the general provider and general client bindings that you want to use as the default bindings for a server. When are using the JAX-WS programming model and want to specify the server default bindings, log on to the administrative console and click **Servers > Server Types > WebSphere application servers > *server_name***. In the Security section of the console page, click **Default policy set bindings**.

Administering message-level security for JAX-RPC web services

The Java™ API for XML-based RPC (JAX-RPC) specification enables you to develop SOAP-based interoperable and portable web services and web service clients. JAX-RPC simplifies development of web services by shielding you from the underlying complexity of SOAP communication, and enables clients to access a web service as if the web service was a local object mapped into the client's address space.

Securing messages using JAX-RPC at the request and response generators

You can secure messages with tokens and encryption to protect message integrity, authenticity, and confidentiality.

About this task

To secure messages, you can:

- Configure generator signing to protect message integrity
- Configure encryption to protect message confidentiality at the server level and at the application level
- Configure tokens to protect message authenticity at the server level and at the application level

Procedure

- To configure generator signing to protect message integrity, see the steps outlined in “Configuring generator signing using JAX-RPC to protect message integrity” on page 3294.
- To configure encryption to protect message confidentiality at the application level, see the steps outlined in “Configuring encryption using JAX-RPC to protect message confidentiality at the application level” on page 3355.
- To configure encryption to protect message confidentiality at the server level, see the steps outlined in “Configuring encryption using JAX-RPC to protect message confidentiality at the server or cell level” on page 3378.
- To configure tokens to protect message authenticity at the application level, see the steps outlined in “Configuring token generators using JAX-RPC to protect message authenticity at the application level” on page 3327.
- To configure tokens to protect message authenticity at the server level, see the steps outlined in “Configuring token generators using JAX-RPC to protect message authenticity at the server level” on page 3382.

Results

By completing the steps in the previous tasks, you have secured messages using tokens and encryption to protect message integrity, authenticity, and confidentiality.

Securing messages using JAX-RPC at the request and response consumers

You can secure messages at the request and response consumer level to protect message confidentiality and security.

About this task

To secure messages, you can:

- Configure signing to protect message confidentiality
- Configure encryption to protect message confidentiality at the server level and at the application level
- Configure tokens to protect message authenticity at the server level and at the application level

Procedure

- To configure consumer signing to protect message confidentiality, see the steps outlined in “Configuring consumer signing using JAX-RPC to protect message integrity” on page 3309
- To configure encryption to protect message confidentiality at the application level, see the steps outlined in “Configuring encryption to protect message confidentiality at the application level” on page 3367.
- To configure encryption to protect message confidentiality at the server level, see the steps outlined in “Configuring encryption to protect message confidentiality at the server level” on page 3380.
- To configure tokens at the application level to protect message authenticity, see the steps outlined in “Configuring token consumers using JAX-RPC to protect message authenticity at the application level” on page 3344.
- To configure tokens at the server level to protect message authenticity, see the steps outlined in “Configuring token consumers using JAX-RPC to protect message authenticity at the server level” on page 3393.

Results

By completing the steps in the previous tasks, you have secured messages at the request and response consumer level.

Configuring message-level security for JAX-RPC at the application level

Modify the application-level configurations in the administrative console.

Configuring generator signing using JAX-RPC to protect message integrity:

You can configure the generator key and signing information at the server and application level to protect message integrity.

About this task

To protect message integrity, you can:

- Configure the signing information for the client-side request generator and the server-side response generator bindings at the server level and at the application level
- Configure the key information for the request generator (client side) and the response generator (server side) bindings on the server level and at the application level

Procedure

- To configure the signing information for the client-side request generator and the server-side response generator bindings at the server , see the steps outlined in “Configuring the signing information using JAX-RPC for the generator binding on the server level” on page 3369.
- To configure the signing information for the client-side request generator and the server-side response generator bindings at the application level, see the steps outlined in “Configuring the signing information using JAX-RPC for the generator binding on the application level” on page 3295
- To configure the key information for the request generator (client side) and the response generator (server side) bindings at the application level, see the steps outlined in “Configuring the key information using JAX-RPC for the generator binding on the application level” on page 3314.

- To configure the key information for the generator binding on the server level, see the steps outlined in "Configuring the key information for the generator binding using JAX-RPC on the server level" on page 3375.

Results

By completing the steps in these tasks, you have configured generator signing to protect the integrity of messages.

Configuring the signing information using JAX-RPC for the generator binding on the application level:

You can configure the signing information for the client-side request generator and the server-side response generator bindings at the application level.

Before you begin

Note: For WebSphere Application Server version 6.x or earlier only, in the server-side extensions file (`ibm-webservices-ext.xmi`) and the client-side deployment descriptor extensions file (`ibm-webservicesclient-ext.xmi`), you must specify which parts of the message are signed. Also, you must configure the key information that is referenced by the key information references on the signing information panel within the administrative console.

About this task

This task explains the required steps to configure the signing information for the client-side request generator and the server-side response generator bindings at the application level. WebSphere Application Server uses the signing information for the default generator to sign parts of the message including the body, time stamp, and user name token. The Application Server provides default values for bindings. However, an administrator must modify the defaults for a production environment. Complete the following steps to configure the signing information for the generator sections of the bindings files on the application level:

Procedure

1. Locate the signing information configuration panel in the administrative console.
   a. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
   b. Under Manage modules, click ***URI_name***.
   c. Under Web Services Security Properties, you can access the signing information for the request generator and the response generator bindings.
      - For the request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
      - For the response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
   d. Under Required properties, click **Signing information**.
   e. Click **New** to create a signing information configuration, select the box next to the configuration and click **Delete** to delete an existing configuration, or click the name of an existing signing information configuration to edit its settings. If you are creating a new configuration, enter a name in the Signing information name field. For example, you might specify `gen_signinfo`.
2. Select a signature method algorithm from the Signature method field. The algorithm that is specified for the generator, which is either the request generator or the response generator configuration, must match the algorithm that is specified for the consumer, which is either the request consumer or response consumer configuration. WebSphere Application Server supports the following pre-configured algorithms:
   - http://www.w3.org/2000/09/xmldsig#rsa-sha1

- http://www.w3.org/2000/09/xmldsig#hmac-sha1
- http://www.w3.org/2000/09/xmldsig#dsa-sha1

Restriction: Do not use this algorithm if you want the configured application to be compliant with the Basic Security Profile (BSP).

Any ds:SignatureMethod/@Algorithm element in a SIGNATURE based on a symmetric key must have a value of http://www.w3.org/2000/09/xmldsig#rsa-sha1 or http://www.w3.org/2000/09/xmldsig#hmac-sha1.

3. Select a canonicalization method from the **Canonicalization method** field. The canonicalization algorithm that you specify for the generator must match the algorithm for the consumer. WebSphere Application Server supports the following pre-configured algorithms:
   - http://www.w3.org/2001/10/xml-exc-c14n#
   - http://www.w3.org/2001/10/xml-exc-c14n#WithComments
   - http://www.w3.org/TR/2001/REC-xml-c14n-20010315
   - http://www.w3.org/TR/2001/REC-xml-c14n-20010315#WithComments
4. Select a key information signature type from the Key information signature type field. WebSphere Application Server supports the following signature types:

   None Specifies that the <KeyInfo> element is not signed.

   Keyinfo
   Specifies that the entire <KeyInfo> element is signed.

   Keyinfochildelements
   Specifies that the child elements of the <KeyInfo> element are signed.

   The key information signature type for the generator must match the signature type for the consumer. You might encounter the following situations:
   - If you do not specify one of the previous signature types, WebSphere Application Server uses `keyinfo`, by default.
   - If you select Keyinfo or Keyinfochildelements and you select http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform as the transform algorithm in a subsequent step, WebSphere Application Server also signs the referenced token.
5. Select a signing key information reference from the Signing key information field. This selection is a reference to the signing key that the Application Server uses to generate digital signatures.
6. Click **OK** and **Save** to save the configuration.
7. Click the name of the new signing information configuration. This configuration is the one that you specified in a previous step.
8. Specify the part reference, digest algorithm, and transform algorithm. The part reference specifies which parts of the message to digitally sign.
   a. Under Additional properties, click **Part references** > **New** to create a new part reference, click **Part references** > **Delete** to delete an existing part reference, or click a part name to edit an existing part reference.
   b. Specify a unique part name for this part reference. For example, you might specify `reqint`.
   c. Select a part reference from the Part reference field.

      The part reference refers to the message part that is digitally signed. The part attribute refers to the name of the <Integrity> element in the deployment descriptor when the <PartReference> element is specified for the signature. You can specify multiple <PartReference> elements within the <SigningInfo> element. The <PartReference> element has two child elements when it is specified for the signature: <DigestTransform> and <Transform>.
   d. Select a digest method algorithm from the menu. The digest method algorithm specified within the <DigestMethod> element is used in the <SigningInfo> element.

      WebSphere Application Server supports the following algorithms:

- http://www.w3.org/2000/09/xmldsig#sha1
- http://www.w3.org/2001/04/xmlenc#sha256
- http://www.w3.org/2001/04/xmlenc#sha512

e. Click **OK** to save the configuration.

f. Click the name of the new part reference configuration. This configuration is the one that you specified in a previous step.

g. Under Additional Properties, click **Transforms** > **New** to create a new transform, click **Transforms** > **Delete** to delete a transform, or click a transform name to edit an existing transform. If you create a new transform configuration, specify a unique name. For example, you might specify `reqint_body_transform1`.

h. Select a transform algorithm from the menu. The transform algorithm is that is specified within the <Transform> element and specifies the transform algorithm for the signature. WebSphere Application Server supports the following algorithms:

- http://www.w3.org/2001/10/xml-exc-c14n#
- http://www.w3.org/TR/1999/REC-xpath-19991116

  Restriction: Do not use this transform algorithm if you want your configured application to be compliant with the Basic Security Profile (BSP). Instead use http://www.w3.org/2002/06/xmldsig-filter2 to ensure compliance.
- http://www.w3.org/2002/06/xmldsig-filter2
- http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform
- http://www.w3.org/2002/07/decrypt#XML
- http://www.w3.org/2000/09/xmldsig#enveloped-signature

The transform algorithm that you select for the generator must match the transform algorithm that you select for the consumer.

Important: If both of the following conditions are true, WebSphere Application Server signs the referenced token:

- You previously selected the Keyinfo or the Keyinfochildelements option from the Key information signature type field on the signing information panel.
- You select http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform as the transform algorithm.

9. Click **Apply**.
10. Optional: Determine whether to disable the Inclusive namespace prefix list. The Exclusive XML Canonicalization Version 1.0 specification recommends that you include all of the namespace declarations that correspond to the namespace prefix in the canonicalization form. For security reasons, WebSphere Application Server, by default, includes the prefix in the digital signature for Web Services Security. However, some implementations of Web Services Security cannot handle this prefix list. WebSphere Application Server can handle digitally signed messages that either contain or do not contain the prefix list. If you experience a signature validation failure when a signed Simple Object Access Protocol (SOAP) message is sent and you are using another vendor in your environment, check with your service provider for a possible fix to their implementation before you disable this property. To disable this property, complete the following steps:

a. Under Additional properties, click **Properties** > **New**.

b. In the Property name field, enter the `com.ibm.wsspi.wssecurity.dsig.inclusiveNamespaces` property.

c. In the Property value field, enter the `false` value.

d. Click **OK**.

You can set this property for both the request generator and the response generator configurations.

11. Click **Save** at the top of the panel to save your configuration.

Results

After completing these steps, the signing information is configured for the generator on the application level.

What to do next

You must specify a similar signing information configuration for the consumer.

Signing information collection:

Use this page to view a list of signing parameters. Signing information is used to sign and validate parts of a message including the body, time stamp, and user name token. You can also use these parameters for X.509 validation when the authentication method is IDAssertion and the ID type is X509Certificate in the server-level configuration. In such cases, you must fill in the certificate path fields only.

To view this administrative console page on the server level for signing information, complete the following steps:

1. Click **Servers > Server Types > WebSphere application Servers > *server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under JAX-RPC Default Generator Bindings or JAX-RPC Default Consumer Bindings, click **Signing information**.
4. Click **New** to create a signing parameter. Click **Delete** to delete a signing parameter.

To view this administrative console page on the application level for signing information, complete the following steps:

1. Click **Applications > Application Types > WebSphere enterprise applications > *application_name***.
2. Under Modules, click **Manage modules > *URI_name***.
3. Under Web Services Security Properties, you can access the signing information for the following bindings:
   - For the Request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
   - For Response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
   - For the Request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
   - For the Response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
4. Under Required properties, click **Signing information**.
5. Under Additional properties, you can use this panel to configure the following bindings:
   - For the Request receiver binding, click **Web services: Server security bindings**. Under Request receiver binding, click **Edit**.
   - For the Response receiver binding, click **Web services: Client security bindings**. Under Response receiver binding, click **Edit**.
6. Under Additional properties, click **Signing information**.
7. Click **New** to create a signing parameter. Click **Delete** to delete a signing parameter.

Signing information name:

Specifies the unique name that is assigned to the signing configuration.

Signature method:

Specifies the signature method algorithm that is chosen for the signing configuration.

Canonicalization method:

Specifies the canonicalization method algorithm that is chosen for the signing configuration.

Signing information configuration settings:

Use this page to configure new signing parameters.

The specifications that are listed on this page for the signature method, digest method, and canonicalization method are located in the World Wide Web Consortium (W3C) document entitled, *XML Signature Syntax and Specification: W3C Recommendation 12 Feb 2002*.

To view this administrative console page on the server level for signing information, complete the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using WebSphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under JAX-RPC Default Generator Bindings or JAX-RPC Default Consumer Bindings, click **Signing information**.
4. Click **New** to create a signing parameter or click the name of an existing configuration to modify its settings.

To view this administrative console page on the application level for signing information, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Click **Manage modules** > ***URI_name***.
3. Under Web Services Security Properties, you can access the signing information for the following bindings:
   - For the Request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
   - For Response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
   - For the Request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
   - For the Response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
4. Under Required properties, click **Signing information**.
5. Under Additional properties, you can access the signing information for the following bindings:
   - For the Request receiver binding, click **Web services: Server security bindings**. Under Request receiver binding, click **Edit**.

- For the Response receiver binding, click **Web services: Client security bindings**. Under Response receiver binding, click **Edit**.

6. Under Additional properties, click **Signing information**.
7. Click **New** to create a signing parameter or click the name of an existing configuration to modify its settings.

Signing information name:

Specifies the name that is assigned to the signing configuration.

Signature method:

Specifies the algorithm Uniform Resource Identifiers (URI) of the signature method.

The following pre-configured algorithms are supported:
- http://www.w3.org/2000/09/xmldsig#rsa-sha1
- http://www.w3.org/2000/09/xmldsig#dsa-sha1

  Do not use this algorithm if you want the configured application to be compliant with the Basic Security Profile (BSP). Any ds:SignatureMethod/@Algorithm element in a signature based on a symmetric key must have a value of http://www.w3.org/2000/09/xmldsig#rsa-sha1 or http://www.w3.org/2000/09/xmldsig#hmac-sha1.
- http://www.w3.org/2000/09/xmldsig#hmac-sha1

For Version 6.0.*x* applications, you can specify additional signature methods on the Algorithm URI panel. To access the Algorithm URI panel, complete the following steps:
1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using WebSphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under Additional properties, click **Algorithm mappings** > ***algorithm_factory_engine_class_name*** > **Algorithm URI** > **New**.

When you specify the Algorithm URI, you also must specify an algorithm type. To have the algorithm display as a selection in the Signature method field on the Signing information panel, you must select **Signature** as the algorithm type.

This field is available for Version 6.*x* and later applications.

Digest method:

Specifies the algorithm URI of the digest method.

The http://www.w3.org/2000/09/xmldsig#sha1 algorithm is supported.

Canonicalization method:

Specifies the algorithm URI of the canonicalization method.

The following pre-configured algorithms are supported:
- http://www.w3.org/2001/10/xml-exc-c14n#
- http://www.w3.org/2001/10/xml-exc-c14n#WithComments
- http://www.w3.org/TR/2001/REC-xml-c14n-20010315
- http://www.w3.org/TR/2001/REC-xml-c14n-20010315#WithComments

This field is for Version 6.*x* and later applications.

Key information signature type:

Specifies how to sign a KeyInfo element if `dsigkey` or `enckey` is specified for the signing part in the deployment descriptor.

This product supports the following keywords:

keyinfo (default)
Specifies that the entire KeyInfo element is signed.

keyinfochildelements
Specifies that the child elements of the KeyInfo element is signed.

If you do not specify a keyword, the application server uses the KeyInfo value, by default.

The Key information signature type field is available for the token consumer binding.

For Version 6.0.*x* applications, this field is also available for the default consumer, request consumer, and response consumer bindings.

Signing key information:

Specifies a reference to the key information that the application server uses to generate the digital signature.

You can specify one signing key only for the default generator binding on the server level. However, you can specify multiple signing keys for the default consumer bindings. The signing keys for the default consumer bindings are specified using the Key Information references link under Additional properties on the Signing information panel.

On the application level, you can specify only one signing key for the request generator and the response generator. You can specify multiple signing keys for the request consumer and response generator. The signing keys for the request consumer and the response consumer are specified using the Key information references link under Additional properties.

You can specify a signing key configuration for the following bindings on the following levels:

Table 290. Signing key binding information. The key is used for digital signature of messages.

Binding name	Server level or application level	Path
Default generator binding	Server level	1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***. 2. Under Security, click **JAX-WS and JAX-RPC security runtime**. **Note:** In a mixed node cell with a server using WebSphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**. 3. Under JAX-RPC Default Generator Bindings, click **Key information**.

Table 290. Signing key binding information (continued). The key is used for digital signature of messages.

Binding name	Server level or application level	Path
Default consumer binding	Server level	1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***. 2. Under Security, click **JAX-WS and JAX-RPC security runtime**. **Note:** In a mixed node cell with a server using WebSphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**. 3. Under JAX-RPC Default Consumer Bindings, click **Key information**.

Certificate path:

Specifies the settings for the certificate path validation. When you select **Trust any**, this validation is skipped and all incoming certificates are trusted.

The certificate path options are available in token consumer attributes.

Trust anchor

The application server searches for trust anchor configurations on the application and server levels and lists the configurations in this menu.

You can specify trust anchors as an additional property for the response receiver binding and the request receiver binding.

You can specify a trust anchor configuration for the following bindings on the following levels:

Table 291. Trust anchor binding information. The trust anchor is used for signing messages.

Binding name	Server level or application level	Path
Default generator binding	Server level	1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***. 2. Under Security, click **JAX-WS and JAX-RPC security runtime**. **Note:** In a mixed node cell with a server using WebSphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**. 3. Under Additional properties, click **Trust anchors > New**.
Default consumer binding	Server level	1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***. 2. Under Security, click **JAX-WS and JAX-RPC security runtime**. **Note:** In a mixed node cell with a server using WebSphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**. 3. Under Additional properties, click **Trust anchors** > **New**.
Response receiver	Application level	1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***. 2. Under Modules, click **Manage modules** > ***URI_name***. 3. Click **Web services: Client security bindings**. 4. Under the Response receiver binding, click **Edit**. 5. Under Additional properties, click **Trust anchors** > **New**.

Table 291. Trust anchor binding information (continued). The trust anchor is used for signing messages.

Binding name	Server level or application level	Path
Request receiver	Application level	1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***. 2. Click **Manage modules** > ***URI_name***. 3. Click **Web services: Server security bindings**. 4. Under the Request receiver binding, click **Edit**. 5. Under Additional properties, click **Trust anchors** > **New**.

For an explanation of the fields on the trust anchor panel, see the help topic Trust anchor configuration settings.

Certificate store

The application server searches for certificate store configurations on the application and server levels and lists the configurations in this menu.

You can specify a certificate store configuration for the following bindings on the following levels:

Table 292. Certificate configurations for bindings. The certificate store is used for signing messages.

Binding name	Server level or application level	Path
Default generator binding	Server level	1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***. 2. Under Security, click **JAX-WS and JAX-RPC security runtime**. **Note:** In a mixed node cell with a server using WebSphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**. 3. Under Additional properties, click **Collection certificate store** > **New**.
Default consumer binding	Server level	1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***. 2. Under Security, click **JAX-WS and JAX-RPC security runtime**. **Note:** In a mixed node cell with a server using WebSphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**. 3. Under Additional properties, click **Collection certificate store** > **New**.
Response receiver	Application level	1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***. 2. Under Modules, click **Manage modules** > ***URI_name***. 3. Click **Web services: Client security bindings**. 4. Under the Response receiver binding, click **Edit**. 5. Under Additional properties, click **Collection certificate store** > **New**.
Request receiver	Application level	1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***. 2. Under Modules, click **Manage modules** > ***URI_name***. 3. Click **Web services: Server security bindings**. 4. Under the Request receiver binding, click **Edit**. 5. Under Additional properties, click **Collection certificate store** > **New**.

For an explanation of the fields on the collection certificate store panel, see the help topic Collection certificate store configuration settings.

Part reference collection:

Use this page to view the message part references for signature and encryption that are defined in the deployment descriptors.

To view this administrative console page on the server level for signing information, complete the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under JAX-RPC Default Generator Bindings or JAX-RPC Default Consumer Bindings, click **Signing information** > ***signing_information_name***.
4. Under Additional properties, click **Part references**.

To view this administrative console page on the application level for signing information, complete the following steps. Part references are available through the administrative console using Version 6.*x* and later applications only.

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Click **Manage modules** > ***URI_name***.
3. Under Web Services Security Properties, you can access the signing information for the following bindings:
   - For the Request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sending) binding, click **Edit custom**.
   - For Response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
   - For the Request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
   - For the Response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
4. Under Required properties, click **Signing information** > ***signing_information_name***.
5. Under Additional properties, click **Part references**.

Part name:

Specifies the name that is assigned to the part reference configuration.

Part reference name:

Specifies the name of the signed part that is defined in the deployment descriptor.

The Part reference name field is specified in the application binding configuration only.

Digest method algorithm:

Specifies the algorithm Uniform Resource Identifier (URI) of the digest method that is used for the signed part that is specified by the part reference.

Part reference configuration settings:

Use this page to specify a reference to the message parts for signature and encryption that are defined in the deployment descriptors.

To view this administrative console page on the server level for signing information, complete the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under JAX-RPC Default Generator Bindings or JAX-RPC Default Consumer Bindings, click **Signing information** > ***signing_information_name***.
4. Under Additional properties, click **Part references**.
5. Click **New** to create a part reference or click the name of an existing configuration to modify its settings.

To view this administrative console page on the application level for signing information, complete the following steps.

Note: Part references are available through the administrative console using Version 6.*x* applications only.

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** .
2. Click **Manage modules** > ***URI_name*** .
3. Under Web Services Security Properties, you can access the signing information for the following bindings:
   - For the Request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sending) binding, click **Edit custom**.
   - For Response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
   - For the Request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
   - For the Response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
4. Under Required properties, click **Signing information** > ***signing_information_name***.
5. Under Additional properties, click **Part references**.
6. Click **New** to create a part reference or click the name of an existing configuration to modify its settings.

You must specify a part name and select a part reference before specifying additional properties. Before specifying the digest method properties that are accessible under Additional properties, specify a digest method algorithm on this panel. If you specify `none` and click **Digest method**, an error message is displayed.

Part name:

Specifies the name that is assigned to the part reference configuration.

Part reference name:

Specifies the name of the <integrity> or <requiredIntegrity> element for the signed part of the message or it specifies the name of the <confidentiality> or <requiredConfidentiality> element for the encrypted part of the message in the deployment descriptor.

The part names that are defined in the deployment descriptor are listed as options in this field. This field is displayed for the binding configuration on the application level only.

Digest method algorithm:

Specifies the algorithm Uniform Resource Identifier (URI) of the digest method that is used for the signed part that is specified by the part reference.

This product provides the following predefined algorithm URIs:

- `http://www.w3.org/2000/09/xmldsig#sha1`
- `http://www.w3.org/2001/04/xmlenc#sha256`
- `http://www.w3.org/2001/04/xmlenc#sha512`

If you want to specify a custom algorithm, you must configure the custom algorithm in the Algorithm URI panel before setting the digest method algorithm.

To access the Algorithm URI panel, complete the following steps for the server level:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under Additional properties, click **Algorithm mappings** > ***algorithm_factory_engine_class_name*** > **Algorithm URI** > **New**.

The specified algorithms are listed as options for this field.

When you specify the Algorithm URI, you also must specify an algorithm type. To have the algorithm display as a selection in the Digest method algorithm field on the Part reference panel, you must select **Digest value calculation (Message digest)** as the algorithm type.

Transforms collection:

Use this page to view the transform algorithm that is used for processing the Web Services Security message.

This administrative console page applies only to Java API for XML-based RPC (JAX-RPC) applications.

To view this administrative console page for the server level, complete the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under JAX-RPC Default Generator Bindings or JAX-RPC Default Consumer Bindings, click **Signing information** > ***signing_information_name***.
4. Under Additional properties, click **Part references** > ***part_name***.
5. Under Additional properties, click **Transforms**.

To view this administrative console page for the application level, complete the following steps.

Note: This option is available for Version 6 and later applications only.

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.

2. Under Modules, click **Manage Modules** > ***URI_name***.
3. Under Web Services Security Properties, you can access the transforms information for the following bindings:
   - For the Request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click `Edit custom`.
   - For the Request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
   - For the Response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
   - For the Response consumer (receiver) binding, click **Web services: Client security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
4. Under Required properties, click **Signing information** > ***signing_information_name***.
5. Under Additional properties, click **Part references** > ***part_name*Transforms** .

Transform name:

Specifies the name that is assigned to the transform algorithm.

Transform algorithm:

Specifies the algorithm Uniform Resource Identifier (URI) of the transform algorithm.

Transforms configuration settings:

Use this page to specify the transform algorithm that is used for processing the Web Services Security message.

This administrative console page applies only to Java API for XML-based RPC (JAX-RPC) applications.

To view this administrative console page for the server level, complete the following steps:
1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using WebSphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under JAX-RPC Default Generator Bindings or JAX-RPC Default Consumer Bindings, click **Signing information** > ***signing_information_name***.
4. Under Additional properties, click **Part references** > ***part_name***.
5. Under Additional properties, click **Transforms**.
6. Click **New** to create a transform configuration or click the name of an existing configuration to modify its settings.

To view this administrative console page for the application level, complete the following steps. This option is available for Version 6.*x* applications only.
1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Click **Manage modules** > ***URI_name***.
3. Under Web Services Security Properties, you can access the transforms information for the following bindings:
   - For the Request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.

- For the Request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
- For the Response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
- For the Response consumer (receiver) binding, click **Web services: Client security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.

4. Under Required properties, click **Signing information** > ***signing_information_name***.
5. Under Additional properties, click **Part references** > ***part_name*** > **Transforms**.
6. Click **New** to create a transform configuration or click the name of an existing configuration to modify its settings.

You must specify a transform name and select a transform algorithm before specifying additional properties.

Transform name:

Specifies the name that is assigned to the transform algorithm.

Transform algorithm:

Specifies the algorithm Uniform Resource Identifier (URI) of the transform algorithm.

This product supports the following algorithms:

http://www.w3.org/2001/10/xml-exc-c14n#
This algorithm specifies the World Wide Web Consortium (W3C) Exclusive Canonicalization recommendation.

http://www.w3.org/TR/1999/REC-xpath-19991116
This algorithm specifies the W3C XML path language recommendation. If you specify this algorithm, you must specify the property name and value by clicking **Properties**, which is displayed under Additional properties. For example, you might specify the following information:

Property
`com.ibm.wsspi.wssecurity.dsig.XPathExpression`

Value `not(ancestor-or-self::*[namespace-uri()='http://www.w3.org/2000/09/xmldsig#' and local-name()='Signature'])`

Note: Do not use this transform algorithm if you want your configured application to be compliant with the Basic Security Profile (BSP). Instead use http://www.w3.org/2002/06/xmldsig-filter2 to ensure compliance.

http://www.w3.org/2002/06/xmldsig-filter2
This algorithm specifies the XML-Signature XPath Filter Version 2.0 proposed recommendation.

When you use this algorithm, you must specify a set of properties. You can use multiple property sets for the XPath Filter Version 2. Therefore, it is recommended that your property names end with the number of the property set, which is denoted by an asterisk in the following examples:

- To specify an XPath expression for the XPath filter2, you might use:

```
name com.ibm.wsspi.wssecurity.dsig.XPath2Expression_*
```

- To specify a filter type for each XPath, you might use:

```
name com.ibm.wsspi.wssecurity.dsig.XPath2Filter_*
```

Following this expression, you can have a value, `[intersect]`, `[subtract]`, or `[union]`.

- To specify the processing order for each XPath, you might use:

```
name com.ibm.wsspi.wssecurity.dsig.XPath2Order_*
```

Following this expression, indicate the processing order of the XPath.

The following is a list of complete examples:

```
com.ibm.wsspi.wssecurity.dsig.XPath2Expression_2 = [XPath expression#1]
com.ibm.wsspi.wssecurity.dsig.XPath2Filter_1 = [intersect]
com.ibm.wsspi.wssecurity.dsig.XPath2Order_1 = [1]
com.ibm.wsspi.wssecurity.dsig.XPath2Expression_2 = [XPath expression#2]
com.ibm.wsspi.wssecurity.dsig.XPath2Filter_2 = [subtract]
com.ibm.wsspi.wssecurity.dsig.XPath2Order_2 = [2]
```

http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform

This algorithm specifies the enhancements to SOAP messaging that provide message integrity and confidentiality.

http://www.w3.org/2002/07/decrypt#XML

This algorithm specifies the W3C decryption transform for XML Signature recommendation.

http://www.w3.org/2000/09/xmldsig#enveloped-signature

This algorithm specifies the W3C recommendation for XML digital signatures.

Configuring consumer signing using JAX-RPC to protect message integrity:

You can configure protect message integrity by configuring signing and key information at the server and application level.

Before you begin

About this task

To protect message integrity, you can:

- Configure the signing information for the consumer binding on the application level or at the server level
- Configure the key information for the consumer binding on the application level or at the server level

Procedure

- To configure the signing information for the consumer binding on the application level, see the steps outlined in “Configuring the signing information using JAX-RPC for the consumer binding on the application level”
- To configure the signing information for the consumer binding on the server level, see the steps outlined in “Configuring the signing information using JAX-RPC for the consumer binding on the server level” on page 3372
- To configure the key information for the consumer binding on the application level, see the steps outlined in “Configuring the key information for the consumer binding on the application level” on page 3324
- To configure the key information for the consumer binding on the server level, see the steps outlined in “Configuring the key information for the consumer binding using JAX-RPC on the server level” on page 3377

Results

By completing the steps in these tasks, you have configured the consumer signing to protect the integrity of messages.

Configuring the signing information using JAX-RPC for the consumer binding on the application level:

You can configure the signing information for the server-side request consumer and the client-side response consumer bindings at the application level.

Before you begin

Note: For WebSphere Application Server version 6.x or earlier only, in the server-side extensions file and the client-side deployment descriptor extensions file, you must specify which parts of the message are signed.

About this task

Configure the key information that is referenced by the key information references on the signing information panel within the administrative console. WebSphere Application Server uses the signing information on the consumer side to verify the integrity of the received SOAP message by validating that the message parts are signed. Complete the following steps to configure the signing information for the server-side request consumer and client-side response consumer sections of the bindings files on the application level.

Procedure

1. Access the administrative console.

   To access the administrative console, enter `http://server_name:port_number/ibm/console` in your web browser unless you have changed the port number.
2. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
3. Under Manage modules, click ***URI_name***.
4. Under Web Services Security Properties you can access the signing information for the request generator and response generator bindings.
   - To configure the request consumer signing information, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
   - To configure the response consumer signing information, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
5. Under Required properties, click **Signing information**.
6. Click **New** to create a signing information configuration, click **Delete** to delete an existing configuration, or click the name of an existing signing information configuration to edit its settings. If you are creating a new configuration, enter a name in the Signing information name field.
7. Select a signature method algorithm from the Signature method field. The signature method is the algorithm that is used to convert the canonicalized <SignedInfo> element in the binding file into the <SignatureValue> element. The algorithm that is specified for the consumer, which is either the request consumer or the response consumer configuration, must match the algorithm specified for the generator, which is either the request generator or response generator configuration. WebSphere Application Server supports the following pre-configured algorithms:
   - http://www.w3.org/2000/09/xmldsig#rsa-sha1
   - http://www.w3.org/2000/09/xmldsig#hmac-sha1
   - http://www.w3.org/2000/09/xmldsig#dsa-sha1

     Do not use this algorithm if you want the configured application to be compliant with the Basic Security Profile (BSP). Any ds:SignatureMethod/@Algorithm element in a signature based on a symmetric key must have a value of http://www.w3.org/2000/09/xmldsig#rsa-sha1 or http://www.w3.org/2000/09/xmldsig#hmac-sha1.
8. Select a canonicalization method from the Canonicalization method field. The canonicalization method algorithm is used to canonicalize the <SignedInfo> element before it is incorporated as part of the digital signature operation. The canonicalization algorithm that you specify for the generator must match the algorithm for the consumer. WebSphere Application Server supports the following pre-configured algorithms:
   - http://www.w3.org/2001/10/xml-exc-c14n#
   - http://www.w3.org/2001/10/xml-exc-c14n#WithComments

- http://www.w3.org/TR/2001/REC-xml-c14n-20010315
- http://www.w3.org/TR/2001/REC-xml-c14n-20010315#WithComments

9. Select a key information signature type from the Key information signature type field. The key information signature type specifies how the <KeyInfo> element in the SOAP message is digitally signed. WebSphere Application Server supports the following signature types:

   None Specifies that the key is not signed.

   Keyinfo
   Specifies that the entire KeyInfo element is signed.

   Keyinfochildelements
   Specifies that the child elements of the KeyInfo element are signed.

   If you do not specify one of the previous signature types, WebSphere Application Server uses keyinfo, by default. The key information signature type for the consumer must match the signature type for the generator.

10. Under Additional properties, click **Key information references**.
    a. Click **New** to create a key information reference or click the name of an existing entry to edit its configuration. The Key information references panel is displayed.
    b. Enter a name in the Name field.
    c. Select a key information reference in the Key information reference field. This reference is the key information configuration name that specifies the key information that is used by this signing information configuration.
11. Return to the Signing information panel. Under Additional properties, click **Part references**. On the Part references panel, you can specify references to the message parts that are defined in the deployment descriptor extensions file.
    a. Click **New** to create a new Part reference or click the name of an existing part reference to edit its configuration. The Part reference panel is displayed.
    b. Enter a name in the Part name field. This name is the name of the required integrity configuration in the deployment descriptor extensions file and specifies the message parts that must be digitally signed.
    c. Select a digest method algorithm from the Digest method algorithm field.

       WebSphere Application Server supports the following pre-configured algorithms:
       - http://www.w3.org/2000/09/xmldsig#sha1
       - http://www.w3.org/2001/04/xmlenc#sha256
       - http://www.w3.org/2001/04/xmlenc#sha512

       If you want to specify a custom algorithm, you must configure the custom algorithm in the Algorithm URI panel before setting the digest method algorithm.
12. Under Additional properties, click **Transforms**.
    a. Click **New** to create a new transform or click the name of an existing transform to edit its configuration.
    b. Enter a name in the Transform name field.
    c. Select a transform algorithm from the Transform algorithm field. WebSphere Application Server supports the following pre-configured algorithms:
       - http://www.w3.org/2001/10/xml-exc-c14n#
       - http://www.w3.org/TR/1999/REC-xpath-19991116

         Do not use this transform algorithm if you want your configured application to be compliant with the Basic Security Profile (BSP). Instead use http://www.w3.org/2002/06/xmldsig-filter2 to ensure compliance.
       - http://www.w3.org/2002/06/xmldsig-filter2

- http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform
- http://www.w3.org/2002/07/decrypt#XML
- http://www.w3.org/2000/09/xmldsig#enveloped-signature

The transform algorithm that you select for the consumer must match the transform algorithm that you select for the generator. For each part reference in the signing information, specify both a digest method algorithm and a transform algorithm.

13. Click **OK**.
14. Click **Save** at the top of the panel to save your configuration.

Results

After completing these steps, you have configured the signing information for the consumer.

What to do next

You must specify a similar signing information configuration for the generator.

Key information references collection:

Use this page to view the key information references that are needed for encryption or signing.

To view this administrative console page on the server level, complete the following steps. On the server level, you can configure the key information references for the default consumer bindings only.

1. Click **Servers > Server Types > WebSphere application servers >** *server_name*.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under JAX-RPC Default Consumer Bindings, click either of the following links:
   - Click **Encryption information > *encryption_information_name***.
   - Click **Signing information > *signing_information_name***.
4. Under Additional properties, click **Key information reference**.

To view this administrative console page on the application level, complete the following steps. On the application level, you can configure the key information reference for the consumer bindings only.

1. Click **Applications > Application Types > WebSphere enterprise applications***application_name*.
2. Under Modules, click **Manage modules > *URI_name***.
3. Under Web Services Security properties, you can access the signing information for the following bindings:
   - For the Response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**. Under Required properties, click **Encryption information**. Click **New** to create a new encryption configuration or click the name of a configuration to modify its settings.
   - For the Request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**. Under Required properties, click **Encryption information**. Click **New** to create a new encryption configuration or click the name of a configuration to modify its settings.

Name:

Specifies the name of the Key information reference.

Key information reference:

Specifies a reference to the message parts that are signed or encrypted.

The value of this field is the name of the <requiredIntegrity> or the <requiredConfidentiality> element in the deployment descriptor.

Key information reference configuration settings:

Use this page to specify a reference to the message parts for signature and encryption that is defined in the deployment descriptors.

To view this administrative console page on the server level for the key information references, complete the following steps. On the server level, you can configure the key information references for the default consumer bindings only.

1. Click **Servers > Server Types > WebSphere application servers >** *server_name*.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under JAX-RPC Default Consumer Bindings, click either of the following links:
   - Click **Encryption information >** ***encryption_information_name***.
   - Click **Signing information >** ***signing_information_name***.
4. Under Additional properties, click **Key information references**.

To view this administrative console page on the application level, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Under Modules, click **Manage modules >** ***URI_name***.
3. Under Web Services Security Properties, you can access the key information references for the following bindings:
   - For the Response consumer (sender) binding, click **Web services: Client security bindings**. Under Response consumer (sender) binding, click **Edit custom**. Under Required properties, click **Encryption information >** ***encryption_information_name***. Under Additional properties, click **Key information references**.
   - For the Request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**. Under Required properties, click **Encryption information >** ***encryption_information_name***. Under Additional properties, click **Key information references**.

Name:

Specifies the name of the key information reference.

Key information reference:

Specifies a reference to the message parts that are signed or encrypted.

The value of this field is the name of the <requiredIntegrity> or the <requiredConfidentiality> element in the deployment descriptor. You can specify a signing key configuration for the following bindings:

Table 293. Key information reference binding configurations. The key is used for signing or encrypting message parts.

Binding name	Server level or application level	Path
Default consumer binding	Server level	1. Click **Servers > Server Types > WebSphere application servers >** *server_name*. 2. Under Security, click **JAX-WS and JAX-RPC security runtime**. **Note:** In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**. 3. Under JAX-RPC Default Consumer Bindings, click **Key information**.
Response consumer (receiver) binding	Application level	1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** . 2. Under Modules, click **Manage modules >** ***URI_name***. 3. Under Web Services Security Properties, click **Web services: Client security bindings**. 4. Under Response consumer (receiver) binding, click **Edit custom**. 5. Under Required properties, click **Key information**.
Request consumer (receiver) binding	Application level	1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***. 2. Under Modules, click **Manage modules >** ***URI_name***. 3. Under Web Services Security Properties, click **Web services: Server security bindings**. 4. Under Request consumer (receiver) binding, click **Edit custom**. 5. Under Required properties, click **Key information**.

Configuring the key information using JAX-RPC for the generator binding on the application level:

The key information is used to specify the configuration needed to generate the key for digital signature and encryption. The signing information and the encryption information configurations can share the key information, so they are both defined at the same level.

Before you begin

Before you begin this task, configure the key locators and the token consumers that are referenced by the Key locator reference and Token reference fields within the key information panel.

About this task

This task provides the steps needed for configuring the key information for the request generator (client side) and the response generator (server side) bindings at the application level.

Complete the following information to configure the key information for the generator binding on the application level:

Procedure

1. Locate the key information configuration panel in the administrative console.
   a. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
   b. Under Manage modules, click ***URI_name***.
   c. Under Web Services Security Properties you can access the key information for the request generator and response generator bindings.

- For the request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
- For the response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.

d. Under Required properties, click **Key information**.

e. Click **New** to create a key information configuration, select the box next to an existing configuration and click **Delete** to delete the configuration, or click the name of an existing signing information configuration to edit its settings. If you are creating a new configuration, enter a name in the Key information name field. For example, you might specify `gen_signkeyinfo`.

2. Select a key information type from the Key information type field. The key information type specifies how to reference the security tokens. WebSphere Application Server supports the following key information types:

Key identifier

The security token is referenced using an opaque value that uniquely identifies the token. The algorithm that is used for generating the <KeyIdentifier> element value depends upon the token type. For example, a hash of the important elements of the security token is used for generating the <KeyIdentifier> element value. The following <KeyInfo> element is generated in the SOAP message for this key information type:

```
<ds:KeyInfo xmlns:ds="http://www.w3.org/2000/09/xmldsig#">
   <wsse:SecurityTokenReference>
      <wsse:KeyIdentifier ValueType="wsse:X509v3">/62wXO...
      </wsse:KeyIdentifier>
   </wsse:SecurityTokenReference>
</ds:KeyInfo>
```

Key name

The security token is referenced using a name that matches an identity assertion within the token. It is recommended that you do not use this key type as it might result in multiple security tokens that match the specified name. The following <KeyInfo> element is generated in the SOAP message for this key information type:

```
<ds:KeyInfo>
   <ds:KeyName>CN=Group1</ds:KeyName>
</ds:KeyInfo>
```

Security token reference

The security token is directly referenced using Universal Resource Identifiers (URIs). The following <KeyInfo> element is generated in the SOAP message for this key information type:

```
<ds:KeyInfo>
   <wsse:SecurityTokenReference>
      <wsse:Reference URI="#mytoken" />
   </wsse:SecurityTokenReference>
</ds:KeyInfo>
```

Embedded token

The security token is directly embedded within the <SecurityTokenReference> element. The following <KeyInfo> element is generated in the SOAP message for this key information type:

```
<ds:KeyInfo>
   <wsse:SecurityTokenReference>
      <wsse:Embedded wsu:Id="tok1" />
         ...
      </wsse:Embedded>
   </wsse:SecurityTokenReference>
</ds:KeyInfo>
```

X509 issuer name and issuer serial

The security token is referenced by an issuer name and an issuer serial number of an X.509 certificate. The following <KeyInfo> element is generated in the SOAP message for this key information type:

```
<ds:KeyInfo>
   <wsse:SecurityTokenReference>
     <ds:X509Data>
        <ds:X509IssuerSerial>
```

```
          <ds:X509IssuerName>CN=Jones, O=IBM, C=US
          </ds:X509IssuerName>
          <ds:X509SerialNumber>1040152879
           </ds:X509SerialNumber>
        </ds:X509IssuerSerial>
     </ds:X509Data>
   </wsse:SecurityTokenReference>
</ds:KeyInfo>
```

Each type of key information is described in the Web Services Security: SOAP Message Security 1.0 (WS-Security 2004) OASIS standard, which is located at: http://www.oasis-open.org/home/index.php under Web Services Security.

3. Select a key locator reference from the Key locator reference field. This reference specifies a key locator that WebSphere Application Server uses to locate the keys that are used for digital signature and encryption. Before you can select a key locator, you must have configured a key locator. For more information on configuring a key locator, see the following articles:
   - "Configuring the key locator using JAX-RPC for the generator binding on the application level" on page 3405
   - "Configuring the key locator using JAX-RPC for the consumer binding on the application level" on page 3412
4. Click **Get keys** to view a list of key name references. After you click **Get keys**, the key names that are defined in the <sig_klocator> element are shown in the key name reference menu. If you change the key locator reference, you must click **Get keys** again to display the list of key names associated with the new key locator.
5. Select a key name reference from the Key name reference field. This reference specifies the name of a key that is used for generating a digital signature and for encryption. The list of key names provided comes from the key locator specified with the key locator reference.
6. Select a token reference from the Token reference field. This token reference specifies the name of token generator that is used for processing the security token. However, WebSphere Application Server requires this field only when you select Security token reference or Embedded token in the Key information type field. Before specifying a token reference, you must configure a token generator. For more information on configuring a token generator, see "Configuring token generators using JAX-RPC to protect message authenticity at the application level" on page 3327.
7. Optional: If you select Key identifier as the key information type on this panel, you must specify an encoding method, calculation method, value type namespace URI, and a value type local name.
   a. Select an encoding method from the Encoding method field. The encoding method specifies the encoding format for the key identifier. WebSphere Application Server supports the following encoding methods:
      - http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#Base64Binary
      - http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#HexBinary
   b. Select a calculation method from the Calculation method field. WebSphere Application Server supports the following calculation methods:
      - http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#ITSHA1
      - http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#IT60SHA1
   c. Specify a value type namespace Uniform Resource Identifier (URI) in the Namespace URI field. In this field, specify the namespace URI of the value type for a security token that is referenced by the key identifier. When you specify the X.509 certificate token, you do not need to specify this option. If you want to specify another token, you must specify the URI of the qualified name (QName) for value type.
   d. Specify a value type local name. This name is the local name of the value type for a security token that is referenced by the key identifier. When this local name is used in conjunction with the corresponding namespace URI, the information is called the value type qualified name or QName.

When you specify the X.509 certificate token, it is recommended that you use the predefined local names. When you specify the predefined local names, you do not need to specify the namespace URI of the value type. However, if you do not use one of the predefined local names, you must specify both the uniform resource identifier (URI) and the local name. WebSphere Application Server provides the following predefined local names:

X.509 certificate token
http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3

X.509 certificates in a PKIPath
http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1

A list of X509 certificates and CRLs in a PKCS#7
http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7

LTPA Lightweight Third-Party Authentication token. When you specify a value type local name of LTPA, you must also specify a namespace URI of http://www.ibm.com/websphere/appserver/tokentype/5.0.2.

LTPA_PROPAGATION
Lightweight Third-Party Authentication propagation token. When you specify a value type local name of LTPA_PROPAGATION, you must also specify a namespace URI of http://www.ibm.com/websphere/appserver/tokentype.

8. Click **OK** and then click **Save** to save the configuration.

Results

You have configured the key information for the generator binding at the application level

What to do next

You must specify a similar key information configuration for the consumer.

Key information collection:

Use this page to view the configurations that are currently available for generating or consuming the key for XML digital signatures and XML encryption.

To view this administrative console page on the server level for the key information references, complete the following steps:

1. Click **Servers > Server Types > WebSphere application servers >** *server_name*.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under JAX-RPC Default Generator Bindings or the JAX-RPC Default Consumer Bindings, click **Key information**.

To view this administrative console page on the application level for the key information references, complete the following steps.

Note: This option is available on the application level for Version 6 and later applications.

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Under Modules, click **Manage modules >** ***URI_name***.

3. Under Web Services Security Properties, you can access the signing information for the following bindings:
   - For the Request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
   - For the Request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
   - For the Response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
   - For the Response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
4. Under Required properties, click **Key information**.

Key information name:

Specifies the name that is given for the key configuration.

Key information class name:

Specifies the class name that is used for the key information type.

Key information type:

Specifies the type of mechanism used to reference the security token. The type corresponds to the class name that is specified in the Key information class name field.

Key information configuration settings:

Use this page to specify the related configuration need to specify the key for XML digital signature or XML encryption.

To view this administrative console page on the server level for the key information references, complete the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under JAX-RPC Default Generator Bindings or the JAX-RPC Default Consumer Bindings, click **Key information**.
4. Click **New** to create a new configuration or click the configuration name to modify its contents.

To view this administrative console page on the application level for the key information references, complete the following steps.

Note: This option is available on the application level for Version 6.*x* applications.

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Under Modules, click **Manage modules** > ***URI_name***.
3. Under Additional properties, you can access the signing information for the following bindings:
   - For the Request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
   - For the Request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.

- For the Response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
- For the Response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.

4. Under Required properties, click **Key information**.
5. Click **New** to create a new configuration or click the configuration name to modify its contents.

Before clicking **Properties** under Additional properties, you must enter a value in the **Key information name** field and select an option for the Key information type and Key locator reference options.

Key information name:

Specifies a name for the key information configuration.

Key information type:

Specifies the type of key information. The key information type specifies how to reference security tokens.

This product supports the following types of key information. Each type of key information is described in Web Services Security: SOAP Message Security 1.0 (WS-Security 2004)

Table 294. Key information types. These types of key information are supported by the product.

Type	Description
Key identifier	The security token is referenced using an opaque value that uniquely identifies the token.
Key name	The security token is referenced using a name that matches an identity assertion within the token.
Security token reference	With this type, the security token is directly referenced.
Embedded token	With this type, the security token reference is embedded.
X509 issuer name and issuer serial	With this type, the security token is referenced by an issuer and serial number of an X.509 certificate

The X.509 issuer name and issuer serial is described in Web Services Security: X.509 Certificate Token Profile Version 1.0. The other types are described in Web Services Security: SOAP Message Security 1.0 (WS-Security 2004).

If you select **Key identifier** for the key information type, you can specify values in the following fields on this panel:

- Encoding method
- Calculation method
- Value type namespace URI
- Value type local name

Key locator reference:

Specifies the reference that is used to retrieve the key for digital signature and encryption.

Before specifying a key locator reference, you must configure a key locator. You can specify a signing key configuration for the following bindings:

Table 295. Signing key binding configurations. The key is used during digital signature and encryption.

Binding name	Server level or application level	Path
Default generator binding	Server level	1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***. 2. Under Security, click **JAX-WS and JAX-RPC security runtime**. **Note:** In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**. 3. Click **New** to create a new key locator or click the name of a configured key locator to modify its configuration.
Default consumer binding	Server level	1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***. 2. Under Security, click **JAX-WS and JAX-RPC security runtime**. **Note:** In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**. 3. Under Additional properties, click **Key locators**. 4. Click **New** to create a new key locator or click the name of a configured key locator to modify its configuration.
Request sender binding	Application level	1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***. 2. Under Modules, click **Manage modules** > ***URI_name***. 3. Click **Web services: Client security bindings**. Under Request sender binding, click **Edit**. 4. Under Additional properties, click **Key locators**. 5. Click **New** to create a new key locator or click the name of a configured key locator to modify its configuration.
Response receiver binding	Application level	1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***. 2. Under Modules, click **Manage modules** > ***URI_name***. 3. Click **Web services: Client security bindings**. Under Response receiver binding, click **Edit**. 4. Under Additional properties, click **Key locators**. 5. Click **New** to create a new key locator or click the name of a configured key locator to modify its configuration.
Request receiver binding	Application level	1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***. 2. Under Modules, click **Manage modules** > ***URI_name***. 3. Click **Web services: Server security bindings**. Under Request receiver binding, click **Edit**. 4. Under Additional properties, click **Key locators**. 5. Click **New** to create a new key locator or click the name of a configured key locator to modify its configuration.
Response sender binding	Application level	1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***. 2. Under Modules, click **Manage modules** > ***URI_name***. 3. Click **Web services: Server security bindings**. Under Response sender binding, click **Edit**. 4. Under Additional properties, click **Key locators**. 5. Click **New** to create a new key locator or click the name of a configured key locator to modify its configuration.
Request generator (sender) binding	Application level	1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***. 2. Under Modules, click **Manage modules** > ***URI_name***. 3. Click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit**. 4. Under Additional properties, click **Key locators**. 5. Click **New** to create a new key locator or click the name of a configured key locator to modify its configuration.

Table 295. Signing key binding configurations (continued). The key is used during digital signature and encryption.

Binding name	Server level or application level	Path
Response consumer (receiver) binding	Application level	1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***. 2. Under Modules, click **Manage modules** > ***URI_name***. 3. Click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**. 4. Under Additional properties, click **Key locators**. 5. Click **New** to create a new key locator or click the name of a configured key locator to modify its configuration.
Request consumer (receiver) binding	Application level	1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***. 2. Under Modules, click **Manage modules** > ***URI_name***. 3. Click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**. 4. Under Additional properties, click **Key locators**. 5. Click **New** to create a new key locator or click the name of a configured key locator to modify its configuration.
Response generator (sender) binding	Application level	1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***. 2. Under Modules, click **Manage modules** > ***URI_name***. 3. Click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**. 4. Under Additional properties, click **Key locators**. 5. Click **New** to create a new key locator or click the name of a configured key locator to modify its configuration.

Key name reference:

Specifies the name of the key that is used for generating digital signature and encryption.

This field is displayed for the default generator and is also displayed for the request generator and response generator.

Table 296. Key name reference binding configurations. The key is used during digital signature and encryption.

Binding name	Server level or application level	Path
Default generator binding	Server level	1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***. 2. Under Security, click **JAX-WS and JAX-RPC security runtime**. **Note:** In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**. 3. Under Additional properties, click **Key locators**. 4. Click **New** to create a new key locator or click the name of a configured key locator to modify its configuration.
Request generator (sender) binding	Application level	1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***. 2. Under Modules, click **Manage modules** > ***URI_name***. 3. Click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit**. 4. Under Additional properties, click **Key locators**. 5. Click **New** to create a new key locator or click the name of a configured key locator to modify its configuration.

Table 296. Key name reference binding configurations (continued). The key is used during digital signature and encryption.

Binding name	Server level or application level	Path
Response generator (sender) binding	Application level	1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***. 2. Under Modules, click **Manage modules** > ***URI_name***. 3. Click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**. 4. Under Additional properties, click **Key locators**. 5. Click **New** to create a new key locator or click the name of a configured key locator to modify its configuration.

Token reference:

Specifies the name of a token generator or token consumer that is used for processing a security token.

The application server requires this field only when you specify Security token reference or Embedded token in the **Key information type** field. The **Token reference** field is also required when you specify a key identifier type for the consumer. Before specifying a token reference, you must configure a token generator or token consumer. You can specify a token configuration for the following bindings on the following levels:

Table 297. Token reference binding configurations. The reference information is used for a security token reference or an embedded token.

Binding name	Server level or application level	Path
Default generator binding	Server level	1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***. 2. Under Security, click **JAX-WS and JAX-RPC security runtime**. **Note:** In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**. 3. Under JAX-RPC Default Generator Bindings, click **Token generator**. 4. Click **New** to create a new token generator or click the name of a configured token generator to modify its configuration.
Default consumer binding	Server level	1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***. 2. Under Security, click **JAX-WS and JAX-RPC security runtime**. **Note:** In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**. 3. Under JAX-RPC Default Consumer Bindings, click **Token consumer**. 4. Click **New** to create a new token consumer or click the name of a configured token consumer to modify its configuration.
Request generator (sender) binding	Application level	1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***. 2. Under Modules, click **Manage modules** > ***URI_name***. 3. Click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**. 4. Under Additional properties, click **Token generators**. 5. Click **New** to create a new token generator or click the name of a configured token generator to modify its configuration.

Table 297. Token reference binding configurations (continued). The reference information is used for a security token reference or an embedded token.

Binding name	Server level or application level	Path
Response consumer (receiver) binding	Application level	1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***. 2. Under Modules, click **Manage modules** > ***URI_name***. 3. Click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**. 4. Under Required properties, click **Token consumers**. 5. Click **New** to create a new token consumer or click the name of a configured token consumer to modify its configuration.
Request consumer (receiver) binding	Application level	1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***. 2. Under Modules, click **Manage modules** > ***URI_name***. 3. Click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**. 4. Under Required properties, click **Token consumers**. 5. Click **New** to create a new token consumer or click the name of a configured token consumer to modify its configuration.
Response generator (sender) binding	Application level	1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***. 2. Under Modules, click **Manage modules** > ***URI_name***. 3. Click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**. 4. Under Additional properties, click **Token generators**. 5. Click **New** to create a new token generator or click the name of a configured token generator to modify its configuration.

Encoding method:

Specifies the encoding method that indicates the encoding format for the key identifier.

This field is valid when you specify Key identifier in the Key information type field. This product supports the following encoding methods:

- http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#Base64Binary
- http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#HexBinary

This field is available for the default generator binding only.

Calculation method:

This field is valid when you specify Key identifier in the **Key information type** field. This product supports the following calculation methods:

- http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#ITSHA1
- http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#IT60SHA1

This field is available for the generator binding only.

Value type namespace URI:

Specifies the namespace Uniform Resource Identifier (URI) of the value type for a security token that is referenced by the key identifier.

This field is valid when you specify Key identifier in the **Key information type** field. When you specify the X.509 certificate token, you do not need to specify this option. If you want to specify another token, specify the URI of `QName` for value type.

This product provides the following predefined value type URIs for the Lightweight Third Party Authentication (LTPA) token:

- http://www.ibm.com/websphere/appserver/tokentype
- http://www.ibm.com/websphere/appserver/tokentype/5.0.2

This field is available for the generator binding only.

Value type local name:

Specifies the local name of the value type for a security token that is referenced by the key identifier.

When this local name is used with the corresponding namespace URI, the information is called the *value type qualified name* or *QName*.

This field is valid when you specify Key identifier in the **Key information type** field. When you specify the X.509 certificate token, it is recommended that you use the predefined local names. When you specify the predefined local names, you do not need to specify the URI of the value type. This product provides the following predefined local names:

X.509 certificate token
http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3

X.509 certificates in a PKIPath
http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1

A list of X509 certificates and CRLs in a PKCS#7
http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7

Lightweight Third Party Authentication (LTPA)

LTPA_PROPAGATION

Attention: For LTPA, the value type local name is `LTPA`. If you enter `LTPA` for the local name, you must specify the `http://www.ibm.com/websphere/appserver/tokentype/5.0.2` URI value in the **Value type URI** field as well. For LTPA token propagation, the value type local name is `LTPA_PROPAGATION`. If you enter `LTPA_PROPAGATION` for the local name, you must specify the `http://www.ibm.com/websphere/appserver/tokentype` URI value in the **Value type URI** field as well. For the other predefined value types (User name token, X509 certificate token, X509 certificates in a PKIPath, and a list of X509 certificates and CRLs in a PKCS#7), the value for the **Value type local name** field begins with `http://`. For example, if you are specifying the user name token for the value type, enter `http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken` in the **Value type local name** field and then you do not need to enter a value in the value type URI field.

When you specify a custom value type for custom tokens, you can specify the local name and the URI of the quality name (QName) of the value type. For example, you might specify `Custom` for the local name and `http://www.ibm.com/custom` for the URI.

This field is also available for the generator binding only.

Configuring the key information for the consumer binding on the application level:

You can configure the key information for the request consumer (server side) and the response consumer (client side) bindings at the application level.

Before you begin

Configure the key locators and the token consumers that are referenced by the Key locator reference and the Token reference fields within the key information panel.

About this task

This task provides the steps that are needed for configuring the key information for the request consumer (server side) and the response consumer (client side) bindings at the application level. The key information on the consumer side is used for specifying the information about the key, which is used for validating the digital signature in the received message or for decrypting the encrypted parts of the message. Complete the following steps to configure the key information for consumer binding on the application level.

Procedure

1. Locate the key information configuration panel in the administrative console.
   a. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
   b. Under Manage modules, click ***URI_name***.
   c. Under Web Services Security Properties, you can access the key information for the request consumer and response consumer bindings.
      - For the request consumer (receiver) binding, click **Web services: Server security bindings**. Under request consumer (receiver) binding, click **Edit custom**.
      - For the response consumer (receiver) binding, click **Web services: Client security bindings**. Under response consumer (receiver) binding, click **Edit custom**.
   d. Under Required properties, click **Key information**.
   e. Click one of the following to work with key information configuration:

      New To create a key information configuration. Enter a name in the Key information name field. For example, you might specify `con_signkeyinfo`.

      Delete To delete a configuration (selected in the box next to that configuration).

      an existing key information configuration
      To edit the settings of a key information configuration.
2. Select a key information type from the Key information type field. The key information types specify different mechanisms for referencing security tokens using the <wsse:SecurityTokenReference> element within the <ds:KeyInfo> element. WebSphere Application Server supports the following key information types:

   Key identifier
   The security token is referenced using an opaque value that uniquely identifies the token. The algorithm that is used for generating the <KeyIdentifier> element value depends upon the token type. For example, you can use the identifier for the public keys that are defined in the Internet Engineering Task Force (IETF) Request for Comment (RFC) 3280. The following <KeyInfo> element is generated in the SOAP message for this key information type:

```
<ds:KeyInfo xmlns:ds="http://www.w3.org/2000/09/xmldsig#">
   <wsse:SecurityTokenReference>
      <wsse:KeyIdentifier ValueType="http://docs.oasis-open.org/wss/2004/01
      /oasis-200401-wss-x509-token-profile-1.0#X509v3SubjectKeyIdentifier">
      /62wXO...
      </wsse:KeyIdentifier>
   </wsse:SecurityTokenReference>
</ds:KeyInfo>
```

   Key name
   The security token is referenced using a name that matches an identity assertion within the token. It is recommended that you do not use this key type as it might result in multiple

security tokens that match the specified name. The following <KeyInfo> element is generated in the SOAP message for this key information type:

```
<ds:KeyInfo>
   <ds:KeyName>CN=Group1</ds:KeyName>
</ds:KeyInfo>
```

In general, use a key name when you use a Key-Hashing Message Authentication Code (HMAC) digital signature algorithm, such as http://www.w3.org/2000/09/xmldsig#hmac-sha1.

Security token reference

The security token is directly referenced using Universal Resource Identifiers (URIs). The following <KeyInfo> element is generated in the SOAP message for this key information type:

```
<ds:KeyInfo>
   <wsse:SecurityTokenReference>
      <wsse:Reference URI='#SomeCert'
       ValueType="http://docs.oasis-open.org/wss/2004/01/
          oasis-200401-wss-x509-token-profile-1.0#X509v3" />
   </wsse:SecurityTokenReference>
</ds:KeyInfo>
```

Attention: As stated in the Web Services Interoperability Organization (WS-I) Basic Security Profile Version 1 draft and shown in the previous example, the wsse:Reference element in a SECURE_ENVELOPE must have a ValueType attribute.

Embedded token

The security token is directly embedded within the <SecurityTokenReference> element. The following <KeyInfo> element is generated in the SOAP message for this key information type:

```
<ds:KeyInfo>
   <wsse:SecurityTokenReference>
      <wsse:Embedded wsu:Id="tok1" />
         ...
      </wsse:Embedded>
   </wsse:SecurityTokenReference>
</ds:KeyInfo>
```

X509 issuer name and issuer serial

The security token is referenced by an issuer name and an issuer serial number of an X.509 certificate. The following <KeyInfo> element is generated in the SOAP message for this key information type:

```
<ds:KeyInfo>
   <wsse:SecurityTokenReference>
     <ds:X509Data>
        <ds:X509IssuerSerial>
           <ds:X509IssuerName>CN=Jones, O=IBM, C=US</ds:X509IssuerName>
           <ds:X509SerialNumber>1040152879</ds:X509SerialNumber>
        </ds:X509IssuerSerial>
     </ds:X509Data>
   </wsse:SecurityTokenReference>
</ds:KeyInfo>
```

Each type of key information is described in the Web Services Security: SOAP Message Security 1.0 (WS-Security 2004) OASIS standard, which is located at: http://www.oasis-open.org/home/index.php under Web Services Security.

3. Select a key locator reference from the Key locator reference field. The value of this field is a reference to a key locator that WebSphere Application Server uses to locate the keys that are used for digital signature and encryption. Before you can select a key locator, you must configure a key locator. For more information on configuring a key locator, see “Configuring the key locator using JAX-RPC for the consumer binding on the application level” on page 3412.
4. Select a token reference from the Token reference field. The token reference specifies a reference to a token consumer that is used for processing the security token in the message. However, WebSphere Application Server requires this field only when you select Security token reference or Embedded token in the Key information type field. Before specifying a token reference, you must configure a

token consumer. For more information on configuring a token consumer, see “Configuring token consumers using JAX-RPC to protect message authenticity at the application level” on page 3344.

Select **(none)** if a token consumer is not required for this key information configuration.

5. Click **OK** and **Save** to save this configuration.

Results

You have configured the key information for the request or response (or both) consumer binding at the application level.

What to do next

If you have not configured the key information for the generator binding, you must specify a similar key information configuration for the generator. After you configure the key information for both the consumer and the generator, configure the signing information or encryption information, which references the key information that is specified in this key information task.

Configuring token generators using JAX-RPC to protect message authenticity at the application level:

When you specify the token generators at the application level, the information is used on the generator side to generate the security token.

Before you begin

You need to understand that the keystore/alias information that you provide for the generator, and the keystore/alias information that you provide for the consumer are used for different purposes. The main difference applies to the Alias for an X.509 callback handler:

Generator

When used in association with an ecryption generator, the alias supplied for the generator is used to retrieve the public key to encrypt the message. A password is not required. The alias that is entered on a callback handler associated with an encryption generator must be accessible without a password. This means that the alias must not have private key information associated with it in the keystore. When used in association with a signature generator, the alias supplied for the generator is used retrieve the private key to sign the message. A password is required.

Consumer

When used in association with an ecryption consumer, the alias supplied for the consumer is used retrieve the private key to decrypt the message. A password is required.

When associated with a signature consumer, the alias supplied for the consumer is used strictly to retrieve the public key that is used to resolve an X.509 certificate that is not passed in the SOAP security header as a BinarySecurityToken. A password is not required.

About this task

Complete the following steps to configure the token generator on the application level:

Procedure

1. Locate the token generator panel in the administrative console.
   a. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
   b. Under Manage modules, click ***URI_name***.
   c. Under Web Services Security Properties you can access the token generators for the following bindings:

- For the request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
- For the response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.

d. Under Additional properties, click **Token generators**.

e. Click **New** to create a token generator configuration, select an existing configuration. Click **Delete** to delete an existing configuration, or click the name of an existing token generator configuration to edit its settings. If you are creating a new configuration, enter a unique name in the **Token generator name** field. For example, you might specify `gen_signtgen`.

2. Specify a class name in the **Token generator class name** field. The token generator class must implement the com.ibm.wsspi.wssecurity.token.TokenGeneratorComponent interface. The token generator class name for the request generator and the response generator must be similar to the token consumer class name for the request consumer and the response consumer. For example, if your application requires a username token consumer, you can specify the com.ibm.wsspi.wssecurity.token.UsernameTokenConsumer class name on the token consumer panel for the application level and the com.ibm.wsspi.wssecurity.token.UsernameTokenGenerator class name in this field.
3. Optional: Select a part reference in the **Part reference** field. The part reference indicates the name of the security token that is defined in the deployment descriptor.

   Important: On the application level, if you do not specify a security token in your deployment descriptor, the **Part reference** field is not displayed. If you define a security token called `user_tgen` in your deployment descriptor, `user_tgen` is displayed as an option in the **Part reference** field. You can specify a security token in the deployment descriptor when you assemble your application using an assembly tool.
4. Select either **None** or **Dedicated signing information** for the certificate path. Select **None** when the token generator does not use the PKCS#7 token type. When the token generator uses the PKCS#7 token type and you want to package certificate revocation lists (CRLs) in the security token, select **Dedicated signing information** and select a certificate store. To configure a collection certificate store and certificate revocation lists for the generator bindings on the application level, complete the following steps:

   a. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.

   b. Under Related Items, click **EJB Modules** or **Web Modules** > ***URI_name***.

   c. Under Additional Properties you can access the collection certificate store configuration for the following bindings:
   - For the request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
   - For the response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.

   d. Under Additional properties, click **Collection certificate store**.

   also see the information about configuring a collection certificate store.
5. Optional: Select the **Add nonce** option. This option indicates whether a nonce is included in the user name token for the token generator. Nonce is a unique, cryptographic number that is embedded in a message to help stop repeat, unauthorized attacks of user name tokens. The **Add nonce** option is valid only when the generated token type is a user name token and is available only for the request generator binding.

   If you select the **Add nonce** option, you can specify the following properties under Additional properties. These properties are used by the request consumer.

Table 298. Additional nonce properties. Use the nonce properties to include nonce in the user name token.

Property name	Default value	Explanation
com.ibm.ws.wssecurity.config.token. BasicAuth.Nonce.cacheTimeout	600 seconds	Specifies the timeout value, in seconds, for the nonce value that is cached on the server.
com.ibm.ws.wssecurity.config.token. BasicAuth.Nonce.clockSkew	0 seconds	Specifies the time, in seconds, before the nonce time stamp expires.
com.ibm.ws.wssecurity.config.token. BasicAuth.Nonce.maxAge	300 seconds	Specifies the clock skew value, in seconds, to consider when WebSphere Application Server checks the timeliness of the message.

On the server level, you can specify these additional properties for a nonce on the Default bindings for Web Services Security panel within the administrative console. To access the panel, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***. Under Security, click **JAX-WS and JAX-RPC security runtime**.

Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.

6. Optional: Select the **Add timestamp** option. This option indicates whether to insert a time stamp into the user name token. The **Add timestamp** option is valid only when the generated token type is a user name token and is available only for the request generator binding.
7. Specify the value type local name in the **Local name** field. For a user name token and an X.509 certificate security token, WebSphere Application Server provides predefined local names for the value type. When you specify any of the following local names, you do not need to specify a value type URI:

   http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken
   This local name specifies a user name token.

   http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3
   This local name specifies an X.509 certificate token.

   http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1
   This local name specifies X.509 certificates in a public key infrastructure (PKI) path.

   http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7
   This local name specifies a list of X.509 certificates and certificate revocation lists in a PKCS#7 format.

   For an LTPA token, you can use `LTPA` for the value type local name and `http://www.ibm.com/websphere/appserver/tokentype/5.0.2` for the value type Uniform Resource Identifier (URI). For LTPA token propagation, you can use `LTPA_PROPAGATION` for the value type local name and `http://www.ibm.com/websphere/appserver/tokentype` for the value type URI.
8. Optional: Specify the value type URI in the **URI** field. This entry specifies the namespace URI of the value type for the generated token.
9. Click **OK** and **Save** to save the configuration.
10. Click the name of your token generator configuration.
11. Under Additional properties, click **Callback handler**.
12. Specify the settings for the callback handler.
    a. Specify a class name in the **Callback handler class name** field. This class name is the name of the callback handler implementation class that is used to plug-in a security token framework. The specified callback handler class must implement the javax.security.auth.callback.CallbackHandler interface and must provide a constructor using the following syntax:

```
MyCallbackHandler(String username, char[] password, java.util.Map properties)
```

Where:

username
Specifies the user name that is passed into the configuration.

password
Specifies the password that is passed into the configuration.

properties
Specifies the other configuration properties that are passed into the configuration.

This constructor is required if the callback handler needs a user name and a password. However, if the callback handler does not need a user name and a password, such as X509CallbackHandler, use a constructor with the following syntax:

```
MyCallbackHandler(java.util.Map properties)
```

WebSphere Application Server provides the following default callback handler implementations:

com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler
This callback handler uses a login prompt to gather the user name and password information. However, if you specify the user name and password on this panel, a prompt is not displayed and WebSphere Application Server returns the user name and password to the token generator. Use this implementation for a Java Platform, Enterprise Edition (Java EE) application client only. If you use this implementation, you must provide a basic authentication user ID and password on this panel.

com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler
This callback handler does not issue a prompt and returns the user name and password if it is specified on this panel. You can use this callback handler when the web service is acting as a client. If you use this implementation, you must provide a basic authentication user ID and password on this panel.

com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler
This callback handler uses a standard-in prompt to gather the user name and password. However, if the user name and password is specified on this panel, WebSphere Application Server does not issue a prompt, but returns the user name and password to the token generator. Use this implementation for a Java Platform, Enterprise Edition (Java EE) application client only. If you use this implementation, you must provide a basic authentication user ID and password on this panel.

com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler
This callback handler is used to obtain the Lightweight Third Party Authentication (LTPA) security token from the Run As invocation Subject. This token is inserted in the Web Services Security header within the SOAP message as a binary security token. However, if the user name and password are specified on this panel, WebSphere Application Server authenticates the user name and password to obtain the LTPA security token rather than obtaining it from the Run As Subject. Use this callback handler only when the web service is acting as a client on the application server. It is recommended that you do not use this callback handler on a Java EE application client. If you use this implementation, you must provide a basic authentication user ID and password on this panel.

com.ibm.wsspi.wssecurity.auth.callback.X509CallbackHandler
This callback handler is used to create the X.509 certificate that is inserted in the Web Services Security header within the SOAP message as a binary security token. A keystore and a key definition is required for this callback handler. If you use this implementation, you must provide a key store password, path, and type on this panel.

com.ibm.wsspi.wssecurity.auth.callback.PKCS7CallbackHandler
This callback handler is used to create X.509 certificates encoded with the PKCS#7 format. The certificate is inserted in the Web Services Security header in the SOAP message as a binary security token. A keystore is required for this callback handler. You can specify a certificate revocation list (CRL) in the collection certificate store. The CRL is

encoded with the X.509 certificate in the PKCS#7 format. If you use this implementation, you must provide a key store password, path, and type on this panel.

com.ibm.wsspi.wssecurity.auth.callback.PkiPathCallbackHandler
This callback handler is used to create X.509 certificates encoded with the PkiPath format. The certificate is inserted in the Web Services Security header within the SOAP message as a binary security token. A keystore is required for this callback handler. A CRL is not supported by the callback handler; therefore, the collection certificate store is not required or used. If you use this implementation, you must provide a key store password, path, and type on this panel.

The callback handler implementation obtains the required security token and passes it to the token generator. The token generator inserts the security token in the Web Services Security header within the SOAP message. Also, the token generator is a plug-in point for the pluggable security token framework. Service providers can provide their own implementation, but the implementation must use the com.ibm.wsspi.wssecurity.token.TokenGeneratorComponent interface.

b. Optional: Select the **Use identity assertion** option. Select this option if you have identity assertion defined in the IBM extended deployment descriptor. This option indicates that only the identity of the initial sender is required and inserted into the Web Services Security header within the SOAP message. For example, WebSphere Application Server sends only the user name of the original caller for a username token generator. For an X.509 token generator, the application server sends the original signer certification only.

c. Optional: Select the **Use RunAs identity** option. Select this option if you have identity assertion defined in the IBM extended deployment descriptor and you want to use the Run As identity instead of the initial caller identity for identity assertion in a downstream call. This option is valid only if you have configured Username TokenGenerator as a token generator.

d. Optional: Specify the basic authentication user ID in the **Basic authentication user ID** field. This entry specifies the user name that is passed to the constructors of the callback handler implementation. The basic authentication user name and password are used if you specified one of the following default callback handler implementations in the **Callback handler class name** field:
   - com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler
   - com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler
   - com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler
   - com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler

e. Optional: Specify the basic authentication password in the **Basic authentication password** field. This entry specifies the password that is passed to the constructors of the callback handler implementation.

f. Optional: Specify the key store password in the **Key store password** field. This entry specifies the password used to access the key store file. The key store and its configuration are used if you select on of the following default callback handler implementations that are provided by WebSphere Application Server:

   com.ibm.wsspi.wssecurity.auth.callback.PKCS7CallbackHandler
   The keystore is used to build the X.509 certificate with the certificate path.

   com.ibm.wsspi.wssecurity.auth.callback.PkiPathCallbackHandler
   The keystore is used to build the X.509 certificate with the certificate path.

   com.ibm.wsspi.wssecurity.auth.callback.X509CallbackHandler
   The keystore is used to retrieve the X.509 certificate.

g. Optional: Specify the key store path in the **Path** field. It is recommended that you use the `${USER_INSTALL_ROOT}` in the path name as this variable expands to the WebSphere Application Server path on your machine. To change the path used by this variable, click **Environment** > **WebSphere variables**, and click **USER_INSTALL_ROOT**. This field is required when you use the

com.ibm.wsspi.wssecurity.auth.callback.PKCS7CallbackHandler, com.ibm.wsspi.wssecurity.auth.callback.PkiPathCallbackHandler, or com.ibm.wsspi.wssecurity.auth.callback.X509CallbackHandler callback handler implementations.

h. Optional: Select the key store type in the **Type** field. This selection indicates the format used by the keystore file. You can select one of the following values for this field:

JKS Use this option if the keystore uses the Java Keystore (JKS) format.

JCEKS
Use this option if the Java Cryptography Extension is configured in the software development kit (SDK). The default IBM JCE is configured in WebSphere Application Server. This option provides stronger protection for stored private keys by using Triple DES encryption.

JCERACFKS
Use JCERACFKS if the certificates are stored in a SAF key ring (z/OS only).

PKCS11KS (PKCS11)
Use this format if your keystore uses the PKCS#11 file format. Keystores using this format might contain RSA keys on cryptographic hardware or might encrypt keys that use cryptographic hardware to ensure protection.

PKCS12KS (PKCS12)
Use this option if your keystore uses the PKCS#12 file format.

13. Click **OK** and then click **Save** to save the configuration.
14. Click the name of your token generator configuration.
15. Under Additional properties, click **Callback handler** > **Keys**.
16. Specify the key name, key alias, and the key password.
    a. Click **New** to create a key configuration, click **Delete** to delete an existing configuration, or click the name of an existing key configuration to edit its settings. If you are creating a new configuration, enter a unique name in the **Key name** field. For digital signatures, the key name is used by the request generator or response generator signing information to determine which key is used to digitally sign the message. For encryption, the key name is used to determine the key used for encryption. The key name must be a fully qualified, distinguished name. For example, CN=Bob,O=IBM,C=US.
    b. Specify the key alias in the **Key alias** field. The key alias is used by the key locator to find the key within the keystore file.
    c. Specify the key password in the **Key password** field. This password is needed to access the key object within the keystore file.
17. Click **OK** and **Save** to save the configuration.

Results

You have configured the token generator for the application level.

What to do next

You must specify a similar token consumer configuration for the application level.

Request generator (sender) binding configuration settings:

Use this page to specify the binding configuration for the request generator.

To view this administrative console page, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** .
2. Under Modules, click **Manage modules**.
3. Click the Uniform Resource Identifier (URI).
4. Under Web Services Security Properties, click **Web services: Client security bindings**.
5. Under Request generator (sender) binding, click **Edit custom**.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

The security constraints or bindings are defined using the application assembly process before the application is installed.

This product provides assembly tools to assemble your application.

If the security constraints are defined in the application, you must either define the corresponding binding information or select the Use defaults option on this panel and use the default binding information for the server level. The default binding provided by this product is a sample. Do not use this sample in a production environment without modifying the configuration. The security constraints define what is signed or encrypted in the Web Services Security message. The bindings define how to enforce the requirements.

Digital signature security constraint (integrity)

The following table shows the required and optional binding information when the digital signature security constraint (integrity) is defined in the deployment descriptor.

Table 299. Binding information for digital signature security constraints. The binding information is used for digitally signing messages.

Information type	Required or optional
Signing information	Required
Key information	Required
Key locators	Optional
Collection certificate store	Optional
Token generator	Optional
Properties	Optional

You can use the key locators and the collection certificate store that are defined at the server-level.

Encryption constraint (confidentiality)

The following table shows the required and optional binding information when the encryption constraint (confidentiality) is defined in the deployment descriptor.

Table 300. Binding information for encryption constraints. The binding information is used for encrypting messages.

Information type	Required or optional
Encryption information	Required
Key information	Required
Key locators	Optional
Collection certificate store	Optional
Token generator	Optional
Properties	Optional

You can use the key locators and the collection certificate store that are defined at the server-level.

Security token constraint

The following table shows the required and optional binding information when the security token constraint is defined in the deployment descriptor.

Table 301. Binding information for security token constraints. The binding information is used for signing or encrypting messages.

Information type	Required or optional
Token generator	Required
Collection certificate store	Optional
Properties	Optional

You can use the collection certificate store that is defined at the server-level.

Use defaults:

Select this option if you want to use the default binding information from the server-level.

Component:

Specifies the enterprise bean in an assembled EJB module.

Port:

Specifies the port in the web service that is defined during application assembly.

Web service:

Specifies the name of the web service that is defined during application assembly.

Response generator (sender) binding configuration settings:

Use this page to specify the binding configuration for the response generator or response sender.

To view this administrative console page, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Click **Manage modules**.
3. Click the Uniform Resource Identifier (URI).
4. Under Web Services Security Properties, click **Web services: Server security bindings**.
5. Under Response generator (sender) binding, click **Edit custom**.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

The security constraints or bindings are defined using the application assembly process before the application is installed.

This product provides assembly tools to assemble your application.

If the security constraints are defined in the application, you must either define the corresponding binding information or select the **Use defaults** option on this panel and use the default binding information for the server-level. The default binding that is provided by this product is a sample. Do not use this sample in a

production environment without modifying the configuration. The security constraints define what is signed or encrypted in the Web Services Security message. The bindings define how to enforce the requirements.

Digital signature security constraint (integrity)

The following table shows the required and optional binding information when the digital signature security constraint (integrity) is defined in the deployment descriptor.

Table 302. Binding information for digital signature constraints. The binding information is used for digitally signing messages.

Information type	Required or optional
Signing information	Required
Key information	Required
Key locators	Optional
Collection certificate store	Optional
Token generator	Optional
Properties	Optional

You can use the key locators and the collection certificate store that are defined at the server-level.

Encryption constraint (confidentiality)

The following table shows the required and optional binding information when the encryption constraint (confidentiality) is defined in the deployment descriptor.

Table 303. Binding information for encryption constraints. The binding information is used for encrypting messages.

Information type	Required or optional
Encryption information	Required
Key information	Required
Key locators	Optional
Collection certificate store	Optional
Token generator	Optional
Properties	Optional

You can use the key locators and the collection certificate store that are defined at the server-level.

Security token constraint

The following table shows the required and optional binding information when the security token constraint is defined in the deployment descriptor.

Table 304. Binding information for security token constraints. The binding information is used for signing and encrypting messages.

Information type	Required or optional
Token generator	Required
Collection certificate store	Optional
Properties	Optional

You can use the collection certificate store that is defined at the server-level.

Use defaults:

Select this option if you want to use the default binding information from the server level.

Port:

Specifies the port number in the web service that is defined during application assembly.

Web service:

Specifies the name of the web service that is defined during application assembly.

Callback handler configuration settings for JAX-WS:

Use this page to specify how to acquire the security token that is inserted in the Web Services Security header for JAX-WS within the SOAP message. The token acquisition is a pluggable framework that leverages the Java Authentication and Authorization Service (JAAS) `javax.security.auth.callback.CallbackHandler` interface for acquiring the security token.

To view this administrative console page for the callback handler on the server level, complete the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** .
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under JAX-RPC Default generator bindings, click **Token generators >** ***token_generator_name***.
4. Under Additional properties, click **Callback handler**.

To view this administrative console page for the callback handler on the application level , complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Under Modules, click **Manage Modules*****URI_name***.
3. Under Web Services Security properties, you can access the callback handler information for the following bindings:
   - For the Request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**. Under Additional properties, click **Token generator**. Click **New** to create a new token generator configuration or click the name of an existing configuration to modify its settings. Under Additional properties, click **Callback handler**.
   - For the Response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**. Under Additional properties, click **Token generator**. Click **New** to create a new token generator configuration or click the name of an existing configuration to modify its settings. Under Additional properties, click **Callback handler**.

Callback handler class name:

Specifies the name of the callback handler implementation class that is used to plug in a security token framework.

The specified callback handler class must implement the `javax.security.auth.callback.CallbackHandler` class. The implementation of the JAAS `javax.security.auth.callback.CallbackHandler` interface must provide a constructor using the following syntax:

```
MyCallbackHandler(String username, char[] password,
    java.util.Map properties)
```

Where:

username
Specifies the user name that is passed into the configuration.

password
Specifies the password that is passed into the configuration.

properties
Specifies the other configuration properties that are passed into the configuration.

The application server provides the following default callback handler implementations:

com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler
This callback handler uses a login prompt to gather user name and password information. However, if you specify the user name and password on this panel, a prompt is not displayed and the application server returns the user name and password to the token generator if it is specified on this panel. Use this implementation for a Java Platform, Enterprise Edition (Java EE) application client only.

com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler
This callback handler does not issue a prompt and returns the user name and password if it is specified on this panel. You can use this callback handler when the web service is acting as a client.

com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler
This callback handler uses a standard-in prompt to gather the user name and password. However, if the user name and password is specified on this panel, the application server does not issue a prompt, but returns the user name and password to the token generator. Use this implementation for a Java Platform, Enterprise Edition (Java EE) application client only.

com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler
This callback handler uses a standard-in prompt to gather the user name and password. However, if the user name and password is specified on this panel, the application server does not issue a prompt, but returns the user name and password to the token generator. Use this implementation for a Java Platform, Enterprise Edition (Java EE) application client only.

com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler
This callback handler is used to obtain the Lightweight Third Party Authentication (LTPA) security token from the RunAs invocation Subject. This token is inserted in the Web Services Security header within the SOAP message as a binary security token. However, if the user name and password are specified on this panel, the application server authenticates the user name and password to obtain the LTPA security token rather than obtaining it from the RunAs Subject. Use this callback handler only when the web service is acting as a client on the application server. It is recommended that you do not use this callback handler on a Java EE application client.

com.ibm.wsspi.wssecurity.auth.callback.X509CallbackHandler
This callback handler is used to create the X.509 certificate that is inserted in the Web Services Security header within the SOAP message as a binary security token. A keystore and a key definition is required for this callback handler.

com.ibm.wsspi.wssecurity.auth.callback.PKCS7CallbackHandler
This callback handler is used to create X.509 certificates encoded with the PKCS#7 format. The certificate is inserted in the Web Services Security header in the SOAP message as a binary security token. A keystore is required for this callback handler. You must specify a certificate revocation list (CRL) in the collection certificate store. The CRL is encoded with the X.509 certificate in the PKCS#7 format.

com.ibm.wsspi.wssecurity.auth.callback.PkiPathCallbackHandler
This callback handler is used to create X.509 certificates encoded with the PkiPath format. The certificate is inserted in the Web Services Security header within the SOAP message as a binary security token. A keystore is required for this callback handler. A CRL is not supported by the callback handler; therefore, the collection certificate store is not required or used.

The callback handler implementation obtains the required security token and passes it to the token generator. The token generator inserts the security token in the Web Services Security header within the SOAP message. Also, the token generator is the plug-in point for the pluggable security token framework. Service providers can provide their own implementation, but the implementation must use the `com.ibm.websphere.wssecurity.wssapi.token.SecurityToken` interface. The Java Authentication and Authorization Service (JAAS) Login Module implementation is used to create the security token on the generator side and to validate (authenticate) the security token on the consumer side, respectively.

Use identity assertion:

Select this option if you have identity assertion defined in the IBM extended deployment descriptor.

This option indicates that only the identity of the initial sender is required and inserted into the Web Services Security header within the SOAP message. For example, the application server sends only the user name of the original caller for a Username TokenGenerator. For an X.509 token generator, the application server sends the original signer certification only.

Use RunAs identity:

Select this option if you have identity assertion defined in the IBM extended deployment descriptor and you want to use the Run As identity instead of the initial caller identity for identity assertion for a downstream call.

This option is valid only if you have Username TokenGenerator configured as a token generator.

Basic authentication user ID:

Specifies the user name that is passed to the constructors of the callback handler implementation.

The basic authentication user name and password are used if you select one of the following default callback handler implementations provided by this product:

- `com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler`
- `com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler`
- `com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler`
- `com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler`

These implementations are described in detail under the **Callback handler class name** field description in this article.

Basic authentication password:

Specifies the password that is passed to the constructor of the callback handler.

The keystore and its related configuration are used if you select one of the following default callback handler implementations provided by this product:

com.ibm.wsspi.wssecurity.auth.callback.PKCS7CallbackHandler
The keystore is used to build the X.509 certificate with the certificate path.

com.ibm.wsspi.wssecurity.auth.callback.PkiPathCallbackHandler
The keystore is used to build the X.509 certificate with the certificate path.

com.ibm.wsspi.wssecurity.auth.callback.X509CallbackHandler
The keystore is used to retrieve the X.509 certificate.

Keystore: Select **None** if no keystore is needed for this configuration.

Select **Predefined keystore** to choose predefined keystores with keystore configuration name.

Select **User-defined keystore** to use user-defined keystores.

The following information needs to be specified:

Key store configuration name:

Specifies the name of the key store configuration defined in the keystore settings in secure communications.

Key store password:

Specifies the password that is used to access the keystore file.

Key store path:

Specifies the location of the keystore file.

Use ${*USER_INSTALL_ROOT*} in the path name because this variable expands to the product path on your machine. To change the path used by this variable, click **Environment** > **WebSphere variables** and click **USER_INSTALL_ROOT**.

Key store type:

Specifies the type of keystore file format

Choose one of the following values for this field:

JKS Use this option if the keystore uses the Java Keystore (JKS) format.

JCEKS
Use this option if the Java Cryptography Extension is configured in the software development kit (SDK). The default IBM JCE is configured in the application server. This option provides stronger protection for stored private keys by using Triple DES encryption.

PKCS11KS (PKCS11)
Use this option if your keystore file uses the PKCS#11 file format. Keystore files that use this format might contain Rivest Shamir Adleman (RSA) keys on cryptographic hardware or might encrypt keys that use cryptographic hardware to ensure protection.

PKCS12KS (PKCS12)
Use this option if your keystore file uses the PKCS#12 file format.

Key collection:

Use this page to view a list of logical names that is mapped to a key alias in the keystore file.

To view this administrative console page for the key locator collection on the server level, complete the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** .
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under JAX-RPC Default generator bindings, click **Token Generators** > ***token_generator_name*** .
4. Under Additional properties, click **Callback handler** > **Keys**.

Keys are also available from the JAX-WS and JAX-RPC security runtime panel by clicking **Key locators** > ***key_locator_name***. Under Additional properties, click **Keys**.

To use this administrative console page for the key locator collection on the application level, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Click **Manage modules** > ***URI_name***.
3. Under Web Services Security Properties, you can access key locators for the following bindings:
   - For the Request generator, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom** > **Key locators**. Under Additional properties, click **Keys**.
   - For the Request consumer, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom** > **Key locators**. Under Additional properties, click **Keys**.
   - For the Response generator, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom** > **Key locators**. Under Additional properties, click **Keys**.
   - For the Response consumer, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom** > **Key locators**. Under Additional properties, click **Keys**.
4. Under Additional properties, you can access key locators for the following bindings:
   - For the Request sender, click **Web services: Client security bindings**. Under Request sender binding, click **Edit** > **Key locators**. Under Additional properties, click **Keys**.
   - For the Request receiver, click **Web services: Server security bindings**. Under Request receiver binding, click **Edit** > **Key locators**. Under Additional properties, click **Keys**.
   - For the Response sender, click **Web services: Server security bindings**. Under Response sender binding, click **Edit** > **Key locators**. Under Additional properties, click `Keys`.
   - For the Response receiver, click **Web services: Client security bindings**. Under Response receiver binding, click **Edit** > **Key locators**. Under Additional properties, click **Keys**.

Key name:

Specifies the name of the key object that is found in the keystore file.

Key alias:

Specifies an alias for the key object.

The alias is used when the key locator searches for the key objects in the keystore file.

Key configuration settings:

Use this page to define the mapping of a logical name to a key alias in a keystore file.

To view this administrative console page for the key locator collection on the server level, complete the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.

3. Under JAX-RPC Default generator bindings, click **Token Generators** > ***token_generator_name***.
4. Under Additional properties, click **Callback handler** > **Keys**.
5. Specify a new key configuration by clicking **New** or by clicking the key configuration name to modify the settings.

Keys are also available from the JAX-WS and JAX-RPC security runtime panel by clicking **Key locators** > ***key_locator_name***. Under Additional properties, click **Keys** > **New**. Specify a new key configuration by clicking New or by clicking the key configuration name to modify the settings.

To use this administrative console page for the key locator collection on the application level, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Under Modules, click **Manage modules** > ***URI_name***.
3. Under Additional properties, you can access key locators for the following bindings:
   - For the Request generator, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom** > **Key locators**. Under Additional properties, click **Keys**.
   - For the Request consumer, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom** > **Key locators**. Under Additional properties, click **Keys**.
   - For the Response generator, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom** > **Key locators**. Under Additional properties, click **Keys**.
   - For the Response consumer, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom** > **Key locators**. Under Additional properties, click **Keys**.
4. Under Web Services Security Properties, you can access key locators for the following bindings:
   - For the Request sender, click **Web services: Client security bindings**. Under Request sender binding, click **Edit** > **Key locators**. Under Additional properties, click **Keys**.
   - For the Request receiver, click **Web services: Server security bindings**. Under Request receiver binding, click **Edit** > **Key locators**. Under Additional properties, click **Keys**.
   - For the Response sender, click **Web services: Server security bindings**. Under Response sender binding, click **Edit** > **Key locators**. Under Additional properties, click **Keys**.
   - For the Response receiver, click **Web services: Client security bindings**. Under Response receiver binding, click **Edit** > **Key locators**. Under Additional properties, click **Keys**.
5. Specify a new key configuration by clicking **New** or by clicking the key configuration name to modify the settings.

Key name:

Specifies the name of the key object. For digital signatures, the key name is used by the request sender or request generator signing information to determine which key is used to digitally sign the message. For encryption, the key name is used to determine the key used for encryption.

The key name must be a fully qualified, distinguished name. For example, `CN:Bob,O=IBM,C=US`.

Note: If you enter the distinguished name with spaces before or after commas and equal symbols, the application server normalizes the distinguished names automatically during run time by removing these extra spaces.

Key alias:

Specifies the alias for the key object, which is used by the key locator to find the key within the keystore file.

Key password:

Specifies the password that is needed to access the key object within the keystore file.

Web services: Client security bindings collection:

Use this page to view a list of application-level, client-side binding configurations for Web Services Security. These bindings are used when a web service is a client to another web service.

This administrative console page applies only to Java API for XML-based RPC (JAX-RPC) applications.

To view this administrative console page, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Under Modules, click **Manage modules** > ***URI_name***.
3. Under Web Services Security Properties, click **Web services: Client security bindings**.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Component:

Specifies the enterprise bean in an assembled Enterprise JavaBeans (EJB) module.

Port:

Specifies the port that is used to send messages to a server and receive messages from a server.

Web service:

Specifies the name of the web service that is defined during application assembly.

Request generator (sender) binding:

Specifies the binding configuration that is used to send request messages to the request consumer.

Click **Edit custom** to configure the required and additional properties such as signing information, key information, token generators, key locators, and collection certificate stores.

The binding information for the request generator that is specified for the client must match the binding information for the request consumer that is specified for the server.

Response consumer (receiver) binding:

Specifies the binding configuration that is used to receive response messages from the response generator.

Click **Edit custom** to configure the required and additional properties such as signing information, key information, token consumers, key locators, collection certificate stores, and trust anchors.

The binding information for the response consumer that is specified for the client must match the binding information for the response generator that is specified for the server.

Request sender binding:

Specifies the binding configuration that is used to send request messages to the request receiver.

Click **Edit** to configure the additional properties for the request sender such as signing information, key information, encryption information, key locators, and the login binding.

The binding information for the request sender that is specified for the client must match the binding information for the request receiver that is specified for the server.

Response receiver binding:

Specifies the binding configuration that is used to receive response messages from the response sender.

Click **Edit** to configure the additional properties for the response receiver such as signing information, encryption information, trust anchors, collection certificate stores, and key locators.

The binding information for the response receiver that is specified for the client must match the binding information for the response sender that is specified for the server.

HTTP basic authentication:

Specifies the user name and password to use for this port with HTTP transport-level basic authentication. You can enable transport-level authentication security independently of message-level security.

Although the name of this field is HTTP basic authentication, you can use this field to specify the user name and password in conjunction with any transport method. This field is not specific to HTTP transport. For example, you can use this same field with Java Message Service (JMS).

Click **Edit** to configure the basic authentication ID and password for transport-level authentication.

HTTP SSL configuration:

Enables and configures transport-level Secure Sockets Layer (SSL) security for this port. You can enable transport-level SSL security independently of message-level security.

Click **Edit** to specify the settings for transport-level HTTP SSL configuration for this port.

Web services: Server security bindings collection:

Use this page to view a list of server-side binding configurations for Web Services Security.

This administrative console page applies only to Java API for XML-based RPC (JAX-RPC) applications.

To view this administrative console page, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Under Modules, click **Manage modules** > ***URI_name***.
3. Under Web Services Security Properties, click **Web services: Server security bindings**.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

Port:

Specifies the port in which messages are received from the request generator.

Web service:

Specifies the name of the web service that is defined during application assembly.

Request consumer (receiver) binding:

Specifies the binding configuration that is used to receive request messages from the request generator (sender) binding.

Click **Edit custom** to configure the required and additional information such as signing information, key information, token consumers, key locators, intermediate certificates in the collection certificate store, and trust anchors.

The binding information for the request consumer that is specified for the server must match the binding information for the request generator that is specified for the client.

Response generator (sender) binding:

Specifies the binding configuration that is used to send response messages to the response consumer.

Click **Edit custom** to configure the required and additional information such as signing information, key information, token generators, key locators, and intermediate certificates in the collection certificate store.

The binding information for the response generator that is specified for the server must match the binding information for the response consumer that is specified for the client.

Request receiver binding:

Specifies the binding configuration that is used to receive request messages from the request sender binding.

Click **Edit** to configure additional properties for the request receiver such as signing information, encryption information, trust anchors, collection certificate stores, key locators, trusted ID evaluators, and login mappings.

The binding information for the request receiver that is specified for the server must match the binding information for the request sender that is specified for the client.

Response sender binding:

Specifies the binding configuration that is used to send response messages to the response receiver.

Click **Edit** to configure additional properties for the response sender such as signing information, encryption information, and key locators.

The binding information for the response sender that is specified for the server must match the binding information for the response receiver that is specified for the client.

Configuring token consumers using JAX-RPC to protect message authenticity at the application level:

You can specify the token consumer on the application level. The token consumer information is used on the consumer side to incorporate the security token.

About this task

Complete the following steps to configure the token consumer on the application level.

Procedure

1. Locate the token consumer panel in the administrative console.
   a. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
   b. Under Modules, click **Manage modules** > ***URI_name***.
   c. Under Web Services Security Properties you can access the token consumer for the following bindings:
      - For the request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
      - For the response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
   d. Under Required properties, click **Token consumer**.
   e. Click **New** to create a token consumer configuration, click **Delete** to delete an existing configuration, or click the name of an existing token consumer configuration to edit its settings. If you are creating a new configuration, enter a unique name in the **Token consumer name** field. For example, you might specify `con_signtcon`.
2. Specify a class name in the **Token consumer class name** field. The Java Authentication and Authorization Service (JAAS) Login Module implementation is used to validate (authenticate) the security token on the consumer side.

   The token consumer class name for the request consumer and the response consumer must be similar to the token generator class name for the request generator and the response generator. For example, if your application requires a user name token consumer, you can specify the com.ibm.wsspi.wssecurity.token.UsernameTokenGenerator class name on the Token generator panel for application level and the com.ibm.wsspi.wssecurity.token.UsernameTokenConsumer class name in this field.
3. Optional: Select a part reference in the **Part reference** field. The part reference indicates the name of the security token that is defined in the deployment descriptor. For example, if you receive a username token in your request message, you might want to reference the token in the username token consumer.

   Important: On the application level, if you do not specify a security token in your deployment descriptor, the **Part reference** field is not displayed. If you define a security token called `user_tcon` in your deployment descriptor, `user_tcon` is displayed as an option in the **Part reference** field.
4. Optional: In the certificate path section of the panel, select a certificate store type and indicate the trust anchor and certificate store name, if necessary. These options and fields are necessary when you specify com.ibm.wsspi.wssecurity.token.X509TokenConsumer as the token consumer class name. The names of the trust anchor and the collection certificate store are created in the certificate path under your token consumer.

   Restriction: The `com.ibm.wsspi.wssecurity.token.TokenConsumingComponent` interface is not used with JAX-WS web services. If you are using JAX-RPC web services, this interface is still valid.

   You can select one of the following options:

   None If you select this option, the certificate path is not specified.

   Trust any
   If you select this option, any certificate is trusted. When the received token is consumed, the Application Server does not validate the certificate path.

Dedicated signing information

If you select this option, you can select a trust anchor and a certificate store configuration. When you select the trust anchor or the certificate store of a trusted certificate, you must configure the trust anchor and the certificate store before setting the certificate path.

Trust anchor

A trust anchor specifies a list of key store configurations that contain trusted root certificates. These configurations are used to validate the certificate path of incoming X.509-formatted security tokens. Keystore objects within trust anchors contain trusted root certificates that are used by the CertPath API to validate the trustworthiness of a certificate chain. You must create the keystore file using the keytool utility. The keytool utility is available using the QShell Interpreter.

You can configure trust anchors for the application level by completing the following steps:

a. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.

b. Under Related Items, click **EJB Modules** or **Web Modules** > ***URI_name***.

c. Access the token consumer from the following bindings:

- For the request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
- For the response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.

d. Under Additional properties, click **Trust anchors**.

Collection certificate store

A collection certificate store includes a list of untrusted, intermediary certificates and certificate revocation lists (CRLs). The collection certificate store is used to validate the certificate path of the incoming X.509-formatted security tokens. You can configure the collection certificate store for the application level by completing the following steps:

a. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.

b. Under Related Items, click **EJB Modules** or **Web Modules** > ***URI_name***.

c. Access the token consumer from the following bindings:

- For the request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
- For the response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.

d. Under Additional properties, click **Collection certificate store**.

5. Optional: Specify a trusted ID evaluator. The trusted ID evaluator is used to determine whether to trust the received ID. You can select one of the following options:

None If you select this option, the trusted ID evaluator is not specified.

Existing evaluator definition

If you select this option, you can select one of the configured trusted ID evaluators. For example, you can select the **SampleTrustedIDEvaluator**, which is provided by WebSphere Application Server as an example.

Binding evaluator definition

If you select this option, you can configure a new trusted ID evaluator by specifying a trusted ID evaluator name and class name.

Trusted ID evaluator name

Specifies the name that is used by the application binding to refer to a trusted identity (ID) evaluator that is defined in the default bindings.

Trusted ID evaluator class name

Species the class name of the trusted ID evaluator. The specified trusted ID evaluator class name must implement the com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator interface. The default TrustedIDEvaluator class is com.ibm.wsspi.wssecurity.id.TrustedIDEvaluatorImpl. When you use this default TrustedIDEvaluator class, you must specify the name and value properties for the default trusted ID evaluator to create the trusted ID list for evaluation. To specify the name and value properties, complete the following steps:

a. Under Additional properties, click **Properties** > **New**.

b. Specify the trusted ID evaluator name in the **Property** field. You must specify the name in the form, `trustedId_n` where `_n` is an integer from 0 to n.

c. Specify the trusted ID in the **Value** field.

For example:

```
property name="trustedId_0", value="CN=Bob,O=ACME,C=US"
property name="trustedId_1, value="user1"
```

If the distinguished name (DN) is used, the space is removed for comparison. See the programming model information in the documentation for an explanation of how to implement the com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator interface. For more information, see Default implementations of the Web Services Security service provider programming interfaces.

Note: Define the trusted ID evaluator on the server level instead of the application level. To define the trusted ID evaluator on the server level, complete the following steps:

a. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.

b. Under Security, click **JAX-WS and JAX-RPC security runtime**.

Note: In a mixed node cell with a server using WebSphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.

c. Under Additional properties, click **Trusted ID evaluators**.

d. Click **New** to define a new trusted ID evaluator.

The trusted ID evaluator configuration is available only for the token consumer on the server-side application level.

6. Optional: Select the **Verify nonce** option. This option indicates whether to verify a nonce in the user name token if it is specified for the token consumer. Nonce is a unique, cryptographic number that is embedded in a message to help stop repeat, unauthorized attacks of user name tokens. The **Verify nonce** option is valid only when the incorporated token type is a user name token.
7. Optional: Select the **Verify timestamp** option. This option indicates whether to verify a time stamp in the user name token. The **Verify nonce** option is valid only when the incorporated token type is a user name token.
8. Specify the value type local name in the **Local name** field. This field specifies the local name of the value type for the consumed token. For a user name token and an X.509 certificate security token, WebSphere Application Server provides predefined local names for the value type.

Table 305. Uniform Resource Identifier (URI) and Local name combinations. The local name value indicates the type of consumed token.

URI	Local name	Description
A namespace URI is not applicable.	Specify `http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3` as the local name value.	Specifies the name of an X.509 certificate token
A namespace URI is not applicable.	Specify `http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1` as the local name value.	Specifies the name of the X.509 certificates in a PKI path
A namespace URI is not applicable.	Specify `http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7` as the local name value.	Specifies a list of X509 certificates and certificate revocation lists (CRL) in a PKCS#7
Specify `http://www.ibm.com/websphere/appserver/tokentype/5.0.2` as the URI value.	Specify `LTPA` as the local name value.	Specifies a binary security token that contains an embedded Lightweight Third Party Authentication (LTPA) token.

9. Optional: Specify the value type URI in the **URI** field. This entry specifies the namespace URI of the value type for the consumed token.

   Remember: If you specify the token consumer for a username token or an X.509 certificate security token, you do not need to specify a value type URI.

   If you want to specify another token, you must specify both the local name and the URI. For example, if you have an implementation of your own custom token, you can specify `CustomToken` in the **Local name** field and `http://www.ibm.com/custom`
10. Click **OK** and **Save** to save the configuration.
11. Click the name of your token consumer configuration.
12. Under Additional properties, click **JAAS configuration**. The Java Authentication and Authorization Service (JAAS) configuration specifies the name of the JAAS configuration that is defined in the JAAS login panel. The JAAS configuration specifies how the token logs in on the consumer side.
13. Select a JAAS configuration from the **JAAS configuration name** field. The field specifies the name of the JAAS system of application login configuration. You can specify additional JAAS system and application configurations by clicking **Global security**. Under Authentication, click **Java Authentication and Authorization Service** and click either **Application logins** > **New** or **System logins** > **New**. Do not remove the predefined system or application login configurations. However, within these configurations, you can add module class names and specify the order in which WebSphere Application Server loads each module. WebSphere Application Server provides the following predefined JAAS configurations:

   ClientContainer
   This selection specifies the login configuration that is used by the client container applications. The configuration uses the CallbackHandler application programming interface (API) that is defined in the deployment descriptor for the client container. To modify this configuration, see the JAAS configuration panel for application logins.

   WSLogin
   This selection specifies whether all of the applications can use the WSLogin configuration to perform authentication for the security run time. To modify this configuration, see the JAAS configuration panel for application logins.

   DefaultPrincipalMapping
   This selection specifies the login configuration that is used by Java 2 Connectors (J2C) to map users to principals that are defined in the J2C authentication data entries. To modify this configuration, see the JAAS configuration panel for application logins.

system.LTPA_WEB
This selection processes login requests that are used by the web container such as servlets and JavaServer Pages (JSPs) files. To modify this configuration, see the JAAS configuration panel for system logins.

system.RMI_OUTBOUND
This selection processes RMI requests that are sent outbound to another server when the com.ibm.CSIOutboundPropagationEnabled property is `true`. This property is set in the CSIv2 authentication panel.

To access the panel, click **Security** > **Global security**. Under Authentication, click **RMI/IIOP security** > **CSIv2 Outbound authentication**. To set the `com.ibm.CSIOutboundPropagationEnabled` property, select **Security attribute propagation**. To modify this JAAS login configuration, see the JAAS - System logins panel.

system.wssecurity.X509BST
This selection verifies an X.509 binary security token (BST) by checking the validity of the certificate and the certificate path. To modify this configuration, see the JAAS configuration panel for system logins.

system.wssecurity.PKCS7
This selection verifies an X.509 certificate within a PKCS7 object that might include a certificate chain, a certificate revocation list, or both. To modify this configuration, see the JAAS configuration panel for system logins.

system.wssecurity.PkiPath
This section verifies an X.509 certificate with a public key infrastructure (PKI) path. To modify this configuration, see the JAAS configuration panel for system logins.

system.wssecurity.UsernameToken
This selection verifies the basic authentication (user name and password) data. To modify this configuration, see the JAAS configuration panel for system logins.

system.wssecurity.IDAssertionUsernameToken
This selection supports the use of identity assertion in Versions 6 and later applications to map a user name to a WebSphere Application Server credential principal. To modify this configuration, see the JAAS configuration panel for system logins.

system.WSS_INBOUND
This selection specifies the login configuration for inbound or consumer requests for security token propagation using Web Services Security. To modify this configuration, see the JAAS configuration panel for system logins.

system.WSS_OUTBOUND
This selection specifies the login configuration for outbound or generator requests for security token propagation using Web Services Security. To modify this configuration, see the JAAS configuration panel for system logins.

None With this selection, you do not specify a JAAS login configuration.

14. Click **OK** and then click **Save** to save the configuration.

Results

You have configured the token consumer for the application level.

What to do next

You must specify a similar token generator configuration for the application level.

Request consumer (receiver) binding configuration settings:

Use this page to specify the binding configuration for the request consumer.

To view this administrative console page, complete the following steps:

1. Click **Applications > Application Types > WebSphere enterprise applications***application_name*.
2. Click **Manage modules**.
3. Click the Uniform Resource Identifier (URI).
4. Under Web Services Security Properties, click **Web services: Server security bindings**.
5. Under Request consumer (receiver) binding, click **Edit custom**.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

The security constraints or bindings are defined using the application assembly process before the application is installed.

This product provides assembly tools to assemble your application.

If the security constraints are defined in the application, you must either define the corresponding binding information or select the **Use defaults** option on this panel and use the default binding information for the server level. The default binding that is provided by this product is a sample. Do not use this sample in a production environment without modifying the configuration. The security constraints define what is signed or encrypted in the Web Services Security message. The bindings define how to enforce the requirements.

Digital signature security constraint (integrity)

The following table shows the required and optional binding information when the digital signature security constraint (integrity) is defined in the deployment descriptor.

Table 306. Binding information for digital signature security constraints. The binding information is used for signing or encrypting messages.

Information type	Required or optional
Signing information	Required
Key information	Required
Token consumer	Required
Key locators	Optional
Collection certificate store	Optional
Trust anchors	Optional
Properties	Optional

You can use the key locators, collection certificate stores, and trust anchors that are defined at the server level.

Encryption constraint (confidentiality)

The following table shows the required and optional binding information when the encryption constraint (confidentiality) is defined in the deployment descriptor.

Table 307. Binding information for encryption constraints. The binding information is used for signing or encrypting messages.

Information type	Required or optional
Encryption information	Required
Key information	Required
Token consumer	Required
Key locators	Optional

Table 307. Binding information for encryption constraints (continued). The binding information is used for signing or encrypting messages.

Information type	Required or optional
Collection certificate store	Optional
Trust anchors	Optional
Properties	Optional

You can use the key locators, collection certificate store, and trust anchors that are defined at the server level.

Security token constraint

The following table shows the required and optional binding information when the security token constraint is defined in the deployment descriptor.

Table 308. Binding information for security token constraints. The binding information is used for signing or encrypting messages.

Information type	Required or optional
Token consumer	Required
Collection certificate store	Optional
Trust anchors	Optional
Properties	Optional

You can use the collection certificate store and trust anchors that are defined at the server level.

Use defaults:

Select this option if you want to use the default binding information from the server level.

If you select this option, the application server checks for binding information on the server level.

Port:

Specifies the port in the web service that is defined during application assembly.

Web service:

Specifies the name of the web service that is defined during application assembly.

Response consumer (receiver) binding configuration settings:

Use this page to specify the binding configuration for the response consumer.

To view this administrative console page, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Under Modules, click **Manage modules**.
3. Click the Uniform Resource Identifier (URI).
4. Under Web Services Security Properties, click **Web services: Client security bindings**.
5. Under Response consumer (receiver) binding, click **Edit custom**.

Depending on your assigned security role when security is enabled, you might not have access to text entry fields or buttons to create or edit configuration data. Review the administrative roles documentation to learn more about the valid roles for the application server.

The security constraints or bindings are defined using the application assembly process before the application is installed.

This product provides assembly tools to assemble your application.

The default binding that is provided by this product is a sample. Do not use this sample in a production environment without modifying the configuration. The security constraints define what is signed or encrypted in the Web Services Security message. The bindings define how to enforce the requirements.

Digital signature security constraint (integrity)

The following table shows the required and optional binding information when the digital signature security constraint (integrity) is defined in the deployment descriptor.

Table 309. Binding information for digital signature security constraints. The binding information is used for validating digital signature.

Information type	Required or optional
Signing information	Required
Key information	Required
Token consumer	Optional
Key locators	Optional
Collection certificate store	Optional
Trust anchors	Optional
Properties	Optional

You can use the key locators, collection certificate stores, and trust anchors that are defined at the server level.

Encryption constraint (confidentiality)

The following table shows the required and optional binding information when the encryption constraint (confidentiality) is defined in the deployment descriptor.

Table 310. Binding information for encryption constraints. The binding information is used for decrypting messages.

Information type	Required or optional
Encryption information	Required
Key information	Required
Token consumer	Optional
Key locators	Optional
Collection certificate store	Optional
Trust anchors	Optional
Properties	Optional

You can use the key locators, collection certificate store, and trust anchors that are defined at the application or server level.

Security token constraint

The following table shows the required and optional binding information when the security token constraint is defined in the deployment descriptor.

Table 311. Binding information for security token constraints. The binding information is used for digital signature verification and for decrypting messages.

Information type	Required or optional
Token consumer	Required
Collection certificate store	Optional
Trust anchors	Optional

Table 311. Binding information for security token constraints (continued). The binding information is used for digital signature verification and for decrypting messages.

Information type	Required or optional
Properties	Optional

You can use the collection certificate store and trust anchors that are defined at the application or server level.

Use defaults:

Select this option if you want to use the default binding information from the server level.

Component:

Specifies the enterprise bean in an assembled Enterprise JavaBeans (EJB) module.

Port:

Specifies the port in the web service that is defined during application assembly.

Web service:

Specifies the name of the web service that is defined during application assembly.

JAAS configuration settings:

Use this page to specify the name of the Java Authentication and Authorization Service (JAAS) configuration that is defined in the JAAS login panel.

Complete the following steps to access this page on the server level:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under JAX-RPC Default Consumer Bindings, click **Token consumers** > ***token_consumer_name*** or click **New** to create a new token consumer.
4. Under Additional properties, click **JAAS configuration**.

Complete the following steps to access this page on the application level:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Under Modules, click **Manage modules** > ***URI_name***.
3. Under Web Services Security Properties, you can access the JAAS configuration settings for the following bindings:
   - For the Response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**. Under Required properties, click **Token consumers** > ***token_consumer_name*** or click **New** to create a new token consumer. Under Additional properties, click **JAAS configuration**.
   - For the Request consumer (receiver) binding, click **Web services: Server security binding**. Under Request consumer (receiver) binding, click **Edit custom**. Under Required properties, click **Token consumers** > ***token_consumer_name*** or click **New** to create a new token consumer. Under Additional properties, click **JAAS configuration**.

Important: If you create a new token consumer, you must click **Apply** before you can proceed to the JAAS configuration.

JAAS configuration name:

Specifies the name of the JAAS system or application login configuration.

Do not remove the predefined system or application login configurations. However, within these configurations, you can add module class names and specify the order in which the application server loads each module.

Preconfigured system login configurations

The following predefined system login configurations are defined on the system logins panel, which is accessible by completing the following steps:

1. Click **Security** > **Global security**.
2. Expand Java Authentication and Authorization Service, click **System logins**.

system.wssecurity.IDAssertionUsernameToken
Enables a Version 6.x application to use identity assertion to map a user name to an application server credential principal.

system.wssecurity.IDAssertion
Enables an application to use identity assertion to map a user name to an application server credential principal.

system.wssecurity.Signature
Enables an application to map a distinguished name (DN) in a signed certificate to an application server credential principal.

system.LTPA_WEB
Processes login requests used by the web container such as servlets and JavaServer Pages (JSP) files.

system.RMI_OUTBOUND
Processes RMI requests that are sent outbound to another server when either the com.ibm.CSI.rmiOutboundLoginEnabled or the com.ibm.CSIOutboundPropagationEnabled properties are `true`. These properties are set in the Common Secure Interoperability Version 2 (CSIv2) authentication panel.

To access the panel, click **Security** > **Global security**. Epand RMI/IIOP security, click **CSIv2 Outbound authentication**. To set the `com.ibm.CSI.rmiOutboundLoginEnabled` property, select the **Custom outbound mapping** option. To set the `com.ibm.CSIOutboundPropagationEnabled` property, select the **Security attribute propagation** option.

system.wssecurity.509BST
Verifies an .509 binary security token (BST) by checking the validity of the certificate and the certificate path.

system.wssecurity.PKCS7
Verifies an .509 certificate with a certificate revocation list in a Public Key Cryptography Standards #7 (PKCS7) object.

system.wssecurity.PkiPath
Verifies an .509 certificate with a public key infrastructure (PKI) path.

system.wssecurity.UsernameToken
Verifies basic authentication (user name and password).

Application login configurations

The following predefined application login configurations are defined on the Application logins panel, which is accessible by completing the following steps:

1. Click **Security** > **Global security**.
2. Expand Java Authentication and Authorization Service, click **Application logins**.

ClientContainer
Specifies the login configuration that is used by the client container application. This application uses the CallbackHandler API that is defined in the deployment descriptor of the client container.

WSLogin
Specifies whether all applications can use the WSLogin configuration to perform authentication for the application server security run time.

DefaultPrincipalMapping
Specifies the login configuration that is used by Java 2 Connectors (J2C) to map users to principals that are defined in the J2C authentication data entries.

Configuring encryption using JAX-RPC to protect message confidentiality at the application level:

You can configure encryption information, used to specify how the generators (senders) encrypt outgoing messages, for the request generator (client side) and the response generator (server side) bindings at the application level.

Before you begin

Configure the key information that is referenced by the key information references in the encryption information panel.

About this task

This task provides the steps that are needed for configuring encryption information for the request generator (client side) and the response generator (server side) bindings at the application level. This encryption information is used to specify how the generators (senders) encrypt outgoing messages.

Complete the following steps to configure the encryption information for the request generator or response generator section of the bindings file on the application level:

Procedure

1. Locate the encryption information configuration panel in the administrative console.
   a. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
   b. Under Manage modules, click ***URI_name***.
   c. Under Web Services Security Properties, you can access the key information for the request generator and response generator bindings.
      - For the request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
      - For the response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
   d. Under Required properties, click **Encryption information**.
   e. Click **New** to create an encryption information configuration. Click **Delete** to delete an existing configuration or click the name of an existing encryption information configuration to edit its settings. If you are creating a new configuration, enter a name in the **Encryption information name** field. For example, you might specify `gen_encinfo`.

2. Select a data encryption algorithm from the **Data encryption algorithm** field. The selection specifies the algorithm that is used to encrypt parts of the message. WebSphere Application Server supports the following pre-configured algorithms:
   - http://www.w3.org/2001/04/xmlenc#tripledes-cbc
   - http://www.w3.org/2001/04/xmlenc#aes128-cbc
   - http://www.w3.org/2001/04/xmlenc#aes256-cbc

     To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.
   - http://www.w3.org/2001/04/xmlenc#aes192-cbc

     To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

     Restriction: Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

     Important: Your country of origin might have restrictions on the import, possession, use, or re-export to another country, of encryption software. Before downloading or using the unrestricted policy files, you must check the laws of your country, its regulations, and its policies concerning the import, possession, use, and re-export of encryption software, to determine if it is permitted.

   The data encryption algorithm that you select for the generator side must match the data encryption method that you select for the consumer side.
3. Select a key encryption algorithm from the **Key encryption algorithm** field. This selection specifies the algorithm that is used to encrypt keys. WebSphere Application Server supports the following pre-configured algorithms:
   - http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p.

     When running with Software Development Kit (SDK) Version 1.4, the list of supported key transport algorithms does not include this one. This algorithm appears in the list of supported key transport algorithms when running with SDK Version 1.5.

     Restriction: This algorithm is not supported when the WebSphere Application Server is running in Federal Information Processing Standard (FIPS) mode.

     By default, the RSA-OAEP algorithm uses the SHA1 message digest algorithm to compute a message digest as part of the encryption operation. Optionally, you can use the SHA256 or SHA512 message digest algorithm by specifying a key encryption algorithm property. For the property name, you can specify `com.ibm.wsspi.wssecurity.enc.rsaoaep.DigestMethod`. The property value is one of the following URIs of the digest method:
     - `http://www.w3.org/2001/04/xmlenc#sha256`
     - `http://www.w3.org/2001/04/xmlenc#sha512`

     By default, the RSA-OAEP algorithm uses a null string for the optional encoding octet string for the OAEPParams. You can provide an explicit encoding octet string by specifying a key encryption algorithm property. For the property name, you can specify `com.ibm.wsspi.wssecurity.enc.rsaoaep.OAEPparams`. The property value is the base 64-encoded value of the octet string.

     Important: You can set these digest method and OAEPParams properties on the generator side only. On the consumer side, these properties are read from the incoming SOAP message.
   - http://www.w3.org/2001/04/xmlenc#rsa-1_5
   - http://www.w3.org/2001/04/xmlenc#kw-tripledes

- http://www.w3.org/2001/04/xmlenc#kw-aes128
- http://www.w3.org/2001/04/xmlenc#kw-aes256

  To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.
- http://www.w3.org/2001/04/xmlenc#kw-aes192

  To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

  Restriction: Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

The key encryption algorithm that you select for the generator side must match the key encryption method that you select for the consumer side.

4. Select an encryption key information reference from the Encryption key information menu. This selection is a reference to the encryption key that is used to encrypt parts of the message. To configure the key information, see "Configuring the key information using JAX-RPC for the generator binding on the application level" on page 3314.
5. Select a part reference from the **Part reference** field. This field specifies the name of the part reference for the generator binding element in the deployment descriptor.
6. Click **OK** and then click **Save** to save the configuration.

Results

The encryption information is configured for the generator binding at the application level.

What to do next

You must specify a similar encryption information configuration for the consumer.

Encryption information collection:

Use this page to specify the configuration for the encrypting and decrypting parameters. This configuration is used to encrypt and decrypt parts of the message, including the body and user name token.

To view the administrative console panel for the encryption information on the server level, complete the following steps:

1. Click **Servers > Server Types > WebSphere application servers >** *server_name*.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under either JAX-RPC Default Generator Bindings or JAX-RPC Default Consumer Bindings, click **Encryption information**.

To view this administrative console page for the collection certificate store on the application level, complete the following steps:

1. Click **Applications > Application Types > WebSphere enterprise applications***application_name*.
2. Under Modules, click **Manage modules >** ***URI_name***.
3. Under Web Services Security Properties, you can access encryption information for the following bindings:

- For the Request generator, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**. Under Required properties, click **Encryption information**.
- For the Request consumer, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**. Under Required properties, click **Encryption information**.
- For the Response generator, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**. Under Required properties, click **Encryption information**.
- For the Response consumer, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**. Under Required properties, click **Encryption information**.

4. Under Additional properties, you can access encryption information for the following bindings:
   - For the Request receiver, click **Web services: Server security bindings**. Under Request receiver binding, click **Edit**. Under Additional properties, click **Encryption information**.
   - For the Response receiver, click **Web services: Client security bindings**. Under Response receiver binding, click **Edit**. Under Additional properties, click **Encryption information**.

Encryption information name:

Specifies the name of the encryption information.

Key locator reference:

Specifies the name of the key locator configuration that retrieves the key for XML digital signature and XML encryption.

Key encryption algorithm: Specifies the algorithm that is used to encrypt and decrypt keys.

Data encryption algorithm: Specifies the algorithm that is used to encrypt and decrypt data.

Encryption information configuration settings: Message parts:

Use this page to configure the encryption and decryption parameters. You can use these parameters to encrypt and decrypt various parts of the message, including the body and the token.

To view the administrative console panel for the encryption information on the server level, complete the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under either JAX-RPC Default Generator Bindings or JAX-RPC Default Consumer Bindings, click **Encryption information**.
4. Click **New** to create a new encryption configuration or click the name of an existing encryption configuration.

To view this administrative console page for the encryption information on the application level, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Under Modules, click **Module update** > ***module_name***.

3. Under Web Services Security Properties, you can access encryption information for the following bindings:
   - For the Request generator, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**. Under Required properties, click **Encryption information**.
   - For the Request consumer, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**. Under Required properties, click **Encryption information**.
   - For the Response generator, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**. Under Required properties, click **Encryption information**.
   - For the Response consumer, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**. Under Required properties, click **Encryption information**.
4. Click either **New** to create a new encryption configuration or click the name of an existing encryption configuration.

Note: Fix packs that include updates to the Software Development Kit (SDK) might overwrite unrestricted policy files. Back up unrestricted policy files before you apply a fix pack and reapply these files after the fix pack is applied.

Encryption information name:

Specifies the name for the encryption information.

Data type String

Data encryption algorithm:

Specifies the algorithm Uniform Resource Identifier (URI) of the data encryption method.

The following algorithms are supported:
- http://www.w3.org/2001/04/xmlenc#tripledes-cbc
- http://www.w3.org/2001/04/xmlenc#aes128-cbc
- http://www.w3.org/2001/04/xmlenc#aes256-cbc. To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html. For more information, see “Encryption information configuration settings: Methods” on page 3363.
- http://www.w3.org/2001/04/xmlenc#aes192-cbc. To use this algorithm, you must download the unrestricted JCE policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html. For more information, see the help topic Encryption information configuration settings: Methods.

  Restriction: Do not use the 192-bit data encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

By default, the Java Cryptography Extension (JCE) is shipped with restricted or limited strength ciphers. To use 192-bit and 256-bit Advanced Encryption Standard (AES) encryption algorithms, you must apply unlimited jurisdiction policy files. For more information, see the **Key encryption algorithm** field description.

Key locator reference:

Specifies the name of the key locator configuration that retrieves the key for XML digital signature and XML encryption.

The Key locator reference field is displayed for the request receiver and response receiver bindings.

You can configure these key locator reference options on the server level and the application level. The configurations that are listed in the field are a combination of the configurations on these two levels.

You can specify an encryption key configuration for the following bindings on the following levels:

Table 312. Encryption key binding configurations. Use these configurations to encrypt and decrypt various parts of a message.

Binding name	Server level or application level	Path
Default generator binding	Server level	1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***. 2. Under Security, click **JAX-WS and JAX-RPC security runtime**. **Note:** In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**. 3. Under Additional properties, click **Key locators**.
Default consumer binding	Server level	1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***. 2. Under Security, click **JAX-WS and JAX-RPC security runtime**. **Note:** In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**. 3. Under Additional properties, click **Key locators**.
Request sender	Application level	1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***. 2. Under Modules, click **Manage modules** > ***URI_name***. 3. Click **Web services: Client security bindings**. Under Request sender binding, click **Edit**. 4. Under Additional properties, click **Key locators**.
Request receiver	Application level	1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***. 2. Under Modules, click **Manage modules** > ***URI_name***. 3. Click **Web services: Server security bindings**. Under Request receiver binding, click **Edit**. 4. Under Additional properties, click **Key locators**.
Response sender	Application level	1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***. 2. Under Modules, click **Manage modules** > ***URI_name***. 3. Click **Web services: Server security bindings**. Under Response sender binding, click **Edit**. 4. Under Additional properties, click **Key locators**.
Response receiver	Application level	1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***. 2. Under Modules, click **Manage modules** > ***URI_name***. 3. Click **Web services: Client security bindings**. Under Response receiver binding, click **Edit**. 4. Under Additional properties, click **Key locators**.

Key encryption algorithm:

Specifies the algorithm Uniform Resource Identifier (URI) of the key encryption method.

The following algorithms are provided by the application server:

- http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p.

  When running with Software Development Kit (SDK) Version 1.4, the list of supported key transport algorithms does not include this one. This algorithm appears in the list of supported key transport algorithms when running with Software Development Kit (SDK) Version 1.5 or later.

  By default, the RSA-OAEP algorithm uses the SHA1 message digest algorithm to compute a message digest as part of the encryption operation. Optionally, you can use the SHA256 or SHA512 message digest algorithm by specifying a key encryption algorithm property. The property name is: `com.ibm.wsspi.wssecurity.enc.rsaoaep.DigestMethod`. The property value is one of the following URIs of the digest method:

  – `http://www.w3.org/2001/04/xmlenc#sha256`

  – `http://www.w3.org/2001/04/xmlenc#sha512`

  By default, the RSA-OAEP algorithm uses a null string for the optional encoding octet string for the OAEPParams. You can provide an explicit encoding octet string by specifying a key encryption algorithm property. For the property name, you can specify `com.ibm.wsspi.wssecurity.enc.rsaoaep.OAEPparams`. The property value is the base 64-encoded value of the octet string.

  Important: You can set these digest method and OAEPParams properties on the generator side only. On the consumer side, these properties are read from the incoming SOAP message.

- http://www.w3.org/2001/04/xmlenc#rsa-1_5
- http://www.w3.org/2001/04/xmlenc#kw-tripledes
- http://www.w3.org/2001/04/xmlenc#kw-aes128
- http://www.w3.org/2001/04/xmlenc#kw-aes192

  Restriction: Do not use the 192-bit data encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

- http://www.w3.org/2001/04/xmlenc#kw-aes256

IBM Software Development Kit Version 1.4:

For IBM i and IBM Software Development Kit Version 1.4, the tuning of Web Services Security is not required. The unrestricted jurisdiction policy files for IBM Software Development Kit Version 1.4 are automatically configured when the prerequisite software is installed.

- For IBM i (formerly known as IBM i V5R3) and IBM Software Development Kit Version 1.4, install product 5722AC3, Crypto Access Provider 128-bit.
- For IBM i 5.4 and IBM Software Development Kit Version 1.4, install product 5722SS1 Option 3, Extended Base Directory Support.

IBM Software Development Kit Version 1.5:

For IBM i 5.4 and IBM i (formerly known as IBM i V5R3) and IBM Software Development Kit 1.5, the restricted JCE jurisdiction policy files are configured, by default. You can download the unrestricted JCE jurisdiction policy files from the following website: IBM developer works: Security Information, Version 5

Note: If Java Platform, Standard Edition 6 (Java SE 6) 32-bit for IBM i is the enabled Java virtual machine (JVM) for your profile, substitute `/QOpenSys/QIBM/ProdData/JavaVM/jdk50/32bit/jre` for `/QIBM/ProdData/Java400/jdk15` as the path name in the following steps.

Important: Your country of origin might have restrictions on the import, possession, use, or re-export to another country, of encryption software. Before downloading or using the unrestricted policy files, you must check the laws of your country, its regulations, and its policies concerning the import, possession, use, and re-export of encryption software, to determine if it is permitted.

To configure the unrestricted jurisdiction policy files for IBM i and the IBM Software Development Kit Version 1.5:

1. Make backup copies of these files:

```
/QIBM/ProdData/Java400/jdk15/lib/security/local_policy.jar
/QIBM/ProdData/Java400/jdk15/lib/security/US_export_policy.jar
```

2. Download the unrestricted policy files from IBM developer works: Security Information to the `/QIBM/ProdData/Java400/jdk15/lib/security` directory.
   a. Go to this website: http://www.ibm.com/developerworks/java/jdk/security/index.html
   b. Click **J2SE 5.0**.
   c. Scroll down and click **IBM SDK Policy files**. The Unrestricted JCE Policy files for the SDK website is displayed.
   d. Click **Sign in** and provide your IBM intranet ID and password.
   e. Select the appropriate unrestricted JCE policy files, and then click **Continue**.
   f. View the license agreement, and then click **I Agree**.
   g. Click **Download Now**.
3. Use the DSPAUT command to ensure *PUBLIC is granted*RX data authority but also ensure that no object authority is provided to both the `local_policy.jar` and the `US_export_policy.jar` files in the `/QIBM/ProdData/Java400/jdk15/lib/security` directory. For example:

```
DSPAUT OBJ('/qibm/proddata/java400/jdk15/lib/security/local_policy.jar')
```

4. Use the CHGAUT command to change authorization, if needed. For example:

```
CHGAUT OBJ('/qibm/proddata/java400/jdk15/lib/security/local_policy.jar')
USER(*PUBLIC) DTAAUT(*RX) OBJAUT(*NONE)
```

Custom algorithms on the server level

To specify custom algorithms on the server level, complete the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under Additional properties, click **Algorithm mappings**.
4. Click **New** to specify a new algorithm mapping or click the name of an existing configuration to modify its settings.
5. Under Additional properties, click **Algorithm URI**.
6. Click **New** to create a new algorithm URI. You must specify **Key encryption** in the **Algorithm type** field to have the configuration display in the **Key encryption algorithm** field on the Encryption information configuration settings panel.

Encryption key information:

Specifies the name of the key information reference that is used for encryption. This reference is resolved to the actual key by the specified key locator and defined in the key information.

You must specify either one or no encryption key configurations for the request generator and response generator bindings.

For the response consumer and the request consumer bindings, you can configure multiple encryption key references. To create a new encryption key reference, under Additional properties, click **Key information references**.

You can specify an encryption key configuration for the following bindings on the following levels:

Table 313. Encryption key binding configurations. Use these configurations to encrypt and decrypt various parts of a message.

Binding name	Server level or application level	Path
Default generator binding	Server level	1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***. 2. Under Security, click **JAX-WS and JAX-RPC security runtime**. **Note:** In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**. 3. Under JAX-RPC Default generator binding, click **Key information**.
Default consumer binding	Server level	1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***. 2. Under Security, click **JAX-WS and JAX-RPC security runtime**. **Note:** In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**. 3. Under JAX-RPC Default consumer binding, click **Key information**.
Request generator (sender) binding	Application level	1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***. 2. Under Modules, click **Manage modules** > ***URI_name***. 3. Under Web Services Security Properties, click **Web services: Client security bindings**. 4. Under Request generator (sender) binding, click **Edit custom**. 5. Under Required properties, click **Key information**.
Response generator (sender) binding	Application level	1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***. 2. Under Modules, click **Manage modules** > ***URI_name***. 3. Under Web Services Security Properties, click **Web services: Server security bindings**. 4. Under Response generator (sender) binding, click **Edit custom**. 5. Under Required properties, click **Key information**.

Part Reference:

Specifies the name of the <confidentiality> element for the generator binding or the <requiredConfidentiality> element for the consumer binding element in the deployment descriptor.

This field is available on the application level only.

Encryption information configuration settings: Methods:

Use this page to configure the encryption and decryption parameters for the signature method, digest method, and canonicalization method.

The specifications that are listed on this page for the signature method, digest method, and canonicalization method are located in the World Wide Web Consortium (W3C) document entitled, *XML Encryption Syntax and Processing: W3C Recommendation 10 Dec 2002*.

To view this administrative console page, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** and complete one of the following steps:

- Click **Manage modules** > ***URI_file_name*** > **Web Services: Client Security Bindings**. Under Request sender binding, click **Edit**. Under Web Services Security Properties, click **Encryption Information**.
- Under Modules, click **Manage modules** > ***URI_file_name*** > **Web Services: Server Security Bindings**. Under Response sender binding, click **Edit**. Under Web Services Security Properties, click **Encryption Information**.

2. Select **None** or **Dedicated encryption information**. The application server can have either one or no encryption configurations for the request sender and the response sender bindings. If you are not using encryption, select **None**. To configure encryption for either of these two bindings, select **Dedicated encryption information** and specify the configuration settings using the fields that are described in this topic.

Note: Fix packs that include updates to the Software Development Kit (SDK) might overwrite unrestricted policy files. Back up unrestricted policy files before you apply a fix pack and reapply these files after the fix pack is applied.

Encryption information name:

Specifies the name for the encryption information.

Key locator reference:

Specifies the name that is used to reference the key locator.

You can configure these key locator reference options on the server level and the application level. The configurations that are listed in the field are a combination of the configurations on these two levels.

To configure the key locators on the server level, complete the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under Additional properties, click **Key locators**.

To configure the key locators on the application level, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Under Modules, click **Manage modules** > ***URI_name***.
3. Under Web Services Security Properties, you can access the key locators for the following bindings:
   - For the Request sender, click **Web services: Client security bindings**. Under Request sender binding, click **Edit**. Under Additional properties, click **Key locators**.
   - For the Request receiver, click **Web services: Server security bindings**. Under Request receiver binding, click **Edit**. Under Additional properties, click **Key locators**.
   - For the Response sender, click **Web services: Server security bindings**. Under Response sender binding, click **Edit**. Under Additional properties, click **Key locators**.
   - For the Response receiver, click **Web services: Client security bindings**. Under Response receiver binding, click **Edit**. Under Additional properties, click **Key locators**.

Encryption key name:

Specifies the name of the encryption key that is resolved to the actual key by the specified key locator.

Data type String

Key encryption algorithm:

Specifies the algorithm uniform resource identifier (URI) of the key encryption method.

The following algorithms are supported:

- http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p.

  When running with IBM Software Development Kit (SDK) Version 1.4, the list of supported key transport algorithms does not include this one. This algorithm appears in the list of supported key transport algorithms when running with JDK 1.5 or later.

  By default, the RSA-OAEP algorithm uses the SHA1 message digest algorithm to compute a message digest as part of the encryption operation. Optionally, you can use the SHA256 or SHA512 message digest algorithm by specifying a key encryption algorithm property. The property name is: `com.ibm.wsspi.wssecurity.enc.rsaoaep.DigestMethod`. The property value is one of the following URIs of the digest method:
  - `http://www.w3.org/2001/04/xmlenc#sha256`
  - `http://www.w3.org/2001/04/xmlenc#sha512`

  By default, the RSA-OAEP algorithm uses a null string for the optional encoding octet string for the OAEPParams. You can provide an explicit encoding octet string by specifying a key encryption algorithm property. For the property name, you can specify `com.ibm.wsspi.wssecurity.enc.rsaoaep.OAEPparams`. The property value is the base 64-encoded value of the octet string.

  Important: You can set these digest method and OAEPParams properties on the generator side only. On the consumer side, these properties are read from the incoming SOAP message.
- http://www.w3.org/2001/04/xmlenc#rsa-1_5.
- http://www.w3.org/2001/04/xmlenc#kw-tripledes.
- http://www.w3.org/2001/04/xmlenc#kw-aes128.
- http://www.w3.org/2001/04/xmlenc#kw-aes192. To use the 192-bit key encryption algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file.

  Restriction: Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).
- http://www.w3.org/2001/04/xmlenc#kw-aes256. To use the 256-bit key encryption algorithm, you must download the unrestricted JCE policy file.

Note: If an InvalidKeyException error occurs and you are using the 129xxx or 256xxx encryption algorithm, the unrestricted policy files might not exist in your configuration.

Java Cryptography Extension

By default, the Java Cryptography Extension (JCE) is shipped with restricted or limited strength ciphers. To use 192-bit and 256-bit Advanced Encryption Standard (AES) encryption algorithms, you must apply unlimited jurisdiction policy files.

Important: Your country of origin might have restrictions on the import, possession, use, or re-export to another country, of encryption software. Before downloading or using the unrestricted policy files, you must check the laws of your country, its regulations, and its policies concerning the import, possession, use, and re-export of encryption software, to determine if it is permitted.

To download the policy files, complete one of the following sets of steps:

After completing these steps, two Java archive (JAR) files are placed in the Java virtual machine (JVM) `jre/lib/security/` directory.

IBM i and IBM Software Development Kit 1.4

For the IBM i and IBM Software Development Kit Version 1.4, the tuning of Web Services Security is not required. The unrestricted jurisdiction policy files for the IBM Software Development Kit Version 1.4 are automatically configured when the prerequisite software is installed.

For the IBM i 5.4 operating system and IBM Software Development Kit Version 1.4, the unrestricted jurisdiction policy files for the IBM Java Developer Kit 1.4 are automatically configured by installing product 5722SS1 Option 3, Extended Base Directory Support.

For IBM i (formerly known as IBM i V5R3) and IBM Software Development Kit Version 1.4, the unrestricted jurisdiction policy files for the IBM Software Development Kit Version 1.4 are automatically configured by installing product 5722AC3, Crypto Access Provider 128-bit.

IBM i and IBM Software Development Kit 1.5

For IBM i 5.4 and IBM i (formerly known as IBM i V5R3) and IBM Software Development Kit 1.5, the restricted JCE jurisdiction policy files are configured, by default. You can download the unrestricted JCE jurisdiction policy files from the following website: Security information: IBM J2SE 5 SDKs

To configure the unrestricted jurisdiction policy files for IBM i and the IBM Software Development Kit Version 1.5:

1. Make backup copies of these files:

```
/QIBM/ProdData/Java400/jdk15/lib/security/local_policy.jar
/QIBM/ProdData/Java400/jdk15/lib/security/US_export_policy.jar
```

2. Download the unrestricted policy files from IBM developer kit: Security information to the `/QIBM/ProdData/Java400/jdk15/lib/security` directory.
   a. Go to this website: IBM developer kit: Security information
   b. Click **J2SE 5.0**.
   c. Scroll down and click **IBM SDK Policy files**. The Unrestricted JCE Policy files for the SDK website is displayed.
   d. Click **Sign in** and provide your IBM intranet ID and password.
   e. Select the appropriate unrestricted JCE policy files, and then click **Continue**.
   f. View the license agreement, and then click **I Agree**.
   g. Click **Download Now**.
3. Use the DSPAUT command to ensure *PUBLIC is granted*RX data authority but also ensure that no object authority is provided to both the `local_policy.jar` and the `US_export_policy.jar` files in the `/QIBM/ProdData/Java400/jdk15/lib/security` directory. For example:

```
DSPAUT OBJ('/qibm/proddata/java400/jdk15/lib/security/local_policy.jar')
```

4. Use the CHGAUT command to change authorization, if needed. For example:

```
CHGAUT OBJ('/qibm/proddata/java400/jdk15/lib/security/local_policy.jar')
USER(*PUBLIC) DTAAUT(*RX) OBJAUT(*NONE)
```

Data encryption algorithm:

Specifies the algorithm Uniform Resource Identifiers (URI) of the data encryption method.

The following algorithms are supported:

- http://www.w3.org/2001/04/xmlenc#tripledes-cbc
- http://www.w3.org/2001/04/xmlenc#aes128-cbc
- http://www.w3.org/2001/04/xmlenc#aes192-cbc

Restriction: Do not use the 192-bit data encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

- http://www.w3.org/2001/04/xmlenc#aes256-cbc

By default, the JCE ships with restricted or limited strength ciphers. To use 192-bit and 256- bit AES encryption algorithms, you must apply unlimited jurisdiction policy files. For more information, see the Key encryption algorithm field description.

Configuring encryption to protect message confidentiality at the application level:

You can configure the encryption information for the request consumer (server side) and response consumer (client side) bindings at the application level.

Before you begin

Configure the key information that is referenced in the encryption information panel. For more information, see "Configuring the key information for the consumer binding on the application level" on page 3324.

About this task

This task provides the steps that are needed for configuring the encryption information for the request consumer (server side) and response consumer (client side) bindings at the application level. The encryption information on the consumer side is used for decrypting the encrypted message parts in the incoming SOAP message.

Complete the following steps to configure the encryption information for the request consumer or response consumer section of the bindings file on the application level:

Procedure

1. Locate the Encryption information configuration panel in the administrative console.
   a. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
   b. Under Manage modules, click ***URI_name***.
   c. Under Web Services Security Properties you can access the encryption information for the request consumer and response consumer bindings.
      - For the request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
      - For the response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
   d. Under Required properties, click **Encryption information**.
   e. Click **New** to create an encryption information configuration, click **Delete** to delete an existing configuration, or click the name of an existing encryption information configuration to edit its settings. If you are creating a new configuration, enter a name in the **Encryption information name** field. For example, you might specify `cons_enc info`.
2. Select a data encryption algorithm from the **Data encryption algorithm** field. The data encryption algorithm is used for encrypting or decrypting parts of a SOAP message such as the SOAP body or the username token. WebSphere Application Server supports the following pre-configured algorithms:
   - http://www.w3.org/2001/04/xmlenc#tripledes-cbc
   - http://www.w3.org/2001/04/xmlenc#aes128-cbc
   - http://www.w3.org/2001/04/xmlenc#aes256-cbc

     To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

- http://www.w3.org/2001/04/xmlenc#aes192-cbc

  To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

  Restriction: Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

  Important: Your country of origin might have restrictions on the import, possession, use, or re-export to another country, of encryption software. Before downloading or using the unrestricted policy files, you must check the laws of your country, its regulations, and its policies concerning the import, possession, use, and re-export of encryption software, to determine if it is permitted.

The data encryption algorithm that you select for the consumer side must match the data encryption method that you select for the generator side.

3. Select a key encryption algorithm from the **Key encryption algorithm** field. The key encryption algorithm is used for encrypting the key that is used for encrypting the message parts within the SOAP message. Select **(none)** if the data encryption key, which is the key that is used for encrypting the message parts, is not encrypted. WebSphere Application Server supports the following pre-configured algorithms:
   - http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p.

     When running with Software Development Kit (SDK) Version 1.4, the list of supported key transport algorithms does not include this one. This algorithm appears in the list of supported key transport algorithms when running with SDK Version 1.5.

     Restriction: This algorithm is not supported when the WebSphere Application Server is running in Federal Information Processing Standard (FIPS) mode.
   - http://www.w3.org/2001/04/xmlenc#rsa-1_5
   - http://www.w3.org/2001/04/xmlenc#kw-tripledes
   - http://www.w3.org/2001/04/xmlenc#kw-aes128
   - http://www.w3.org/2001/04/xmlenc#kw-aes256

     To use the http://www.w3.org/2001/04/xmlenc#aes256-cbc algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.
   - http://www.w3.org/2001/04/xmlenc#kw-aes192

     To use the http://www.w3.org/2001/04/xmlenc#kw-aes192 algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

     Restriction: Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

   The key encryption algorithm that you select for the consumer side must match the key encryption method that you select for the generator side.
4. Optional: Select a part reference in the **Part reference** field. The part reference specifies the name of the message part that is encrypted and is defined in the deployment descriptor. For example, you can encrypt the bodycontent message part in the deployment descriptor. The name of this Required Confidentiality part is `conf_con`. This message part is shown as an option in the **Part reference** field.
5. Under Additional properties, click **Key information references**.
6. Click **New** to create a key information configuration, click **Delete** to delete an existing configuration, or click the name of an existing key information configuration to edit its settings. If you are creating a new configuration, enter a name in the **Name** field. For example, you might specify `con_ekeyinfo`. This entry is the name of the <encryptionKeyInfo> element in the binding file.

7. Select a key information reference from the **Key information reference** field. This reference is the value of the keyinfoRef attribute of the <encryptionKeyInfo> element and it is the name of the <keyInfo> element that is referenced by this key information reference. Each key information reference entry generates an <encryptionKeyInfo> element under the <encryptionInfo> element in the binding configuration file. For example, if you enter `con_ekeyinfo` in the **Name** field and `dec_keyinfo` in the **Key information reference** field, the following <encryptionKeyInfo> element is generated in the binding file:

```
<encryptionKeyInfo xmi:id="EncryptionKeyInfo_1085092248843"
keyinfoRef="dec_keyinfo" name="con_ekeyinfo"/>
```

8. Click **OK** and then click **Save** to save the configuration.

Results

You have configured the encryption information for the consumer binding at the application level

What to do next

You must specify a similar encryption information configuration for the generator.

Configuring message-level security for JAX-RPC at the server or cell level

Specify the server-level or cell-level configuration.

Configuring the signing information using JAX-RPC for the generator binding on the server level:

You can configure the signing information for the client-side request generator and the server-side response generator bindings at the server level.

Before you begin

Note: For WebSphere Application Server version 6.x or earlier only, in the server-side extensions file (`ibm-webservices-ext.xmi`) and the client-side deployment descriptor extensions file (`ibm-webservicesclient-ext.xmi`), you must specify which parts of the message are signed. Also, you need to configure the key information that is referenced by the key information references on the Signing information panel within the administrative console.

About this task

This task explains the steps that are needed for you to configure the signing information for the client-side request generator and the server-side response generator bindings at the server level. WebSphere Application Server uses the signing information for the default generator to sign parts of the message that include the body, time stamp, and user name token if these bindings are not defined at the application level. The Application Server provides default values for bindings. However, an administrator must modify the defaults for a production environment.

Complete the following steps to configure the signing information for the generator sections of the bindings files on the server level:

Procedure

1. Access the default bindings for the server level.
   a. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
   b. Under Security, click **JAX-WS and JAX-RPC security runtime**.

      Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
2. Under Default generator bindings, click **Signing information**.

3. Click **New** to create a signing information configuration, click **Delete** to delete an existing configuration, or click the name of an existing signing information configuration to edit the settings. If you are creating a new configuration, enter a unique name for the signing configuration in the Signing information name field. For example, you might specify `gen_signinfo`.
4. Select a signature method algorithm from the Signature method field. The algorithm that is specified for the default generator must match the algorithm that is specified for the default consumer. WebSphere Application Server supports the following pre-configured algorithms:
   - http://www.w3.org/2000/09/xmldsig#rsa-sha1
   - http://www.w3.org/2000/09/xmldsig#hmac-sha1
   - http://www.w3.org/2000/09/xmldsig#dsa-sha1

     Do not use this algorithm if you want the configured application to be compliant with the Basic Security Profile (BSP). Any ds:SignatureMethod/@Algorithm element in a SIGNATURE based on a symmetric key must have a value of http://www.w3.org/2000/09/xmldsig#rsa-sha1 or http://www.w3.org/2000/09/xmldsig#hmac-sha1.
5. Select a canonicalization method from the Canonicalization method field. The canonicalization algorithm that you specify for the generator must match the algorithm for the consumer. WebSphere Application Server supports the following pre-configured canonical XML and exclusive XML canonicalization algorithms:
   - http://www.w3.org/2001/10/xml-exc-c14n#
   - http://www.w3.org/2001/10/xml-exc-c14n#WithComments
   - http://www.w3.org/TR/2001/REC-xml-c14n-20010315
   - http://www.w3.org/TR/2001/REC-xml-c14n-20010315#WithComments
6. Select a key information signature type from the **Key information signature type** field. The key information signature type determines how to digitally sign the key. WebSphere Application server supports the following signature types:

   None Specifies that the <KeyInfo> element is not signed.

   Keyinfo
   Specifies that the entire <KeyInfo> element is signed.

   Keyinfochildelements
   Specifies that the child elements of the <KeyInfo> element are signed.

   The key information signature type for the generator must match the signature type for the consumer. You might encounter the following situations:
   - If you do not specify one of the previous signature types, WebSphere Application Server uses `keyinfo`, by default.
   - If you select Keyinfo or Keyinfochildelements and you select http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform as the transform algorithm in a subsequent step, WebSphere Application Server also signs the referenced token.
7. Select a signing key information reference from the Signing key information field. This selection is a reference to the signing key that the Application Server uses to generate digital signatures. In the binding files, this information is specified within the <signingKeyInfo> tag. The key that is used for signing is specified by the key information element, which is defined at the same level as the signing information. For more information, see “Configuring the key information for the generator binding using JAX-RPC on the server level” on page 3375.
8. Click **OK** to save the configuration.
9. Click the name of the new signing information configuration. This configuration is the one that you specified in the previous steps.
10. Specify the part reference, digest algorithm, and transform algorithm. The part reference specifies which parts of the message to digitally sign.

a. Under Additional Properties, click **Part references** > **New** to create a new part reference, click **Part references** > **Delete** to delete an existing part reference, or click a part name to edit an existing part reference.

b. Specify a unique part name for the message part that needs signing. This message part is specified on both the server side and the client side. You must specify an identical part name for both the server side and the client side. For example, you might specify `reqint` for both the generator and the consumer.

   Important: You do not need to specify a value for the Part reference in the default bindings like you specify on the application level because the part reference on the application level points to a particular part of the message that is signed. Because the default bindings for the server level is applicable to all of the services that are defined on a particular server, you cannot specify this value.

c. Select a digest method algorithm in the **Digest method algorithm** field. The digest method algorithm that is specified in the binding files within the <DigestMethod> element is used in the <SigningInfo> element.

   WebSphere Application Server supports the following algorithms:

   - http://www.w3.org/2000/09/xmldsig#sha1
   - http://www.w3.org/2001/04/xmlenc#sha256
   - http://www.w3.org/2001/04/xmlenc#sha512

d. Click **OK** and **Save** to save the configuration.

e. Click the name of the new part reference configuration. This configuration is the one that you specified in the previous steps.

f. Under Additional properties, click **Transforms** > **New** to create a new transform, click **Transforms** > **Delete** to delete a transform, or click a transform name to edit an existing transform. If you create a new transform configuration, specify a unique name. For example, you might specify `reqint_body_transform1`.

g. Select a transform algorithm from the menu. The transform algorithm is specified within the <Transform> element. This algorithm element specifies the transform algorithm for the digital signature. WebSphere Application Server supports the following algorithms:

   - http://www.w3.org/2001/10/xml-exc-c14n#
   - http://www.w3.org/TR/1999/REC-xpath-19991116

     Restriction: Do not use this transform algorithm if you want your configured application to be compliant with the Basic Security Profile (BSP). Instead use http://www.w3.org/2002/06/xmldsig-filter2 to ensure compliance.

   - http://www.w3.org/2002/06/xmldsig-filter2
   - http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform
   - http://www.w3.org/2002/07/decrypt#XML
   - http://www.w3.org/2000/09/xmldsig#enveloped-signature

   The transform algorithm that you select for the generator must match the transform algorithm that you select for the consumer.

   Important: If both of the following conditions are true, WebSphere Application Server signs the referenced token:

   - You previously selected the **Keyinfo** or the **Keyinfochildelements** option from the Key information signature type field on the signing information panel.
   - You select **http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform** as the transform algorithm.

11. Click **Apply**.

12. Click **Save** at the top of the panel to save your configuration.

Results

After completing these steps, you have configured the signing information for the generator on the server level.

What to do next

You must specify a similar signing information configuration for the consumer.

Configuring the signing information using JAX-RPC for the consumer binding on the server level:

You can configure the signing information for the client-side request generator and server-side response generator bindings at the server level.

Before you begin

Note: For WebSphere Application Server version 6.x or earlier only, in the server-side extensions file (`ibm-webservices-ext.xmi`) and the client-side deployment descriptor extensions file (`ibm-webservicesclient-ext.xmi`), you must specify which parts of the message are signed. Also, you need to configure the key information that is referenced by the key information references on the signing information panel within the administrative console.

About this task

This task explains the steps that are needed for you to configure the signing information for the client-side request generator and server-side response generator bindings at the server level. WebSphere Application Server uses the signing information for the default generator to sign parts of the message including the body, time stamp, and user name token, if these bindings are not defined at the application level. The Application Server provides default values for bindings. However, an administrator must modify the defaults for a production environment.

Complete the following steps to configure the signing information for the consumer sections of the bindings files on the server level:

Procedure

1. Access the default bindings for the server level.
   a. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
   b. Under Security, click **JAX-WS and JAX-RPC security runtime**.

      Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
2. Under Default consumer bindings, click **Signing information**.
3. Click **New** to create a signing information configuration, click **Delete** to delete an existing configuration, or click the name of an existing signing information configuration to edit the settings. If you are creating a new configuration, enter a unique name for the signing configuration in the Signing information name field. For example, you might specify `gen_signinfo`.
4. Select a signature method algorithm from the Signature method field. The algorithm that is specified for the default consumer must match the algorithm that is specified for the default generator. WebSphere Application Server supports the following pre-configured algorithms:
   - http://www.w3.org/2000/09/xmldsig#rsa-sha1
   - http://www.w3.org/2000/09/xmldsig#hmac-sha1
   - http://www.w3.org/2000/09/xmldsig#dsa-sha1

Do not use this algorithm if you want the configured application to be compliant with the Basic Security Profile (BSP). Any ds:SignatureMethod/@Algorithm element in a SIGNATURE based on a symmetric key must have a value of http://www.w3.org/2000/09/xmldsig#rsa-sha1 or http://www.w3.org/2000/09/xmldsig#hmac-sha1.

5. Select a canonicalization method from the Canonicalization method field. The canonicalization algorithm that you specify for the generator must match the algorithm for the consumer. WebSphere Application Server supports the following pre-configured canonical XML and exclusive XML canonicalization algorithms:
   - http://www.w3.org/2001/10/xml-exc-c14n#
   - http://www.w3.org/2001/10/xml-exc-c14n#WithComments
   - http://www.w3.org/TR/2001/REC-xml-c14n-20010315
   - http://www.w3.org/TR/2001/REC-xml-c14n-20010315#WithComments
6. Select a key information signature type from the Key information signature type field. The key information signature type determines how to digitally sign the key. WebSphere Application Server supports the following signature types:

   None Specifies that the KeyInfo element is not signed.

   Keyinfo
   Specifies that the entire KeyInfo element is signed.

   Keyinfochildelements
   Specifies that the child elements of the KeyInfo element are signed.

   The key information signature type for the consumer must match the signature type for the generator. You might encounter the following situations:
   - If you do not specify one of the previous signature types, WebSphere Application Server uses keyinfo, by default.
   - If you select **Keyinfo** or **Keyinfochildelements** and you select **http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform** as the transform algorithm in a subsequent step, WebSphere Application Server also signs the referenced token.
7. Click **OK** to save the configuration.
8. Click the name of the new signing information configuration. This configuration is the one that you specified in the previous steps.
9. Specify the key information reference, part reference, digest algorithm, and transform algorithm.
   a. Under Additional properties, click **Key information references** > **New** to create a new reference, click **Key information references** > **Delete** to delete an existing reference, or click a reference name to edit an existing key information reference.
   b. Enter a name for the configuration in the Name field. For example, enter `con_skeyinfo`.
   c. Select a key information reference from the Key information reference field. The key Information reference points to the key that WebSphere Application Server uses for digital signing. In the binding files, the reference is specified within the <signingKeyInfo> element. The key that is used for signing is specified by the Key information element, which is defined at the same level as the signing information. For more information, see “Configuring the key information for the consumer binding on the application level” on page 3324.
   d. Click **OK** and **Save** to save the configuration.
   e. Under Additional Properties, click **Part references** > **New** to create a new part reference, click **Part references** > **Delete** to delete an existing part reference, or click a part name to edit an existing part reference. The part reference specifies which parts of the message to digitally sign. The part attribute refers to the name of the `<RequiredIntegrity>` element in the deployment descriptor when `<PartReference>` is specified for the digital signature. WebSphere Application Server enables you to specify multiple `<PartReference>` elements for the `<SigningInfo>` element. The `<PartReference>` element has two child elements: `<DigestMethod>` and `<Transform>`.
   f. Specify a unique part name for this part reference. For example, you might specify `reqint`.

Important: You do not need to specify a value for the Part reference field like you specify on the application level because the part reference on the application level points to a particular part of the message that is signed. Because the default bindings for the server level is applicable to all of the services that are defined on a particular server, you cannot specify this value.

g. Select a digest method algorithm in the **Digest method algorithm** field. The digest method algorithm specified within the `<DigestMethod>` element that is used in the `<SigningInfo>` element.

   WebSphere Application Server supports the following algorithms:

   - http://www.w3.org/2000/09/xmldsig#sha1
   - http://www.w3.org/2001/04/xmlenc#sha256
   - http://www.w3.org/2001/04/xmlenc#sha512

h. Click **OK** and **Save** to save the configuration.

i. Click the name of the new part reference configuration. This configuration is the one that you specified in the previous steps.

j. Under Additional properties, click **Transforms** > **New** to create a new transform, click **Transforms** > **Delete** to delete a transform, or click a transform name to edit an existing transform. If you create a new transform configuration, specify a unique name. For example, you might specify `reqint_body_transform1`.

k. Select a transform algorithm from the menu. The transform algorithm is specified within the <Transform> element. It specifies the transform algorithm for the signature. WebSphere Application Server supports the following algorithms:

   - http://www.w3.org/2001/10/xml-exc-c14n#
   - http://www.w3.org/TR/1999/REC-xpath-19991116

     Restriction: Do not use this transform algorithm if you want your configured application to be compliant with the Basic Security Profile (BSP). Instead use http://www.w3.org/2002/06/xmldsig-filter2 to ensure compliance.

   - http://www.w3.org/2002/06/xmldsig-filter2
   - http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform
   - http://www.w3.org/2002/07/decrypt#XML
   - http://www.w3.org/2000/09/xmldsig#enveloped-signature

   The transform algorithm that you select for the consumer must match the transform algorithm that you select for the generator.

   Important: If both of the following conditions are true, WebSphere Application Server signs the referenced token:

   - You previously selected the Keyinfo or the Keyinfochildelements option from the Key information signature type field on the signing information panel.
   - You select http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#STR-Transform as the transform algorithm.

10. Click **OK**.
11. Click **Save** at the top of the panel to save your configuration.

Results

After completing these steps, you have configured the signing information for the consumer on the server level.

What to do next

You must specify a similar signing information configuration for the generator.

Configuring the key information for the generator binding using JAX-RPC on the server level:

Use the key information for the default generator to specify the key that is used by the signing or the encryption information configurations if these bindings are not defined at the application level.

About this task

The signing and encryption information configurations can share the same key information, which is why they are both defined on the same level. WebSphere Application Server provides default values for these bindings. However, an administrator must modify these values for a production environment.

Complete the following steps to configure the key information for the generator binding on the server level:

Procedure

1. Access the default bindings for the server level.
   a. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
   b. Under Security, click **JAX-WS and JAX-RPC security runtime**.

      Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
2. Under Default generator bindings, click **Key information**.
3. Click **New** to create a key information configuration, click **Delete** to delete an existing configuration, or click the name of an existing key information configuration to edit the settings. If you are creating a new configuration, enter a unique name for the key configuration in the Key information name field. For example, you might specify `sig_keyinfo`.
4. Select a key information type from the Key information type field. WebSphere Application Server supports the following types of key information:

   Key identifier
   This key information type is used when two parties agree on how to create a key identifier. For example, a field of X.509 certificates can be used for the key identifier according to the X.509 profile.

   Key name
   This key information type is used when the sender and receiver agree on the name of the key.

   Security token reference
   This key information type is typically used when an X.509 certificate is used for digital signature.

   Embedded token
   This key information type is used to embed a security token in an embedded element.

   X509 issuer name and issuer serial
   This key information type specifies an X.509 certificate with its issuer name and serial number.

   Select **Security token reference** if you are using an X.509 certificate for the digital signature. In these steps, it is assumed that **Security token reference** is selected for this field.

   Important: This key information type must match the key information type that is specified for the consumer.

5. Select a key locator reference from the Key locator reference menu. In these steps, assume that the key locator reference is called `sig_klocator`. The key locator reference is the name of the key locator that is used to generate the key for digital signature. You must configure a key locator before you can select it in this field. For more information on configuring the key locator, see “Configuring the key locator using JAX-RPC on the server level” on page 3414.
6. Click **Get keys** to view a list of key name references. After you click **Get keys**, the key names that are defined in the <sig_klocator> element are shown in the key name reference menu. If you change the key locator reference, you must click **Get keys** again to display the list of key names that are associated with the new key locator.
7. Select a key name reference from the Key name reference menu. The key name reference specifies the name of the key that is used for generating the digital signature or for encryption. The Key name reference menu displays a list of key names that are defined for the selected key locator in the Key locator reference field. For example, select **signerkey**. It is assumed that signer key is a key name that is defined for the `sig_klocator` key locator.
8. Select a token reference from the Token reference field. The token reference refers to the name of a configured token generator. When a security token is required in the deployment descriptor, the token reference attribute is required. If you select **Security token reference** in the Key information type field, the token reference is required and you can specify an X.509 token generator. To specify an X.509 token generator, you must have an X.509 token generator configured. To configure an X.509 token generator, see “Configuring token generators using JAX-RPC to protect message authenticity at the server level” on page 3382. For the remaining steps, it is assumed that an X.509 token generator that is named gen_tcon is already configured.
9. Optional: Select an encoding method from the Encoding method field This field specifies the encoding format for the key identifier. The encoding method attribute is valid when you select **Key identifer** as the key information type. WebSphere Application Server supports the following encoding methods:
   - http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#Base64Binary
   - http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#HexBinary
10. Optional: Select a calculation method from the Calculation method field. The calculation method specifies the calculation algorithm that is used for the key identifier. This attribute is valid when you select **Key identifier** as the key information type. WebSphere Application Server supports the following calculation methods:
    - http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#ITSHA1
    - http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-soap-message-security-1.0#IT60SHA1
11. Optional: Specify a Uniform Resource Identifier (URI) of the value type for a security token from the Namespace URI field. The namespace URI is referenced by the key identifier. This attribute is valid when you select **Key identifier** as the key information type. When you specify the X.509 certificate token, you do not need to specify the namespace URI. If another token is specified, you must specify the namespace URI. For example, you can specify `http://www.ibm.com/websphere/appserver/tokentype/5.0.2` for the Lightweight Third Party Authentication (LTPA) token and `http://www.ibm.com/websphere/appserver/tokentype` for the LTPA_PROPAGATION token.
12. Optional: Specify the local name of the value type for a security token in the **Local name** field. The local name is referenced by the key identifier. This attribute is valid when you select **Key identifier** as the key information type. WebSphere Application Server supports the following local names:

    For an X.509 certificate token
    http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3

    For X.509 certificates in a PKIPath
    http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1

    For a list of X.509 certificates and CRLs in a PKCS#7
    http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7

For LTPA
LTPA

For LTPA_PROPAGATION
LTPA_PROPAGATION

13. Click **OK** and **Save** to save the configuration.

Results

You have configured the key information for the generator binding at the server level.

What to do next

You must specify a similar key information configuration for the consumer.

Configuring the key information for the consumer binding using JAX-RPC on the server level:

The key information for the default consumer is used to specify the key for the signing or the encryption information configurations if these bindings are not defined at the application level.

About this task

The signing and encryption information configurations can share the same key information, which is why they are both defined on the same level. WebSphere Application Server provides default values for these bindings. However, an administrator must modify these values for a production environment.

Complete the following steps to configure the key information for the consumer binding on the server level:

Procedure

1. Access the default bindings for the server level.
   a. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
   b. Under Security, click **JAX-WS and JAX-RPC security runtime**.

      Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
2. Under Default consumer bindings, click **Key information**.
3. Click **New** to create a key information configuration, click **Delete** to delete an existing configuration, or click the name of an existing key information configuration to edit the settings. If you are creating a new configuration, enter a unique name for the key configuration in the Key information name field. For example, you might specify `con_signkeyinfo`.
4. Select a key information type from the Key information type field. WebSphere Application Server supports the following types of key information:

   Key identifier
   This key information type is used when two parties agree on how to create a key identifier. For example, a field of X.509 certificates can be used for the key identifier according to the X.509 profile.

   Key name
   This key information type is used when the sender and receiver agree on the name of the key.

   Security token reference
   This key information type is typically used when an X.509 certificate is used for digital signature.

   Embedded token
   This key information type is used to embed a security token in an embedded element.

X509 issuer name and issuer serial
This key information type specifies an X.509 certificate with its issuer name and serial number.

Select **Security token reference** if you are using an X.509 certificate for the digital signature. In these steps, it is assumed that **Security token reference** is selected for this field.

Important: This key information type must match the key information type that is specified for the generator.

5. Select a key locator reference from the Key locator reference menu. In these steps, assume that the key locator reference is called `sig_klocator`. You must configure a key locator before you can select it in this field. For more information on configuring the key locator, see "Configuring the key locator using JAX-RPC on the server level" on page 3414.
6. Select a token reference from the Token reference field. The token reference refers to the name of a configured token consumer. When a security token is required in the deployment descriptor, the token reference attribute is required. If you select **Security token reference** in the Key information type field, the token reference is required and you can specify an X.509 token consumer. To specify an X.509 token consumer, you must have an X.509 token consumer configured. To configure an X.509 token consumer, see "Configuring token consumers using JAX-RPC to protect message authenticity at the server level" on page 3393.
7. Click **OK** and **Save** to save the configuration.

Results

You have configured the key information for the consumer binding at the server level.

What to do next

You must specify a similar key information configuration for the generator.

Configuring encryption using JAX-RPC to protect message confidentiality at the server or cell level:

You can configure the encryption information for the generator binding on the server or cell level.

About this task

The encryption information for the default generator specifies how to encrypt the information on the sender side if these bindings are not defined at the application level. WebSphere Application Server provides default values for the bindings. However, an administrator must modify the defaults for a production environment.

Complete the following steps to configure the encryption information for the generator binding on the server level:

Procedure

1. Access the default bindings for the server level.
   a. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
   b. Under Security, click **JAX-WS and JAX-RPC security runtime**.

      Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
2. Under Default generator bindings, click **Encryption information**.
3. Click **New** to create an encryption information configuration, click **Delete** to delete an existing configuration, or click the name of an existing encryption information configuration to edit the settings.

If you are creating a new configuration, enter a unique name for the encryption configuration in the Encryption information name field. For example, you might specify `gen_encinfo`.

4. Select a data encryption algorithm from the Data encryption algorithm field. This algorithm is used to encrypt the data. WebSphere Application Server supports the following pre-configured algorithms:
   - http://www.w3.org/2001/04/xmlenc#tripledes-cbc
   - http://www.w3.org/2001/04/xmlenc#aes128-cbc
   - http://www.w3.org/2001/04/xmlenc#aes256-cbc

     To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.
   - http://www.w3.org/2001/04/xmlenc#aes192-cbc

     To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

     Restriction: Do not use this algorithm, the 192-bit key encryption algorithm, if you want your configured application to be in compliance with the Basic Security Profile (BSP).

   Important: Your country of origin might have restrictions on the import, possession, use, or re-export to another country, of encryption software. Before downloading or using the unrestricted policy files, you must check the laws of your country, its regulations, and its policies concerning the import, possession, use, and re-export of encryption software, to determine if it is permitted.

   The data encryption algorithm that you select for the generator side must match the data encryption algorithm that you select for the consumer side.
5. Select a key encryption algorithm from the Key encryption algorithm field. This algorithm is used to encrypt the key. WebSphere Application Server supports the following pre-configured algorithms:
   - http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p.

     When running with JDK 1.4, the list of supported key transport algorithms will not include this one. This algorithm will appear in the list of supported key transport algorithms when running with JDK 1.5.

     Restriction: This algorithm is not supported when the WebSphere Application Server is running in Federal Information Processing Standard (FIPS) mode.

     By default, the RSA-OAEP algorithm uses the SHA1 message digest algorithm to compute a message digest as part of the encryption operation. Optionally, you can use the SHA256 or SHA512 message digest algorithm by specifying a key encryption algorithm property. The property name is: `com.ibm.wsspi.wssecurity.enc.rsaoaep.DigestMethod`. The property value is one of the following URIs of the digest method:
     - `http://www.w3.org/2001/04/xmlenc#sha256`
     - `http://www.w3.org/2001/04/xmlenc#sha512`

     By default, the RSA-OAEP algorithm uses a null string for the optional encoding octet string for the OAEPParams. You can provide an explicit encoding octet string by specifying a key encryption algorithm property. For the property name, you can specify `com.ibm.wsspi.wssecurity.enc.rsaoaep.OAEPparams`. The property value is the base 64-encoded value of the octet string.

     Important: You can set these digest method and OAEPParams properties on the generator side only. On the consumer side, these properties are read from the incoming SOAP message.
   - http://www.w3.org/2001/04/xmlenc#rsa-1_5
   - http://www.w3.org/2001/04/xmlenc#kw-tripledes

- http://www.w3.org/2001/04/xmlenc#kw-aes128
- http://www.w3.org/2001/04/xmlenc#kw-aes256

  To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.
- http://www.w3.org/2001/04/xmlenc#kw-aes192

  To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

  Restriction: Do not use this algorithm, the 192-bit key encryption algorithm, if you want your configured application to be in compliance with the Basic Security Profile (BSP).

If you select **None**, the key is not encrypted.

The key encryption algorithm that you select for the generator side must match the key encryption algorithm that you select for the consumer side.

6. Select a encryption key configuration from the Encryption key information field. This attribute specifies the name of the key that is used to encrypt the message. To configure the key information, see "Configuring the key information for the generator binding using JAX-RPC on the server level" on page 3375.
7. Click **OK** and then click **Save** to save the configuration.

Results

You have configured the encryption information for the generator binding at the server or cell level.

What to do next

You must specify a similar encryption information configuration for the consumer.

Configuring encryption to protect message confidentiality at the server level:

The encryption information for the default consumer specifies how to process the encryption information on the receiver side if these bindings are not defined at the application level. WebSphere Application Server provides default values for the bindings. However, an administrator must modify the defaults for a production environment.

About this task

Complete the following steps to configure the encryption information for the consumer binding on the server level:

Procedure

1. Access the default bindings for the server level.
   a. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
   b. Under Security, click **JAX-WS and JAX-RPC security runtime**.

      Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
2. Under Default consumer bindings, click **Encryption information**.
3. Click **New** to create an encryption information configuration, click **Delete** to delete an existing configuration, or click the name of an existing encryption information configuration to edit the settings. If you are creating a new configuration, enter a unique name for the encryption configuration in the Encryption information name field. For example, you might specify `con_encinfo`.

4. Select a data encryption algorithm from the Data encryption algorithm field. This algorithm is used to encrypt the data. WebSphere Application Server supports the following pre-configured algorithms:
   - http://www.w3.org/2001/04/xmlenc#tripledes-cbc
   - http://www.w3.org/2001/04/xmlenc#aes128-cbc
   - http://www.w3.org/2001/04/xmlenc#aes256-cbc

     To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.
   - http://www.w3.org/2001/04/xmlenc#aes192-cbc

     To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

     Restriction: Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

     Important: Your country of origin might have restrictions on the import, possession, use, or re-export to another country, of encryption software. Before downloading or using the unrestricted policy files, you must check the laws of your country, its regulations, and its policies concerning the import, possession, use, and re-export of encryption software, to determine if it is permitted.

   The data encryption algorithm that you select for the consumer side must match the data encryption algorithm that you select for the generator side.
5. Select a key encryption algorithm from the Key encryption algorithm field. This algorithm is used to encrypt the key. WebSphere Application Server supports the following pre-configured algorithms:
   - http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p.

     When running with Software Development Kit (SDK) Version 1.4, the list of supported key transport algorithms does not include this one. This algorithm appears in the list of supported key transport algorithms when running with SDK Version 1.5.

     Restriction: This algorithm is not supported when the WebSphere Application Server is running in Federal Information Processing Standard (FIPS) mode.
   - http://www.w3.org/2001/04/xmlenc#rsa-1_5
   - http://www.w3.org/2001/04/xmlenc#kw-tripledes
   - http://www.w3.org/2001/04/xmlenc#kw-aes128
   - http://www.w3.org/2001/04/xmlenc#kw-aes256

     To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.
   - http://www.w3.org/2001/04/xmlenc#kw-aes192

     To use this algorithm, you must download the unrestricted Java Cryptography Extension (JCE) policy file from the following website: http://www.ibm.com/developerworks/java/jdk/security/index.html.

     Restriction: Do not use the 192-bit key encryption algorithm if you want your configured application to be in compliance with the Basic Security Profile (BSP).

   If you select **None**, the key is not encrypted.

   The key encryption algorithm that you select for the consumer side must match the key encryption algorithm that you select for the generator side.
6. Under Additional properties, click **Key information references**.

7. Click **New** to create a key information configuration, click **Delete** to delete an existing configuration, or click the name of an existing key information configuration to edit the settings. If you are creating a new configuration, enter a unique name for the key information configuration in the name field. For example, you might specify `con_enckeyinfo`.
8. Select a key information reference from the Key information reference field. This selection refers to the name of the key information that is used for encryption. For more information, see "Configuring the key information for the consumer binding using JAX-RPC on the server level" on page 3377.
9. Click **OK** and **Save** to save the configuration.

Results

You have configured the encryption information for the consumer binding at the server level.

What to do next

You must specify a similar encryption information configuration for the generator.

Configuring token generators using JAX-RPC to protect message authenticity at the server level:

The token generator on the server level is used to specify the information for the token generator if these bindings are not defined at the application level. The signing information and the encryption information can share the token generator information, which is why they are all defined at the same level.

About this task

WebSphere Application Server provides default values for bindings. You must modify the defaults for a production environment.

Complete the following steps to configure the token generators on the server level:

Procedure

1. Access the default bindings for the server level.
   a. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
   b. Under Security, click **JAX-WS and JAX-RPC security runtime**.

      Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
2. Under Default generator bindings, click **Token generators**.
3. Click **New** to create a token generator configuration, click **Delete** to delete an existing configuration, or click the name of an existing token generator configuration to edit its settings. If you are creating a new configuration, enter a unique name for the token generator configuration in the **Token generator name** field. For example, you might specify `sig_tgen`. This field specifies the name of the token generator element.
4. Specify a class name in the **Token generator class name** field. The Java Authentication and Authorization Service (JAAS) Login Module implementation is used to create the security token on the generator side.

   Restriction: The com.ibm.wsspi.wssecurity.token.TokenGeneratorComponent interface is not used with JAX-WS web services. If you are using JAX-RPC web services, this interface is still valid.

   The token generator class name must be similar to the token consumer class name. For example, if your application requires an X.509 certificate token consumer, you can specify the com.ibm.wsspi.wssecurity.token.X509TokenConsumer class name on the Token consumer panel and

the com.ibm.wsspi.wssecurity.token.X509TokenGenerator class name in this field. WebSphere Application Server provides the following default token generator class implementations:

com.ibm.wsspi.wssecurity.token.UsernameTokenGenerator
This implementation generates a username token.

com.ibm.wsspi.wssecurity.token.X509TokenGenerator
This implementation generates an X.509 certificate token.

com.ibm.wsspi.wssecurity.token.LTPATokenGenerator
This implementation generates a Lightweight Third Party Authentication (LTPA) token.

5. Select a certificate path option. The certificate path specifies the certificate revocation list (CRL), which is used for generating a security token that is wrapped in a PKCS#7 with a CRL. WebSphere Application Server provides the following certificate path options:

   None Select this option in case the CRL is not used for generating a security token. You must select this option when the token generator does not use the PKCS#7 token type.

   Dedicated signing information
   If the CRL is wrapped in a security token, select **Dedicated signing information** and select a collection certificate store name from the **Certificate store** field. The **Certificate store** field shows the names of collection certificate stores already defined.

6. Select the **Add nonce** option to include a nonce in the user name token for the token generator. Nonce is a unique cryptographic number that is embedded in a message to help stop repeat, unauthorized attacks of user name tokens. The **Add nonce** option is available if you specify a user name token for the token generator.
7. Select the **Add timestamp** option to include a time stamp in the user name token for the token generator.
8. Specify a value type local name in the **Local name** field. This entry specifies the local name of the value type for a security token that is referenced by the key identifier. This attribute is valid when **Key identifier** is selected as Key information type. To specify the Key information type, see “Configuring the key information for the generator binding using JAX-RPC on the server level” on page 3375. WebSphere Application Server provides the following predefined X.509 certificate token configurations:

   X.509 certificate token
   http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3

   X.509 certificates in a PKIPath
   http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1

   A list of X.509 certificates and CRLs in a PKCS#7
   http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7

   LTPA For LTPA, the value type local name is LTPA. If you enter `LTPA` for the local name, you must specify the http://www.ibm.com/websphere/appserver/tokentype/5.0.2 uniform resource identifier (URI) value in the **Value type URI** field as well.

   LTPA version 2
   For LTPA version 2, the value type local name is LTPAv2. If you enter LTPAv2 for the local name, you must specify the http://www.ibm.com/websphere/appserver/tokentype uniform resource identifier (URI) value in the **Value type URI** field as well.

   LTPA_PROPAGATION
   For LTPA token propagation, the value type local name is `LTPA_PROPAGATION`. If you enter `LTPA_PROPAGATION` for the local name, you must specify the `http://www.ibm.com/websphere/appserver/tokentype` URI value in the **Value type URI** field as well.

For example, when an X.509 certificate token is specified, you can use `http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3` for the local name.

9. Specify the value type URI in the **URI** field. This entry specifies the namespace URI of the value type for a security token that is referenced by the key identifier. This attribute is valid when **Key identifier** is selected as Key information type on the Key information panel for the default generator. When the X.509 certificate token is specified, you do not need to specify the namespace URI. If another token is specified, you must specify the namespace URI of the value type.
10. Click **OK** and then **Save** to save the configuration.
11. Click the name of your token generator configuration.
12. Under Additional properties, click **Callback handler** to configure the callback handler properties. The callback handler specifies how to acquire the security token that is inserted in the Web Services Security header within the SOAP message. The token acquisition is a pluggable framework that leverages the Java Authentication and Authorization Service (JAAS) `javax.security.auth.callback.CallbackHandler` interface for acquiring the security token.
    a. Specify a callback handler class implementation in the **Callback handler class name** field. This attribute specifies the name of the Callback handler class implementation that is used to plug in a security token framework. The specified callback handler class must implement the `javax.security.auth.callback.CallbackHandler` class. WebSphere Application Server provides the following default callback handler implementations:

    com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler
    This callback handler uses a login prompt to gather the user name and password information. However, if you specify the user name and password on this panel, a prompt is not displayed and WebSphere Application Server returns the user name and password to the token generator. Use this implementation for a Java Platform, Enterprise Edition (Java EE) application client only.

    com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler
    This callback handler does not issue a prompt and returns the user name and password if it is specified in the basic authentication section of this panel. You can use this callback handler when the web service is acting as a client.

    com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler
    This callback handler uses a standard-in prompt to gather the user name and password. However, if the user name and password is specified in the basic authentication section of this panel, WebSphere Application Server does not issue a prompt, but returns the user name and password to the token generator. Use this implementation for a Java Platform, Enterprise Edition (Java EE) application client only.

    com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler
    This callback handler is used to obtain the Lightweight Third Party Authentication (LTPA) security token from the Run As invocation Subject. This token is inserted in the Web Services Security header within the SOAP message as a binary security token. However, if the user name and password are specified in the basic authentication section of this panel, WebSphere Application Server authenticates the user name and password to obtain the LTPA security token. It obtains the security token this way rather than obtaining it from the Run As Subject. Use this callback handler only when the web service is acting as a client on the application server. It is recommended that you do not use this callback handler on a Java EE application client.

    com.ibm.wsspi.wssecurity.auth.callback.X509CallbackHandler
    This callback handler is used to create the X.509 certificate that is inserted in the Web Services Security header within the SOAP message as a binary security token. A keystore file and a key definition are required for this callback handler.

    com.ibm.wsspi.wssecurity.auth.callback.PKCS7CallbackHandler
    This callback handler is used to create X.509 certificates that are encoded with the PKCS#7 format. The certificate is inserted in the Web Services Security header in the

SOAP message as a binary security token. A keystore file is required for this callback handler. You must specify a certificate revocation list (CRL) in the collection certificate store. The CRL is encoded with the X.509 certificate in the PKCS#7 format. For more information on configuring the collection certificate store, see “Configuring the collection certificate on the server level” on page 3433.

com.ibm.wsspi.wssecurity.auth.callback.PkiPathCallbackHandler
This callback handler is used to create X.509 certificates that are encoded with the PkiPath format. The certificate is inserted in the Web Services Security header within the SOAP message as a binary security token. A keystore file is required for this callback handler. A CRL is not supported by the callback handler; therefore, the collection certificate store is not required or used.

For an X.509 certificate token, you might specify the `com.ibm.wsspi.wssecurity.auth.callback.X509CallbackHandler` implementation.

b. Optional: Select the **Use identity assertion** option. Select this option if you have identity assertion that is defined in the IBM extended deployment descriptor. This option indicates that only the identity of the initial sender is required and inserted into the Web Services Security header within the SOAP message. For example, WebSphere Application Server sends only the user name of the original caller for a user name token generator. For an X.509 token generator, the application server sends the original signer certification only.

c. Optional: Select the **Use RunAs identity** option. Select this option if the following conditions are true:
   - You have identity assertion defined in the IBM extended deployment descriptor.
   - You want to use the Run As identity instead of the initial caller identity for identity assertion for a downstream call.

d. Optional: Specify a basic authentication user ID and password in the **User ID** and **Password** fields. This entry specifies the user name and password that is passed to the constructors of the callback handler implementation. The basic authentication user ID and password are used if you specify one of the following default callback handler implementations that are provided by WebSphere Application Server:
   - com.ibm.wsspi.wssecurity.auth.callback.GUIPromptCallbackHandler
   - com.ibm.wsspi.wssecurity.auth.callback.LTPATokenCallbackHandler
   - com.ibm.wsspi.wssecurity.auth.callback.NonPromptCallbackHandler
   - com.ibm.wsspi.wssecurity.auth.callback.StdinPromptCallbackHandler

e. Optional: Specify a keystore password and path. The keystore and its related information are necessary when the key or certificate is used for generating a token. For example, the keystore information is required if you select one of the following default callback handler implementations that are provided by WebSphere Application Server:
   - com.ibm.wsspi.wssecurity.auth.callback.PKCS7CallbackHandler
   - com.ibm.wsspi.wssecurity.auth.callback.PkiPathCallbackHandler
   - com.ibm.wsspi.wssecurity.auth.callback.X509CallbackHandler

   The keystore files contain public and private keys, root certificate authority (CA) certificates, intermediate CA certificates, and so on. Keys that are retrieved from the keystore file are used to sign and validate or encrypt and decrypt messages or message parts. To retrieve a key from a keystore file, you must specify the keystore password, the keystore path, and the keystore type.

13. Select a keystore type from the **Type** field. WebSphere Application Server provides the following options:

JKS Use this option if you are not using Java Cryptography Extensions (JCE) and if your keystore file uses the Java Keystore (JKS) format.

JCEKS
Use this option if you are using Java Cryptography Extensions.

PKCS11KS (PKCS11)
Use this format if your keystore file uses the PKCS#11 file format. Key store files using this format might contain RSA keys on cryptographic hardware or might encrypt the keys that use cryptographic hardware to ensure protection.

PKCS12KS (PKCS12)
Use this option if your keystore file uses the PKCS#12 file format.

14. Click **OK** and then **Save** to save the configuration.
15. Click the name of your token generator configuration.
16. Under Additional properties, click **Callback handler** > **Keys**.
17. Click **New** to create a key configuration, click **Delete** to delete an existing configuration, or click the name of an existing key configuration to edit its settings. If you are creating a new configuration, enter a unique name for the key configuration in the **Key name** field. This name refers to the name of the key object that is stored within the keystore file.
18. Specify an alias for the key object in the **Key alias** field. Use the alias when the key locator searches for the key objects in the keystore.
19. Specify the password that is associated with the key in the **Key password** field.
20. Click **OK** and **Save** to save the configuration.

Results

You have configured the token generators at the server level.

What to do next

You must specify a similar token consumer configuration.

Token generator collection:

Use this page to view the token generators. The information is used on the generator side only to generate the security token.

To view this administrative console page for the server level, complete the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under JAX-RPC Default Generator Bindings, click **Token generators**.

Token generator name:

Specifies the name of the token generator configuration.

For example, the default X509 token generator names are either `gen_enctgen` for encrypting or `gen_signtgen` for signing. Or a custom token generator name might be `sig_tgen` for signing.

Token generator class name:

Specifies the name of the token generator implementation class.

This class must implement the `com.ibm.wsspi.wssecurity.token.TokenGeneratorComponent` interface.

Token generator class name:

Specifies the name of the token generator implementation class.

The Java Authentication and Authorization Service (JAAS) Login Module implementation is used to create the security token on the generator side.

Token generator configuration settings:

Use this page to specify the information for the token generator. The information is used at the generator side only to generate the security token.

To view this administrative console page for the server level, complete the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under JAX-RPC Default Generator Bindings, click **Token generators** > ***token_generator_name*** or click **New** to create a new token generator.

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Under Modules, click **Manage modules** > ***URI_name***.
3. Under Additional properties, you can access the token generator information for the following bindings:
   - For the Request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
   - For the Response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
4. Click **New** to create a new token generator or click the name of an existing token generator name to specify its settings.

To view this administrative console page for the application level, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Under Modules, click **Manage modules** > ***URI_name***.
3. Under Web Services Security Properties, click **Web services: Client security bindings**.
4. Under Request generator (sender) binding, click **Edit custom**.
5. Under Additional properties, click **Token generators** > **New**.

Before specifying additional properties, specify a value in the **Token generator name** and the **Token generator class name** fields.

Token generator name:

Specifies the name of the token generator configuration.

For example, the default X509 token generator names are either `gen_enctgen` for encrypting or `gen_signtgen` for signing. Or, a custom token generator name might be `sig_tgen` for signing.

Token generator class name:

Specifies the name of the token generator implementation class.

This class must implement the `com.ibm.wsspi.wssecurity.token.TokenGeneratorComponent` interface.

Token generator class name:

Specifies the name of the token generator implementation class.

Certificate path:

Specifies the certificate revocation list (CRL) that is used for generating a security token wrapped in a PKCS#7 token type with CRL.

When the token generator is not for a PKCS#7 token type, you must select **None**. When the token generator is for the PKCS#7 token type and you want to package CRL in the security token, select **Dedicated signing information** and specify the CRL for the collection certificate store.

You can specify a certificate store configuration for the following bindings on the following levels:

Table 314. Certificate path binding settings. The certificate is used for signing messages.

Binding name	Server level or application level	Path
Default generator bindings	Server level	1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***. 2. Under Security, click **JAX-WS and JAX-RPC security runtime**. **Note:** In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**. 3. Under Additional properties, click **Collection certificate store**.

Using the collection certificate store, you can configure a related certificate revocation list by clicking **Certificate revocation list** under Additional properties.

Add nonce:

Indicates whether nonce is included in the user name token for the token generator. *Nonce* is a unique cryptographic number that is embedded in a message to help stop repeat, unauthorized attacks of user name tokens.

On the application level, if you select the **Add nonce** option, you can specify the following properties under Additional properties:

Table 315. Additional nonce properties. Nonce is used to add additional security to a message.

Property name	Default value	Explanation
`com.ibm.ws.wssecurity.config.token. BasicAuth.Nonce.cacheTimeout`	600 seconds	Specifies the timeout value, in seconds, for the nonce value that is cached on the server.
`com.ibm.ws.wssecurity.config.token. BasicAuth.Nonce.clockSkew`	0 seconds	Specifies the time, in seconds, before the nonce time stamp expires.
`com.ibm.ws.wssecurity.config.token. BasicAuth.Nonce.maxAge`	300 seconds	Specifies the clock skew value, in seconds, to consider when the application server checks the timeliness of the message.

These properties are available on the administrative console at the cell and server level. However, on the application level, you can configure the properties under Additional properties.

This option is displayed on the cell, server, and application levels. This option is valid only when the generated token type is a user name token.

Add timestamp:

Specifies whether to insert the time stamp into the user name token.

This option is displayed on the cell, server, and application levels. This option is valid only when the generated token type is a user name token.

Value type local name:

Specifies the local name of the value type for the generated token.

For a user name token and an X.509 certificate security token, this product provides predefined value types. When you specify the following local names, you do not need to specify the Uniform Resource Identifier (URI) of value type.

Username token
http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken

X509 certificate token
http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3

X509 certificates in a PKIPath
http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1

A list of X509 certificates and CRLs in a PKCS#7
http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7

Lightweight Third Party Authentication (LTPA)

LTPA_PROPAGATION

Important: For LTPA, the value type local name is `LTPA`. If you enter `LTPA` for the local name, you must specify the `http://www.ibm.com/websphere/appserver/tokentype/5.0.2` URI value in the Value type URI field as well. For LTPA token propagation, the value type local name is `LTPA_PROPAGATION`. If you enter `LTPA_PROPAGATION` for the local name, you must specify the `http://www.ibm.com/websphere/appserver/tokentype` URI value in the Value type URI field as well. For the other predefined value types (Username token, X509 certificate token, X509 certificates in a PKIPath, and a list of X509 certificates and CRLs in a PKCS#7), the value for the local name field begins with `http://`. For example, if you are specifying the user name token for the value type, enter `http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken` in the Value type local name field and then you do not need to enter a value in the Value type URI field.

When you specify a custom value type for custom tokens, you can specify the local name and the URI of the quality name (QName) of the value type. For example, you might specify `Custom` for the local name and `http://www.ibm.com/custom` for the URI.

Value type URI:

Specifies the namespace URI of the value type for the generated token.

When you specify the token generator for the user name token or the X.509 certificate security token, you do not need to specify this option. If you want to specify another token, specify the URI of the QName of the value type.

The application server provides the following predefined value type URIs:

- For the LTPA token: http://www.ibm.com/websphere/appserver/tokentype/5.0.2
- For the LTPA token propagation: http://www.ibm.com/websphere/appserver/tokentype

Algorithm URI collection:

Use this page to view a list of uniform resource identifier (URI) algorithms for XML digital signature or XML encryption that are mapped to an algorithm factory engine class. With algorithm mappings, service providers can use other cryptographic algorithms for digest value calculation, digital signature signing and verification, data encryption and decryption, and key encryption and decryption.

To view administrative console page on the server level, complete the following steps:

1. Click **Servers > Server Types > WebSphere application servers >** ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under Additional properties, click **Algorithm mappings**.
4. Click on an algorithm mapping name.
5. Under Additional properties, click **Algorithm URI**.

Algorithm URI:

Specifies the algorithm uniform resource identifier (URI) for the specified algorithm type.

Algorithm type:

Specifies the algorithm type.

Algorithm URI configuration settings:

Use this page to specify the algorithm uniform resource identifier (URI) and its usage type.

This product supports the following algorithm URI types:

Message digest
Specifies the algorithm URI that is used for digest value calculation.

Signature
Specifies the algorithm URI that is used for digital signature, including both signature and signing verification.

Data encryption
Specifies the algorithm URI that is used for both encrypting and decrypting data.

Key encryption
Specifies the algorithm URI that is used for encrypting and decrypting the encryption key.

If the URI is used for multiple usage types, then you must define a mapping of the URI to each usage type.

To view this administrative console page on the server level, complete the following steps:

1. Click **Servers > Server Types > WebSphere application servers >** *server_name*.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under Additional properties, click **Algorithm mappings**.

   Note: The Algorithm mappings feature is not supported when the **Use the Federal Information Processing Standard (FIPS)** option has been selected on the SSL certificate and key

management panel of the administrative console. When this option is selected, the **New** button in the Algorithm mappings panel is not available.

4. Click **New**.
5. Under Additional properties, click **Algorithm URI** > ***algorithm_URI_name***.

To view the administrative console page on the cell level:

1. Click **Security > JAX-WS and JAX-RPC security runtime**, or **Services > JAX-WS and JAX-RPC security runtime**.
2. Under Additional properties, click **Algorithm mappings**.
3. Click **New**.
4. Under Additional properties, click **Algorithm URI** > ***algorithm_URI_name***.

Algorithm URI:

Specifies the algorithm uniform resource identifier (URI) for the specified algorithm type.

The algorithm URI that is defined on this page is available to the various binding configurations. For example, if you specify an algorithm URI and select **Signature** from the Algorithm type field, the URI displays in the Signature method field on the signing information panel.

Algorithm type:

Specifies the type of algorithm that is specified in the Algorithm URI field.

The following types of algorithms are supported by this product. The following list shows where configurations that are specified on this panel are displayed for a binding configuration:

Table 316. Algorithm types. The algorithm types in the table are supported by the product.

Algorithm type	Explanation	Location of the configuration
Signature	This algorithm type is used for digital signatures.	This configuration displays in the Signature method field on the Signing information panel. For information on how to access the Signing information panel, see the help topic Signing information configuration settings.
Digest value calculation (message digest)	This algorithm type is used for calculating the digest value.	This configuration displays in the Digest method algorithm field on the Part references panel. For information on how to access the Part references panel, see the help topic Part reference configuration settings.
Data encryption	This algorithm type is used for encrypting data.	This configuration displays in the Data encryption algorithm field on the Encryption information panel. For information on how to access the Encryption information panel, see the help topic Encryption information configuration settings: Message parts.
Key encryption	This algorithm type is used for encrypting the key that is used for data encryption.	This configuration displays in the Key encryption algorithm field on the Encryption information panel. For information on how to access the Encryption information panel, see the help topic Encryption information configuration settings: Message parts.

The actual implementation of the algorithm is done in the implementation class for the engine factory.

Algorithm mapping collection:

You can view a list of custom uniform resource identifier (URI) algorithms for digest value calculation, signature, key encryption, and data encryption. The application server maps these algorithms to an implementation of the algorithm factory engine interface. With algorithm mappings, service providers can extend the cryptographic algorithms for XML digital signature and XML encryption.

To view this administrative console page on the cell level, complete the following steps:

1. Click **Security > JAX-WS and JAX-RPC security runtime**.
2. Under Additional properties, click **Algorithm mappings**.

To view this administrative console page on the server level, complete the following steps:

1. Click **Servers > Server Types > WebSphere application servers >** ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under Additional properties, click **Algorithm mappings**.

Algorithm factory engine class:

Specifies the custom class that implements the engine factory implementation class for the algorithm factory engine.

The implementation class for the engine factory implements the cryptographic functions of the defined uniform resource identifier (URI).

Note: The Algorithm mappings feature is not supported when the **Use the Federal Information Processing Standard (FIPS) algorithms** option has been selected on the Global security panel of the administrative console. When this option is selected, the **New** button in the Algorithm mappings panel is not available.

Algorithm mapping configuration settings:

Use this page to view a list of custom uniform resource identifier (URI) algorithms for digest value calculation, signature, key encryption, and data encryption. The application server maps these algorithms to an implementation of the algorithm factory engine interface. With algorithm mappings, service providers can extend the cryptographic algorithms for XML digital signature and XML encryption.

To view this administrative console page on the server level, complete the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under Additional properties, click **Algorithm mappings*****algorithm_factory_engine_class_name***.

   Note: The Algorithm mappings feature is not supported when the **Use the Federal Information Processing Standard (FIPS)** option has been selected on the SSL certificate and key management panel of the administrative console. When this option is selected, the **New** button in the Algorithm mappings panel is not available.
4. Click **New**.

To view this administrative console page on the cell level:

1. Click **Security** > **JAX-WS and JAX-RPC security runtime**, or **Services** > **JAX-WS and JAX-RPC security runtime**.
2. Under Additional properties, click **Algorithm mappings** > ***algorithm_factory_engine_class_name***.
3. Click **New**.

Algorithm factory engine class:

Specifies the custom class that implements the engine factory interface.

To use this algorithm mapping feature, you must specify a custom algorithm class in the Algorithm factory engine class field for digital signature, data encryption, digest value calculation, and key encryption. The

algorithm factory engine provides a plug-in point for service providers to provide their implementation for digest value calculation, digital signature, key encryption, and data encryption that is based on a specified algorithm uniform resource identifier (URI). By clicking **Algorithm URI** under Additional properties, you can specify the algorithm URI and its usage type. This product supports the following algorithm types:

Message digest
Specifies the algorithm URI that is used for digest value calculation.

Signature
Specifies the algorithm URI that is used for digital signatures including both signing and signature verification.

Data encryption
Specifies the algorithm URI that is used for both encrypting and decrypting data.

Key encryption
Specifies the algorithm URI that is used for both encrypting and decrypting the encryption key.

If the URI is used for multiple usage types, then you must define a mapping of the URI to each usage type. The actual implementation of the algorithm is provided by the custom class that implements the engine factory interface. For more information, refer to the information center documentation on how to implement a factory class.

By clicking **Properties** under Additional properties, you can specify name-value pair properties for the factory class.

Configuring token consumers using JAX-RPC to protect message authenticity at the server level:

The token consumer on the server level is used to specify the information that is needed to process the security token if it is not defined at the application level.

About this task

WebSphere Application Server provides default values for bindings. You must modify the defaults for a production environment.

Complete the following steps to configure the token consumers on the server level.

Procedure

1. Access the default bindings for the server level.
   a. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
   b. Under Security, click **JAX-WS and JAX-RPC security runtime**.

      Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
2. Under Default consumer bindings, click **Token consumers**.
3. Click **New** to create a token consumer configuration, click **Delete** to delete an existing configuration, or click the name of an existing token consumer configuration to edit its settings. If you are creating a new configuration, enter a unique name for the token consumer configuration in the **Token consumer name** field. For example, you might specify `sig_tcon`. This field specifies the name of the token consumer element.
4. Specify a class name in the Token consumer class name field. The Java Authentication and Authorization Service (JAAS) Login Module implementation is used to validate (authenticate) the security token on the consumer side.

Restriction: The com.ibm.wsspi.wssecurity.token.TokenConsumingComponent interface is not used with JAX-WS web services. If you are using JAX-RPC web services, this interface is still valid.

The token consumer class name must be similar to the token generator class name.

For example, if your application requires an X.509 certificate token consumer, you can specify the com.ibm.wsspi.wssecurity.token.X509TokenGenerator class name on the Token generator panel and the com.ibm.wsspi.wssecurity.token.X509TokenConsumer class name in this field. WebSphere Application Server provides the following default token consumer class implementations:

com.ibm.wsspi.wssecurity.token.UsernameTokenConsumer
This implementation integrates a user name token.

com.ibm.wsspi.wssecurity.token.X509TokenConsumer
This implementation integrates an X.509 certificate token.

com.ibm.wsspi.wssecurity.token.LTPATokenConsumer
This implementation integrates a Lightweight Third Party Authentication (LTPA) token.

com.ibm.wsspi.wssecurity.token.IDAssertionUsernameTokenConsumer
This implementation integrates an IDAssertionUsername token.

A corresponding token generator class does not exist for this implementation.

5. Select a certificate path option. The certificate path specifies the certificate revocation list (CRL) that is used for generating a security token wrapped in a PKCS#7 with a CRL. WebSphere Application Server provides the following certificate path options:

   None If you select this option, the certificate path is not specified.

   Trust any
   If you select this option, any certificate is trusted. When the received token is consumed, the certificate path validation is not processed.

   Dedicated signing information
   If you select this option, you can specify a trust anchor and a certificate store. When you select the trust anchor or the certificate store of a trusted certificate, you must configure the collection certificate store before setting the certificate path. To define a collection certificate store on the server level, see “Configuring the collection certificate on the server level” on page 3433.

   a. Select a trust anchor in the Trust anchor field. WebSphere Application Server provides two sample trust anchors. However, it is recommended that you configure your own trust anchors for a production environment. For information on configuring a trust anchor, see “Configuring trust anchors on the server level” on page 3422.
   b. Select a collection certificate store in the Certificate store field. WebSphere Application Server provides a sample collection certificate store. If you select **None**, the collection certificate store is not specified. For information on specifying a list of certificate stores that contain untrusted, intermediary certificate files awaiting validation, see “Configuring trusted ID evaluators on the server level” on page 3435.

6. Select a trusted ID evaluator from the Trusted ID evaluation reference field. This field specifies a reference to the Trusted ID evaluator class name that is defined in Trusted ID evaluators panel. The trusted ID evaluator is used for evaluating whether the received ID is trusted. If you select **None**, the trusted ID evaluator is not referenced in this token consumer configuration. To configure a trusted ID evaluator, see “Configuring trusted ID evaluators on the server level” on page 3435.
7. Select the **Verify nonce** option if a nonce is included in a user name token on the generator side. Nonce is a unique cryptographic number that is embedded in a message to help stop repeat, unauthorized attacks of user name tokens. The **Verify nonce** option is available if you specify a user name token for the token consumer and nonce is added to the user name token on the generator side.

8. Select the **Verify timestamp** option if a time stamp is included in the user name token on the generator side. The **Verify Timestamp** option is available if you specify a user name token for the token consumer and a time stamp is added to the user name token on the generator side.
9. Specify the local name of the value type for the integrated token. This entry specifies the local name of the value type for a security token that is referenced by the key identifier. This attribute is valid when **Key identifier** is selected as the key information type. To specify the key information type, see "Configuring the key information for the consumer binding using JAX-RPC on the server level" on page 3377. WebSphere Application Server has predefined value type local names for the user name token and the X.509 certificate security token. Enter one of the following local names for the user name token and the X.509 certificate security token. When you specify the following local names, you do not need to specify the URI of the value type:

   Username token
   http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken

   X.509 certificate token
   http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3

   X.509 certificates in a PKIPath
   http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1

   A list of X.509 certificates and CRLs in a PKCS#7
   http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7

   Note: To specify Lightweight Third Party Authentication (LTPA) or token propagation (LTPA_PROPAGATION), you must specify both the value type local name and the Uniform Resource Identifier (URI). For LTPA, specify `LTPA` for the local name and `http://www.ibm.com/websphere/appserver/tokentype/5.0.2` for the URI. For LTPA token propagation, specify `LTPA_PROPAGATION` for the local name and `http://www.ibm.com/websphere/appserver/tokentype` for the URI.

   For example, when an X.509 certificate token is specified, you can use `http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3` for the local name. When you specify the local name of another token, you must specify a value type Qname. For example: uri=`http://www.ibm.com/custom`, localName=`CustomToken`
10. Specify the value type uniform resource identifier (URI) in the URI field. This entry specifies the namespace URI of the value type for a security token that is referenced by the key identifier. This attribute is valid when **Key identifier** is selected as the key information type on the Key information panel for the default generator. When you specify the token consumer for the user name token or an X.509 certificate security token, you do not need to specify this option. If you specify another token, you need to specify the URI of the QName for the value type.
11. Click **OK** and then **Save** to save the configuration. After saving the token generator configuration, you can specify a JAAS configuration for your token consumer.
12. Click the name of your token generator configuration.
13. Under Additional properties, click **JAAS configuration**.
14. Select a JAAS configuration from the JAAS configuration name field.

    The field specifies the name of the JAAS system for application login configuration. You can specify additional JAAS system and application configurations by clicking **Security** > **Global security**. Expand Java Authentication and Authorization Service, then click **Application logins** > **New** or **System logins** > **New**. Do not remove the predefined system or application login configurations. However, within these configurations, you can add module class names and specify the order in which WebSphere Application Server loads each module. WebSphere Application Server provides the following predefined JAAS configurations:

    ClientContainer
    This selection specifies the login configuration that is used by the client container

applications. The configuration uses the CallbackHandler application programming interface (API) that is defined in the deployment descriptor for the client container. To modify this configuration, see the JAAS configuration panel for application logins.

WSLogin
This selection specifies whether all of the applications can use the WSLogin configuration to perform authentication for the security run time. To modify this configuration, see the JAAS configuration panel for application logins.

DefaultPrincipalMapping
This selection specifies the login configuration that is used by Java 2 Connectors (J2C) to map users to principals that are defined in the J2C authentication data entries. To modify this configuration, see the JAAS configuration panel for application logins.

system.wssecurity.IDAssertion
This selection enables a Version 5.*x* application to use identity assertion to map a user name to a WebSphere Application Server credential principal. To modify this configuration, see the JAAS configuration panel for system logins.

system.wssecurity.Signature
This selection enables a Version 5.*x* application to map a distinguished name (DN) in a signed certificate to a WebSphere Application Server credential principal. To modify this configuration, see the JAAS configuration panel for system logins.

system.LTPA_WEB
This selection processes login requests that are used by the web container such as servlets and JavaServer Pages (JSP) files. To modify this configuration, see the JAAS configuration panel for system logins.

system.WEB_INBOUND
This selection handles login requests for web applications, which include servlets and JavaServer Pages (JSP) files. This login configuration is used by WebSphere Application Server Version 5.1.1. To modify this configuration, see the JAAS configuration panel for system logins.

system.RMI_INBOUND
This selection handles logins for inbound Remote Method Invocation (RMI) requests. This login configuration is used by WebSphere Application Server Version 5.1.1. To modify this configuration, see the JAAS configuration panel for system logins.

system.DEFAULT
This selection handles the logins for inbound requests that are made by internal authentications and most of the other protocols except web applications and RMI requests. This login configuration is used by WebSphere Application Server Version 5.1.1. To modify this configuration, see the JAAS configuration panel for system logins.

system.RMI_OUTBOUND
This selection processes RMI requests that are sent outbound to another server when the `com.ibm.CSIOutboundPropagationEnabled` property is `true`. This property is set in the CSIv2 authentication panel. To access the panel, click **Security** > **Global security**. Under Authentication, expand **RMI/IIOP security** and click **CSIv2 outbound authentication**. To set the `com.ibm.CSIOutboundPropagationEnabled` property, select **Security attribute propagation**. To modify this JAAS login configuration, see the JAAS - System logins panel.

system.wssecurity.X509BST
This section verifies an X.509 binary security token (BST) by checking the validity of the certificate and the certificate path. To modify this configuration, see the JAAS configuration panel for system logins.

system.wssecurity.PKCS7
This selection verifies an X.509 certificate with a certificate revocation list in a PKCS7 object. To modify this configuration, see the JAAS configuration panel for system logins.

system.wssecurity.PkiPath
This section verifies an X.509 certificate with a public key infrastructure (PKI) path. To modify this configuration, see the JAAS configuration panel for system logins.

system.wssecurity.UsernameToken
This selection verifies the basic authentication (user name and password) data. To modify this configuration, see the JAAS configuration panel for system logins.

system.wssecurity.IDAssertionUsernameToken
This selection enables Versions 6 and later applications to use identity assertion to map a user name to a WebSphere Application Server credential principal. To modify this configuration, see the JAAS configuration panel for system logins.

system.WSS_INBOUND
This selection specifies the login configuration for inbound or consumer requests for security token propagation using Web Services Security. To modify this configuration, see the JAAS configuration panel for system logins.

system.WSS_OUTBOUND
This selection specifies the login configuration for outbound or generator requests for security token propagation using Web Services Security. To modify this configuration, see the JAAS configuration panel for system logins.

None With this selection, you do not specify a JAAS login configuration.

15. Click **OK** and then **Save** to save the configuration.

Results

You have configured the token consumer at the server level.

What to do next

You must specify a similar token generator configuration for the server level.

Token consumer collection:

Use this page to view the token consumer. The information is used on the consumer side only to process the security token.

To view this administrative console page for the server level, complete the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under Default Generator Bindings, click **Token consumers**.

To view this administrative console page for Version 6.*x* and later applications on the application level, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Click **Manage modules** > ***URI_name*** .

3. Under Web Services Security Properties, you can access the signing information for the following bindings:
   - For the Response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**. Under Required properties, click **Token consumers**.
   - For the Response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**. Under Required properties, click **Token consumers**.

Token consumer name:

Specifies the name of the token consumer configuration.

For example, the default X509 token consumer names can be either `con_enctcon` for encrypting or `con_signtcon` for signing. Or a custom token consumer name might be `sig_tcon` for signing.

Token consumer class name:

Specifies the name of the token consumer implementation class.

This class must implement the `com.ibm.wsspi.wssecurity.token.TokenConsumerComponent` interface.

Token consumer class name:

Specifies the name of the token consumer implementation class.

The Java Authentication and Authorization Service (JAAS) Login Module implementation is used to validate (authenticate) the security token on the consumer side.

Token consumer configuration settings:

Use this page to specify the information for the token consumer. The information is used at the consumer side only to process the security token.

To view this administrative console page for the server level, complete the following steps:
1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** .
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under JAX-RPC Default Consumer Bindings, click **Token consumers** > ***token_consumer_name*** or click **New** to create a new token consumer.

To view this administrative console page for Version 6 and later applications on the application level, complete the following steps:
1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Click **Manage modules** > ***URI_name***.
3. Under Web Services Security Properties, you can access the signing information for the following bindings:
   - For the Response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**. Under Required properties, click **Token consumers**.

- For the Response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**. Under Required properties, click **Token consumers**.

4. Click **New** to specify a new configuration or click the name of an existing configuration to modify its settings.

Before specifying additional properties, specify a value in the Token consumer name, the Token consumer class name, and the Value type local name fields.

Token consumer name:

Specifies the name of the token consumer configuration.

For example, the default X509 token consumer names are either `con_enctcon` for encrypting or `con_signtcon` for signing. Or a custom, the token consumer name might be `sig_tcon` for signing.

Token consumer class name:

Specifies the name of the token consumer implementation class.

This class must implement the `com.ibm.wsspi.wssecurity.token.TokenConsumerComponent` interface.

Token consumer class name:

Specifies the name of the token consumer implementation class.

The Java Authentication and Authorization Service (JAAS) Login Module implementation is used to validate (authenticate) the security token on the consumer side.

Part reference:

Specifies a reference to the name of the security token that is defined in the deployment descriptor.

On the application level, when the security token is not specified in the deployment descriptor, the Part reference field is not displayed.

Certificate path:

Specifies the trust anchor and the certificate store.

You can select the following options:

None If you select this option, the certificate path is not specified.

Trust any
If you select this option, any certificate is trusted. When the received token is incorporated, the certificate path validation is not processed.

Dedicated signing information
If you select this option, you can specify the trust anchor and the certificate store. When you select the trust anchor or the certificate store of a trusted certificate, you must configure the collection certificate store before setting the certificate path.

Trust anchor

You can specify a trust anchor for the following bindings on the following levels:

Table 317. Trust anchor binding settings. The trust anchor is used for signing messages.

Binding name	Server level or application level	Path
Default consumer binding	Server level	1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***. 2. Under Security, click **JAX-WS and JAX-RPC security runtime**. **Note:** In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**. 3. Under Additional properties, click **Trust anchors**.

Certificate store

You can specify a certificate path configuration for the following bindings on the following levels:

Table 318. Certificate store binding settings. The certificate is used for signing messages.

Binding name	Server level or application level	Path
Default consumer binding	Server level	1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***. 2. Under Security, click **JAX-WS and JAX-RPC security runtime**. **Note:** In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**. 3. Under Additional properties, click **Collection certificate store**.

Trusted ID evaluator reference:

Specifies the reference to the Trusted ID evaluator class name that is defined in the Trusted ID evaluators panel. The trusted ID evaluator is used for determining whether the received ID is trusted.

You can select the following options:

None If you select this option, the trusted ID evaluator is not specified.

Existing evaluator definition
If you select this option, you can select one of the configured trusted ID evaluators.

You can specify a certificate path configuration for the following bindings on the following levels:

Table 319. Trusted ID evaluator bindings settings. The trusted ID evaluator is used to determine if a received ID is trusted.

Binding name	Server level or application level	Path
Default consumer binding	Server level	1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***. 2. Under Security, click **JAX-WS and JAX-RPC security runtime**. **Note:** In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**. 3. Under Additional properties, click **Trusted ID evaluators**.

Binding evaluator definition
If you select this option, you can specify a new trusted ID evaluator and its class name.

When you select a trusted ID evaluator reference, you must configure the trusted ID evaluators before setting the token consumer.

The Trusted ID evaluator field is displayed in the default binding configuration and the application server binding configuration.

Verify nonce:

Specifies whether the nonce of the user name token is verified.

This option is displayed on the cell, server, and application levels. This option is valid only when the type of incorporated token is the user name token.

Verify timestamp:

Specifies whether the time stamp of user name token is verified.

This option is displayed on the cell, server, and application levels. This option is valid only when the type of incorporated token is the user name token.

Value type local name:

Specifies the local name of value type for the consumed token.

This product has predefined value type local names for the user name token and the X.509 certificate security token. Use the following local names for the user name token and the X.509 certificate security token. When you specify the following local names, you do not need to specify the Uniform Resource Identifier (URI) of the value type:

Username token
http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken

X509 certificate token
http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509v3

 # X509 certificates in a PKIPath
http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#X509PKIPathv1

A list of X509 certificates and CRLs in a PKCS#7
http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-x509-token-profile-1.0#PKCS7

Lightweight Third Party Authentication (LTPA)

LTPA_PROPAGATION

Important: For Lightweight Third Party Authentication (LTPA), the value type local name is `LTPA`. If you enter `LTPA` for the local name, you must specify the `http://www.ibm.com/websphere/appserver/tokentype/5.0.2` URI value in the Value type URI field as well. For LTPA token propagation, the value type local name is `LTPA_PROPAGATION`. If you enter `LTPA_PROPAGATION` for the local name, you must specify the `http://www.ibm.com/websphere/appserver/tokentype` URI value in the Value type URI field as well. For the other predefined value types (Username token, X509 certificate token, X509 certificates in a PKIPath, and a list of X509 certificates and CRLs in a PKCS#7), the value for the local name field begins with `http://`. For example, if you are specifying the username token for the value type, enter `http://docs.oasis-open.org/`

wss/2004/01/oasis-200401-wss-username-token-profile-1.0#UsernameToken in the value type local name field and then you do not need to enter a value in the value type URI field.

When you specify a custom value type for custom tokens, you can specify the local name and the URI of the Quality name (QName) of the value type. For example, you might specify Custom for the local name and http://www.ibm.com/custom for the URI.

Value type URI:

Specifies the namespace URI of the value type for the integrated token.

When you specify the token consumer for the user name token or the X.509 certificate security token, you do not need to specify this option. If you want to specify another token, specify the URI of the QName for the value type.

The application server provides the following predefined value type URIs:

- For the LTPA token: http://www.ibm.com/websphere/appserver/tokentype/5.0.2
- For the LTPA token propagation: http://www.ibm.com/websphere/appserver/tokentype

Configuring Web Services Security using JAX-RPC at the platform level

In the platform configuration, general properties and additional properties can be specified, and the default binding is included. You can configure security for web services at a platform level with a variety of tasks including configuring key locators, trust anchors, and the collection certificate at the generator, consumer binding, and sever levels.

Before you begin

best-practices: IBM WebSphere Application Server supports the Java API for XML-Based Web Services (JAX-WS) programming model and the Java API for XML-based RPC (JAX-RPC) programming model. JAX-WS is the next generation web services programming model extending the foundation provided by the JAX-RPC programming model. Using the strategic JAX-WS programming model, development of web services and clients is simplified through support of a standards-based annotations model. Although the JAX-RPC programming model and applications are still supported, take advantage of the easy-to-implement JAX-WS programming model to develop new web services applications and clients.

Besides the application-level constraints, there is a server-level Web Services Security (WSS) configuration called a *platform-level configuration*:

- These configurations are global for all applications and include some configurations only for WebSphere Application Server Version 5.*x* applications and some only for version 6.0.*x* applications.
- You can use the default binding as an application-level binding configuration so that applications do not have to define the binding in the application. There is only one set of default bindings that can be shared by multiple applications. This set is only available for WebSphere Application Server Version 6.*x* applications.

Therefore, binding configuration files can be specified at these levels: application and server. Each binding configuration overrides the next higher one. For any deployed application, the nearest configuration binding is applied. The visibility scope of the binding depends on where the file is located. If the binding is defined in an application, its visibility is scoped to that particular application. If it is located at the server level, the visibility scope is all applications that are deployed on that server.

About this task

To ensure Web Services Security at the platform level, you can configure:

- A nonce on the server level
- The key locator for the generator or consumer binding on the application level or at the server level
- Trust anchors for the generator or consumer binding on the application level or at the server level
- The collection certificate store for the generator or consumer binding on the application level or server level
- Trusted ID evaluators on the server level
- Hardware cryptographic devices for Web Services Security
- The `rrdSecurity.props` property file

Procedure

- To configure a nonce on the server level, see the steps in "Configuring a nonce on the server level"
- To configure the key locator for the generator binding on the application level, see the steps in "Configuring the key locator using JAX-RPC for the generator binding on the application level" on page 3405
- To configure the key locator for the consumer binding on the application level, see the steps in "Configuring the key locator using JAX-RPC for the consumer binding on the application level" on page 3412
- To configure the key locator on the server level, see the steps in "Configuring the key locator using JAX-RPC on the server level" on page 3414
- To configure trust anchors for the generator binding on the application level, see the steps in "Configuring trust anchors for the generator binding on the application level" on page 3416
- To configure trust anchors for the consumer binding on the application level, see the steps in "Configuring trust anchors for the consumer binding on the application level" on page 3420
- To configure trust anchors on the server level, see the steps in "Configuring trust anchors on the server level" on page 3422
- To configure the collection certificate store for the generator binding on the application level, see the steps in "Configuring the collection certificate store for the generator binding on the application level" on page 3423
- To configure the collection certificate store for the consumer binding on the application level, see the steps in "Configuring the collection certificate store for the consumer binding on the application level" on page 3431
- To configure the collection certificate on the server level, see the steps in "Configuring the collection certificate on the server level" on page 3433
- To configure trusted ID evaluators on the server level, see the steps in "Configuring trusted ID evaluators on the server level" on page 3435
- To enable hardware cryptographic devices for Web Services Security, see the steps in "Enabling hardware cryptographic devices for Web Services Security" on page 3440
- To work with the `rrdSecurity.props` file, see "rrdSecurity.props file" on page 3438

Results

By completing these steps, you have configured Web Services Security at the platform level.

Configuring a nonce on the server level:

You can configure nonce for the server by using the WebSphere Application Server administrative console.

About this task

Nonce is a randomly generated, cryptographic token that is used to prevent replay attacks of user name tokens that are used with SOAP messages. Typically, nonce is used with the user name token.

You can configure nonce at the application level and the server level. However, you must consider the order of precedence.

The following list shows the order of precedence:

1. Application level

   The application level settings for the nonce maximum age and nonce clock skew fields are specified through the additional properties.
2. Server level

If you configure nonce on the application level and the server level, the values that are specified for the application level take precedence over the values that are specified for the server level. Likewise, the values that are specified for the application level take precedence over the values specified for the server level. Complete the following steps to configure nonce on the server level:

Complete the following steps to configure a nonce on the server level:

Procedure

1. Access the default bindings for the server level.
   a. Click **Servers > Server Types > WebSphere application servers > *server_name***.
   b. Under Security, click **JAX-WS and JAX-RPC security runtime**.

      Note: In a mixed node cell with a server using WebSphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
2. Specify a value, in seconds, for the **Nonce cache timeout** field. The value that is specified for the **Nonce cache timeout** field indicates how long the nonce remains cached before it is discarded. You must specify a minimum of 300 seconds. However, if you do not specify a value, the default is 600 seconds. This field is optional on the server level.
3. Specify a value, in seconds, for the **Nonce maximum age** field. The value that is specified for the **Nonce maximum age** field indicates how long the nonce is valid. You must specify a minimum of 300 seconds, but the value cannot exceed the number of seconds that is specified for the **Nonce cache timeout** field. If you do not specify a value, the default is 300 seconds. This field is optional on the server level.
4. Specify a value, in seconds, for the **Nonce clock skew** field. The value that is specified for the **Nonce clock skew** field specifies the amount of time, in seconds, to consider when the message receiver checks the freshness of the value. Consider the following information when you set this value:
   - Difference in time between the message sender and the message receiver, if the clocks are not synchronized.
   - Time that is needed to encrypt and transmit the message.
   - Time that is needed to get through network congestion.

   At a minimum, you must specify 0 seconds in this field. However, the maximum value cannot exceed the number of seconds indicated in the Nonce maximum age field. If you do not specify a value, the default is 0 seconds. This field is optional on the server level.
5. Optional: For WebSphere Application Server, Network Deployment only, select **Distribute nonce caching**. This option enables you to distribute the caching for a nonce using a Data Replication Service (DRS). In previous releases of WebSphere Application Server, the nonce was cached locally. By selecting this option, the nonce is propagated to other servers in your environment. However, the nonce might be subject to a one-second delay in propagation and subject to any network congestion.

6. Restart the server. If you change the nonce cache timeout value and do not restart the server, the change is not recognized by the server.

Distributing nonce caching to servers in a cluster:

Distributed nonce caching enables you to distribute the cache for a nonce to different servers in a cluster.

Before you begin

Before configuring distributed nonce caching, configure cache replication.

About this task

In previous releases of WebSphere Application Server, the nonce was cached locally. To use this feature, you must complete the following actions:

Procedure

1. Verify that you created an appropriate domain setting when you form a cluster.
2. Verify that replication domain is properly secured. The nonce cache is crucial to the integrity of the nonce validation process. If the nonce cache is compromised, then you cannot trust the result of the validation process.
3. In the administrative console for the server level, select the **Distribute nonce caching** option. You can enable the option by completing the following steps:
   a. Click **Security > Web services**.
   b. Select the **Distribute nonce caching** option.
4. Restart the servers within your cluster.

Results

When you select the **Distribute nonce caching** option in the administrative console, the nonce is propagated to other servers in your environment. However, the nonce might be subject to a one-second delay in propagation and subject to any network congestion.

What to do next

For more information on distributed nonce caching, see Web Services Security enhancements.

Configuring the key locator using JAX-RPC for the generator binding on the application level:

The key locator information for the default generator specifies which key locator implementation is used to locate the key to be used for signature and encryption information. The key locator information for the generator specifies which key locator implementation is used to locate the key to be used for signature validation or encryption.

About this task

WebSphere Application Server provides default values for the bindings. However, you must modify the defaults for a production environment.

Complete the following steps to configure the key locator for the generator binding on the application level:

Procedure

1. Locate the encryption information configuration panel in the administrative console.

a. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
b. Under Manage modules, click ***URI_name***.
c. Under Web Services Security Properties you can access the key information for the request generator and response generator bindings.
   - For the request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
   - For the response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
d. Under Additional properties, click **Key locators**.
e. Click **New** to create a key locator configuration, select the box next to the configuration and click **Delete** to delete an existing configuration, or click the name of an existing key locator configuration to edit its settings. If you are creating a new configuration, enter a unique name in the **Key locator name** field. For example, you might specify `gen_keyloc`.

2. Specify a class name for the key locator class implementation in the **Key locator class name** field. The Java Authentication and Authorization Service (JAAS) Login Module implementation is used to create the security token on the generator side. Specify a class name according to the requirements of the application. For example, if the application requires that the key is read from a keystore file, specify the com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator implementation. WebSphere Application Server supports the following default key locator class implementations for Versions 6.0.*x* and later applications that are available to use with the request generator or response generator:

   com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator
   This implementation locates and obtains the key from the specified keystore file.

   com.ibm.wsspi.wssecurity.keyinfo.SignerCertKeyLocator
   This implementation uses the public key from the signer certificate and is used by the response generator.

3. Specify the keystore password, the keystore location, and the keystore type. Keystore files contain public and private keys, root certificate authority (CA) certificates, the intermediate CA certificate, and so on. Keys retrieved from the keystore are used to sign and validate or encrypt and decrypt messages or message parts. If you specified the com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator implementation for the key locator class implementation, you must specify a keystore password, location, and type.
   a. Specify a password in the keystore **Password** field. This password is used to access the keystore file.
   b. Specify the location of the keystore file in the keystore **Path** field.
   c. Select a keystore type from the **Type** field. The Java Cryptography Extension (JCE) that is used by IBM supports the following keystore types:

      JKS Use this option if you are not using Java Cryptography Extensions (JCE) and if your keystore file uses the Java Keystore (JKS) format.

      JCEKS
      Use this option if you are using Java Cryptography Extensions.

      JCERACFKS
      Use JCERACFKS if the certificates are stored in a SAF key ring (z/OS only).

      PKCS11KS (PKCS11)
      Use this format if your keystore uses the PKCS#11 file format. Keystores using this format might contain RSA keys on cryptographic hardware or might encrypt keys that use cryptographic hardware to ensure protection.

      PKCS12KS (PKCS12)
      Use this option if your keystore uses the PKCS#12 file format.

WebSphere Application Server provides some sample keystore files in the ${USER_INSTALL_ROOT}/etc/ws-security/samples directory. For example, you might use the enc-receiver.jceks keystore file for encryption keys. The password for this file is Storepass and the type is JCEKS.

Restriction: Do not use the sample keystore files in a production environment. These samples are provided for testing purposes only.

4. Click **OK** and then click **Save** to save the configuration.
5. Under Additional properties, click **Keys**.
6. Click **New** to create a key configuration, select the box next to the configuration and click **Delete** to delete an existing configuration, or click the name of an existing key configuration to edit its settings. This entry specifies the name of the key object within the keystore file. If you are creating a new configuration, enter a unique name in the **Key name** field. For digital signatures, the key name is used by the request generator or the response generator signing information to determine which key is used to digitally sign the message.

   You must use a fully qualified distinguished name for the key name. For example, you might use CN=Bob,O=IBM,C=US.

   Important: Do not use the sample key files in a production environment. These samples are provided for testing purposes only.
7. Specify an alias in the **Key alias** field. The key alias is used by the key locator to search for key objects in the keystore.
8. Specify a password in the **Key password** field. The password is used to access the key object within the keystore file.
9. Click **OK** and **Save** to save the configuration.

Results

You have configured the key locator for the generator binding at the application level.

What to do next

You must specify a similar key information configuration for the consumer.

Key locator collection:

Use this page to view a list of key locator configurations that retrieve keys from the keystore for digital signature and encryption. A key locator must implement the com.ibm.wsspi.wssecurity.config.KeyLocator interface.

To view this administrative console page for the key locator collection on the server level, complete the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under Additional properties, click **Key locators**.

To use this administrative console page for the key locator collection on the application level, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Click **Manage modules** > ***URI_name***.

3. Under Web Services Security Properties, you can access key locators for the following bindings:
   - For the Request generator, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom** > **Key locators**.
   - For the Request consumer, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom** > **Key locators**.
   - For the Response generator, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom** > **Key locators**.
   - For the Response consumer, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom** > **Key locators**.
4. Under Additional properties, you can access key locators for the following bindings:
   - For the Request sender, click **Web services: Client security bindings**. Under Request sender binding, click **Edit** > **Key locators**.
   - For the Request receiver, click **Web services: Server security bindings**. Under Request receiver binding, click **Edit** > **Key locators**.
   - For the Response sender, click **Web services: Server security bindings**. Under Response sender binding, click **Edit** > **Key locators**.
   - For the Response receiver, click **Web services: Client security bindings**. Under Response receiver binding, click **Edit** > **Key locators**.

Tip: The bindings for a Version 6.x. or later application has a link that says **Edit custom**.

Using this **Key locator collection** panel, complete the following steps:

1. Specify a key locator name and a key locator class name on the panel.
2. Save your changes by clicking **Save** in the messages section at the top of the administrative console. The administrative console home panel is displayed.
3. After saving your changes, update the Web Services Security run time with the default binding information by clicking **Update runtime**. When you click **Update runtime**, the configuration changes made to the other Web services also are updated in the Web Services Security run time.
4. After you define key locators, click the key locator name to specify additional properties and keys under **Additional Properties**.

Key locator name:

Specifies the unique name of the key locator.

Key locator class name:

Specifies the class name of the key locator, which retrieves the key that is used for digital signing and encryption.

Key locator configuration settings:

Use this page to specify the settings for a key locator configuration. The key locators retrieve keys from the keystore file for digital signature and encryption. This product enables you to plug in a custom key locator configuration.

To view this administrative console page for the key locator collection on the server level, complete the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.

3. Under Additional properties, click **Key locators**.
4. Click **New** to create a new configuration or click the name of a configuration to modify its settings.

To use this administrative console page for the key locator collection on the application level, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Click **Manage modules** > ***URI_name***.
3. Under Web Services Security properties, you can access key locators for the following bindings:
   - For the Request generator, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom** > **Key locators**.
   - For the Request consumer, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom** > **Key locators**.
   - For the Response generator, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom** > **Key locators**.
   - For the Response consumer, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom** > **Key locators**.
4. Click **New** to create a new configuration or click the name of a configuration to modify its settings.

Key locator name:

Specifies the name of the key locator.

Data type String

Key locator class name:

Specifies the name for the key locator class implementation.

Key locators that are associated with Versions 6 and later applications must implement the `com.ibm.wsspi.wssecurity.keyinfo.KeyLocator` interface. This product provides the following default key locator class implementations for Versions 6 and later applications:

com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator
This implementation locates and obtains the key from the specified keystore file.

com.ibm.wsspi.wssecurity.keyinfo.SignerCertKeyLocator
This implementation uses the public key from the certificate of the signer. This class implementation is used by the response generator.

This property is for the JAX-RPC programming model only. To implement signer certificate encryption for the JAX-WS programming model, set a custom property on the callback handler for the encryption token generator. For more information, read the topic Callback handler settings.

com.ibm.wsspi.wssecurity.keyinfo.X509TokenKeyLocator
This implementation uses the X.509 security token from the sender message for digital signature validation and encryption. This class implementation is used by the request consumer and the response consumer.

Data type String

Keystore: Specifies information about the key store that is used by this key locator configuration.

None Use this option if a key store is not required to be specified for this key locator configuration.

Predefined keystore
Use this option if you want to specify a predefined keystore for this key locator configuration.

User-defined keystore
Use this option if you want to specify a user-defined key store for this key locator configuration.

Keystore configuration name:

Specifies the name of the key store configuration that is defined in the keystore settings in secure communications.

The keystore configuration name is located under the **Predefined keystore** field, which is located under the **Keystore** section of the page.

Data type String

Keystore password:

Specifies the password that is used to access the keystore file.

The keystore password is located under the **User-defined keystore** field, which is located under the **Keystore** section of the page.

Data type String

Keystore path:

Specifies the location of the keystore file.

The path is located under the **User-defined keystore** field, which is located under the **Keystore** section of the page.

Data type String

Keystore type:

Specifies the type of keystore file.

The type is located under the **User-defined keystore** field, which is located under the **Keystore** section of the page.

JKS Use this option if you are not using Java Cryptography Extensions (JCE) and if your keystore file uses the Java Keystore (JKS) format.

JCEKS
Use this option if you are using Java Cryptography Extensions.

PKCS11KS (PKCS11)
Use this format if your keystore file uses the PKCS#11 file format. Keystores files that use this format might contain Rivest Shamir Adleman (RSA) keys on cryptographic hardware or might encrypt keys that use cryptographic hardware to ensure protection.

PKCS12KS (PKCS12)
Use this option if your keystore file uses the PKCS#12 file format.

Default JKS
Range JKS, JCEKS, PKCS11KS (PKCS11), PKCS12KS (PKCS12)

Web Services Security property collection:

Use this page to a view a list of additional properties for the configuration.

You can view a Web Services Security property collection panel at the cell level. Complete the following steps to view one of these administrative console pages:

1. Click **Security** > **JAX-WS and JAX-RPC security runtime**.
2. Under JAX-RPC Default Generator Bindings or JAX-RPC Default Consumer Bindings, click **Properties**.
3. Click **New** to create a new property.
4. Click **Delete** to a delete a property that you specified previously.

Property name:

Specifies the name of the property.

Property value:

Specifies the value for the property.

Web Services Security property configuration settings:

Use this page to configure additional security properties.

You can view a Web Services Security property configuration settings panel at the cell level. Complete the following steps to view one of these administrative console pages:

1. Click **Security** > **JAX-WS and JAX-RPC security runtime**.
2. Under JAX-RPC Default Generator Bindings or JAX-RPC Default Consumer Bindings, click **Properties** > **New**.

Property Name:

Specifies the name of the property.

Data type: String

Property Value:

Specifies the value for the property.

Data type: String

The following table lists the properties that you can configure by using the Web Services Security property panels.

Table 320. Property configuration settings. The properties are used to secure web services.

Configuration panel name	Property name	Property value	Description
JAAS configuration	com.ibm.wsspi.wssecurity.token.X509.issuerName	Specify the SubjectDN or the IssuerDN of the issuer for the X.509 certificate.	This property is used to specify the issuer of the certificate in the token consumer component.
JAAS configuration	com.ibm.wsspi.wssecurity.token.X509.issuerSerial	Specify the serial number of the X.509 certificate.	This property is used to specify the serial number of the certificate in the token consumer component.
Key information	com.ibm.wsspi.wssecurity.keyinfo.EncodingNS	Specify the namespace Uniform Resource Identifier (URI) for the qualified name (QName).	This property is used to specify the namespace URI part of the QName that represents the encoding method.
Properties	com.ibm.ws.wssecurity.handler.hardwareCacheEntryRefreshHours	Specify a numeric value from 1 to 24 that represents the number of hours that a temporary key is valid.	This property is used to specify the amount of time before a key is retranslated. Temporary keys outside the keystore typically expire in a short period of time, measured in days or hours. If the server is configured to use a hardware acceleration card, but not the hardware keystore, you can configure it to translate the temporary keys periodically before they expire. If this property is not set, a key will be retranslated after 8 hours. Setting this value to 0 disables retranslation.
Request generator and Response generator	com.ibm.wsspi.wssecurity.timestamp.SOAPHeaderElement	Specify `1` or `true`.	This property is used with the **Add nonce** option to set the mustUnderstand flag in the deployment descriptor.
Request generator and Response generator	com.ibm.wsspi.wssecurity.timestamp.dialect		
Signing information	com.ibm.wsspi.wssecurity.dsig.dumpPath	Specify the path used to locate the output file.	This property is used to specify an output file for dumping the target UTF-8 binary data before signing and verifying messages.
Token generator	com.ibm.wsspi.wssecurity.token.username.timestampExpires	Specify `1` or `true`.	This property is used to specify an expiration date for the user name token.
Transform algorithms	com.ibm.wsspi.wssecurity.dsig.XPathExpression	`not(ancestor-or-self::*[namespace-uri()='http://www.w3.org/2000/09/xmldsig#' and local-name()='Signature'])`	This property is used with this algorithm: `http://www.w3.org/TR/1999/REC-xpath-19991116`

Configuring the key locator using JAX-RPC for the consumer binding on the application level:

The key locator information for the consumer at the application level specifies which key locator implementation is used. The key locator implementation locates the key to be used to validate the digital signature or the encryption information by the application.

About this task

Complete the following steps to configure the key locator for the consumer binding on the application level:

Procedure

1. Locate the key locator configuration panel in the administrative console.
   a. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
   b. Under Manage modules, click ***URI_name***.
   c. Under Web Services Security Properties, you can access the key information for the request consumer and response consumer bindings.

- For the request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
- For the response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.

d. Under Additional properties, click **Key locators**.

e. Click **New** to create a key locator configuration, click **Delete** and select the box next to the configuration to delete an existing configuration, or click the name of an existing key locator configuration to edit its settings. If you are creating a new configuration, enter a unique name in the **Key locator name** field. For example, you might specify `klocator`.

2. Specify a name for the key locator class implementation. The Java Authentication and Authorization Service (JAAS) Login Module implementation is used to validate (authenticate) the security token on the consumer side. Specify a class name according to the requirements of the application. For example, if the application requires that the key is read from a keystore file, specify the com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator implementation. WebSphere Application Server provides the following default key locator class implementations for Version 6.0.*x* applications that are available to use with the request consumer or response consumer:

   com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator
   This implementation locates and obtains the key from the specified keystore file.

   com.ibm.wsspi.wssecurity.keyinfo.X509TokenKeyLocator
   This implementation uses the X.509 security token from the sender message for digital signature validation and encryption. This class implementation is used by the request consumer and the response consumer.

3. Specify the keystore password, the keystore location, and the keystore type. Keystore files contain public and private keys, root certificate authority (CA) certificates, the intermediate CA certificate, and so on. Keys that are retrieved from the keystore files are used to sign and validate or encrypt and decrypt messages or message parts. If you specified the com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator implementation for the key locator class implementation, you must specify a keystore password, location, and type.

   a. Specify a password in the keystore **Password** field. This password is used to access the keystore file.

   b. Specify the location of the keystore file in the keystore **Path** field.

   c. Select a keystore type from the keystore **Type** field. The Java Cryptography Extension (JCE) that is used by IBM supports the following keystore types:

      JKS Use this option if you are not using Java Cryptography Extensions (JCE) and if your keystore file uses the Java Keystore (JKS) format.

      JCEKS
      Use this option if you are using Java Cryptography Extensions.

      PKCS11KS (PKCS11)
      Use this format if your keystore file uses the PKCS#11 file format. Keystore files that use this format might contain RSA keys on cryptographic hardware or might encrypt keys that use cryptographic hardware to ensure protection.

      PKCS12KS (PKCS12)
      Use this option if your keystore uses the PKCS#12 file format.

      WebSphere Application Server provides some sample keystore files in the `${USER_INSTALL_ROOT}/etc/ws-security/samples` directory. For example, you might use the `enc-receiver.jceks` keystore file for encryption keys. The password for this file is `Storepass` and the type is `JCEKS`.

      Attention: Do not use these keystore files in a production environment. These samples are provided for testing purposes only.

4. Click **OK** and **Save** to save the configuration.
5. Under Additional properties, click **Keys**.

6. Click **New** to create a key configuration, click **Delete** and select the box next to the configuration to delete an existing configuration, or click the name of an existing key configuration to edit its settings. This entry specifies the name of the key object within the keystore file. If you are creating a new configuration, enter a unique name in the **Key name** field.

   It is recommended that you use a fully qualified distinguished name for the key name. For example, you might use `CN=Bob,O=IBM,C=US`.
7. Specify an alias in the **Key alias** field. The key alias is used by the key locator to search for key objects in the keystore file.
8. Specify a password in the **Key password** field. The password is used to access the key object within the keystore file.
9. Click **OK** and then click **Save** to save the configuration.

Results

You have configured the key locator for the consumer binding at the application level.

What to do next

You must specify a similar key information configuration for the generator.

Configuring the key locator using JAX-RPC on the server level:

The key locator information for the default generator bindings specifies which key locator implementation is used to locate the key for signature and encryption information if these bindings are not defined at the application level.

About this task

The key locator information for the default consumer bindings specifies which key locator implementation is used to locate the key that is used for signature validation or decryption if these bindings are not defined at the application level. WebSphere Application Server provides default values for the bindings. However, you must modify the defaults for a production environment.

Complete the following steps to configure the key locator on the server level:

Procedure

1. Access the default bindings for the server level.
   a. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
   b. Under Security, click **JAX-WS and JAX-RPC security runtime**.

      Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
2. Under Additional properties, click **Key locator**. You can configure the key locator configurations for both the default generator and the default consumer in this location.
3. Click one of the following to work with the key locator configurations:

   New To create a key locator configuration. Enter a unique name for the key locator configuration in the **Key locator name** field. For example, you might specify `sig_klocator`.

   Delete To delete an existing configuration

   an existing key locator configuration
   To edit the settings of an existing configuration.

4. Specify a name for the key locator class implementation in the **Key locator class name** field. The key locators that are associated with Version 6.0.*x* applications must implement the `com.ibm.wsspi.wssecurity.keyinfo.KeyLocator` interface.

   Note: This interface is valid only for JAX-RPC applications. For JAX-WS applications, the Java Authentication and Authorization Service (JAAS) Login Module implementation is used to create the security token on the generator side and to validate (authenticate) the security token on the consumer side.

   WebSphere Application Server provides the following default key locator class implementations for Version 6.0.*x* applications:

   com.ibm.wsspi.wssecurity.keyinfo.KeyStoreLeyLocator
   This implementation locates and obtains the key from a specified keystore file.

   com.ibm.wsspi.wssecurity.keyinfo.SignerCertKeyLocator
   This implementation uses the public key from the certificate of the signer. This class implementation is used by the response generator.

   com.ibm.wsspi.wssecurity.keyinfo.X509TokenKeyLocator
   This implementation uses the X.509 security token from the sender message for digital signature validation and encryption. This class implementation is used by the request consumer and the response consumer.

   For example, you might specify the `com.ibm.wsspi.wssecurity.keyinfo.KeyStoreLeyLocator` implementation if you need the configuration to be the key locator for signing information.
5. Specify the keystore password, the keystore location, and the keystore type. Keystore files contain public and private keys, root certificate authority (CA) certificates, the intermediate CA certificate, and so on. Keys that are retrieved from the keystore file are used to sign and validate or encrypt and decrypt messages or message parts. If you specified the `com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator` implementation for the key locator class implementation, you must specify a key store password, location, and type.
   a. Specify a password in the **Key store password** field. This password is used to access the keystore file.
   b. Specify the location of the keystore file in the **Key store path** field.
   c. Select a keystore type from the **Key store type** field. The Java Cryptography Extension (JCE) that is used supports the following key store types:

      JKS Use this option if you are not using Java Cryptography Extensions (JCE) and if your keystore file uses the Java Keystore (JKS) format.

      JCEKS
      Use this option if you are using Java Cryptography Extensions.

      PKCS11
      Use this format if your keystore file uses the PKCS#11 file format. Keystore files that use this format might contain Rivest Shamir Adleman (RSA) keys on cryptographic hardware or might encrypt keys that use cryptographic hardware to ensure protection.

      PKCS12
      Use this option if your keystore file uses the PKCS#12 file format.

      WebSphere Application Server provides some sample keystore files in the `${USER_INSTALL_ROOT}/etc/ws-security/samples` directory. For example, you might use the `enc-receiver.jceks` keystore file for encryption keys. The password for this file is `storepass` and the type is `JCEKS`.

      Restriction: Do not use these keystore files in a production environment. These samples are provided for testing purposes only.
6. Click **OK** and **Save** to save the configuration.
7. Under Additional properties, click **Keys**.

8. Click one of the following to work with the key configurations:

   New To create a key configuration. Enter a unique name in the **Key name** field. You must use a fully qualified distinguished name for the key name. For example, you might use `CN=Bob,O=IBM,C=US`.

   Delete To delete an existing configuration.

   an existing key configuration
   To edit the settings of the existing configuration.

   This entry specifies the name of the key object within the keystore file.
9. Specify an alias in the **Key alias** field. The key alias is used by the key locator to search for key objects in the keystore file.
10. Specify a password in the **Key password** field. The password is used to access the key object within the keystore file.
11. Click **OK** and then click **Save** to save the configuration.

Results

You have configured the key locator for the server level.

What to do next

Configure the key information for the default generator and the default consumer bindings that reference this key locator.

Configuring trust anchors for the generator binding on the application level:

A *trust anchor* specifies key stores that contain trusted root certificates, which validate the signer certificate. These key stores are used by the request generator and the response generator (when web services are acting as client) to generate the signer certificate for the digital signature. You can configure trust anchors for the generator binding at the application level by using the administrative console.

Before you begin

You can configure a trust anchor using an assembly tool or the administrative console. This task describes how to configure the application-level trust anchor using the administrative console. For more information on assembly tools, see the related information.

About this task

The keystores are critical to the integrity of the digital signature validation. If they are tampered with, the result of the digital signature verification is doubtful and comprised. Therefore, it is recommended that you secure these keystores. The binding configuration that is specified for the request generator must match the binding configuration for the response generator.

The trust anchor configuration for the request generator on the client must match the configuration for the request consumer on the server. Also, the trust anchor configuration for the response generator on the server must match the configuration for the response consumer on the client.

Complete the following steps to configure trust anchors for the generator binding on the application level:

Procedure

1. Locate the trust anchor panel in the administrative console.

a. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
b. Under Manage modules, click ***URI_name***.
c. Under Web Services Security Properties you can access the trust anchor configuration for the following bindings:
   - For the request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
   - For the response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
d. Under Additional properties, click **Trust anchors**.
e. Click **New** to create a trust anchor configuration, click **Delete** to delete an existing configuration, or click the name of an existing trust anchor configuration to edit its settings. If you are creating a new configuration, enter a unique name in the **Trust anchor name** field.

2. Specify the keystore password, the keystore location, and the keystore type. Key store files contain public and private keys, root certificate authority (CA) certificates, the intermediate CA certificate, and so on. Keys retrieved from the keystore are used to sign and validate or encrypt and decrypt messages or message parts. If you specified the `com.ibm.wsspi.wssecurity.keyinfo.KeyStoreKeyLocator` implementation for the key locator class implementation, you must specify a key store password, location, and type.
   a. Specify a password in the **Key store password** field. This password is used to access the keystore file.
   b. Specify the location of the key store file in the **Key store path** field.
   c. Select a keystore type from the **Key store type** field. The Java Cryptography Extension (JCE) used by IBM supports the following key store types:

      JKS Use this option if you are not using Java Cryptography Extensions (JCE) and if your keystore file uses the Java Keystore (JKS) format.

      JCEKS
      Use this option if you are using Java Cryptography Extensions.

      PKCS11KS (PKCS11)
      Use this format if your keystore uses the PKCS#11 file format. Keystores using this format might contain RSA keys on cryptographic hardware or might encrypt keys that use cryptographic hardware to ensure protection.

      PKCS12KS (PKCS12)
      Use this option if your keystore uses the PKCS#12 file format.

      WebSphere Application Server provides some sample keystore files in the following directory, using the *USER_INSTALL_ROOT* variable:

      For example, you might use the `enc-receiver.jceks` keystore file for encryption keys. The password for this file is `Storepass` and the type is `JCEKS`.

      Restriction: Do not use these keystore files in a production environment. These samples are provided for testing purposes only.

Results

This task configures trust anchors for the generator binding at the application level.

What to do next

You must specify a similar trust anchor configuration for the consumer.

Trust anchor collection:

Use this page to view a list of keystore objects that contain trusted root certificates. These objects are used for certificate path validation of incoming X.509-formatted security tokens. Keystore objects within trust anchors contain trusted root certificates that are used by the CertPath API to validate the trust of a certificate chain.

This administrative console page applies only to Java API for XML-based RPC (JAX-RPC) applications.

To create the keystore file, use the keytool utility. The keytool utility is available using the QShell Interpreter.

To view this administrative console page for trust anchors on the server level, complete the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under Additional properties, click **Trust anchors**.

To view this administrative console page for trust anchors on the application level,

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Click **Manage modules** > ***URI_name***.
3. Under Web Services Security Properties, you can access trust anchors information for the following bindings:
   - For the Response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
   - For the Request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
4. Under Additional properties, you can access the trust anchors information for the following bindings:
   - For the Response receiver binding, click **Web services: Client security bindings**. Under Response receiver binding, click **Edit**.
   - For the Request receiver binding, click **Web services: Server security bindings**. Under Request receiver binding, click **Edit**.
5. Under Additional properties, click **Trust anchors**.

If you click **Update runtime**, the Web Services Security run time is updated with the default binding information, which is contained in the `ws-security.xml` file that was previously saved. If you make changes on this panel, you must complete the following steps:

1. Save your changes by clicking **Save** at the top of the administrative console. When you click **Save**, you are returned to the administrative console home panel.
2. Return to the Trust anchors collection panel and click **Update runtime**. When you click **Update runtime**, the configuration changes made to the other web services also are updated in the Web Services Security run time.

Trust anchor name:

Specifies the unique name that is used to identify the trust anchor.

Key store path:

Specifies the location of the keystore file that contains the trust anchors.

Key store type:

Specifies the type of keystore file.

The value for this field is **JKS**, **JCEKS**, **JCERACFKS** (z/OS only), **JCE4758RACFKS** (z/OS only), **PKCS11KS (PKCS11)**, or **PKCS12KS (PKCS12)**.

Trust anchor configuration settings:

Use this information to configure a trust anchor. Trust anchors point to keystores that contain trusted root or self-signed certificates. This information enables you to specify a name for the trust anchor and the information that is needed to access a keystore. The application binding uses this name to reference a predefined trust anchor definition in the binding file (or the default).

This administrative console page applies only to Java API for XML-based RPC (JAX-RPC) applications.

To view this administrative console page for trust anchors on the server level, complete the following steps:

1. Click **Servers > Server Types > WebSphere application servers > *server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under Additional properties, click **Trust anchors**.
4. Click **New** to create a trust anchor or click the name of an existing configuration to modify its settings.

To view this administrative console page for trust anchors on the application level,

1. Click **Applications > Application Types > WebSphere enterprise applications > *application_name***.
2. Under Modules, click **Manage modules > *URI_name***.
3. Under Web Services Security Properties, you can access trust anchors information for the following bindings:
   - For the Response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
   - For the Request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
4. Under Additional properties, you can access the trust anchors information for the following bindings:
   - For the Response receiver binding, click **Web services: Client security bindings**. Under Response receiver binding, click **Edit**.
   - For the Request receiver binding, click **Web services: Server security bindings**. Under Request receiver binding, click **Edit**.
5. Under Additional properties, click **Trust anchors**.
6. Click **New** to create a trust anchor or click the name of an existing configuration to modify its settings.

Trust anchor name:

Specifies the unique name that is used by the application binding to reference a predefined trust anchor definition in the default binding.

Key store configuration name:

Specifies the name of the key store configuration defined in the keystore settings in secure communications.

Key store password:

Specifies the password that is needed to access the key store file.

Key store path:

Specifies the location of the keystore file.

Use ${*USER_INSTALL_ROOT*} as this path expands to the WebSphere Application Server path on your machine.

Key store type:

Specifies the type of keystore file.

Choose from the following options:

JKS Use this option if you are not using Java Cryptography Extensions (JCE).

JCEKS
Use this option if you are using Java Cryptography Extensions.

PKCS11KS (PKCS11)
Use this format if your keystore uses the PKCS#11 file format. Keystores that use this format might contain Rivest Shamir Adleman (RSA) keys on cryptographic hardware or might encrypt keys that use cryptographic hardware to ensure protection.

PKCS12KS (PKCS12)
Use this option if your keystore uses the PKCS#12 file format.

Default	JKS
Range	JKS, JCEKS, PKCS11KS (PKCS11), PKCS12KS (PKCS12)

Configuring trust anchors for the consumer binding on the application level:

You can configure trust anchors for the consumer binding at the application level.

About this task

This article does not describe how to configure trust anchors at the server or cell level. Trust anchors that are defined at the application level have a higher precedence over trust anchors that are defined at the server or cell level. For more information on creating and configuring trust anchors on the server or cell level, see “Configuring trust anchors on the server level” on page 3422.

You can configure a trust anchor at the application level using an assembly tool or the administrative console. This article describes how to configure the application-level trust anchor using the administrative console.

A trust anchor specifies key stores that contain trusted root Certificate Authority (CA) certificates, which validate the signer certificate. These keystores are used by the request consumer (as defined in the `ibm-webservices-bnd.xmi` file) and the response consumer (as defined in the `ibm-webservicesclient-bnd.xmi` file when a web service is acting as a client) to validate the X.509 certificate in the SOAP message. The keystores are critical to the integrity of the digital signature validation. If the keystores are tampered with, the result of the digital signature verification is doubtful and comprised. Therefore, it is recommended that you secure these keystores. The binding configuration specified for the request consumer in the `ibm-webservices-bnd.xmi` file must match the binding configuration for the response consumer in the `ibm-webservicesclient-bnd.xmi` file. The trust anchor configuration for the request

consumer on the server side must match the request generator configuration on the client side. Also, the trust anchor configuration for the response consumer on the client side must match the response generator configuration on the server side.

Complete the following steps to configure trust anchors for the consumer binding on the application level:

Procedure

1. Locate the trust anchor panel in the administrative console.
   a. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
   b. Under Manage modules, click ***URI_name***.
   c. Under Web Services Security Properties you can access the trust anchor configuration for the following bindings:
      - For the request consumer (receiver) binding, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom**.
      - For the response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
   d. Under Additional properties, click **Trust anchors**.
   e. Click one of the following to work with trust anchor configuration:

      New To create a trust anchor configuration. Enter a unique name in the Trust anchor name field.

      Delete To delete the existing configuration selected in the box next to the configuration.

      an existing trust anchor configuration
      To edit the settings of an existing trust anchor configuration.
2. Specify the keystore password, the keystore location, and the keystore type. A trust anchor keystore file contains the trusted root Certificate Authority (CA) certificates that are used for validating the X.509 certificate that is used in digital signature or XML encryption.
   a. Specify a password in the Key store password field. This password is used to access the keystore file.
   b. Specify the location of the keystore file in the Key store path field.
   c. Select a keystore type from the Key store type field. The Java Cryptography Extension (JCE) that is used by IBM supports the following keystore types:

      JKS Use this option if you are not using Java Cryptography Extensions (JCE) and if your keystore file uses the Java Keystore (JKS) format.

      JCEKS
      Use this option if you are using Java Cryptography Extensions.

      PKCS11KS (PKCS11)
      Use this format if your keystore file uses the PKCS#11 file format. Keystore files that use this format might contain RSA keys on cryptographic hardware or might encrypt keys that use cryptographic hardware to ensure protection.

      PKCS12KS (PKCS12)
      Use this option if your keystore file uses the PKCS#12 file format.

      WebSphere Application Server provides some sample keystore files in the following directory, using the *USER_INSTALL_ROOT* variable:

      For example, you might use the `enc-receiver.jceks` keystore file for encryption keys. The password for this file is `storepass` and the type is `JCEKS`.

      Restriction: Do not use these keystore files in a production environment. These samples are provided for testing purposes only.

Results

You have configured trust anchors for the consumer binding at the application level.

What to do next

You must specify a similar trust anchor information for the generator.

Configuring trust anchors on the server level:

You can configure a list of keystore objects that contain trusted root certificates to be used for certificate path validation of incoming X.509-formatted security tokens.

Before you begin

Prior to completing the steps to configure trust anchors, you must create the keystore file using the keytool utility. The keytool utility is available using the QShell Interpreter.

About this task

This task provides the steps that are needed to configure a list of keystore objects that contain trusted root certificates. These objects are used for certificate path validation of incoming X.509-formatted security tokens. Keystore objects within trust anchors contain trusted root certificates that are used by the CertPath application programming interface (API) to determine whether to trust a certificate chain.

Complete the following steps to configure the trust anchors on the server level:

Procedure

1. Access the default bindings for the server level.
   a. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
   b. Under Security, click **JAX-WS and JAX-RPC security runtime**.

      Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
2. Under Additional properties, click **Trust anchors**.
3. Click one of the following to work with trust anchor configuration:

   New To create a trust anchor configuration. Enter a unique name for the trust anchor in the Trust anchor name field.

   Delete To delete an existing configuration.

   an existing trust anchor configuration
   To edit the settings for an existing trust anchor.
4. Specify a password in the Key store password field that is used to access the keystore file.
5. Specify the absolute location of the keystore file in the **Key store path** field. It is recommended that you use the *USER_INSTALL_ROOT* variable as a portion of the keystore path. To change this predefined variable, click **Environment** > **WebSphere variables**. The *USER_INSTALL_ROOT* variable might display on the second page of variables.
6. Specify the type of keystore file in the key store type field. WebSphere Application Server supports the following keystore types:

   JKS Use this option if you are not using Java Cryptography Extensions (JCE) and your keystore file uses the Java Key Store (JKS) format.

   JCEKS
   Use this option if you are using Java Cryptography Extensions.

PKCS11KS (PKCS11)
Use this option if your keystore file uses the PKCS#11 file format. Keystore files that use this format might contain Rivest Shamir Adleman (RSA) keys on cryptographic hardware or might encrypt keys that use cryptographic hardware to ensure protection.

PKCS12KS (PKCS12)
Use this option if your keystore file uses the PKCS#12 file format.

7. Click **OK** and **Save** to save your configuration.

Results

You have configured trust anchors at the server level.

Configuring the collection certificate store for the generator binding on the application level:

You can configure a collection certificate for the generator bindings on the application level.

About this task

A *collection certificate store* is a collection of non-root, certificate authority (CA) certificates and certificate revocation lists (CRLs). This collection of CA certificates and CRLs is used to check for a valid signature in a digitally signed SOAP message.

Complete the following steps to configure a collection certificate for the generator bindings on the application level:

Procedure

1. Locate the collection certificate store configuration panel in the administrative console.
   a. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
   b. Under Manage modules, click ***URI_name***.
   c. Under Web Services Security Properties, you can access the key information for the request generator and response generator bindings.
      - For the request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
      - For the response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
   d. Under Additional properties, click **Collection certificate store**.
2. Specify the Certificate store name. Click **New** to create a collection certificate store configuration, select the box next to the configuration and click **Delete** to delete an existing configuration, .or click the name of an existing collection certificate store configuration to edit its settings. If you are creating a new configuration, enter a name in the Certificate store name field.

   The name of the collection certificate store must be unique to the level of the application server. For example, if you create the collection certificate store for the application level, the store name must be unique to the application level. The name that is specified in the Certificate store name field is used by other configurations to refer to a predefined collection certificate store. WebSphere Application Server searches for the collection certificate store based on proximity.

   For example, if an application binding refers to a collection certificate store named `cert1`, the Application Server searches for `cert1` at the application level before searching the server level.
3. Specify a certificate store provider in the Certificate store provider field. WebSphere Application Server supports the IBMCertPath certificate store provider. To use another certificate store provider, you must define the provider implementation in the provider list within the *`profile_root`*`/properties/java.security` file. However, make sure that your provider supports the same requirements of the certificate path algorithm as WebSphere Application Server.

4. Click **OK** and **Save** to save the configuration.
5. Click the name of your certificate store configuration. After you specify the certificate store provider, you must specify either the location of a certificate revocation list or the X.509 certificates. However, you can specify both a certificate revocation list and the X.509 certificates for your certificate store configuration.
6. Under Additional properties, click **Certificate revocation lists**.
7. Click **New** to specify a certificate revocation list path, click **Delete** to delete an existing list reference, or click the name of an existing reference to edit the path. You must specify the fully qualified path to the location where WebSphere Application Server can find your list of certificates that are not valid. For portability reasons, it is recommended that you use the WebSphere Application Server variables to specify a relative path to the certificate revocation lists (CRL). This recommendation is especially important when you are working in a WebSphere Application Server, Network Deployment environment. For example, you might use the *USER_INSTALL_ROOT* variable to define a path such as $*USER_INSTALL_ROOT*/mycertstore/mycrl1. For a list of supported variables, click **Environment** > **WebSphere variables** in the administrative console. The following list provides recommendation for using certificate revocation lists:
   - If CRLs are added to the collection certificate store, add the CRLs for the root certificate authority and each intermediate certificate, if applicable. When the CRL is in the certificate collection store, the certificate revocation status for every certificate in the chain is checked against the CRL of the issuer.
   - When the CRL file is updated, the new CRL does not take effect until you restart the web service application.
   - Before a CRL expires, you must load a new CRL into the certificate collection store to replace the old CRL. An expired CRL in the collection certificate store results in a certificate path (CertPath) build failure.
8. Click **OK** and **Save** to save the configuration.
9. Return to the collection certificate store configuration panel. To access the panel, complete the following steps:
   a. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
   b. Under Manage modules, click ***URI_name***.
   c. Under Web Services Security properties, you can access the key information for the request generator and response generator bindings.
      - For the request generator (sender) binding, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom**.
      - For the response generator (sender) binding, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom**.
   d. Under Additional properties, click **Collection certificate store** > ***certificate_store_name***.
10. Under Additional properties, click **X.509 certificates**.
11. Click **New** to create a X.509 certificate configuration, click **Delete** to delete an existing configuration, or click the name of an existing X.509 certificate configuration to edit its settings. If you are creating a new configuration, enter a name in the Certificate store name field.
12. Specify a path in the X.509 certificate path field. This entry is the absolute path to the location of the X.509 certificate. The collection certificate store is used to validate the certificate path of incoming X.509-formatted security tokens.

    You can use the *USER_INSTALL_ROOT* variable as part of path name. For example, you might type: `USER_INSTALL_ROOT/etc/ws-security/samples/intca2.cer`. Do not use this certificate path for production use. You must obtain your own X.509 certificate from a certificate authority before putting your WebSphere Application Server environment into production.

    Click **Environment** > **WebSphere variables** in the administrative console to configure the *USER_INSTALL_ROOT* variable.

13. Click **OK** and then **Save** to save your configuration.

Results

You have configured the collection certificate store for the generator binding.

What to do next

You must specify a similar collection certificate store configuration for the consumer.

Collection certificate store collection:

Use this page to view a list of certificate stores that contains untrusted, intermediary certificate files awaiting validation. Validation might consist of checking to see if the certificate is on a certificate revocation list (CRL), checking that the certificate is not expired, and checking that the certificate is issued by a trusted signer.

The following list provides recommendations for using CRLs:

- If CRLs are added to the collection certificate store collection, add the CRLs for the root certificate authority and each intermediate certificate, if applicable. When the CRL is in the certificate collection store, the certificate revocation status for every certificate in the chain is checked against the CRL of the issuer.
- When the CRL file is updated, the new CRL does not take effect until you restart the web service application.
- Before a CRL expires, you must load a new CRL into the certificate collection store to replace the old CRL. An expired CRL in the collection certificate store results in a certificate path (CertPath) build failure.

To view the administrative console panel for the collection certificate store on the server level, complete the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under Additional properties, click **Collection certificate store**.

To view this administrative console page for the collection certificate store on the application level, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Under Modules, click **Manage modules** > ***URI_name***.
3. Under Web Services Security Properties, you can access collection certificate stores for the following bindings:
   - For the Request generator, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom** > **Collection certificate store**.
   - For the Request consumer, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom** > **Collection certificate store**.
   - For the Response generator, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom** > **Collection certificate store**.
   - For the Response consumer, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom** > **Collection certificate store**.
4. Under Additional properties, you can access collection certificate stores for the following bindings:

- For the Request receiver binding, click **Web services: Server security bindings**. Under Response receiver binding, click **Edit** > **Collection certificate store**.
- For the Response receiver binding, click **Web services: Client security bindings**. Under Response receiver binding, click **Edit** > **Collection certificate store**.

Complete the following steps:

1. Click **New** to specify a new certificate store name and certificate store provider.
2. Click **OK** and messages display at the top of the administrative console panel.
3. Within the messages at the top of the administrative console panel, click **Save**.
4. Return to the collection certificate store collection panel and click **Update runtime** to update the Web Services Security run time with the default binding information, which is found in the `ws-security.xml` file. When you click **Update runtime**, the configuration changes made to the other web services are also updated in the Web Services Security run time.

Certificate store name:

Specifies the name of the certificate store.

Certificate store provider:

Specifies the provider of the certificate store.

Collection certificate store configuration settings:

Use this page to specify the name and the provider for a collection certificate store. A *collection certificate store* is a collection of non-root, certificate authority (CA) certificates and certificate revocation lists (CRLs). This collection of CA certificates and CRLs is used to check the signature of a digitally signed SOAP message.

To view the administrative console panel for the collection certificate store on the server level, complete the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under Additional properties, click **Collection certificate store**.
4. Specify a new collection certificate store by clicking **New** or by clicking the collection certificate store name to modify its settings.

To view this administrative console page for the collection certificate store on the application level, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Under Modules, click **Manage modules** > ***URI_name***.
3. Under Web Services Security Properties, you can access collection certificate stores for the following bindings:
   - For the Request generator, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom** > **Collection certificate store**.
   - For the Request consumer, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom** > **Collection certificate store**.

- For the Response generator, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom** > **Collection certificate store**.
- For the Response consumer, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom** > **Collection certificate store**.

4. Under Additional properties, you can access collection certificate stores for the following bindings:
   - For the Request receiver binding click **Edit** > **Collection certificate store**.
   - For the Response receiver binding, click **Edit** > **Collection certificate store**.
5. Specify a new collection certificate store by clicking **New** or by clicking the collection certificate store name to modify its settings.

After configuring a collection certificate store, you can select the new configuration under Certificate store on the token generator and token consumer panels. To access these panels, complete the following steps:

1. Click **Security** > **JAX-WS and JAX-RPC security runtime**.
2. Under JAX-RPC Default Generator Bindings, click **Token generators** or under JAX-RPC Default Consumer Bindings, click **Token consumers**.
3. Click **New** to create a new token generator or token consumer, or click the name of an existing configuration to make modifications.

After you configure your collection certificate store on this panel, you must click **Apply** before configuring either the certificate revocation list or an X.509 certificate. After you configure your certificate revocation list or X.509 certificate, complete the following steps:

1. Click **Save**, at the top of the administrative console panel, which returns you to the list of the configured collection certificate stores.
2. Click **Update runtime** to update the Web Services Security run time with the default binding information, which is found in the `ws-security.xml` file.

Certificate store name:

Specifies the name for the certificate store.

The name of the collection certificate store must be unique in the scope. For example, the name must be unique at the server level. The name specified in **Certificate store name** field is used by other configurations to refer to a pre-defined collection certificate store. For example, the application binding refers to a collection certificate store that is defined on the server level. The application server looks up the collection certificate store based on proximity. For example, if *cert1* is defined as the name of the certificate store on the cell and server levels and *cert1* is referenced in the application binding, the application server uses the server-level collection certificate store.

Certificate Store Provider:

Specifies the provider for the certificate store implementation.

This product supports the IBMCertPath certificate path provider. If you need to use another certificate path provider, define the provider implementation in the provider list within the `java.security` file in the Software Development Kit (SDK).

Data type	String
Default	IBMCertPath

X.509 certificates collection:

Use this page to view a list of untrusted, intermediate certificate files. This collection certificate store is used for certificate path validation of incoming X.509-formatted security tokens.

To view the administrative console page for the collection certificate store on the server level, complete the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under Additional properties, click **Collection certificate store**.
4. Click the name of a configured collection certificate store or create a new collection certificate store first.
5. Under Additional properties, click **X.509 certificates**.

To view this administrative console page for an X.509 certificate on the application level, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Under Modules, click **Manage modules** > ***URI_name***.
3. Under Web Services Security Properties, you can access collection certificate stores for the following bindings:
   - For the Request generator, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom** > **Collection certificate store**.
   - For the Request consumer, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom** > **Collection certificate store**.
   - For the Response generator, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom** > **Collection certificate store**.
   - For the Response consumer, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom** > **Collection certificate store**.
4. Under Additional properties, you can access the collection certificate stores for the following bindings.
   - For the Response receiver binding, click **Web services: Client security bindings**. Under Response receiver binding, click **Edit** > **Collection certificate store**.
   - For the Request receiver binding, click **Web services: Server security bindings**. Under Request receiver binding, click **Edit** > **Collection certificate store**.
5. Click the name of a configured collection certificate store or create a new collection certificate store first.
6. Under Additional properties, click **X.509 certificates**.

X.509 certificate path:

Specifies the location of the X.509 certificate.

X.509 certificate configuration settings:

Use this page to specify a list of untrusted, intermediate certificate files. This collection certificate store is used for certificate path validation of incoming X.509-formatted security tokens.

To view the administrative console page for the collection certificate store on the server level, complete the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.

3. Under Additional properties, click **Collection certificate store**.
4. Click the name of a configured collection certificate store or create a new collection certificate store first.
5. Under Additional properties, click **X.509 certificates**.
6. Specify a new X.509 certificate path by clicking **New** or by clicking the X.509 certificate path to modify its settings.

To view this administrative console page for an X.509 certificate on the application level, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Under Modules, click **Manage modules** > ***URI_name***.
3. Under Web Services Security Properties, you can access collection certificate stores for the following bindings:
   - For the Request generator, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom** > **Collection certificate store**.
   - For the Request consumer, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom** > **Collection certificate store**.
   - For the Response generator, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom** > **Collection certificate store**.
   - For the Response consumer, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom** > **Collection certificate store**.
4. Click the name of a configured collection certificate store or create a new collection certificate store first.
5. Under Additional properties, click **X.509 certificates**.
6. Specify a new X.509 certificate path by clicking **New** or click the X.509 certificate path to modify its settings.

X.509 Certificate Path:

Specifies the absolute path to the location of the X.509 certificate.

As shown in the following example, you can use the USER_INSTALL_ROOT variable as part of the path name: {*USER_INSTALL_ROOT*}/etc/ws-security/samples/intca2.cer. This X.509 certificate path is not for production use. Obtain your own X.509 from a certificate authority before putting your application server environment into production.

You can configure the USER_INSTALL_ROOT variable in the administrative console by clicking **Environment** > **WebSphere Variables**.

Certificate revocation list collection:

Use this page to determine the location of the certificate revocation list (CRL) known to the application server. The Application Server checks the CRL to determine the validity of the client certificate. A certificate that is found in a certificate revocation list might not be expired, but is no longer trusted by the certificate authority (CA) that issued the certificate. The CA might add the certificate to the certificate revocation list if it believes that the client authority is compromised.

View the administrative console panel for the collection certificate store on the server level.

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.

2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under Additional properties, click **Collection certificate store**.
4. Click the name of a configured collection certificate store or create a new collection certificate store first.
5. Under Additional properties, click **Certificate revocation list** > **New**to specify the path to a new list or click the name of the certificate revocation list to modify its path.

View the administrative console page for the collection certificate store on the application level.

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Under Modules, click **Manage modules** > ***URI_name***.
3. Under Web Services Security Properties, you can access collection certificate stores for the following bindings:
   - For the Request generator, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom** > **Collection certificate store**.
   - For the Request consumer, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom** > **Collection certificate store**.
   - For the Response generator, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom** > **Collection certificate store**.
   - For the Response consumer, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom** > **Collection certificate store**.
4. Click the name of a configured collection certificate store or create a new collection certificate store first.
5. Under Additional properties, click **Certificate revocation list** > **New** to specify the path to a new list or click the name of the certificate revocation list to modify its path.
6. Under Additional properties, you can access collection certificate stores for the following bindings:
   - For the Response receiver binding, click **Web services: Client security bindings**. Under Response receiver binding, click **Edit**.
7. Under Additional properties, click **Collection certificate store** > ***certificate_store_name***.
8. Under Additional properties, click **X.509 certificates**.
9. Click **New** and specify the path to the certificate revocation list.

Certificate revocation list path:

Specifies the location where you can find the list of certificates that are not valid.

Certificate revocation list configuration settings:

Use this page to specify a list of certificate revocations that check the validity of a certificate. The application server checks the certificate revocation lists (CRL) to determine the validity of the client certificate. A certificate that is found in a certificate revocation list might not be expired, but is no longer trusted by the certificate authority (CA) that issued the certificate. The CA might add the certificate to the certificate revocation list if it believes that the client authority is compromised.

To view the administrative console panel for the collection certificate store on the server level, complete the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

Note: In a mixed node cell with a server using WebSphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.

3. Under Additional properties, click **Collection certificate store**.
4. Click the name of a configured collection certificate store or create a new collection certificate store first.
5. Under Additional properties, click **Certificate revocation lists** > **New** to specify the path to a new list or click the name of a certificate revocation list to modify its path.

To view this administrative console page for the collection certificate store on the application level, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Under Modules, click **Manage modules** > ***URI_name***.
3. Under Web Services Security Properties, you can access collection certificate stores for the following bindings:
   - For the Request generator, click **Web services: Client security bindings**. Under Request generator (sender) binding, click **Edit custom** > **Collection certificate store**.
   - For the Request consumer, click **Web services: Server security bindings**. Under Request consumer (receiver) binding, click **Edit custom** > **Collection certificate store**.
   - For the Response generator, click **Web services: Server security bindings**. Under Response generator (sender) binding, click **Edit custom** > **Collection certificate store**.
   - For the Response consumer, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom** > **Collection certificate store**.
4. Click the name of a configured collection certificate store or create a new collection certificate store first.
5. Under Additional properties, click **Certificate revocation lists** > **New** to specify the path to a new list or click the name of a certificate revocation list to modify its path.

Certificate revocation list path:

Specifies a fully qualified path to the location where you can find the list of certificates that are not valid.

For portability reasons, it is recommended that you use application server variables to specify a relative path to the certificate revocation list. This recommendation is especially important when you are working in a WebSphere Application Server, Network Deployment environment. For example, you might use the *USER_INSTALL_ROOT* variable to define a path such as *$USER_INSTALL_ROOT/mycertstore/mycrl* where *mycertstore* represents the name of your certificate store and *mycrl* represents the certificate revocation list. For a list of the supported variables, click **Environment** > **WebSphere variables** in the administrative console.

The following list provides recommendations for using CRLs:

- If CRLs are added to the collection certificate store collection, add the CRLs for the root certificate authority and each intermediate certificate, if applicable. When the CRL is in the certificate collection store, the certificate revocation status for every certificate in the chain is checked against the CRL of the issuer.
- When the CRL file is updated, the new CRL does not take effect until you restart the web service application.
- Before a CRL expires, you must load a new CRL into the certificate collection store to replace the old CRL. An expired CRL in the collection certificate store results in a certificate path (CertPath) build failure.

Configuring the collection certificate store for the consumer binding on the application level:

A collection certificate store is a collection of non-root, certificate authority (CA) certificates and certificate revocation lists (CRLs). This collection of CA certificates and CRLs is used to check for a valid signature in a digitally signed SOAP message.

About this task

A collection certificate store is a collection of non-root, certificate authority (CA) certificates and certificate revocation lists (CRLs) that can be used to check for a valid signature in a digitally signed SOAP message. Complete the following steps to configure a collection certificate for the consumer bindings on the application level:

Procedure

1. Locate the collection certificate store configuration panel in the administrative console.
   a. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
   b. Under Modules, click **Manage modules** > ***URI_name***.
   c. Under Web Services Security properties, you can access the collection certificate store information for the response consumer and request consumer bindings.
      - For the response consumer (receiver) binding, click **Web services: Client security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
      - For the request consumer (receiver) binding, click **Web services: Server security bindings**. Under Response consumer (receiver) binding, click **Edit custom**.
   d. Under Additional properties, click **Collection certificate store**.
2. Click **New** to create a collection certificate store configuration, click **Delete** to delete an existing configuration, or click the name of an existing collection certificate store configuration to edit its settings. If you are creating a new configuration, enter a name in the Certificate store name field.

   The name of the collection certificate store must be unique to the level of the application server. For example, if you create the collection certificate store for the application level, the store name must be unique to the application level. The name that is specified in the Certificate store name field is used by other configurations to refer to a predefined collection certificate store. WebSphere Application Server searches for the collection certificate store based on proximity.

   For example, if an application binding refers to a collection certificate store named `cert1`, the Application Server searches for `cert1` at the application level before searching the server level.
3. Specify a certificate store provider in the Certificate store provider field. WebSphere Application Server supports the IBMCertPath certificate store provider. To use another certificate store provider, you must define the provider implementation in the provider list within the *`profile_root`*`/properties/java.security` file. However, make sure that your provider supports the same requirements of the certificate path algorithm as WebSphere Application Server.
4. Click **OK** and **Save** to save the configuration.
5. Click the name of your certificate store configuration. After you specify the certificate store provider, you must specify either the location of a certificate revocation list or the X.509 certificates. However, you can specify both a certificate revocation list and the X.509 certificates for your certificate store configuration.
6. Under Additional properties, click **Certificate revocation lists**.
7. Click **New** to specify a certificate revocation list path, click **Delete** to delete an existing list reference, or click the name of an existing reference to edit the path. You must specify the fully qualified path to the location where WebSphere Application Server can find your list of certificates that are not valid. For portability reasons, it is recommended that you use the WebSphere Application Server variables to specify a relative path to the certificate revocation lists (CRL). This recommendation is especially important when you are working in a WebSphere Application Server, Network Deployment environment. For example, you might use the *USER_INSTALL_ROOT* variable to define a path such

as $*USER_INSTALL_ROOT*/mycertstore/mycrl1. For a list of supported variables, click **Environment** > **WebSphere variables** in the administrative console. The following list provides recommendation for using certificate revocation lists:

- If CRLs are added to the collection certificate store, add the CRLs for the root certificate authority and each intermediate certificate, if applicable. When the CRL is in the certificate collection store, the certificate revocation status for every certificate in the chain is checked against the CRL of the issuer.
- When the CRL file is updated, the new CRL does not take effect until you restart the web service application.
- Before a CRL expires, you must load a new CRL into the certificate collection store to replace the old CRL. An expired CRL in the collection certificate store results in a certificate path (CertPath) build failure.

8. Click **OK** and **Save** to save the configuration.
9. Return to the Collection certificate store configuration panel. See the first few steps of this article to locate the collection certificate store panel.
10. Under Additional properties, click **X.509 certificates**.
11. Click **New** to create a new configuration for X.509 certificates, click **Delete** to delete an existing configuration, or click the name of an existing X.509 certificate configuration to edit its settings. If you are creating a new configuration, enter a name in the Certificate store name field.
12. Specify a path in the X.509 certificate path field. This entry is the absolute path to the location of the X.509 certificates. The collection certificate store is used to validate the certificate path of incoming X.509-formatted security tokens.

    You can use the *USER_INSTALL_ROOT* variable as part of the path name. For example, you might type: `USER_INSTALL_ROOT/etc/ws-security/samples/intca2.cer`. Do not use this certificate path for production use. You must obtain your own X.509 certificate from a certificate authority before putting your WebSphere Application Server environment into production.

    Click **Environment** > **WebSphere variables** in the administrative console to configure the *USER_INSTALL_ROOT* variable.
13. Click **OK** and then **Save** to save your configuration.

Results

You have configured the collection certificate store for the consumer binding.

What to do next

You must configure a token consumer configuration that references this certificate store configuration.

Configuring the collection certificate on the server level:

Collection certificate stores contain untrusted, intermediary certificate files awaiting validation. You can configure the collection certificate store on the server level and the cell level.

About this task

Validation might consist of checking for a valid signature in a digitally signed SOAP message to see if the certificate is on a certificate revocation list (CRLs), checking that the certificate is not expired, and checking that the certificate is issued by a trusted signer.

Complete the following steps to configure a collection certificate store on the server level:

Procedure

1. Access the default bindings for the server level.
   a. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
   b. Under Security, click **JAX-WS and JAX-RPC security runtime**.

      Note: In a mixed node cell with a server using WebSphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
2. Under Additional properties, click **Collection certificate store**.
3. Click **New** to create a collection certificate store configuration, click **Delete** to delete an existing configuration, or click the name of an existing collection certificate store configuration to edit its settings. If you are creating a new configuration, enter a name in the Certificate store name field. For example, you might name your certificate store `sig_certstore`.

   The name of the collection certificate store must be unique to the level of the application server. For example, if you create the collection certificate store for the server level, the store name must be unique to the server level. The name that is specified in the Certificate store name field is used by other configurations to refer to a predefined collection certificate store. WebSphere Application Server searches for the collection certificate store based on proximity.

   For example, if an application binding refers to a collection certificate store named `cert1`, the Application Server searches for `cert1` at the application level before searching the server level.
4. Specify a certificate store provider in the Certificate store provider field. WebSphere Application Server supports the IBMCertPath certificate store provider. To use another certificate store provider, you must define the provider implementation in the provider list within the *`profile_root`*`/properties/java.security` file. However, make sure that your provider supports the same requirements of the certificate path algorithm as WebSphere Application Server.
5. Click **OK** and **Save** to save the configuration.
6. Click the name of your certificate store configuration. After you specify the certificate store provider, you must specify either the location of a certificate revocation list or the X.509 certificates. However, you can specify both a certificate revocation list and the X.509 certificates for your certificate store configuration.
7. Under Additional properties, click **Certificate revocation lists**. For the generator binding, a certificate revocation list (CRL) is used when it is included in a generated security token. For example, a security token might be wrapped in a PKCS#7 format with a CRL. For more information on certificate revocation lists, see Certificate revocation list.
8. Click **New** to specify a certificate revocation list path, click **Delete** to delete an existing list reference, or click the name of an existing reference to edit the path. You must specify the fully qualified path to the location where WebSphere Application Server can find your list of certificates that are not valid. WebSphere Application Server uses the certificate revocation list to check the validity of the sender certificate.

   For portability reasons, it is recommended that you use the WebSphere Application Server variables to specify a relative path to the certificate revocation lists. This recommendation is especially important when you are working in a WebSphere Application Server, Network Deployment environment.

   For example, you might use the *USER_INSTALL_ROOT* variable to define a path such as *$USER_INSTALL_ROOT/mycertstore/mycrl1* where *mycertstore* represents the name of your certificate store and *mycrl1* represents the certificate revocation list. For a list of supported variables, click **Environment** > **WebSphere variables** in the administrative console. The following list provides recommendations for using certificate revocation lists:

   - If CRLs are added to the collection certificate store, add the CRLs for the root certificate authority and each intermediate certificate, if applicable. When the CRL is in the certificate collection store, the certificate revocation status for every certificate in the chain is checked against the CRL of the issuer.

- When the CRL file is updated, the new CRL does not take effect until you restart the web service application.
- Before a CRL expires, you must load a new CRL into the certificate collection store to replace the old CRL. An expired CRL in the collection certificate store results in a certificate path (CertPath) build failure.

9. Click **OK** and then **Save** to save the configuration.
10. Return to the Collection certificate store configuration panel.
11. Under Additional properties, click **X.509 certificates**. The X.509 certificate configuration specifies intermediate certificate files that are used for certificate path validation of incoming X.509-formatted security tokens.
12. Click **New** to create an X.509 certificate configuration, click **Delete** to delete an existing configuration, or click the name of an existing X.509 certificate configuration to edit its settings. If you are creating a new configuration, enter a name in the Certificate store name field.
13. Specify a path in the X.509 certificate path field. This entry is the absolute path to the location of the X.509 certificate. The collection certificate store is used to validate the certificate path of the incoming X.509-formatted security tokens.

    You can use the *USER_INSTALL_ROOT* variable as part of path name. For example, you might type: `$USER_INSTALL_ROOT/etc/ws-security/samples/intca2.cer`. Do not use this certificate path for production use. You must obtain your own X.509 certificate from a certificate authority before putting your WebSphere Application Server environment into production.

    Click **Environment** > **WebSphere variables** in the administrative console to configure the *USER_INSTALL_ROOT* variable.
14. Click **OK** and then **Save** to save your configuration.
15. Return to the Collection certificate store collection panel and click **Update run time** to update the Web Services Security run time with the default binding information, which is located in the `ws-security.xml` file. When you click **Update run time**, the configuration changes made to other web services are also updated in the run time for Web Services Security. Policy sets can only be used with JAX-WS applications. Policy sets cannot be used for JAX-RPC applications.

Results

You have configured the collection certificate store for the server level.

Configuring trusted ID evaluators on the server level:

You can configure trusted identity (ID) evaluators. The trusted ID evaluator determines whether or not to trust the identity-asserting authority.

About this task

This task provides the steps that are needed to configure trusted identity (ID) evaluators. The trusted ID evaluator determines whether to trust the identity-asserting authority. After the ID is trusted, the WebSphere Application Server issues the proper credentials based on the identity, which are used in a downstream call to another server for invoking resources. The trusted ID evaluator implements the `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator` interface.

Complete the following steps to configure the trusted ID evaluators on the server level:

Procedure

1. Access the default bindings for the server level.
   a. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
   b. Under Security, click **JAX-WS and JAX-RPC security runtime**.

Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.

2. Under Additional properties, click **Trusted ID evaluators**.
3. Click **New** to create a trusted ID evaluator configuration, click **Delete** to delete an existing configuration, or click the name of an existing configuration to edit the settings. If you are creating a new configuration, enter a unique name for the trusted ID evaluator configuration in the Trusted ID evaluator name field. This field specifies the name that is used by the application binding to refer to a trusted identity (ID) evaluator that is defined in the default binding.
4. Specify a class name in the Trusted ID evaluator class name field. The default class name is `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluatorImpl`. The specified trusted ID evaluator class name must implement the `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator` class. When you use the default `TrustedIDEvaluator` class, you must specify the name and value properties for the default trusted ID evaluator to create the trusted ID list for evaluation.
5. Under Additional properties, click **Properties > New**.
6. Specify the trusted ID evaluator name as a property name. You must specify the trusted ID evaluator name in the form, `trustedId_n`, where `_n` is an integer from zero (0) to n.
7. Specify the trusted ID as a property value.

```
property name="trustedId_0", value="CN=Bob,O=ACME,C=US"
property name="trustedId_1, value="user1"
```

   If a distinguished name (DN) is used, the space is removed for comparison.
8. Click **OK** and then **Save**.

Results

You have configured the trusted ID evaluators at the server level.

Trusted ID evaluator collection:

Use this page to view a list of trusted identity (ID) evaluators. The trusted ID evaluator determines whether to trust the identity-asserting authority. After the ID is trusted, the application server issues the proper credentials based on the identity, which are used in a downstream call for invoking resources. The trusted ID evaluator implements the `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator` interface.

This administrative console page applies only to Java API for XML-based RPC (JAX-RPC) applications.

To view this administrative console page for trusted ID evaluators on the server level, complete the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under Additional properties, click **Trusted ID evaluators**.
4. Click **New** to create a trusted ID evaluator or click **Delete** to a delete a trusted ID evaluator.

To view this administrative console page for trusted ID evaluators on the application level, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Under Modules, click **Manage Modules** > ***URI_name***.
3. Under Web Services Security Properties, click **Web services: Server security bindings**.
4. Under Request receiver binding, click **Edit**.

5. Click **Trusted ID evaluators**.
6. Click **New** to create a trusted ID evaluator or click **Delete** to delete a trusted ID evaluator.

Important: Trusted ID evaluators are only required for the request consumer (Version 6.*x* applications), if identity assertion is configured.

Using this trusted ID evaluator collection panel, complete the following steps:

1. Specify a trusted ID evaluator name and a trusted ID evaluator class name.
2. Save your changes by clicking **Save** in the messages section at the top of the administrative console.
3. Click **Update run time** to update the Web Services Security run time with the default binding information, which is found in the `ws-security.xml` file. The configuration changes made to the other web services also are updated in the Web Services Security run time.

Trusted ID evaluator name:

Specifies the unique name of the trusted ID evaluator.

Trusted ID evaluator class name:

Specifies the class name of the trusted ID evaluator.

Trusted ID evaluator configuration settings:

Use this information to configure trust identity (ID) evaluators.

This administrative console page applies only to Java API for XML-based RPC (JAX-RPC) applications.

To view this administrative console page for trusted ID evaluators on the server level, complete the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under Additional properties, click **Trusted ID evaluators**.
4. Click **New** to create a trusted ID evaluator or click the name of an existing configuration to modify the settings.

To view this administrative console page for trusted ID evaluators on the application level, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Under Modules, click **Manage modules** > ***URI_name***.
3. Under Web Services Security Properties, click **Web services: Server security bindings**.
4. Under Request receiver binding, click **Edit**.
5. Click **Trusted ID evaluators**.
6. Click **New** to create a trusted ID evaluator or click **Delete** to delete a trusted ID evaluator.

Important: Trusted ID evaluators are only required for the request consumer (Version 6.*x* applications), if identity assertion is configured.

You can specify one of the following options:

None Choose this option if you are not specifying a trusted ID evaluator.

Existing evaluator definition
Choose this option to specify a currently defined trusted ID evaluator.

Binding evaluator definition
Choose this option to specify a new trusted ID evaluator. A description of the required fields follows.

Trusted ID evaluator name:

Specifies the name that is used by the application binding to refer to a trusted identity (ID) evaluator that is defined in the default binding.

Trusted ID evaluator class name:

Specifies the class name of the trusted ID evaluator.

The specified trusted ID evaluator class name must implement the `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator` interface. The default TrustedIDEvaluator class is `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluatorImpl`. When you use this default TrustedIDEvaluator class, you must specify the name and the value properties for the default trusted ID evaluator to create the trusted ID list for evaluation.

To specify the name and value properties, complete the following steps:

1. Under Additional properties, click **Properties** > **New**.
2. Specify the trusted ID evaluator name as a property name. You must specify the trusted ID evaluator name in the form, `trustedId_n`, where `_n` is an integer from zero (0) to n.
3. Specify the trusted ID as a property value.

For example:

```
property name="trustedId_0", value="CN=Bob,O=ACME,C=US"
property name="trustedId_1", value="user1"
```

If a distinguished name (DN) is used, the space is removed for comparison.

Default `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluatorImpl`

See the programming model information in the documentation for an explanation of how to implement the `com.ibm.wsspi.wssecurity.id.TrustedIDEvaluator` interface.

rrdSecurity.props file:

Remote request dispatcher (RRD) supports LTPA and security attribute propagation for Web Services Security (WS-Security). You can enable token propagation in the `<was_install>/profiles/<profileName>/properties/rrdSecurity.props` file.

The `rrdSecurity.props` file contains comments to describe the security attributes.

The following is the format of the `rrdSecurity.props` file. The default values are in bold face type.

- `LTPAPropagation= ( True | False)`
- `SecurityAttributePropagation= ( True | False)`
- `SSLRequired= ( True | False)`

The WS-Security run time inspects the run as (invocation) subject and propagates the security tokens in the subject. The default setting is to only propagate the LTPA tokens.

Custom security tokens can be passed as attributes of the LTPA tokens. The security attribute propagation support uses the same pluggable JAAS login module as the CSIv2 support. The security attribute is not signed or encrypted, therefore, you should not send the attribute in clear text form. You must require SSL to ensure integrity and confidentiality. If SSL is not required, RRD uses the same scheme, such as HTTP or HTTPS, to make the web services call that the original request used.

You must also configure the target web service to validate the LTPA tokens and security attributes.

Enabling or disabling single sign-on interoperability mode for the LTPA token

You can set an interoperability flag on the token generator to determine whether an LTPA Version 1 token or an LTPA Version 2 token is retrieved when a request message is received.

About this task

In WebSphere Application Server Version 7.0 and later, a flag is set in the global security settings to enable single sign-on interoperability mode for the LTPA token. This option determines whether an LTPA Version 1 token or an LTPA Version 2 token is sent when a message request is received. When the interoperability flag is set to true, then the AuthenticationToken is an LTPA Version 1 token, and the SingleSignonToken is an LTPA Version 2 token. When the interoperability flag is set to false, then both the AuthenticationToken and the SingleSignonToken are LTPA Version 2 tokens.

When the interoperability mode is enabled (the flag is set to true), and the Web Services Security binding configuration specifies LTPA Version 1 as the token, the AuthenticationToken is used to retrieve the token that is sent with the message. If interoperability mode is not enabled (the flag is set to false), and the Web Services Security binding configuration specifies LTPA Version 1 as the token, an exception error is logged.

You can disable the interoperability checking function by setting the custom property, com.ibm.wsspi.wssecurity.tokenGenerator.ltpav1.pre.v7, on the token generator. This setting determines the LTPA token without checking the state of the interoperability flag, providing compatibility with servers running WebSphere Application Server Version 6.1 and earlier.

To enforce use of the LTPA Version 2 token, edit the token settings, and set the **Enforce token version** option for the token.

Procedure

1. Click **Applications > Application Types > WebSphere enterprise applications**.
2. Select an application that contains web services. The application must contain a service provider or a service client.
3. Click the **Service provider policy sets and bindings** link or the **Service client policy sets and bindings** link in the Web Services Properties section.
4. Select a binding. You must have previously attached a policy set and assigned an application specific binding.
5. Click the **WS-Security** policy in the Policies table.
6. Click the **Authentication and protection** link in the Main message security policy bindings section.
7. Click a consumer or generator token link from the Protection Tokens table.
8. Select the **Enforce token version** check box after the **Token type** field.

Enabling cryptographic keys stored in hardware devices for Web Services Security

You can enable Web Services Security by using cryptographic hardware devices for both web service clients and web service providers that are running in the WebSphere® Application Server environment.

Enabling hardware cryptographic devices for Web Services Security

You can enable Web Services Security by using cryptographic hardware devices for both web service clients and web service providers that are running in the WebSphere Application Server environment. A cryptographic token is a hardware or software device with a built-in keystore implementation. Cryptographic devices are used to manage certificates stored on the cryptographic tokens. These devices are also called *smartcards*. You enable hardware cryptographic devices for Web Service Security by either using keys that are stored in hardware devices or by using keys stored in a Java keystore file.

About this task

Web Services Security using cryptographic hardware devices is supported for both web (JavaServer Pages (JSP) or servlet) and Enterprise JavaBeans (EJB) web service clients. You can enable Web Services Security by using cryptographic hardware devices for both web service clients and web service providers that are running in the WebSphere Application Server environment.

There are two ways to enable hardware cryptographic devices for Web Service Security: use keys that are stored in hardware devices or use keys stored in a Java keystore file.

Procedure

1. Determine whether to use keys that are stored in hardware devices or in a Java keystore file for the individual application.
2. Enable hardware cryptographic devices for Web Service Security by using one of the following two methods:
   - Enable cryptographic operations on hardware devices. See “Configuring hardware cryptographic devices for Web Services Security” for more details.
   - Enable cryptographic keys that are stored in hardware devices. See “Enabling cryptographic keys stored in hardware devices in Web Services Security” on page 3441

   Note: Hardware cryptographic devices for Web Services Security are not supported on the Java Platform, Enterprise Edition (Java EE) Application Client on distributed platform.

Configuring hardware cryptographic devices for Web Services Security:

Before you can use a hardware cryptographic device, you must configure and enable it. You must first configure a hardware cryptographic device using the Secure Sockets Layer (SSL) certificate and key management panels in the administrative console. The key for the cryptographic operation can be stored in an ordinary Java keystore file and need not be stored on the hardware devices.

Before you begin

You must first configure a hardware cryptographic device using the Secure Sockets Layer (SSL) certificate and key management panels in the administrative console.

Note: Fix packs that include updates to the Software Development Kit (SDK) might overwrite unrestricted policy files. Back up unrestricted policy files before you apply a fix pack and reapply these files after the fix pack is applied.

Procedure

1. In the administrative console, click **Servers** > **Server Types** > **WebSphere application servers** and then select the server name.
2. Under **Security**, select **JAX-WS and JAX-RPC security runtime**.
3. Under Cryptographic Hardware, select **Enable cryptographic operations on hardware device** and then specify the name of the hardware cryptographic device configuration name. For more information, read about configuring a hardware cryptographic keystore.

4. Click **OK**.

Results

This procedure configures a hardware cryptographic device for all Web Services Security applications running on this application server.

Enabling cryptographic keys stored in hardware devices in Web Services Security:

You can enable individual web service applications to use cryptographic keys stored in hardware devices in Web Services Security.

Before you begin

You must first configure the hardware acceleration device using the key management panels in the administrative console. See “Configuring hardware cryptographic devices for Web Services Security” on page 3440

Procedure

1. In the administrative console, click **Servers** > **Server types** > **WebSphere application servers** and then select the server name.
2. Under **Security**, click **JAX-WS and JAX-RPC security runtime**.
3. Under **Additional properties**, click **key locators**.
4. Select the key locator name.
5. Under **Key store**, specify the name of the keystore configuration.

   If the keystore reference is specified to a hardware device configuration, the Web Services Security runtime first attempts to obtain the cryptographic algorithm from the hardware device. If the hardware device is not supported or if it fails, the runtime for Web Services Security obtains the cryptographic algorithm from the security providers list. Read about creating a keystore configuration for a preexisting keystore file for more information about how to create the name of a keystore configuration.
6. Click **OK**.

Results

If the name of the keystore reference is a Java keystore file, a hardware acceleration device that is configured at the application server level (`ws-security.xml`) will be used for cryptographic operations.

Configuring XML digital signature for Version 5.x web services with the administrative console

XML digital signature provides both message integrity and authentication capabilities when it is used with SOAP messages. XML digital signature is one of the methods WebSphere® Application Server provides to secure web services. You can use the WebSphere® Application Server administrative console to configure XML digital signature.

Login mappings collection

Use this page to view a list of configurations for validating security tokens within incoming messages. Login mappings map an authentication method to a Java Authentication and Authorization Service (JAAS) login configuration to validate the security token. Four authentication methods are predefined in the WebSphere Application Server: BasicAuth, Signature, IDAssertion, and Lightweight Third Party Authentication (LTPA).

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with

WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications. Version 5.*x* applications are based on Java 2 platform, Enterprise Edition (J2EE) 1.3.

To view this administrative console page for the server level, complete the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under Additional properties, click **Login mappings**.
4. Click either **New** to create a new login mapping configuration or click the name of an existing configuration.

To view this administrative console page for the application level, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Under Modules, click **Manage modules** > ***URI_name***.
3. Under Web Services Security properties, click **Web services: Server security bindings**.
4. Click **Edit** under Request receiver binding.
5. Click **Login mappings**.

If you click **Update runtime**, the Web Services Security run time is updated with the default binding information, which is contained in the `ws-security.xml` file that was previously saved. After you specify the authentication method, the JAAS configuration name, and the Callback Handler Factory class name on this panel, you must complete the following steps:

1. Click **Save** in the messages section at the top of the administrative console.
2. Click **Update runtime**. When you click **Update runtime**, the configuration changes made to the other web services also are updated in the Web Services Security run time.

Important: If the login mapping configuration is not found on the application level, the web services run time searches for the login mapping configuration on the server level.

Authentication method:

Specifies the authentication method used for validating the security tokens.

The following authentication methods are available:

BasicAuth
The basic authentication method includes both a user name and a password in the security token. The information in the token is authenticated by the receiving server and is used to create a credential.

Signature
The signature authentication method sends an X.509 certificate as a security token. For Lightweight Directory Access Protocol (LDAP) registries, the distinguished name (DN) is mapped to a credential, which is based on the LDAP certificate filter settings. For local OS registries, the first attribute of the certificate, usually the common name (CN) is mapped directly to a user name in the registry.

IDAssertion
The identity assertion method maps a trusted identity (ID) to a WebSphere Application Server credential. This authentication method only includes a user name in the security token. An additional token is included in the message for trust purposes. When the additional token is trusted, the IDAssertion token user name is mapped to a credential.

LTPA Lightweight Third Party Authentication (LTPA) validates an LTPA token.

JAAS configuration name:

Specifies the name of the Java Authentication and Authorization Service (JAAS) configuration.

Callback handler factory class name:

Specifies the name of the factory for the CallbackHandler class.

Login mapping configuration settings

Use this page to specify the Java Authentication and Authorization Service (JAAS) login configuration settings that are used to validate security tokens within incoming messages.

Important: There is an important distinction between Version 6 and later applications. The information in this article supports Version 6.*x* applications only that are used with WebSphere Application Server Version 6.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

To view this administrative console page for the server level, complete the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
3. Under Additional properties, click **Login mappings**.
4. Click either **New** to create a new login mapping configuration or click the name of an existing configuration.

To use this administrative console page for the application level, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Under Modules, click **Manage modules** > ***URI_name***.
3. Under Web Services Security Properties, click **Web services: Server security bindings**.
4. Click **Edit** under Request receiver binding.
5. Click **Login mappings**.
6. Click either **New** to create a new login mapping configuration or click the name of an existing configuration.

Important: If the login mapping configuration is not found on the application level, the web services run time searches for the login mapping configuration on the server level.

Authentication method:

Specifies the method of authentication.

You can use any string, but the string must match the element in the service-level configuration. The following words are reserved and have special meanings:

BasicAuth
Uses both a user name and a password.

IDAssertion
Uses only a user name, but requires that additional trust is established on the receiving server using a TrustedIDEvaluator mechanism.

Signature
Uses the distinguished name (DN) of the signer.

LTPA Validates a token.

JAAS configuration name:

Specifies the name of the Java Authentication and Authorization Service (JAAS) configuration.

Among the predefined system login configurations that you can use are the following:

system.wssecurity.IDAssertion
Enables a version 6.*x* application to use identity assertion to map a user name to a WebSphere Application Server credential principal.

system.wssecurity.Signature
Enables a version 6.*x* application to map a distinguished name (DN) in a signed certificate to a WebSphere Application Server credential principal.

system.LTPA_WEB
Processes login requests that are used by the web container such as servlets and JavaServer Pages (JSP) files.

system.WEB_INBOUND
Handles logins for web application requests, which include servlets and JavaServer Pages..

system.RMI_INBOUND
Handles logins for inbound Remote Method Invocation (RMI) requests.

system.DEFAULT
Handles the logins for inbound requests made by internal authentications and most of the other protocols except web applications and RMI requests.

system.RMI_OUTBOUND
Processes RMI requests that are sent outbound to another server when the com.ibm.CSIOutboundPropagationEnabled property is `true`. This property is set in the CSIv2 authentication panel. To access the panel, click **Security** > **Global security**. Expand RMI/IIOP security, then click on **CSIv2 Outbound authentication**. To set the `com.ibm.CSIOutboundPropagationEnabled` property, select **Security attribute propagation**.

system.wssecurity.X509BST
Verifies an X.509 binary security token (BST) by checking the validity of the certificate and the certificate path.

system.wssecurity.PKCS7
Verifies an X.509 certificate with a certificate revocation list in a PKCS7 object.

system.wssecurity.PkiPath
Verifies an X.509 certificate with a public key infrastructure (PKI) path.

system.wssecurity.UsernameToken
Verifies basic authentication (user name and password).

These system login configurations are defined on the System logins panel, which is accessible by completing the following steps:

1. Click **Security** > **Global security**.
2. Expand Java Authentication and Authorization Service, then click **System logins**.

Attention: The predefined system login configurations are listed on the System logins configuration panel without the system prefix. For example, the system.wssecurity.UsernameToken configuration listed in the Java Authentication and Authorization Service (JAAS) configuration name option corresponds to the wssecurity.UsernameToken configuration that is on the System logins configuration panel.

You can use the following predefined application login configurations:

ClientContainer
Specifies the login configuration that is used by the client container application, which uses the CallbackHandler API that is defined in the deployment descriptor of the client container.

WSLogin
Specifies whether all applications can use the WSLogin configuration to perform authentication for the WebSphere Application Server security run time.

DefaultPrincipalMapping
Specifies the login configuration used by Java 2 Connectors (J2C) to map users to principals that are defined in the J2C authentication data entries.

These application login configurations are defined on the Application logins panel, which is accessible by completing the following steps:

1. Click **Security** > **Global security**.
2. Expand Java Authentication and Authorization Service, then click **Application logins**.

Do not remove these predefined system or application login configurations. Within these configurations, you can add module class names and specify the order in which WebSphere Application Server loads each module.

Callback handler factory class name:

Specifies the name of the factory for the CallbackHandler class.

You must implement the `com.ibm.wsspi.wssecurity.auth.callback.CallbackHandlerFactory` class in this field.

Token type URI:

Specifies the namespace Uniform Resource Identifiers (URI), which denotes the type of security token that is accepted.

If binary security tokens are accepted, the value denotes the ValueType attribute in the element. The ValueType element identifies the type of security token and its namespace. If Extensible Markup Language (XML) tokens are accepted, the value denotes the top-level element name of the XML token.

If the reserved words are specified previously in the Authentication method field, this field is ignored.

Data type: Unicode characters except for non-ASCII characters, but including the number sign (#), the percent sign (%), and the square brackets ([ ]).

Token type local name:

Specifies the local name of the security token type, for example, X509v3.

If binary security tokens are accepted, the value denotes the ValueType attribute in the element. The ValueType attribute identifies the type of security token and its namespace. If Extensible Markup Language (XML) tokens are accepted, the value denotes the top-level element name of the XML token.

If the reserved words are specified previously in the Authentication method field, this field is ignored.

Nonce maximum age:

Specifies the time, in seconds, before the nonce timestamp expires. Nonce is a randomly generated value.

You must specify a minimum of 300 seconds for the Nonce maximum age field. However, the maximum value cannot exceed the number of seconds specified in the Nonce cache timeout field for the server level.

You can specify the Nonce maximum age value for the server level by completing the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.

Important: The Nonce maximum age field on this panel is optional and only valid if the BasicAuth authentication method is specified. If you specify another authentication method and attempt to specify values for this field, the following error message displays and you must remove the specified value: `Nonce is not supported for authentication methods other than BasicAuth.`

If you specify the BasicAuth method, but do not specify values for the Nonce maximum age field, the Web Services Security run time searches for a Nonce maximum age value on the server level.

Default	300 seconds
Range	300 to Nonce cache timeout seconds

Nonce clock skew:

Specifies the clock skew value, in seconds, to consider when WebSphere Application Server checks the freshness of the message. Nonce is a randomly generated value.

You can specify the **Nonce clock skew** value for the server level by completing the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **JAX-WS and JAX-RPC security runtime**.

Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.

You must specify a minimum of zero (0) seconds for the Nonce Clock Skew field. However, the maximum value cannot exceed the number of seconds that is specified in the Nonce maximum age field on this Login mappings panel.

Important: The Nonce clock skew field on this panel is optional and only valid if the BasicAuth authentication method is specified. If you specify another authentication method and attempt to specify values for this field, the following error message displays and you must remove the specified value: `Nonce is not supported for authentication methods other than BasicAuth.`

Note: If you specify BasicAuth, but do not specify values for the Nonce clock skew field, WebSphere Application Server searches for a Nonce clock skew value on the server level.

Default	0 seconds
Range	0 to Nonce Maximum Age seconds

Configuring nonce using Web Services Security tokens

Nonce is a randomly generated, cryptographic token that is used to thwart the highjacking of user name tokens, which are used with SOAP messages. Use nonce in conjunction with the BasicAuth authentication method.

About this task

Important: The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

You can configure nonce at the application level and server level.

If you configure nonce on the application level and the server level, the values specified for the application level take precedence over the values specified for the server level.

You must consider the order of precedence:

1. Application level
2. Server level

Complete these high-level tasks in the order listed:

Procedure

1. Configure nonce for the application level.
2. Configure nonce for the server level.

What to do next

After completing these steps, restart the server if it has not already been restarted.

Configuring nonce for the server level:

Nonce is a randomly generated, cryptographic token that is used to prevent the theft of username tokens, which are used with SOAP messages. Nonce is used in conjunction with the basic authentication (BasicAuth) method. You can configure nonce for the server level by using the WebSphere Application Server administrative console.

About this task

Important: The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

You can configure nonce at the application level and the cell level.

However, you must consider the order of precedence:

1. Application level
2. Server level

If you configure nonce on the application level and the server level, the values specified for the application level take precedence over the values specified for the server level.

In a WebSphere Application Server (base) or WebSphere Application Server, Express environment, you must specify values for the Nonce cache timeout, Nonce maximum age, and Nonce clock skew fields on the server level to use nonce effectively.

Complete the following steps to configure nonce on the server level:

Procedure

1. Connect to the administrative console.

   Type `http://server_name:port_number/ibm/console` in your web browser unless you have changed the port number.
2. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_level***.
3. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using WebSphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
4. Specify a value, in seconds, for the Nonce cache timeout field. The value specified for the Nonce cache timeout field indicates how long the nonce remains cached before it is expunged. You must specify a minimum of 300 seconds. However, if you do not specify a value, the default is 600 seconds. This field is required for the server level.
5. Specify (optional) a value, in seconds, for the Nonce maximum age field.

   The value specified for the Nonce Maximum Age field indicates how long the nonce is valid. You must specify a minimum of 300 seconds, but the value cannot exceed the number of seconds specified for the Nonce cache timeout field on the server level.

   This field is required for the server level.
6. Specify a value, in seconds, for the Nonce clock skew field. The value specified for the Nonce clock skew field specifies the amount of time, in seconds, to consider when the message receiver checks the timeliness of the value. Consider the following information when you set this value:
   - Difference in time between the message sender and the message receiver if the clocks are not synchronized.
   - Time needed to encrypt and transmit the message.
   - Time needed to get through network congestion.

   You must specify at least 0 seconds for the Nonce clock skew field. However, the maximum value cannot exceed the number of seconds specified in the Nonce maximum age field on the server level. If you do not specify a value, the default is 0 seconds.
7. Restart the server. If you change the Nonce cache timeout value and do not restart the server, the change is not recognized by the server.

Configuring nonce for the application level:

Nonce is a randomly generated, cryptographic token that is used to thwart the highjacking of Username tokens, which are used with SOAP messages. Use nonce in conjunction with the basic authentication (BasicAuth) method. You can configure nonce for the application level by using the WebSphere Application Server administrative console.

About this task

Important: The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

You can configure nonce at the application level and server level.

However, you must consider the order of precedence:

1. Application level
2. Server level

If you configure nonce on the application level and the server level, the values specified for the application level take precedence over the values specified for the server level.

Procedure

1. Connect to the administrative console.

   Type `http://server_name:port_number/ibm/console` in your web browser unless you have changed the port number.
2. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
3. Under Manage modules, click ***URI_name***.
4. Under Web Services Security Properties, click **Web services: Server security bindings**.
5. Click **Edit** under Request receiver binding
6. Under Additional properties, click **Login mappings** > **New**.
7. Specify (optional) a value, in seconds, for the **Nonce maximum age** field. This panel is optional and only valid if the BasicAuth authentication method is specified. If you specify another authentication method and attempt to specify values for this field, the following error message displays and you must remove the specified value:

```
Nonce is not supported for authentication methods other than
BasicAuth.
```

   If you specify BasicAuth, but do not specify values for the **Nonce maximum age** field, the Web Services Security runtime searches for a nonce maximum age value on the server level.

   The value specified for the **Nonce maximum age** field indicates how long the nonce is valid. You must specify a minimum of 300 seconds; however, the value cannot exceed the number of seconds that is specified for the **Nonce cache timeout** field for the server level.

   You can specify the nonce cache timeout value for the server level by completing the following steps:

   a. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
   b. Under Security, click **JAX-WS and JAX-RPC security runtime**.

      Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
8. Specify (optional) a value, in seconds, for the **Nonce clock skew** field. The value specified for the **Nonce clock skew** field specifies the amount of time, in seconds, to consider when the message receiver checks the timeliness of the value. This panel is optional and only valid if the BasicAuth authentication method is specified. If you specify another authentication method and attempt to specify values for this field, the following error message displays and you must remove the specified value:

```
Nonce is not supported for authentication methods other than
BasicAuth.
```

   If you specify BasicAuth, but do not specify values for the **Nonce clock skew** field, the Web Services Security runtime searches for a Nonce clock skew value on the server level.

   Consider the following information when you set this value:

   - Difference in time between the message sender and the message receiver if the clocks are not synchronized.
   - Time needed to encrypt and transmit the message.
   - Time needed to get through network congestion.
9. Restart the server.

Configuring trust anchors using the administrative console

Use the WebSphere Application Server administrative console to configure trust anchors that specify key stores which contain trusted root certificates to validate the signer certificate.

Before you begin

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

This document describes how to configure trust anchors or trust stores at the application level. It does not describe how to configure trust anchors at the server or cell level. Trust anchors defined at the application level have a higher precedence over trust anchors defined at the server or cell level. For more information on creating and configuring trust anchors at the server or cell level, see either Configuring the server security bindings using an assembly tool or “Configuring the server security bindings using the administrative console” on page 3457.

You can configure an application-level trust anchor using an assembly tool or the administrative console. This document describes how to configure the application-level trust anchor using the administrative console.

About this task

A trust anchor specifies key stores that contain trusted root certificates, which validate the signer certificate. These key stores are used by the request receiver (as defined in the `ibm-webservices-bnd.xmi` file) and the response receiver (as defined in the `ibm-webservicesclient-bnd.xmi` file when web services are acting as client) to validate the signer certificate of the digital signature. The keystores are critical to the integrity of the digital signature validation. If they are tampered with, the result of the digital signature verification is doubtful and comprised. Therefore, it is recommended that you secure these keystores. The binding configuration specified for the request receiver in the `ibm-webservices-bnd.xmi` file must match the binding configuration for the response receiver in the `ibm-webservicesclient-bnd.xmi` file.

The following steps are for the client-side response receiver, which is defined in the `ibm-webservicesclient-bnd.xmi` file and the server-side request receiver, which is defined in the `ibm-webservices-bnd.xmi` file.

Procedure

1. Configure an assembly tool to work with a Java Platform, Enterprise Edition (Java EE) enterprise application. For more information, see the related information on Assembly Tools.
2. Create a web services-enabled Java EE enterprise application. See either Configuring the server security bindings using an assembly tool or “Configuring the server security bindings using the administrative console” on page 3457 for an introduction on how to manage Web Services Security binding information on the server.
3. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***enterprise_application***.
4. Under Manage modules, click ***URI_name***.
5. Under Web Services Security Properties, click **Web services: client security bindings** to edit the response receiver binding information, if web services are acting as a client.
   a. Under Response receiver binding, click **Edit**.
   b. Under Additional properties, click **Trust anchors**.
   c. Click **New** to create a new trust anchor.
   d. Enter a unique name within the request receiver binding for the Trust anchor name field. The name is used to reference the trust anchor that is defined.

e. Enter the key store password, path, and key store type.
f. Click the trust anchor name link to edit the selected trust anchor.
g. Click **Remove** to remove the selected trust anchor or anchors.

When you start the application, the configuration is validated in the run time while the binding information is loading.

6. Return to the web services-enabled module panel accessed in step 2.
7. Under Web Services Security Properties, click **Web services: server security bindings** to edit the request receiver binding information.
   a. Under Request receiver binding, click **Edit**.
   b. Under Additional properties, click **Trust anchors**.
   c. Click **New** to create a new trust anchor

   Enter a unique name within the request receiver binding for the Trust anchor name field. The name is used to reference the trust anchor that is defined.

   Enter the key store password, path, and key store type.

   Click the trust anchor name link to edit the selected trust anchor.

   Click **Remove** to remove the selected trust anchor or anchors.

   When you start the application, the configuration is validated in the run time while the binding information is loading.
8. Save the changes.

Results

This procedure defines trust anchors that can be used by the request receiver or the response receiver (if the web services is acting as client) to verify the signer certificate.

Example

The request receiver or the response receiver (if the web service is acting as a client) uses the defined trust anchor to verify the signer certificate. The trust anchor is referenced using the trust anchor name.

What to do next

To complete the signing information configuration process for request receiver, complete the following tasks:

1. Configuring the server for request digital signature verification: Verifying the message parts
2. Configuring the server for request digital signature verification: choosing the verification method

To complete the process for the response receiver, if the web services is acting as client, complete the following tasks:

1. Configuring the client for response digital signature verification: verifying the message parts
2. Configuring the client for response digital signature verification: choosing the verification method

Configuring the client-side collection certificate store using the administrative console

You can configure the client-side collection certificate store by using the administrative console.

About this task

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6 and later applications.

A *collection certificate store* is a collection of non-root, certificate authority (CA) certificates and certificate revocation lists (CRLs). This collection of CA certificates and CRLs are used to check the signature of a digitally signed SOAP message.

You can configure the collection certificate either by using the assembly tools or the WebSphere Application Server administrative console. Complete the following steps to configure the client-side collection certificate store using the administrative console.

Procedure

1. Connect to the WebSphere Application Server administrative console.

   You can connect to the administrative console by typing `http://server_name:port_number/ibm/console` in your web browser unless you have changed the port number.
2. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
3. Under Manage modules, click *URI_name*.
4. Under Web Services Security Properties, click **Web services: Client security bindings** to add the collection certificate store to the client security bindings. If you do not see any entries, return to the assembly tool and configure the security extensions for either the client or the server.

   To configure the security extensions for the client, see the following topics:
   - Configuring the client for response digital signature verification: verifying the message parts
   - Configuring the client for response digital signature verification: choosing the verification method
5. Under Response receiver binding, click **Edit** to edit the client security bindings.
6. Click **Collection certificate store**.
7. Click a Certificate store name to edit an existing certificate store or click **New** to add a new certificate store name.
8. Enter a name in the Certificate store name field. The name entered in this field is a name that is referenced in the Certificate store field on the Signing information configuration page.
9. Leave the Certificate store provider field value as `IBMCertPath`.
10. Click **Apply**.
11. Under Additional properties, click **X.509 certificates** > **New**.
12. Enter the path to your certificate store. For example, the path might be: `${USER_INSTALL_ROOT}/etc/ws-security/samples/intca2.cer`. If you have any additional certificate store paths to enter, click **New** and add the path names.
13. Click **OK**.

Configuring the server-side collection certificate store using the administrative console

You can configure the collection certificate either by using an assembly tool or the WebSphere Application Server administrative console.

About this task

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6 and later applications.

A *collection certificate store* is a collection of non-root, certificate authority (CA) certificates and certificate revocation lists (CRLs). This collection of CA certificates and CRLs is used to check the signature of a digitally signed SOAP message.

Complete the following steps to configure the server-side collection certificate store using the administrative console.

Procedure

1. Connect to the WebSphere Application Server administrative console.

   You can connect to the administrative console by typing `http://server_name:port_number/ibm/console` in your web browser unless you have changed the port number.
2. Click **Applications > Application Types > WebSphere enterprise applications > *application_name***.
3. Under Manage modules, click ***URI_name***
4. Under Web Services Security Properties, click **Web services: server security bindings** to add the collection certificate store to the server security bindings. If you do not see any entries, return to the assembly tool and configure the security extensions for the server.

   To configure the security extensions for the server, see the following topics:
   - Configuring the server for request digital signature verification: Verifying the message parts
   - Configuring the server for request digital signature verification: choosing the verification method
5. Click **Edit** under Request Receiver Binding to edit the server security bindings.
6. Click **Collection certificate store**.
7. Click a Certificate store name to edit an existing certificate store or click **New** to add a new certificate store name.
8. Enter a name in the Certificate store name field. The name entered in this field is a name that is referenced in the Certificate store field on the Signing information configuration page.
9. Leave the Certificate store provider field as `IBMCertPath`.
10. Click **Apply**.
11. Under Additional Properties, click **X.509 Certificates > New**.
12. Enter the path to your certificate store. For example, the path might be: `${USER_INSTALL_ROOT}/etc/ws-security/samples/intca2.cer`. If you have any additional certificate store paths to enter, click **New** and add the path names.
13. Click **OK**.

Configuring default collection certificate stores at the server level in the WebSphere Application Server administrative console

You can define a single collection certificate store for all of the applications that need to use the same certificates. Use the WebSphere Application Server administrative console to configure the default collection certificate store at the server level.

About this task

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

A *collection certificate store* is a collection of non-root, certificate authority (CA) certificates and certificate revocation lists (CRLs). This collection of CA certificates and CRLs are used to check the signature of a digitally signed SOAP message. A certificate store typically refers to a certificate store located in the file system. The location of the certificate store can vary from machine to machine, so you might configure a default collection certificate store for a specific machine and reference it from within the signing information. The signing information is found within the binding configurations of any application installed on the machine. This suggestion enables you to define a single collection certificate store for all of the applications that need to use the same certificates. You also can specify the default binding information at the cell level.

Complete the following steps to configure the default collection certificate store at the server level using the WebSphere Application Server administrative console:

Procedure

1. Connect to the administrative console.

   You can access the administrative console by typing `http://server_name:port_number/ibm/console` in your web browser unless you have changed the port number.
2. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
3. Under Security, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using Websphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.
4. Under Additional properties, click **Collection certificate store**.
5. Enter a name in the **Certificate store name** field. This name is referenced in the **Certificate store** field on the Signing information configuration page.
6. Leave the **Certificate store provider** field value as `IBMCertPath`.
7. Click **Apply**.
8. Under Additional properties, click **X.509 certificates** > **New**.
9. Enter the path to your certificate store. For example, the path might be: `${USER_INSTALL_ROOT}/etc/ws-security/samples/intca2.cer`.

   If you have any additional certificate store paths to enter, click **New** and add the path names.
10. Click **OK**.

Configuring key locators using the administrative console

You can configure binding information and key locators using the WebSphere Application Server administrative console.

About this task

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

This task provides instructions on how to configure key locators using the WebSphere Application Server administrative console. You can configure binding information in the administrative console. You must use an assembly tool to configure extensions. The following steps are used to configure a key locator in the administrative console for a specific application:

Procedure

1. Open the administrative console.

   Type `http://server_name:port_number/ibm/console` in your web browser unless you have changed the port number.
2. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
3. Under Related Items, click either **Web Modules** or **EJB Modules**, depending on the type of module you are securing.
4. Click the name of the module you are securing.
5. Under Additional Properties, click either **Web services: Client security bindings** or **Web services: Server security bindings**, depending on whether you are adding the key locator to the client security bindings or to the server security bindings. If you do not see any entries, return to the assembly tool and configure the security extensions.

6. Edit the Request Sender Binding, Response Receiver Binding, Request Receiver Binding, or Response Sender Binding.
   - If you are editing your client security bindings, click **Edit** for either the Request Sender Binding or the Response Receiver Binding.
   - If you are editing your server security bindings, click **Edit** for either the Request Receiver Binding or the Response Sender Binding.
7. Click **Key Locators**.
8. Click **New** to configure a new key locator, select the box next to a key locator name and click **Delete** to delete a key locator, or click the name of a key locator to edit its configuration. If you are configuring a new key locator or editing an existing one, complete the following steps:
   a. Specify a name for the key locator in the **Key Locator Name** field.
   b. Specify a name for the key locator class implementation in the **Key Locator Classname** field. WebSphere Application Server has the following default key locator class implementations:

      com.ibm.wsspi.wssecurity.config.WSIdKeyStoreMapKeyLocator
      This class is used by the response sender to map an authenticated identity to a key. If encryption is used, this class is used to locate a key to encrypt the response message. The `com.ibm.wsspi.wssecurity.config.WSIdKeyStoreMapKeyLocator` class has the capability to map an authenticated identity from the invocation credential of the current thread to a key that is used to encrypt the message. If an authenticated identity is present on the current thread, the class maps the ID to the mapped name. For example, `user1` is mapped to `mappedName_1`. Otherwise, `name="default"`. When a matching key is not found, the authenticated identity is mapped to the default key specified in the binding file.

      com.ibm.wsspi.wssecurity.config.KeyStoreKeyLocator
      This class is used by the response receiver, the request sender, and the request receiver to map a name to an alias. Encryption uses this class to obtain a key to encrypt a message and digital signature uses this class to obtain a key to sign a message. The `com.ibm.wsspi.wssecurity.config.KeyStoreKeyLocator` class maps a logical name to a key alias in the key store file. For example, key #105115176771 maps to `CN=Alice, O=IBM, C=US`.

   c. Specify the password used to access the key store password in the **Key Store Password** field. This field is optional because the key locator does not use a key store.
   d. Specify the path name used to access the key store in the **Key Store Path** field. This field is optional because the key locator does not use a key store. Use `${USER_INSTALL_ROOT}` because this path expands to the WebSphere Application Server path on your machine.
   e. Select a keystore type from the **Key Store Type** field. This field is optional because the key locator does not use a key store. Use the `JKS` option if you are not using the Java Cryptography Extensions (JCE) policy and use `JCEKS` if you are using the JCE policy.

Configuring the security bindings on a server acting as a client using the administrative console

Use the web services client editor within an assembly tool to include the binding information, that describes how to run the security specifications found in the extensions, in the client enterprise archive (EAR) file.

About this task

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

When configuring a client for Web Services Security, the bindings describe how to run the security specifications found in the extensions. Use the web services client editor within an assembly tool to include the binding information in the client enterprise archive (EAR) file.

You can configure the client-side bindings from a pure client accessing a web service or from a web service accessing a downstream web service. Complete the following steps to find the location in which to edit the client bindings from a web service that is running on the server. When a web service communicates with another web service, you must configure client bindings to access the downstream web service.

Procedure

1. Deploy the web service using the WebSphere Application Server administrative console. Click **Applications** > **Install New Application**.

   You can access the administrative console by typing `http://server_name:port_number/ibm/console` in your web browser unless you have changed the port number.

   For more information, read about installing a new application.
2. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
3. Under Manage modules, click ***URI_name***.
4. Under Web Services Security Properties, click **Web Services: Client security bindings**. A table displays with the following columns:
   - Component Name
   - Port
   - Web Service
   - Request Sender Binding
   - Request Receiver Binding
   - HTTP Basic Authentication
   - HTTP SSL Configuration

   For Web Services Security, you must edit the request sender binding and response receiver binding configurations. You can use the defaults for some of the information at the server level. Default bindings are convenient because you can configure commonly reused elements such as key locators once and then reference their aliases in the application bindings.
5. View the default bindings for the server using the administrative console by clicking **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** . Under Additional Properties, click **JAX-WS and JAX-RPC security runtime**.

   Note: In a mixed node cell with a server using WebSphere Application Server version 6.1 or earlier, click **Web services: Default bindings for Web Services Security**.

   You can configure the following sections. These topics are discussed in more detail in other sections of the documentation.
   - Request sender binding
     - Signing parameter configuration settings
     - “Encryption information configuration settings: Methods” on page 3363
     - “Key locator configuration settings” on page 3408
     - “Login bindings configuration settings” on page 3458
   - Response receiver binding
     - “Signing information configuration settings” on page 3299
     - “Encryption information configuration settings: Message parts” on page 3358
     - “Trust anchor configuration settings” on page 3419

– “Collection certificate store configuration settings” on page 3426
– “Key locator configuration settings” on page 3408

What to do next

Important: When configuring the security request sender binding configuration, you must synchronize the information used to perform the specified security with the security request receiver binding configuration, which is configured in the server EAR file. These two configurations must be synchronized in all respects because there is no negotiation during run time to determine the requirements of the server. For example, when configuring the encryption information in the security request sender binding configuration, you must use the public key from the server for encryption. Therefore, the key locator that you choose must contain the public key from the server configuration. The server must contain the private key to decrypt the message. This example illustrates the important relationship between the client and server configuration. Additionally, when configuring the security response receiver binding configuration, the server must send the response using security information known by this client security response receiver binding configuration.

The following table shows the related configurations between the client and the server. The client request sender and the server request receiver are relative configurations that must be synchronized with each other. The server response sender and the client response receiver are related configurations that must be synchronized with each other. Note that related configurations are end points for any request or response. One end point must communicate its actions with the other end point because run time requirements are not required.

Table 321. Related configurations. The configurations must be synchronized with each other.

Client configuration	Server configuration
Request sender	Request receiver
Response receiver	Response sender

Configuring the server security bindings using the administrative console

Use the WebSphere Application Server administrative console to edit bindings for a web service after these bindings are deployed on a server.

About this task

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Create an Enterprise JavaBeans (EJB) file Java archive (JAR) file or web application archive (WAR) file containing the security binding file (`ibm-webservices-bnd.xmi`) and the security extension file (`ibm-webservices-ext.xmi`). If this archive is acting as a client to a downstream service, you also need the client-side binding file (`ibm-webservicesclient-bnd.xmi`) and the client-side extension file (`ibm-webservicesclient-ext.xmi`). These files are generated using the WSDL2Java command. For more information, read about the WSDL2Java command for JAX-RPC applications. You can edit these files using the Web Services Editor in the assembly tools. For more information, read about assembly tools.

When configuring server-side security for Web Services Security, the security extensions configuration specifies what security is to be performed while the security bindings configuration indicates how to perform what is specified in the security extensions configuration. You can use the defaults for some elements at the cell and server levels in the bindings configuration, including key locators, trust anchors, the collection certificate store, trusted ID evaluators, and login mappings and reference them from the WAR and JAR binding configurations.

The following steps describe how to edit bindings for a web service after these bindings are deployed on a server. When one web service communicates with another web service, you also must configure the client bindings to access the downstream web service.

Procedure

1. Deploy the web service using the WebSphere Application Server administrative console.

   Type `http://server_name:port_number/ibm/console` in your web browser unless you have changed the port number.

   After you log into the administration console, click **Applications** > **Install new application** to deploy the web service. For more information, read about installing enterprise application files with the console.
2. After you deploy the web service, click **Applications** > **Enterprise applications** > ***application_name*** .
3. Under Manage modules, click ***URI_name***.
4. Under Web Services Security Properties, click **Web services: client security bindings** for outbound requests and inbound responses. Click **Web services: server security bindings** for inbound requests and outbound responses.
5. If you click **Web services: server security bindings**, the following sections can be configured. These topics are discussed in more detail in other sections of the documentation.
   - Request receiver binding
     - Signing information
     - Encryption information
     - Trust anchors
     - Collection certificate store
     - Key locator
     - Trusted ID evaluator
     - Login mappings
   - Response sender binding
     - Signing parameters
     - Encryption information
     - Key locator

Configuring XML encryption for Version 5.x web services with the administrative console

XML encryption is one method that WebSphere® Application Server provides to secure web services. You can use XML encryption in conjunction with XML digital signature to scramble the content while verifying the authenticity of the message sender. Using XML encryption, you can encrypt an XML element, the content of an XML element, or arbitrary data such as an XML document.

Login bindings configuration settings

Use this page to specify the Java Authentication and Authorization Service (JAAS) login configuration settings that are used to validate security tokens within incoming messages.

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications. Version 5.*x* applications are based on Java 2 platform, Enterprise Edition (J2EE) 1.3.

The pluggable token uses the Java Authentication and Authorization Service (JAAS) CallBackHandler (javax.security.auth.callback.CallBackHandler) interface to generate the token that is inserted into the message. The following list describes the CallBack support implementations:

com.ibm.wsspi.wssecurity.auth.callback.BinaryTokenCallback
This implementation is used for generating binary tokens inserted as `<wsse:BinarySecurityToken/@ValueType>` in the message.

javax.security.auth.callback.NameCallback and javax.security.auth.callback.PasswordCallback
This implementation is used for generating user name tokens inserted as `<wsse:UsernameToken>` in the message.

com.ibm.wsspi.wssecurity.auth.callback.XMLTokenSenderCallback
This implementation is used to generate Extensible Markup Language (XML) tokens and is inserted as the `<SAML: Assertion>` element in the message.

com.ibm.wsspi.wssecurity.auth.callback.PropertyCallback
This implementation is used to obtain properties that are specified in the binding file.

To view this administrative console page, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Under Modules, click **Manage modules** > ***URI_file_name***. Under Web Services Security Properties, click **Web Services: Client security bindings**.
3. Under Request Sender Bindings, click **Edit**.
4. Under Additional properties, click **Login binding**.

If the encryption information is not available, select **None**.

If the encryption information is available, select **Dedicated login binding** and specify the configuration in the following fields:

Authentication method:

Specifies the unique name for the authentication method.

You can uses any string to name the authentication method. However, the string must match the element in the server-level configuration. The following words are reserved by WebSphere Application Server:

BasicAuth
This method uses both a user name and a password.

IDAssertion
This method uses a user name, but it requires that additional trust is established by the receiving server using a trusted ID evaluator mechanism.

Signature
This method uses the distinguished name (DN) of the signer.

LTPA This method validates the token.

Callback handler:

Specifies the name of the callback handler. The callback handler must implement the `javax.security.auth.callback.CallbackHandler` interface.

Basic authentication user ID:

Specifies the user name for basic authentication. With the basic authentication method, you can define a user name and a password in the binding file.

Basic authentication password:

Specifies the password for basic authentication.

Token type URI:

Specifies the namespace Uniform Resource Identifiers (URI), which denotes the type of security token that is accepted.

The value of this field if is impacted by the following conditions:

- If binary security tokens are accepted, the value denotes the ValueType attribute in the element. The ValueType element identifies the type of security token and its namespace.
- If Extensible Markup Language (XML) tokens are accepted, the value denotes the top-level element name of the XML token.
- The Token type URI field is ignored if the reserved words, which are listed in the description of the Authentication method field, are specified.

This information is inserted as `<wsse:BinarySecurityToken>/ValueType` for the <SAML: Assertion> XML token.

Token type local name:

Specifies the local name of the security token type. For example, X509v3.

The value of this field if is impacted by the following conditions:

- If binary security tokens are accepted, the value denotes the ValueType attribute in the element. The ValueType element identifies the type of security token and its namespace.
- If Extensible Markup Language (XML) tokens are accepted, the value denotes the top-level element name of the XML token.
- The Token type URI field is ignored if the reserved words, which are listed in the description of the Authentication method field, are specified.

This information is inserted as `<wsse:BinarySecurityToken>/ValueType` for the <SAML: Assertion> XML token.

Request sender binding collection

Use this page to specify the binding configuration to send request messages for Web Services Security.

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications. Version 5.*x* applications are based on Java 2 platform, Enterprise Edition (J2EE) 1.3.

To view this administrative console page, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Under Modules, click **Manage modules** > ***URI_file_name***.
3. Under Web Services Security Properties, click **Web services: Client security bindings**.
4. Under Request sender binding, click **Edit**.

Web Services Security namespace: Specifies the namespace that is used by Web Services Security to send a request. However, this field configures the namespace value only and does not enforce the semantics of the specification related to the namespace. Web Services Security uses the processing semantic only in draft 13 of the OASIS specification. The following schemas are available:

- http://schemas.xmlsoap.org/ws/2003/06/secext
- http://schemas.xmlsoap.org/ws/2002/07/secext
- http://schemas.xmlsoap.org/ws/2002/04/secext
- None

The namespace used by the response sender is based on the namespace of the incoming message in the request receiver.

Signing information:

Specifies the configuration for the signing parameters. Signing information is used to sign and validate parts of the message including the body and time stamp.

You can also use these parameters for X.509 validation when the Authentication method is `IDAssertion` and the ID Type is `X509Certificate`, in the server-level configuration. In such cases, you must fill in the Certificate Path fields only.

Encryption information:

Specifies the configuration for the encrypting and decrypting parameters. Encryption information is used for encrypting and decrypting various parts of a message, including the body and user name token.

Key locators:

Specifies a list of key locator objects that retrieve the keys for digital signature and encryption from a keystore file or a repository. The key locator maps a name or a logical name to an alias or maps an authenticated identity to a key. This logical name is used to locate a key in a key locator implementation.

Login mappings:

Specifies a list of configurations for validating tokens within incoming messages.

Login mappings map the authentication method to the Java Authentication and Authorization Service (JAAS) configuration.

To configure JAAS, complete the following steps:

1. Click **Security** > **Global security**.
2. Under the Java Authentication and Authorization Service field, select **Application logins** or **System logins**.

Request receiver binding collection

Use this page to specify the binding configuration to receive request messages for Web Services Security.

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications. Version 5.*x* applications are based on Java 2 platform, Enterprise Edition (J2EE) 1.3.

To view this administrative console page, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Under Modules, click **Manage modules** > ***URI_file_name***.
3. Under Web Services Security Properties, click **Web services: Server security bindings**.
4. Under Request receiver binding, click **Edit**.

Signing information:

Specifies the configuration for the signing parameters. Signing information is used to sign and validate parts of a message including the body, the timestamp, and the user name token.

You also can use these parameters for X.509 certificate validation when the authentication method is `IDAssertion` and the ID Type is `X509Certificate` in the server-level configuration. In such cases, you must fill in the Certificate Path fields only.

Encryption information:

Specifies the configuration for the encrypting and decrypting parameters. This configuration is used to encrypt and decrypt parts of the message that include the body and the user name token.

Trust anchors:

Specifies a list of keystore objects that contain the trusted root certificates that are issued by a certificate authority (CA).

The certificate authority authenticates a user and issues a certificate. The CertPath API uses the certificate to validate the certificate chain of incoming, X.509-formatted security tokens or trusted, self-signed certificates.

Collection certificate store:

Specifies a list of the untrusted, intermediate certificate files.

The collection certificate store contains a chain of untrusted, intermediate certificates. The CertPath API attempts to validate these certificates, which are based on the trust anchor.

Key locators:

Specifies a list of key locator objects that retrieve the keys for digital signature and encryption from a keystore file or a repository. The key locator maps a name or a logical name to an alias or maps an authenticated identity to a key. This logical name is used to locate a key in a key locator implementation.

Trusted ID evaluators:

Specifies a list of trusted ID evaluators that determine whether to trust the identity-asserting authority or message sender.

The trusted ID evaluators are used to authenticate additional identities from one server to another server. For example, a client sends the identity of user A to server 1 for authentication. Server 1 calls downstream to server 2, asserts the identity of user A, and includes the user name and password of server 1. Server 2 attempts to establish trust with server 1 by authenticating its user name and password and checking the trust based on the TrustedIDEvaluator implementation. If the authentication process and the trust check are successful, server 2 trusts that server 1 authenticated user A and a credential is created for user A on server 2 to invoke the request.

Login mappings:

Specifies a list of configurations for validating tokens within incoming messages.

Login mappings map the authentication method to the Java Authentication and Authorization Service (JAAS) configuration.

To configure JAAS, complete the following steps:

1. Click **Security** > **Global security**.
2. Under the Java Authentication and Authorization Service, click **Application logins** or **System logins**.

Response sender binding collection

Use this page to specify the binding configuration for sender response messages for Web Services Security.

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications. Version 5.*x* applications are based on Java 2 platform, Enterprise Edition (J2EE) 1.3.

To view this administrative console page, complete the following steps:

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** .
2. Under Modules, click **Manage modules** > ***URI_file_name***.
3. Under Web Services Security Properties, click **Web services: Server security bindings**.
4. Under Response sender binding, click **Edit**.

Signing information:

Specifies the configuration for the signing parameters.

You also can use these parameters for X.509 certificate validation when the authentication method is IDAssertion and the ID Type is X509Certificate in the server-level configuration. In such cases, you must fill-in the Certificate Path fields only.

Encryption information:

Specifies the configuration for the encryption and decryption parameters.

Key locators:

Specifies a list of key locator objects that retrieve the keys for a digital signature and encryption from a keystore file or a repository. The key locator maps a name or logical name to an alias or maps an authenticated identity to a key. This logical name is used to locate a key in a key locator implementation.

Response receiver binding collection

Use this page to specify the binding configuration for receiver response messages for Web Services Security.

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications. Version 5.*x* applications are based on Java 2 platform, Enterprise Edition (J2EE) 1.3.

To view this administrative console page, complete the following steps:

1. Click **Applications > Application Types > WebSphere enterprise applications***application_name*.
2. Under Modules, click **Manage modules > *URI_file_name* > Web Services: Client security bindings**.
3. Under Response receiver binding, click **Edit**.

Signing information:

Specifies the configuration for the signing parameters. Signing information is used to sign and to validate parts of the message including the body and the timestamp.

You can also use these parameters for X.509 validation when the authentication method is IDAssertion and the ID type is X509Certificate, in the server-level configuration. In such cases, you must fill in the certificate path fields only.

Encryption information:

Specifies the configuration for the encryption and decryption parameters.

Encryption information is used for encrypting and decrypting various parts of a message, including the body and the user name token.

Trust anchors:

Specifies a list of keystore objects that contain the trusted root certificates that are self-signed or issued by a certificate authority.

The certificate authority authenticates a user and issues a certificate. After the certificate is issued, the keystore objects, which contain these certificates, use the certificate for certificate path or certificate chain validation of incoming X.509-formatted security tokens.

Collection certificate store:

Specifies a list of the untrusted, intermediate certificate files.

The collection certificate store contains a chain of untrusted, intermediate certificates. The CertPath API attempts to validate these certificates, which are based on the trust anchor.

Key locators:

Specifies a list of key locator objects that retrieve the keys for a digital signature and encryption from a keystore file or a repository.

The key locator maps a name or a logical name to an alias or maps an authenticated identity to a key. This logical name is used to locate a key in a key locator implementation.

Configuring pluggable tokens using the administrative console

You can configure the client-side request sender (`ibm-webservicesclient-bnd.xmi` file) or server-side request receiver (`ibm-webservices-bnd.xmi` file) by using the WebSphere Application Server administrative console.

Before you begin

Important: There is an important distinction between Version 5.*x* and Version 6 and later applications. The information in this article supports Version 5.*x* applications only that are used with WebSphere Application Server Version 6.0.*x* and later. The information does not apply to Version 6.0.*x* and later applications.

Prior to completing these steps, it is assumed that you have already created a web service that is based on the Java Platform, Enterprise Edition (Java EE) specification. See either of the following topics for an introduction of how to manage Web Services Security binding information for the server:

- Configuring the server security bindings using an assembly tool
- "Configuring the server security bindings using the administrative console" on page 3457

About this task

This document describes how to configure a pluggable token in the request sender (`ibm-webservicesclient-ext.xmi` and `ibm-webservicesclient-bnd.xmi` file) and request receiver (`ibm-webservices-ext.xmi` and `ibm-webservices-bnd.xmi` file).

Important: The pluggable token is required for the request sender and request receiver as they are a pair. The request sender and the request receiver must match for a request to be accepted by the receiver.

Prior to completing these steps, it is assumed that you deployed a web services-enabled enterprise application to the WebSphere Application Server.

Use the following steps to configure the client-side request sender (`ibm-webservicesclient-bnd.xmi` file) or server-side request receiver (`ibm-webservices-bnd.xmi` file) using the WebSphere Application Server administrative console.

1. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***enterprise_application***.
2. Under Modules, click **Manage modules** > ***URI_name***. The *URI* is the web services-enabled module.
   a. Under Web Services Security Properties, click **Web services: client security bindings** to edit the response sender binding information, if web services are acting as client.
      1) Under Response sender binding, click **Edit**.
      2) Under Additional Properties, click **Login binding**.
      3) Select **Dedicated login binding** to define a new login binding.
         a) Enter the authentication method, this must match the authentication method defined in IBM extension deployment descriptor. The authentication method must be unique in the binding file.
         b) Enter an implementation of the JAAS `javax.security.auth.callback.CallbackHandler` interface.
         c) Enter the basic authentication information (User ID and Password) and the basic authentication information is passed to the construct of the CallbackHandler implementation. The usage of the basic authentication information is up to the implementation of the CallbackHandler.
         d) Enter the token value type, it is optional for BasicAuth, Signature and IDAssertion authentication methods but required for any other authentication method. The token value type is inserted into the <wsse:BinarySecurityToken>@ValueType for binary security token and used as the namespace of the XML based token.
         e) Click **Properties**. Define the property with name and value pairs. These pairs are passed to the construct of the CallbackHandler implementation as `java.util.Map`.

      Select **None** to deselect the login binding.
   b. Under Web Services Security Properties, click **Web services: server security bindings** to edit the request receiver binding information.
      1) Under Request Receiver Binding, click **Edit**.
      2) Under Additional Properties, click **Login mappings**.
      3) Click **New** to create new login mapping.

a) Enter the authentication method, this must match the authentication method defined in the IBM extension deployment descriptor. The authentication method must be unique in the login mapping collection of the binding file.

b) Enter a JAAS Login Configuration name. The JAAS Login Configuration must be defined under **Security** > **Global security**. Under Authentication, click **Java Authentication and Authorization Service** > **Application logins**. For more information, read about configuring programmatic logins for Java Authentication and Authorization Service.

c) Enter an implementation of the `com.ibm.wsspi.wssecurity.auth.callback.CallbackHandlerFactory` interface. This is a mandatory field.

d) Enter the token value type, it is optional for BasicAuth, Signature and IDAssertion authentication methods but required for any other authentication method. The token value type is used to validate against the <wsse:BinarySecurityToken>@ValueType for binary security token and against the namespace of the XML based token.

e) Enter the name and value pairs for the "Login Mapping Property" by clicking **Properties** . These name and value pairs are available to the JAAS Login Module or Modules by `com.ibm.wsspi.wssecurity.auth.callback.PropertyCallback` JAAS Callback. **Note**: This is true when editing existing login mappings but not when creating new login mappings.

f) Enter the name and value pairs for the "Callback Handler Factory Property", these name and value pairs is passed as `java.util.Map` to the `com.ibm.wsspi.wssecurity.auth.callback.CallbackHandlerFactory.init()` method. The usage of these name and value pairs is up to the `CallbackHandlerFactory` implementation.

c. Click authentication method link to edit the selected login mapping.

d. Click **Remove** to remove the selected login mapping or mappings.

3. Click **Save**.

Results

The previous steps define how to configure the request sender to create security tokens in the SOAP message and the request receiver to validate the security tokens found in the incoming SOAP message. WebSphere Application Server supports pluggable security tokens.

You can use the authentication method defined in the login bindings and login mappings to generate security tokens in the request sender and validate security tokens in the request receiver.

What to do next

After you have configured pluggable tokens, you must configure both the client and the server to support pluggable tokens. See the following topics to configure the client and the server:

- Configuring the client for LTPA token authentication: specifying LTPA token authentication
- Configuring the client for LTPA token authentication: collecting the authentication method information
- Configuring the server to handle LTPA token authentication information
- Configuring the server to validate LTPA token authentication information

Chapter 37. Administering web services - Transaction support (WS-Transaction)

WS-Transaction is an interoperability standard that includes the WS-AtomicTransaction, WS-BusinessActivity, and WS-Coordination specifications. The Web Services Atomic Transaction (WS-AT) support in the application server provides transactional quality of service to the web services environment. Distributed web services applications, and the resources they use, can take part in distributed global transactions. With Web Services Business Activity (WS-BA) support in the application server, web services on different systems can coordinate activities that are more loosely coupled than atomic transactions. Such activities can be difficult or impossible to roll back atomically, and therefore require a compensation process if an error occurs. Web Services Coordination (WS-COOR) specifies a CoordinationContext and a Registration service with which participant web services can enlist to take part in the protocols that are offered by specific coordination types.

Using WS-Transaction policy to coordinate transactions or business activities for web services

You can use WS-Transaction policy to configure how a Java API for XML Web Services (JAX-WS) service or client handles Web Services Atomic Transaction (WS-AT) or Web Services Business Activity (WS-BA) context.

About this task

The Web Services Atomic Transaction (WS-AT) support in the application server provides transactional quality of service to the web services environment. Distributed web services applications, and the resources they use, can take part in distributed global transactions. With Web Services Business Activity (WS-BA) support in the application server, web services on different systems can coordinate activities that are more loosely coupled than atomic transactions. Such activities can be difficult or impossible to roll back atomically, and therefore require a compensation process if an error occurs.

Procedure

- Configure a JAX-WS client for WS-Transaction context.
- Configure a JAX-WS web service for WS-Transaction context.
- Configure the WS-Transaction policy.
- Configure a WS-Transaction policy set by using wsadmin scripting.
- Configure transaction properties for an application server.
- Configure the WS-Transaction specification level by using wsadmin scripting.
- Configure WS-Transaction support in a secure environment.
- Configure an intermediary node for web services transactions.
- Enable WebSphere Application Server to use an intermediary node for web services transactions.
- Configure a server to use business activity support.

Configuring a JAX-WS client for WS-Transaction context

You can configure the way that a Java API for XML Web Services (JAX-WS) client handles Web Services Atomic Transaction (WS-AT) or Web Services Business Activity (WS-BA) context by configuring the Web Services Transaction (WS-Transaction) policy type. You can specify that the client must send context, can send context if it is available, or must not send context.

Before you begin

A JAX-WS client must be installed.

About this task

You can configure a WS-Transaction policy set by using the administrative console, as described in this task, or you can configure a WS-Transaction policy set by using wsadmin scripting.

To configure a JAX-WS client for WS-Transaction context by using the administrative console, complete the following steps.

Procedure

1. Create a new policy set, or copy and rename an existing policy set. You can copy an existing user-defined policy set, or one of the WS-Transaction default policy sets (WSTransaction or SSL WSTransaction). See “Creating policy sets using the administrative console” on page 2668.
2. Check that your policy set includes the WS-Transaction policy type. If necessary, add the WS-Transaction policy type. See “Adding policies to policy sets using the administrative console” on page 2712.
3. Configure the WS-Transaction policy.
4. Associate the policy set with the JAX-WS client. See Managing policy sets and bindings for service clients.
5. Choose a WS-Policy application rule that includes the configured policy of the client, that is, client only or client and provider. See “Configuring the client policy to use a service provider policy” on page 3107.
6. Save your changes to the master configuration.

Results

The JAX-WS client is configured to use WS-Transaction context in the way that you specified.

Configuring a JAX-WS web service for WS-Transaction context

You can configure the way that a Java API for XML Web Services (JAX-WS) service handles Web Services Atomic Transaction (WS-AT) or Web Services Business Activity (WS-BA) context by configuring the Web Services Transaction (WS-Transaction) policy type. You can specify that the web service must receive context, can receive context if it is available, or must not receive context.

Before you begin

A JAX-WS client must be installed.

About this task

You can configure a WS-Transaction policy set by using the administrative console as described in this task, or you can configure a WS-Transaction policy set by using wsadmin scripting.

To configure a JAX-WS service for WS-Transaction context by using the administrative console, complete the following steps.

Procedure

1. Create a new policy set, or copy and rename an existing policy set. You can copy an existing user-defined policy set, or one of the WS-Transaction default policy sets (WSTransaction or SSL WSTransaction). See “Creating policy sets using the administrative console” on page 2668.
2. Check that your policy set includes the WS-Transaction policy type. If necessary, add the WS-Transaction policy type. See “Adding policies to policy sets using the administrative console” on page 2712.
3. Configure the WS-Transaction policy.

4. Associate the policy set with the JAX-WS web service, endpoint, or operation for which the specified behavior is required. See Managing policy sets and bindings for service providers.
5. Save your changes to the master configuration.

Results

The JAX-WS web service, endpoint, or operation is configured to use WS-Transaction context in the way that you specified.

Configuring a WS-Transaction policy set by using wsadmin scripting

You can configure the way that a Java API for XML Web Services (JAX-WS) client or web service handles Web Services Atomic Transaction (WS-AT) or Web Services Business Activity (WS-BA) context by configuring the Web Services Transaction (WS-Transaction) policy type. You can specify that the client or service must use context, can use context if it is available, or must not use context. Use command scripts to configure a policy set for web services transactions.

About this task

You can configure a WS-Transaction policy set by using wsadmin scripting as described in this task, or you can configure a WS-Transaction policy set by using the administrative console.

Procedure

1. Start the wsadmin scripting client if it is not already running.
2. Use the createPolicySet command to create a new policy set, or the copyPolicySet command to copy and rename an existing policy set. You can copy an existing user-defined policy set, or one of the WS-Transaction default policy sets (WSTransaction or SSL WSTransaction).
3. Check that your policy set includes the WS-Transaction policy type. If necessary, add the WS-Transaction policy type. For example:

```
AdminTask.importPolicySet('[-defaultPolicySet WSTransaction]')
AdminTask.addPolicyType('[-policySet policy_set_name
-policyType WSTransaction -enabled true]')
```

4. Use the setPolicyType command to configure the WS-Transaction policy type attributes. The WS-Transaction policy type has the following attributes:
   - ATAssertion
   - BAAtomicOutcomeAssertion

   Each attribute can have the value supports, mandatory, or never. For detailed information about these configurable attributes, see the topic about WS-Transaction policy settings. For example:

```
AdminTask.setPolicyType('[-policySet policy_set_name
-policyType WSTransaction
-attributes "[ [BAAtomicOutcomeAssertion mandatory] [ATAssertion supports] ]"]
-replace')
```

5. Save your changes to the master configuration. For example, enter the following command:

```
AdminConfig.save()
```

What to do next

You are now ready to associate the policy set with the JAX-WS client, or with the JAX-WS web service, endpoint, or operation.

Configuring Web Services Transaction support in a secure environment

If you use Web Services Atomic Transaction (WS-AT) or Web Services Business Activity (WS-BA) support when administrative security is enabled, you might have to change the default transaction service configuration. You can disable the transaction coordination authorization setting, create a new web container transport chain, or do both.

About this task

You might disable transaction coordination authorization if you want to interoperate with other servers and you do not want to set up security for the transaction manager to support the Common Criteria EAL4 evaluated configuration. When transaction coordination authorization is disabled, WebSphere Application Server does not automatically reject secure WS-Transactions protocol messages.

You might configure a new web container transport chain for use by WS-Transactions in the following situations:

- You want to use an alternative port number for WS-AT or WS-BA protocol messages.
- You want to interoperate with a non-WebSphere Application Server that requires client certificate authentication on the Secure Sockets Layer (SSL) connection that is used for protocol messages.

The transaction service, by default, selects a suitable web container transport chain from the list of those configured and uses it for protocol messages. You can configure a new transport chain and specify your own settings. For example, you can specify an alternative SSL configuration that requires client certificate authentication, which is then used specifically for WS-Transactions protocol messages.

Procedure

1. Optionally, use the following steps to disable transaction coordination authorization.
   a. In the administrative console, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Container Settings] Container Services** > **Transaction Service**.
   b. Clear the **Enable transaction coordination authorization** check box.
   c. Click **Apply** or **OK**.
   d. Save your changes to the master configuration.
2. Optionally, use the following steps to create a new web container transport chain.
   a. In the administrative console, click **Servers** > **Application servers** > ***server_name*** > **[Container Settings] Web Container Settings** > **Web container transport chains**.
   b. Click **New** to create a new transport chain.
   c. Type a name for the transport chain.
   d. From the Transport chain template list, select an appropriate template.
   e. Click **Next** to select a new port for the chain.
   f. Type a name, host, and port number for the port. For a secure chain, the host must match the common name in the certificate that is used.
   g. Click **Next**, confirm the settings, then click **Finish**.
   h. Save your changes to the master configuration.
   i. If necessary, create a new SSL configuration and associate it with the SSL channel associated with your new chain. For more information, see “Creating a Secure Sockets Layer configuration” on page 1741. You are now ready to configure the transaction service to use the new transport chain.
   j. Click **Servers** > **Application servers** > ***server_name*** > **[Container Settings] Container Services** > **Transaction Service**.
   k. In the External WS-Transaction HTTP(S) URL prefix section, click **Select prefix**, then select the web container transport chain that you have just created from the list.

If you are using an intermediary, such as an HTTP proxy, in front of the application server, click **Specify custom prefix**, then type the external endpoint URL information for the intermediary node in the field. For more information, see “Enabling WebSphere Application Server to use an intermediary node for web services transactions” on page 3472.

l. Click **Apply** or **OK**, then save your changes to the master configuration.

3. After you save all the configuration changes, restart the server for the changes to take effect.

Results

You configured your system to use WS-AT or WS-BA in a secure environment.

Configuring an intermediary node for web services transactions

Intermediary nodes allow the exchange of Web Services Atomic Transaction (WS-AT) and Web Services Business Activity (WS-BA) protocol messages across firewalls and outside the WebSphere Application Server domain. You configure an intermediary node to specify which WebSphere Application servers the node routes requests to.

Procedure

1. Configure the HTTP server so that it routes WS-AT and WS-BA requests that are targeted at WebSphere Application Server to WebSphere Application Server, rather than processing them itself.
2.
3.

Results

You configured the intermediary node ready for use by WebSphere Application Server.

Example

What to do next

Configure WebSphere Application Server to use the intermediary node by specifying, for each server, the appropriate virtual host of the intermediary node.

Example: Configuring IBM HTTP server as an intermediary node for web services transactions

You can use an HTTP server intermediary nodes to enable the exchange of Web Services Atomic Transaction and Web Services Business Activity protocol messages across firewalls and outside the WebSphere Application Server domain. For IBM HTTP server, you achieve this behavior by modifying the plugin-cfg.xml file of the IBM HTTP server node.

Routing requests to WebSphere Application Server

You can use the IBM HTTP server as a single intermediary node, or you can combine it with a Proxy Server for IBM WebSphere Application Server. In both cases, update the plugin-cfg.xml file to indicate that the HTTP server should route requests that are targeted at WebSphere Application Server, those of the form http://*host:port*/_IBMSYSAPP/*, to WebSphere Application Server, rather than processing them itself.

To update the plugin-cfg.xml file, add a URI element with a name of _IBMSYSAPP, as shown in the following example. Add this URI to all UriGroup elements in the plugin-cfg.xml file.

```
<UriGroup Name="default_host_server1_99T73NKNode01_Cluster_URIs">
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/snoop/*" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/hello" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/hitcount" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="*.jsp" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="*.jsv" />
```

```
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="*.jsw" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/j_security_check" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/ibm_security_logout" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/servlet/*" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/SamplesGallery/*" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/WSsamples/*" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/PlantsByWebSphere/*" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/PlantsByWebSphere/docs/*" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/_IBMSYSAPP/*" />
</UriGroup>
```

Configuring virtual host mapping

If you are using IBM HTTP as the only intermediary node, in other words you are not also using Proxy Server for IBM WebSphere Application Server, configure virtual hosts to represent each WebSphere Application Server that the HTTP node routes requests to. Update the plugin-cfg.xml file by adding VirtualHostGroup, VirtualHost and Route elements.

The following example shows part of the plugin-cfg.xml file for a configuration in which the IBM HTTP server routes requests to one of two servers, server1 and server2, in WebSphere Application Server.

The plugin-cfg.xml file contains two virtual host aliases, with names name1.acme.com and name2.acme.com, that are defined using VirtualHost and VirtualHostGroup elements. The Route elements define the association between the virtual hosts and the ServerCluster elements. When a request is made, IBM HTTP server finds the best matching route to dispatch the request to. A request made to virtual host name1.acme.com, with a URI that matches a pattern in the default_URIs URI group, is sent to the server1_Cluster server cluster. This server cluster contains only one server, server1, so requests targeted at virtual host name1.acme.com are sent to server1, and similarly, requests targeted at virtual host name2.acme.com are sent to server2.

```
<UriGroup Name="default_URIs">
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/snoop/*" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/hello" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/hitcount" />
...
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/PlantsByWebSphere/*" />
<Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/PlantsByWebSphere/docs/*" />
  <Uri AffinityCookie="JSESSIONID" AffinityURLIdentifier="jsessionid" Name="/_IBMSYSAPP/*" />
</UriGroup>

<ServerCluster CloneSeparatorChange="false" LoadBalance="Round Robin" Name="server1_Cluster" PostBufferSize="64"
PostSizeLimit="-1" RemoveSpecialHeaders="true" RetryInterval="60">
      <Server ConnectTimeout="0" ExtendedHandshake="false" MaxConnections="-1" Name="server1" ServerIOTimeout="0" WaitForContinue="false">
         ...
      </Server>
      <PrimaryServers> <Server Name="server1"/> </PrimaryServers>
   </ServerCluster>
<ServerCluster CloneSeparatorChange="false" LoadBalance="Round Robin" Name="server2_Cluster" PostBufferSize="64" PostSizeLimit="-1"
 RemoveSpecialHeaders="true" RetryInterval="60">
      <Server ConnectTimeout="0" ExtendedHandshake="false" MaxConnections="-1" Name="server2" ServerIOTimeout="0" WaitForContinue="false">
         ...
     </Server>
      <PrimaryServers> <Server Name="server2"/>  </PrimaryServers>
</ServerCluster>
<VirtualHostGroup Name="vhost_server1"> <VirtualHost Name="name1.acme.com:9081"/> </VirtualHostGroup>
<VirtualHostGroup Name="vhost_server2"> <VirtualHost Name="name2.acme.com:9081"/> </VirtualHostGroup>
<Route ServerCluster="server1_Cluster" UriGroup="default_URIs" VirtualHostGroup=" vhost_server1 "/>
<Route ServerCluster="server2_Cluster" UriGroup="default_URIs" VirtualHostGroup=" vhost_server2"/>
```

Enabling WebSphere Application Server to use an intermediary node for web services transactions

You can use intermediary nodes with Web Services Atomic Transactions (WS-AT) or Web Services Business Activities (WS-BA) to support the exchange of associated requests across firewalls and outside the WebSphere Application Server domain. You configure WebSphere Application Server to use an intermediary node by specifying the external endpoint URL information for the intermediary node in each server that is accessed through the intermediary.

Before you begin

Configure the intermediary node that you want to use, and ensure that you know the address or addresses of the intermediary node that you want to map to servers in your WebSphere Application Server configuration.

Configure the intermediary to listen on a specific port for protocol messages and to route these messages to the specific WebSphere Application Server instance that you want to enable. See the related information for an example configuration where an IBM HTTP server is the intermediary.

Procedure

1. In the administrative console, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Container Services] Transaction Service**.
2. In the External WS-Transaction HTTP(S) URL prefix section, click **Specify custom prefix**, then type the external endpoint URL information for the intermediary node in the field. Use one of the following formats for the prefix, where *host_name* and *port* represent the intermediary node that is an HTTP or HTTPS proxy for the server, and *port* is optional.
   - `http://host_name:port`
   - `https://host_name:port`
3. Click **Apply** or **OK**.
4. Save your changes to the master configuration.
5. Repeat the previous steps for each server that is accessed through the intermediary node.
6. Restart the servers.

Results

You configured your system to use an intermediary node. Test your configuration to ensure that messages are routed as you expect.

Configuring a server to use business activity support

Business activity support provides compensation for activities such as sending an email, which can be difficult or impossible to roll back atomically. With this compensation, applications on disparate systems can coordinate activities that are more loosely coupled than atomic transactions. To use the business activity support, you must first enable it on each server that you plan to use.

About this task

If an application component uses business activity support, you must enable the support on each server that runs the application.

Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

Procedure

1. In the administrative console, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Container Settings] Container Services** > **Compensation Service**.
2. Select the **Enable service at server startup** check box.

3. If required, modify the compensation handler retry interval and limit. These values control the frequency with which the compensation handler compensate and close methods are retried, when either throw a RetryCompensationHandlerException exception, and the number of times that these methods are retried.
4. Save your changes to the master configuration.
5. Repeat the previous steps for each server that you plan to use.
6. Restart all the servers for the changes to take effect.

Results

The business activity support is enabled for the application server. Verify a successful enablement by checking for the message, `CWSCP0005I: The Compensation service started successfully.` in the `SystemOut.log` file for the relevant server.

Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

What to do next

Deploy the business-activity-enabled application to the server.

Chapter 38. Administering web services - Transports

Transport chains represent a network protocol stack that is used for I/O operations within an application server environment. Transport chains are part of the channel framework function that provides a common networking service for all components.

Invoking JAX-WS web services asynchronously using the HTTP transport

Using the JAX-WS asynchronous response servlet

Java API for XML-Based Web Services (JAX-WS) includes an asynchronous response servlet, which is used within the application server environment to receive responses for JAX-WS requests that are invoked asynchronously.

Before you begin

JAX-WS provides support for invoking web services using an asynchronous client invocation by using either a callback or polling model. Both the callback model and the polling model are available on the Dispatch client and the dynamic proxy client. When a JAX-WS client that is running within the application server environment uses an asynchronous client invocation, the responses are received by the asynchronous response servlet. To learn how to use the asynchronous client invocation model, read about invoking JAX-WS web services asynchronously.

About this task

The asynchronous response servlet is used within an application server to handle incoming asynchronous responses. The servlet uses the same secure and unsecure HTTP ports assigned to the application server. The servlet starts automatically when the application server starts. Because the asynchronous response servlet does not perform role-based authorization checks, only user authentication checks are performed.

The asynchronous response servlet supports both the HTTP and HTTPS protocols. Since the servlet inherits the SSL configuration of the application server, configuring the application server also configures the servlet. The asynchronous response servlet is not affected by the custom HTTP and SSL port properties used by the asynchronous response listener and only runs on the application ports for the application server.

Procedure

1. Determine if you want the JAX-WS client to use the HTTP or HTTPS transport mechanism.
2. Configure the web container transport chains to modify the SSL configuration of the application server. The servlet inherits these settings. Read about configuring transport chains to learn how to configure the web container transport chains.

Results

The asynchronous response servlet is configured to enable your JAX-WS clients to receive asynchronous responses on the HTTP or HTTPS transport protocol.

Note: When you add a new application server to your environment, the asynchronous response servlet is automatically restarted so the deployment.xml file can be updated for the new application server. If your application receives an incoming response when the asynchronous response servlet is restarting, the incoming response might fail with an HTTP 404 error.

Note: JAX-WS services do not successfully return asynchronous responses to clients that are installed in application security-enabled WebSphere Application Servers. Because the Asynchronous Response Servlet for WebSphere Application Server, which handles asynchronous web services responses, is protected when application security is enabled, you must supply a credential together with the JAX-WS service incoming response. Attach the HTTPTransport policy set binding to the JAX-WS service in the service attachment. Additionally, enter a valid basic authentication user ID and password, which are defined in the user registry of the client, into the Basic authentication for outbound asynchronous service responses field.

Using the JAX-WS asynchronous response listener

Java API for XML-Based Web Services (JAX-WS) includes an asynchronous response listener, which is used within the Thin Client for JAX-WS and application client environments to receive responses for requests that are invoked asynchronously.

Before you begin

JAX-WS provides support for invoking web services using an asynchronous client invocation by using either a callback or polling model. Both the callback model and the polling model are available on the Dispatch client and the dynamic proxy client. When the JAX-WS client uses an asynchronous client invocation, the responses are received by the asynchronous response listener. To learn how to use the asynchronous client invocation model, read about invoking JAX-WS web services asynchronously.

About this task

The asynchronous response listener is used within a Web services client to handle incoming asynchronous responses. You can use the listener in Thin Client for JAX-WS environments and application client environments. By default, the listener opens a random port to listen for asynchronous responses or you can optionally configure a specific port for the listener to use. The listener starts automatically in the JAX-WS run time when the JAX-WS client is configured to expect an asynchronous response.

There are two versions of the asynchronous response listener. The unsecure version of the asynchronous response listener supports the HTTP protocol, and the secure version of the asynchronous response listener supports the HTTPS protocol. The correct asynchronous response listener is automatically started based on the particular transport used by the JAX-WS client. To ensure that the correct Secure Sockets Layer (SSL) handshaking occurs between the asynchronous response listener and the application server, configure the SSL properties using the SSL transport policy or the Java system properties.

For web services clients running in the application server environment, use the asynchronous response servlet for receiving asynchronous responses.

Procedure

1. Determine if you want the JAX-WS client to use the HTTP or HTTPS transport mechanism.
2. Configure the asynchronous response listener for unsecure communication using HTTP.

   You can configure the HTTP port for the asynchronous response listener as a Java system property or as a custom property within the transport policy. Properties that are defined in the policy set binding files override any Java system property that might have been defined.

   a. Define the `com.ibm.websphere.webservices.http.listenerPort` property as a Java system property. If this property is set as a Java system property, then all asynchronous response listeners within that Java Virtual Machine (JVM) are affected.

   b. Define the `com.ibm.websphere.webservices.http.listenerPort` property within the `HTTPTransport` transport policy set bindings files. If this property is set as a custom property within a transport policy set binding, then only the services for which the policy set has been configured are affected.
3. Configure the asynchronous response listener for secure communication using HTTPS.

You can configure the HTTPS port for the asynchronous response listener as a Java system property or as a custom property within the transport policy.

a. Define the `com.ibm.websphere.webservices.https.listenerPort` property as a Java system property. If this property is set as a Java system property, thenall asynchronous response listeners within that JVM are affected.
b. Define the `com.ibm.websphere.webservices.https.listenerPort` property within the `SSLTransport` transport policy set bindings files. If this property is set as a custom property within a transport policy set binding, then only the services for which the policy set has been configured are affected.

Results

Your JAX-WS web services client is configured to use the asynchronous response listener to receive incoming asynchronous responses.

Example

The following examples demonstrate how to enable the asynchronous response listener when defining the custom port of 9999:

Use the following Java command to configure the custom HTTP port for the asynchronous response listener in a thin client environment:

```
- java.exe -Dcom.ibm.websphere.webservices.http.listenerPort=9999 com.ibm.websphere.my_program
```

Use the following launchClient command to configure the custom HTTP port for the asynchronous response listener in an application client container:

```
- launchClient.bat MyClient.ear -CCDcom.ibm.websphere.webservices.http.listenerPort=9999
```

The following is an excerpt from an HTTPTransport policy binding.xml file that includes the asynchronous response listener properties:

```
</wsp:Policy>
   </wsp:ExactlyOne>
 </wsp:All>
    <wshttp:outAsyncResponseProxy>
     <wshttp:connectInfo host="" port=""></wshttp:connectInfo>
                  <wshttp:basicAuth userid="" password=""></wshttp:basicAuth>
    </wshttp:outAsyncResponseProxy>
    <wshttp:properties>
  <wshttp:customProperty name="com.ibm.websphere.webservices.http.listenerPort" value="9999" />
   </wshttp:properties>
 </wsp:All>
   </wsp:ExactlyOne>
</wsp:Policy>
```

What to do next

Run the JAX-WS client with the specified asynchronous response listener options.

Invoking JAX-WS web services asynchronously using the SOAP over JMS transport

Using the JAX-WS JMS asynchronous response message listener

Java API for XML-Based Web Services (JAX-WS) includes a Java Message Service (JMS) asynchronous response message listener, which is used to receive responses to asynchronous JAX-WS requests that use the JMS transport. The JMS asynchronous response message listener is used in the application server and application client environments.

Before you begin

JAX-WS provides support for invoking web service operations asynchronously by using either a callback or a polling model. When the JAX-WS client uses the JMS transport to invoke asynchronous operations, the responses are received by the asynchronous response message listener. To learn how to use the JAX-WS asynchronous client invocation model, read about invoking JAX-WS web services asynchronously.

About this task

The JMS asynchronous response message listener is used within the web services client environment to receive incoming asynchronous responses when the client application is using the JMS Transport. The listener requires a connection factory and a queue to function correctly. Begin by configuring the connection factory and queue, and then specify the JNDI names of the connection factory and queue to the listener by setting Java system properties. The environment in which the client is running determines how the system properties are set.

The JMS asynchronous response message listener is started automatically by the web services client runtime environment when the client invokes the first asynchronous JAX-WS operation using the JMS transport.

The connection factory and the queue configured with the asynchronous response message listener is used for all requests that are invoked within a particular Java process such as for the application server or an application client container. You can share the connection factory among different Java processes. However, you cannot share a queue among Java processes.

Procedure

1. Determine if you want the JAX-WS client to use the JMS transport mechanism.
2. For each Java process that will use JMS as a transport for asynchronous JAX-WS requests, configure the connection factory and queue that are used by the JMS asynchronous response listener for that process. You can share a connection factory among multiple Java processes, but you cannot share a queue among Java processes.
3. For each Java process, set the com.ibm.websphere.webservices.jms.AsyncReplyQueueName and com.ibm.websphere.webservices.jms.AsyncReplyCFName Java system properties to specify the JNDI names of the queue and connection factory that are used by the JMS asynchronous response message listener for that process.

   If the JNDI name of the queue is the default value, jms/DefaultAsyncReplyQueue, then you do not need to set the AsyncReplyQueueName property. Likewise, if the JNDI name of the connection factory is the default value, jms/DefaultAsyncReplyCF, then you do not need to set the AsyncReplyCFName property as well.

   If your client runs within the application server environment, then set the properties as application server system properties by using the administrative console or the wsadmin command.

   If your client runs within the application client container environment, then you should set the properties by using the –CCD option on the launchClient command line.

Results

Your JAX-WS web services client is configured to use the JMS asynchronous response message listener to receive asynchronous response messages when using the JMS transport.

Example

Suppose that you have a JAX-WS web services client that runs in the application client container environment and uses the JMS transport to communicate with the server. Suppose also that the client invokes asynchronous JAX-WS operations. You can create a connection factory with the JNDI name,

jms/MyAppCF, and a queue with the JNDI name, jms/MyAppAsyncReplyQueue. When you invoke the client with the launchClient command, specify the JNDI names of the queue and connection factory as illustrated in the following command:

```
launchClient MyAppClient.ear \
   -CCDcom.ibm.websphere.webservices.jms.AsyncReplyQueueName=jms/MyAppReplyQueue \
   -CCDcom.ibm.websphere.webservices.jms.AsyncReplyCFName=jms/MyAppCF \
   <application arguments>
```

Chapter 39. Administering web services - UDDI registry

The Universal Description, Discovery, and Integration (UDDI) specification defines a way to publish and discover information about web services. The UDDI specification defines a standard for the visibility, reusability, and manageability that are essential for a service-oriented architecture (SOA) registry service. The UDDI registry is a directory for web services that is implemented using the UDDI specification. It is a component of WebSphere® Application Server.

Web services are self-contained, modular applications that can be described, published, located, and invoked over a network. They implement a services oriented architecture (SOA), which supports the connecting or sharing of resources and data in a very flexible and standardized manner. Services are described and organized to support their dynamic, automated discovery and reuse.

Administering the UDDI registry

You can set up and deploy a UDDI registry, then remove, reinstall, or apply an upgrade to a UDDI registry. You can configure SOAP API and GUI services for the UDDI registry. You can use the administrative console or the Java Management Extensions (JMX) management interface to manage UDDI registries.

Procedure

- Set up and deploy a new UDDI registry
- Remove a UDDI registry node
- Reinstall the UDDI registry application
- Apply an upgrade to the UDDI registry
- Configure SOAP API and GUI services for the UDDI registry
- Manage the UDDI registry

Setting up and deploying a new UDDI registry

A UDDI registry node consists of the UDDI registry application (an enterprise application that is supplied as part of WebSphere Application Server), a store of data (using a relational database management system) referred to as the UDDI database, and a means to connect the application to the data (a data source and related elements). To set up a new UDDI registry, you create the UDDI database and data source, and deploy the supplied application.

Before you begin

Start WebSphere Application Server, and create a server to host the UDDI registry. Use the starting and stopping quick reference information for information about starting WebSphere Application Server using either commands or the administrative console.

About this task

The subtopics describe how to create the UDDI database (which can be local or remote) and data source, and how to deploy the UDDI registry application.

You can create either a *default* UDDI node or a *customized* UDDI node. The main difference between the two nodes is the number of mandatory UDDI registry properties, such as the UDDI node ID and description, and the prefix to use for generated discovery URLs.

Default UDDI node

The mandatory properties are automatically set to default values and you cannot change them. A default UDDI node is a suitable option for initial evaluation of the UDDI registry, and for development and test purposes.

Customized UDDI node

You must set the mandatory properties. After these properties are set, you cannot change them for this configuration. With a customized UDDI node, you have more control over the database management system that is used for the UDDI database, and the properties that are used to set up the UDDI database. With a customized UDDI node, you create the UDDI database and data source to your own specifications before deploying the UDDI registry application. A customized node is a suitable option for production purposes. To move from a default UDDI node to a customized UDDI node, see “Changing the UDDI registry application environment after deployment” on page 3505.

Procedure

- To set up a UDDI registry quickly for test or development purposes, follow the instructions in “Setting up a default UDDI node with a default data source.” The database, data source, and UDDI registry application are created or deployed by a single script. The database type is embedded Apache Derby.
- To create a default UDDI registry with a database other than embedded Apache Derby, or to use an embedded Apache Derby database but create the data source manually, follow the instructions in “Setting up a default UDDI node” on page 3483.
- To create a customized UDDI registry, follow the instructions in “Setting up a customized UDDI node” on page 3493.

Setting up a default UDDI node with a default data source

You can create a UDDI node with predetermined property values and an embedded Apache Derby database. You can do this to set up a UDDI registry quickly for test or development purposes.

About this task

When you set up a default UDDI node with a default data source, the mandatory node properties, such as node ID, are set automatically and you cannot change them. You run a single script to create the UDDI database and data source, and to deploy the UDDI registry application. This type of node is suitable for initial evaluation of the UDDI registry and for development and test purposes.

If you want to create a default UDDI node with an embedded Apache Derby database but a different data source, or with a different database, see “Setting up a default UDDI node” on page 3483.

If you want to set up a UDDI node with your own properties, including the mandatory node properties, you must set up a customized node. See “Setting up a customized UDDI node” on page 3493.

Procedure

1. Create the UDDI node by running the wsadmin script uddiDeploy.jacl from the *app_server_root*/bin directory.

   Use the following syntax:

```
wsadmin [-conntype none] [-profileName profile_name]
              -wsadmin_classpath app_server_root/derby/lib
              -f uddiDeploy.jacl
              node_name
              server_name
              default
```

   where:

   - `-profileName` *profile_name* is optional, and is the name of the profile in which the UDDI application is deployed. If you do not specify a profile, the default profile is used.
   - `-conntype none` is optional, and is needed only if the application server is not running.
   - *app_server_root* is the directory name of the WebSphere Application Server installation location.

- *node_name* is the name of the WebSphere node on which the target server runs. Note that the node name is case sensitive.
- *server_name* is the name of the target server that deploys the UDDI registry, for example, server1. The server name is case sensitive.
- `default` creates a UDDI node with default policies in an Apache Derby database and data source. This option is specific to the Apache Derby database only and creates everything required to run a UDDI node.

  If the Apache Derby database already exists, you are asked if you want to re-create it. If you choose to re-create the database, the existing database is deleted and a new one is created in its place. If you choose not to re-create the database, the command exits and a new database is not created.

  Note: If the application server has already accessed the existing Apache Derby database, the uddiDeploy.jacl script cannot re-create the database. Use the uddiRemove.jacl script to remove the database, as described in the topic about removing a UDDI registry node, restart the server, and run the uddiDeploy.jacl script again.

For example, to create a UDDI node named MyNode on a server named server1 when server1 is started, you might enter the following command. Enter the command on a single line.

```
wsadmin -profileName myProfile -wsadmin_classpath /QIBM/ProdData/WebSphere/
AppServer/was_version/Base/derby/lib -f uddiDeploy.jacl MyNode server1 default
```

To create a UDDI node named MyNode on a server named server1 when server1 is not started, you might enter the following command. Enter the command on a single line.

```
wsadmin -conntype none -profileName myProfile -wsadmin_classpath /QIBM/ProdData/
WebSphere/AppServer/was_version/Base/derby/lib -f uddiDeploy.jacl MyNode server1 default
```

2. Click **Applications** > **Application Types** > **WebSphere enterprise applications** to display the installed applications. Start the UDDI registry application by selecting the check box next to the application name and clicking **Start**. Alternatively, if the application server is not already running, start the application server. This action automatically starts the UDDI registry application. The UDDI node is now active.

   If you restart the UDDI application or the application server, the UDDI node always reactivates, even if the node was previously deactivated.
3. Click **UDDI** > **UDDI Nodes** > *UDDI_node_id* to display the properties page for the UDDI registry node. Set **Prefix for generated discoveryURLs** to a valid URL for your configuration. This property specifies the URL prefix that is applied to generated discovery URLs that are used by the HTTP GET service for UDDI Version 2.

What to do next

Follow the instructions in “Using the UDDI registry installation verification test (IVT)” on page 3504 to verify that you have successfully set up the UDDI node.

Setting up a default UDDI node

You can create a UDDI node with predetermined property values. This UDDI node is suitable for initial evaluation of the UDDI registry and for development and test purposes.

About this task

When you set up a default UDDI node, the mandatory node properties, such as node ID, are set automatically and you cannot change them. You can create a default UDDI node with an embedded Apache Derby database but a different data source, or with a database other than Apache Derby.

If you want to set up a UDDI node with your own properties, including the mandatory node properties, you must set up a customized node. See “Setting up a customized UDDI node” on page 3493.

Procedure

1. Create a database schema to hold the UDDI registry by completing one of the following tasks, ensuring that you use the default node options where specified:
   - "Creating a DB2 distributed database for the UDDI registry"
   - "Creating a DB2 for i database for the UDDI registry" on page 3486
   - "Creating an Apache Derby database for the UDDI registry" on page 3487
   - "Creating an Oracle database for the UDDI registry" on page 3488
2. Set up a data source for the UDDI registry application to use to access the database, as described in "Creating a data source for the UDDI registry" on page 3489.
3. Deploy the UDDI registry application, as described in "Deploying the UDDI registry application" on page 3492.
4. Click **Applications** > **Application Types** > **WebSphere enterprise applications** to display the installed applications. Start the UDDI registry application by selecting the check box next to the application name and clicking **Start**. Alternatively, if the application server is not already running, start the application server. This action automatically starts the UDDI registry application. The UDDI node is now active.

   If you restart the UDDI application or the application server, the UDDI node always reactivates, even if the node was previously deactivated.
5. Click **UDDI** > **UDDI Nodes** > *UDDI_node_id* to display the properties page for the UDDI registry node. Set **Prefix for generated discoveryURLs** to a valid URL for your configuration. This property specifies the URL prefix that is applied to generated discovery URLs that are used by the HTTP GET service for UDDI Version 2.

What to do next

Because you chose to use a default UDDI node, the node is initialized when the UDDI application is started for the first time. Follow the instructions in "Using the UDDI registry installation verification test (IVT)" on page 3504 to verify that you have successfully set up the UDDI node.

Creating a DB2 distributed database for the UDDI registry:

Complete this task if you want to use DB2 on the Windows, Linux, or UNIX operating systems as the database store for your UDDI registry data.

Before you begin

The following steps use a number of variables. Before you start, decide appropriate values to use for these variables. The variables, and suggested values, are:

DataBaseName
: The name of the UDDI registry database. A suggested value is UDDI30. The UDDI information uses the suggested name of UDDI30, so if you use a different name, remember to substitute it when you see UDDI30 in the UDDI information.

DB2UserID
: A DB2 user ID with administrative privileges.

DB2Password
: The password for the DB2 user ID.

BufferPoolName
: The name of a buffer pool for the UDDI registry database to use. A suggested value is uddibp, but you can use any name because the buffer pool is created as part of this task.

TableSpaceName
: The name of a table space. A suggested value is uddits, but you can use any name.

TempTableSpaceName
The name of a temporary table space. A suggested value is udditstemp, but you can use any name because the temporary table space is created as part of this task.

If you want to create a remote database, refer first to the database product documentation about the relevant capabilities of the product.

About this task

You complete this task only once for each UDDI registry, as part of setting up and deploying a UDDI registry.

Procedure

1. Change the directory to *app_server_root*/UDDIReg/databaseScripts.
2. Start the DB2 Command Line Processor. Enter the following command at the command prompt:
   ```
   db2
   ```
3. Set up the DB2 environment variables. Enter the following command:
   ```
   set DB2CODEPAGE=1208
   ```
4. Create the DB2 database. Enter the following command:
   ```
   create database DataBaseName using codeset UTF-8 territory en
   ```
5. Configure the DB2 database. Enter the following commands:
   a.
   ```
   connect to DataBaseName user DB2UserID using DB2Password
   ```
   b.
   ```
   update db cfg for DataBaseName using applheapsz 2048
   ```
   c.
   ```
   update db cfg for DataBaseName using logfilsiz 8192
   ```
   d.
   ```
   connect reset
   ```
   e.
   ```
   terminate
   ```
   f.
   ```
   force application all
   ```
   g.
   ```
   terminate
   ```
   h.
   ```
   stop
   ```
   i.
   ```
   start
   ```
6. Restart the DB2 Command Line Processor. For all operating systems except Windows, enter the following command at the command prompt:
   ```
   db2
   ```
7. Create further database structures. Enter the following commands:
   a.
   ```
   connect to DataBaseName user DB2UserID using DB2Password
   ```
   b.
   ```
   create regular tablespace uddits pagesize 32K managed by system using
   ('TableSpaceName') extentsize 64 prefetchsize 32 bufferpool BufferPoolName
   ```
   c.
   ```
   create system temporary tablespace TempTableSpacename pagesize 32K managed by
   system using ('TempTableSpacename') extentsize 32 overhead 14.06
   prefetchsize 32 transferrate 0.33 bufferpool BufferPoolName
   ```
8. Define the database structures that are needed to store the UDDI data.

   Exit the DB2 Command Line Processor and enter the following commands exactly as shown. Note that one step uses `-vf` rather than `-tvf`.
   a.
   ```
   db2 -tvf uddi30crt_10_prereq_db2.sql
   ```

b.
```
db2 -tvf uddi30crt_20_tables_generic.sql
```
c.
```
db2 -tvf uddi30crt_25_tables_db2udb.sql
```
d.
```
db2 -tvf uddi30crt_30_constraints_generic.sql
```
e.
```
db2 -tvf uddi30crt_35_constraints_db2udb.sql
```
f.
```
db2 -tvf uddi30crt_40_views_generic.sql
```
g.
```
db2 -tvf uddi30crt_45_views_db2udb.sql
```
h.
```
db2 -vf uddi30crt_50_triggers_db2udb.sql
```
i.
```
db2 -tvf uddi30crt_60_insert_initial_static_data.sql
```

9. Optional: To use the database as a default UDDI node, enter the following command:
```
db2 -tvf uddi30crt_70_insert_default_database_indicator.sql
```
10. Issue the following commands:
```
connect reset
terminate
```
11. Issue the following commands:
```
connect reset
terminate
```

What to do next

Continue with setting up and deploying your UDDI registry node.

Creating a DB2 for i database for the UDDI registry:

Complete this task if you want to use DB2 for i as the database store for your UDDI registry data.

Before you begin

The default names of the UDDI registry schema in the SQL scripts listed in the following topic are IBMUDI30 and IBMUDS30. These names are the recommended values and are assumed throughout the UDDI information. To use different names, modify the SQL files listed, then substitute the new names when IBMUDI30 and IBMUDS30 are used in the information center.

About this task

You complete this task only once for each UDDI registry, as part of setting up and deploying a UDDI registry.

Procedure

1. Use IBM Navigator for i to run SQL scripts.
   a. Open IBM Navigator for i.
   b. Expand **My Connections** > **iSeriesName** > **Databases**.
   c. Select **iSeriesName**.
   d. Right-click **Run SQL Scripts...**.

   A **Run SQL Scripts** window opens.
2. Open the IBM i DB2 SQL files.
   a. Map a network drive to the root directory of your IBM i server integrated file system.
   b. In Windows Explorer, expand the `WAS_HOME/UDDIReg/databaseScripts` directory.

c. Open the following SQL files with a text editor (for example, Windows Notepad):
   - uddi30crt_10_prereq_db2_iSeries.sql
   - uddi30crt_20_tables_generic_iSeries.sql
   - uddi30crt_25_tables_db2udb_iSeries.sql
   - uddi30crt_30_constraints_generic_iSeries.sql
   - uddi30crt_35_constraints_db2udb_iSeries.sql
   - uddi30crt_40_views_generic_iSeries.sql
   - uddi30crt_45_views_db2udb_iSeries.sql
   - uddi30crt_50_triggers_db2udb_iSeries.sql
   - uddi30crt_60_insert_initial_static_data_iSeries.sql

3. Copy the text to the **Run SQL Scripts** window.
   a. In the text editor of the file `uddi30crt_10_prereq_db2_iSeries.sql`, click **Edit** > **Select All**.
   b. Click **Edit** > **Copy**.
   c. In the **Run SQL Scripts** window, click **Edit** > **Paste**.
   d. Click **Run** > **All**.
   e. After the script completes running, select all the SQL text and delete it from the **Run SQL Scripts** window.
   f. Repeat the previous steps for all the SQL scripts listed in step 2.
4. Optional: If you want to use the database as a default UDDI node, complete the following steps:
   a. Open `uddi30crt_70_insert_default_database_indicator.sql` as described in step 2.
   b. Copy and run `uddi30crt_70_insert_default_database_indicator.sql` as described in step 3.

What to do next

Continue to set up and deploy your UDDI registry node.

Creating an Apache Derby database for the UDDI registry:

Complete this task to use an Apache Derby database as the database store for your UDDI registry. You can use an embedded or network Apache Derby database, and the database store can be local or remote.

Before you begin

The following steps use a number of variables. Before you start, decide appropriate values to use for these variables. The variables, and suggested values, are:

arg1 The path of the SQL files. On a standard installation, the path is *app_server_root*/UDDIReg/databasescripts.

arg2 The path to the location where you want to install the Apache Derby database.

For example, *profile_root*/databases/com.ibm.uddi.

arg3 The name of the Apache Derby database. A recommended value is UDDI30, and this name is assumed throughout the UDDI information. If you use another name, substitute that name when UDDI30 is used in the UDDI information.

arg4 An optional argument. Either use the value DEFAULT, or omit this argument. Specify DEFAULT to use the database as a default UDDI node. This argument is case sensitive.

If you want to create a remote database, refer first to the database product documentation about the relevant capabilities of the product.

About this task

You complete this task only once for each UDDI registry, as part of setting up and deploying a UDDI registry.

Procedure

1. Start a Qshell session. Enter the STRQSH command from the IBM i command line.
2. Create a UDDI Apache Derby database by using UDDIDerbyCreate.jar. Run the following Java -jar command from the *app_server_root*/UDDIReg/databaseScripts directory.

```
java -Djava.ext.dirs=app_server_root/derby/lib:app_server_root/java/jre/lib/ext -jar UDDIDerbyCreate.jar
arg1 arg2 arg3 arg4
```

   If the Apache Derby database already exists, you are asked if you want to re-create it. If you choose to re-create the database, the existing database is deleted and a new one is created in its place. If you choose not to re-create the database, the command exits and a new database is not created.

   Note: If the application server has already accessed the existing Apache Derby database, the uddiDeploy.jacl script cannot re-create the database. Use the uddiRemove.jacl script to remove the database, as described in the topic about removing a UDDI registry node, restart the server, and run the uddiDeploy.jacl script again.
3. If you are using a remote database, which requires network Apache Derby, or if you want to use network Apache Derby for other reasons, for example, to use Apache Derby with a cluster, configure the Apache Derby Network Server framework. For details, see the section about managing the Derby Network Server in the Derby Server and Administration Guide.

What to do next

Continue with setting up and deploying your UDDI registry node.

Creating an Oracle database for the UDDI registry:

Complete this task if you want to use Oracle as the database store for your UDDI registry data.

Before you begin

This task creates three new schemas: ibmuddi, ibmudi30 and ibmuds30. You cannot complete this task if schemas with these names exist already.

The following steps use a number of variables. Before you start, decide appropriate values to use for these variables. The variables, and suggested values, are:

OracleUserID
: The Oracle user ID to use to create the database.

OraclePassword
: The password for the Oracle user ID.

The Oracle database must be a remote database; you cannot create a local database. Refer first to the database product documentation about the relevant capabilities of the product.

About this task

You complete this task only once for each UDDI registry, as part of setting up and deploying a UDDI registry.

The supported versions of Oracle are Version 9i and Version 10g. Each version has the following restrictions:

Table 322. UDDI restrictions and Oracle versions. The table lists the Version 9i and Version 10g restrictions for different UDDI parameters.

	Version 9i restrictions		Version 10g restrictions	
discoveryURL (Business)	maximum 4000 bytes	UDDI specification 4096 characters	maximum 4000 bytes	UDDI specification 4096 characters
accessPoint (bindingTemplate)	maximum 4000 bytes	UDDI specification 4096 characters	maximum 4000 bytes	UDDI specification 4096 characters
instanceParms (tModelInstanceInfo)	maximum 4000 bytes	UDDI specification 8192 characters		
overviewURL (tModelInstanceInfo)	maximum 4000 bytes	UDDI specification 4096 characters		
Digital Signature	maximum 4000 bytes			

Procedure

1. Run the following commands:
   a.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_10_prereq_oracle.sql
```
   b.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_20_tables_generic.sql
```
2. Run one of the following commands, depending on the version of Oracle.
   - For Oracle Version 9i:
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_25_tables_oracle_pre10g.sql
```
   - For Oracle Version 10g and later:
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_25_tables_oracle.sql
```
3. Run the following commands:
   a.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_30_constraints_generic.sql
```
   b.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_35_constraints_oracle.sql
```
   c.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_40_views_generic.sql
```
   d.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_45_views_oracle.sql
```
   e.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_50_triggers_oracle.sql
```
   f.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_60_insert_initial_static_data.sql
```
4. Optional: To use the database as a default UDDI node, run the following command:
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_70_insert_default_database_indicator.sql
```

What to do next

Continue with setting up and deploying your UDDI registry node.

Creating a data source for the UDDI registry:

You create a data source so that the UDDI registry can use it to access the UDDI database.

Before you begin

You must have already created the database for the UDDI registry.

About this task

Complete this task as part of setting up and deploying a new UDDI registry. The UDDI registry uses the data source to access the UDDI database.

Procedure

1. Optional: For network Apache Derby, create a Java 2 Connector (J2C) authentication data entry. This step is not required for embedded Apache Derby.
   a. Click **Security** > **Global security** > **[Authentication] Java Authentication and Authorization Service** > **J2C authentication data**.
   b. Click **New** to create a new J2C authentication data entry.
   c. Enter the following details:

      Alias A suitable short name, for example `UDDIAlias`.

      Userid

      The database user ID, for example `db2admin` for DB2, or `IBMUDDI` for Oracle, which is used to read and write to the UDDI registry database. For network Apache Derby, the user ID can be any value.

      Password
      The password that is associated with the user ID specified previously. For network Apache Derby, the password can be any value.

      Description
      A description of the user ID.

      Click **Apply**, then save the changes to the master configuration.
2. Create a JDBC provider, if a suitable one does not already exist, by using the following table to determine the provider type and implementation type for your chosen database.

Table 323. Provider types and implementation types. The table lists the correct provider type and implementation type for each database.

Database	Provider type	Implementation type
DB2	DB2 UDB for iSeries (Native)	Connection pool data source
Oracle	Oracle JDBC Driver	Connection pool data source
Embedded Apache Derby	Derby JDBC Driver	Connection pool data source
Network Apache Derby	Derby Network Server JDBC Driver provider	Connection pool data source
Microsoft SQL Server	DataDirect Connect JDBC Driver Microsoft SQL Server JDBC Driver	Connection pool data source

   For details about how to create a JDBC provider, see the topic about configuring a JDBC provider by using the administrative console.
3. Create the data source for the UDDI registry:
   a. Click **Resources** > **JDBC** > **JDBC Providers**.
   b. Select the scope of the JDBC provider that you selected or created earlier, that is, the level at which the JDBC provider is defined. For example, for a JDBC provider that is defined at the level of server1, select the following:

```
Node=Node01, Server=server1
```

      All the JDBC providers that are defined at the selected scope are displayed.
   c. Select the JDBC provider that you created earlier.
   d. Under **Additional Properties**, select **Data sources**. Do not select the **Data sources (WebSphere Application Server V4)** option.

e. Click **New** to create a new data source.

f. In the **Create a data source** wizard, enter the following data:

Name A suitable name, for example `UDDI Datasource`.

JNDI name
Enter `datasources/uddids`. This is a mandatory field.

You must not have any other data sources that use this Java Naming and Directory Interface (JNDI) name. If another data source uses this JNDI name, you must either remove it or change its JNDI name. For example, if you created a default UDDI node previously that uses an Apache Derby database, before you continue, use the uddiRemove.jacl script with the default option to remove the data source and the UDDI application instance.

Component-managed authentication alias

- For DB2, Oracle, or network Apache Derby, select the alias that you created in step 2. The alias is prefixed by the node name, for example MyNode/UDDIAlias.
- For embedded Apache Derby, select `(none)`.

g. Click **Next**.

h. On the database-specific properties page of the wizard, enter the following data:

- For DB2:

  Database name
  The name of the database, for example `*LOCAL`.

- For Oracle:

  URL The Uniform Resource Locator (URL) of the database from which the datasource obtains connections, for example `jdbc:oracle:oci8:@`*`Oracle_database_name`*.

- For Apache Derby (embedded or network):

  Database name
  The name of the database, for example:

profile_root`/databases/com.ibm.uddi/UDDI30`

For network Apache Derby, ensure that the **Server name** and **Port number** values match the network server.

Leave all other fields unchanged.

Use this Data Source in container-managed persistence (CMP)
Ensure that the check box is cleared.

i. Click **Next**, then check the summary and click **Finish**.

j. Click the data source to display its properties, and add the following information:

Description
A description of the data source.

Category
Enter `uddi`.

Data store helper class name
This value is provided automatically:

Table 324. Data store helper class names

Database	Data store helper class name
DB2	com.ibm.websphere.rsadapter.DB2AS400DataStoreHelper
Oracle 11g	com.ibm.websphere.rsadapter.Oracle11gDataStoreHelper
Embedded Apache Derby	com.ibm.websphere.rsadapter.DerbyDataStoreHelper

Table 324. Data store helper class names (continued)

Database	Data store helper class name
Network Apache Derby	com.ibm.websphere.rsadapter.DerbyNetworkServerDataStoreHelper

Mapping-configuration alias
Select `DefaultPrincipalMapping`.

k. Click **Apply**.

l. Select **Additional Properties** > **Custom Properties** > **libraries**.

m. Enter `IBMUDI30,IBMUDS30` in the **Value** field and click **OK**.

n. Save the changes to the master configuration.

4. Test the connection to your UDDI database by selecting the check box next to the data source and clicking **Test connection**. A message similar to `Test Connection for datasource UDDI Datasource on server server1 at node Node01 was successful` is displayed. If a different message is displayed, use the information in that message to investigate and resolve the problem.

What to do next

Continue with setting up and deploying your UDDI registry node.

Deploying the UDDI registry application:

You deploy a UDDI registry application as part of setting up a UDDI node. You can use a supplied script, the administrative console, or wsadmin scripting commands.

Before you begin

Before you deploy a UDDI registry application, you must create the database and data source for the UDDI registry.

About this task

Use this task as part of setting up a default UDDI node or setting up a customized UDDI node. You can deploy a UDDI registry application in two ways:

- You can use a script that performs all the necessary steps.

  This script deploys the UDDI registry to a server that you specify.
- You can use the administrative console. You deploy the UDDI registry application, the `uddi.ear` file, then complete additional steps, as described later in this topic. Alternatively, you can follow the same procedure using wsadmin scripting commands.

Procedure

1. Optional: To deploy a UDDI registry application using the supplied script:

   a. Start a Qshell session by entering the STRQSH command from the IBM i command line.

   b. Run the `uddiDeploy.jacl` wsadmin script as shown, from the *app_server_root*/bin directory.

```
wsadmin [-conntype none] [-profileName profile_name] -f uddiDeploy.jacl
        node_name server_name
```

The attributes of the command are as follows:

- `-conntype none` is optional, and is needed only if the application server is not running.
- `-profileName` *profile_name* is optional, and is the name of the profile in which the UDDI application is deployed. If you do not specify a profile, the default profile is used.
- *node_name* is the name of the WebSphere Application Server node on which the target server runs. The node name is case sensitive.

- *server_name* is the name of the target server on which you want to deploy the UDDI registry, for example, server1. The server name is case sensitive.

For example, to deploy UDDI on the node MyNode and the server server1, assuming that server1 is already started:

```
wsadmin -f uddiDeploy.jacl MyNode server1
```

2. Optional: To deploy a UDDI registry application using the administrative console, use the following steps.
   a. Install the UDDI application (the `uddi.ear` file) to the server that you require.
   b. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***uddi_application*** > **[Detail Properties] Class loading and update detection**.
   c. Ensure that **Class loader order** is set to **Classes loaded with local class loader first (parent last)**.
   d. Ensure that **WAR class loader policy** is set to **Single class loader for application**.
   e. Click **Apply**, then save your changes to the master configuration.

What to do next

Continue setting up the UDDI node.

Setting up a customized UDDI node

You can set up a UDDI node with your own properties, including the mandatory node properties. This type of UDDI node is suitable for production purposes.

About this task

You can set up a customized UDDI node with property values that you choose. After the node is initialized, you cannot change the mandatory node properties, for example, the node ID.

Procedure

1. Review the information in Databases and production use of the UDDI registry to decide which database system to use, then create a database schema to hold the UDDI registry by completing one of the following tasks. Do not use the default node options where specified.
   - “Creating a DB2 distributed database for the UDDI registry” on page 3484
   - “Creating a DB2 for i database for the UDDI registry” on page 3486
   - “Creating an Apache Derby database for the UDDI registry” on page 3487
   - “Creating an Oracle database for the UDDI registry” on page 3488
2. Set up a data source for the UDDI registry application to use to access the database, as described in “Creating a data source for the UDDI registry” on page 3489.
3. Deploy the UDDI registry application, as described in “Deploying the UDDI registry application” on page 3492.
4. Click **Applications** > **Application Types** > **WebSphere enterprise applications** to display the installed applications. Start the UDDI registry application by selecting the check box next to the application name and clicking **Start**. Alternatively, if the application server is not already running, start the application server. This action automatically starts the UDDI registry application. The UDDI node is now active.

   If you restart the UDDI application or the application server, the UDDI node always reactivates, even if the node was previously deactivated.

What to do next

Because you chose a user-customized UDDI node, you must set the properties for the UDDI node by using UDDI administration, and initialize the node, before it is ready to accept UDDI requests. See

“Initializing the UDDI registry node” on page 3502 for details.

Creating a DB2 distributed database for the UDDI registry:

Complete this task if you want to use DB2 on the Windows, Linux, or UNIX operating systems as the database store for your UDDI registry data.

Before you begin

The following steps use a number of variables. Before you start, decide appropriate values to use for these variables. The variables, and suggested values, are:

DataBaseName
The name of the UDDI registry database. A suggested value is UDDI30. The UDDI information uses the suggested name of UDDI30, so if you use a different name, remember to substitute it when you see UDDI30 in the UDDI information.

DB2UserID
A DB2 user ID with administrative privileges.

DB2Password
The password for the DB2 user ID.

BufferPoolName
The name of a buffer pool for the UDDI registry database to use. A suggested value is uddibp, but you can use any name because the buffer pool is created as part of this task.

TableSpaceName
The name of a table space. A suggested value is uddits, but you can use any name.

TempTableSpaceName
The name of a temporary table space. A suggested value is udditstemp, but you can use any name because the temporary table space is created as part of this task.

If you want to create a remote database, refer first to the database product documentation about the relevant capabilities of the product.

About this task

You complete this task only once for each UDDI registry, as part of setting up and deploying a UDDI registry.

Procedure

1. Change the directory to *app_server_root*/UDDIReg/databaseScripts.
2. Start the DB2 Command Line Processor. Enter the following command at the command prompt:
   ```
   db2
   ```
3. Set up the DB2 environment variables. Enter the following command:
   ```
   set DB2CODEPAGE=1208
   ```
4. Create the DB2 database. Enter the following command:
   ```
   create database DataBaseName using codeset UTF-8 territory en
   ```
5. Configure the DB2 database. Enter the following commands:
   a.
   ```
   connect to DataBaseName user DB2UserID using DB2Password
   ```
   b.
   ```
   update db cfg for DataBaseName using applheapsz 2048
   ```
   c.
   ```
   update db cfg for DataBaseName using logfilsiz 8192
   ```

d.
```
connect reset
```
e.
```
terminate
```
f.
```
force application all
```
g.
```
terminate
```
h.
```
stop
```
i.
```
start
```

6. Restart the DB2 Command Line Processor. For all operating systems except Windows, enter the following command at the command prompt:
```
db2
```
7. Create further database structures. Enter the following commands:
   a.
   ```
   connect to DataBaseName user DB2UserID using DB2Password
   ```
   b.
   ```
   create regular tablespace uddits pagesize 32K managed by system using
   ('TableSpaceName') extentsize 64 prefetchsize 32 bufferpool BufferPoolName
   ```
   c.
   ```
   create system temporary tablespace TempTableSpacename pagesize 32K managed by
   system using ('TempTableSpacename') extentsize 32 overhead 14.06
   prefetchsize 32 transferrate 0.33 bufferpool BufferPoolName
   ```
8. Define the database structures that are needed to store the UDDI data.

   Exit the DB2 Command Line Processor and enter the following commands exactly as shown. Note that one step uses `-vf` rather than `-tvf`.
   a.
   ```
   db2 -tvf uddi30crt_10_prereq_db2.sql
   ```
   b.
   ```
   db2 -tvf uddi30crt_20_tables_generic.sql
   ```
   c.
   ```
   db2 -tvf uddi30crt_25_tables_db2udb.sql
   ```
   d.
   ```
   db2 -tvf uddi30crt_30_constraints_generic.sql
   ```
   e.
   ```
   db2 -tvf uddi30crt_35_constraints_db2udb.sql
   ```
   f.
   ```
   db2 -tvf uddi30crt_40_views_generic.sql
   ```
   g.
   ```
   db2 -tvf uddi30crt_45_views_db2udb.sql
   ```
   h.
   ```
   db2 -vf uddi30crt_50_triggers_db2udb.sql
   ```
   i.
   ```
   db2 -tvf uddi30crt_60_insert_initial_static_data.sql
   ```
9. Optional: To use the database as a default UDDI node, enter the following command:
```
db2 -tvf uddi30crt_70_insert_default_database_indicator.sql
```
10. Issue the following commands:
```
connect reset
terminate
```
11. Issue the following commands:
```
connect reset
terminate
```

What to do next

Continue with setting up and deploying your UDDI registry node.

Creating a DB2 for i database for the UDDI registry:

Complete this task if you want to use DB2 for i as the database store for your UDDI registry data.

Before you begin

The default names of the UDDI registry schema in the SQL scripts listed in the following topic are IBMUDI30 and IBMUDS30. These names are the recommended values and are assumed throughout the UDDI information. To use different names, modify the SQL files listed, then substitute the new names when IBMUDI30 and IBMUDS30 are used in the information center.

About this task

You complete this task only once for each UDDI registry, as part of setting up and deploying a UDDI registry.

Procedure

1. Use IBM Navigator for i to run SQL scripts.
   a. Open IBM Navigator for i.
   b. Expand **My Connections** > **iSeriesName** > **Databases**.
   c. Select **iSeriesName**.
   d. Right-click **Run SQL Scripts...**.

   A **Run SQL Scripts** window opens.
2. Open the IBM i DB2 SQL files.
   a. Map a network drive to the root directory of your IBM i server integrated file system.
   b. In Windows Explorer, expand the `WAS_HOME/UDDIReg/databaseScripts` directory.
   c. Open the following SQL files with a text editor (for example, Windows Notepad):
      - uddi30crt_10_prereq_db2_iSeries.sql
      - uddi30crt_20_tables_generic_iSeries.sql
      - uddi30crt_25_tables_db2udb_iSeries.sql
      - uddi30crt_30_constraints_generic_iSeries.sql
      - uddi30crt_35_constraints_db2udb_iSeries.sql
      - uddi30crt_40_views_generic_iSeries.sql
      - uddi30crt_45_views_db2udb_iSeries.sql
      - uddi30crt_50_triggers_db2udb_iSeries.sql
      - uddi30crt_60_insert_initial_static_data_iSeries.sql
3. Copy the text to the **Run SQL Scripts** window.
   a. In the text editor of the file `uddi30crt_10_prereq_db2_iSeries.sql`, click **Edit** > **Select All**.
   b. Click **Edit** > **Copy**.
   c. In the **Run SQL Scripts** window, click **Edit** > **Paste**.
   d. Click **Run** > **All**.
   e. After the script completes running, select all the SQL text and delete it from the **Run SQL Scripts** window.
   f. Repeat the previous steps for all the SQL scripts listed in step 2.
4. Optional: If you want to use the database as a default UDDI node, complete the following steps:

a. Open `uddi30crt_70_insert_default_database_indicator.sql` as described in step 2.
b. Copy and run `uddi30crt_70_insert_default_database_indicator.sql` as described in step 3.

What to do next

Continue to set up and deploy your UDDI registry node.

Creating an Apache Derby database for the UDDI registry:

Complete this task to use an Apache Derby database as the database store for your UDDI registry. You can use an embedded or network Apache Derby database, and the database store can be local or remote.

Before you begin

The following steps use a number of variables. Before you start, decide appropriate values to use for these variables. The variables, and suggested values, are:

arg1 The path of the SQL files. On a standard installation, the path is *app_server_root*/UDDIReg/databasescripts.

arg2 The path to the location where you want to install the Apache Derby database.

For example, *profile_root*/databases/com.ibm.uddi.

arg3 The name of the Apache Derby database. A recommended value is UDDI30, and this name is assumed throughout the UDDI information. If you use another name, substitute that name when UDDI30 is used in the UDDI information.

arg4 An optional argument. Either use the value DEFAULT, or omit this argument. Specify DEFAULT to use the database as a default UDDI node. This argument is case sensitive.

If you want to create a remote database, refer first to the database product documentation about the relevant capabilities of the product.

About this task

You complete this task only once for each UDDI registry, as part of setting up and deploying a UDDI registry.

Procedure

1. Start a Qshell session. Enter the STRQSH command from the IBM i command line.
2. Create a UDDI Apache Derby database by using UDDIDerbyCreate.jar. Run the following Java -jar command from the *app_server_root*/UDDIReg/databaseScripts directory.

```
java -Djava.ext.dirs=app_server_root/derby/lib:app_server_root/java/jre/lib/ext -jar UDDIDerbyCreate.jar
arg1 arg2 arg3 arg4
```

   If the Apache Derby database already exists, you are asked if you want to re-create it. If you choose to re-create the database, the existing database is deleted and a new one is created in its place. If you choose not to re-create the database, the command exits and a new database is not created.

   Note: If the application server has already accessed the existing Apache Derby database, the uddiDeploy.jacl script cannot re-create the database. Use the uddiRemove.jacl script to remove the database, as described in the topic about removing a UDDI registry node, restart the server, and run the uddiDeploy.jacl script again.
3. If you are using a remote database, which requires network Apache Derby, or if you want to use network Apache Derby for other reasons, for example, to use Apache Derby with a cluster, configure the Apache Derby Network Server framework. For details, see the section about managing the Derby Network Server in the Derby Server and Administration Guide.

What to do next

Continue with setting up and deploying your UDDI registry node.

Creating an Oracle database for the UDDI registry:

Complete this task if you want to use Oracle as the database store for your UDDI registry data.

Before you begin

This task creates three new schemas: ibmuddi, ibmudi30 and ibmuds30. You cannot complete this task if schemas with these names exist already.

The following steps use a number of variables. Before you start, decide appropriate values to use for these variables. The variables, and suggested values, are:

OracleUserID
The Oracle user ID to use to create the database.

OraclePassword
The password for the Oracle user ID.

The Oracle database must be a remote database; you cannot create a local database. Refer first to the database product documentation about the relevant capabilities of the product.

About this task

You complete this task only once for each UDDI registry, as part of setting up and deploying a UDDI registry.

The supported versions of Oracle are Version 9i and Version 10g. Each version has the following restrictions:

Table 325. UDDI restrictions and Oracle versions. The table lists the Version 9i and Version 10g restrictions for different UDDI parameters.

	Version 9i restrictions		**Version 10g restrictions**	
discoveryURL (Business)	maximum 4000 bytes	UDDI specification 4096 characters	maximum 4000 bytes	UDDI specification 4096 characters
accessPoint (bindingTemplate)	maximum 4000 bytes	UDDI specification 4096 characters	maximum 4000 bytes	UDDI specification 4096 characters
instanceParms (tModelInstanceInfo)	maximum 4000 bytes	UDDI specification 8192 characters		
overviewURL (tModelInstanceInfo)	maximum 4000 bytes	UDDI specification 4096 characters		
Digital Signature	maximum 4000 bytes			

Procedure

1. Run the following commands:
   a.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_10_prereq_oracle.sql
```
   b.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_20_tables_generic.sql
```
2. Run one of the following commands, depending on the version of Oracle.
   - For Oracle Version 9i:
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_25_tables_oracle_pre10g.sql
```
   - For Oracle Version 10g and later:

```
sqlplus OracleUserID/OraclePassword @ uddi30crt_25_tables_oracle.sql
```

3. Run the following commands:
   a.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_30_constraints_generic.sql
```
   b.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_35_constraints_oracle.sql
```
   c.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_40_views_generic.sql
```
   d.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_45_views_oracle.sql
```
   e.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_50_triggers_oracle.sql
```
   f.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_60_insert_initial_static_data.sql
```
4. Optional: To use the database as a default UDDI node, run the following command:
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_70_insert_default_database_indicator.sql
```

What to do next

Continue with setting up and deploying your UDDI registry node.

Creating a data source for the UDDI registry:

You create a data source so that the UDDI registry can use it to access the UDDI database.

Before you begin

You must have already created the database for the UDDI registry.

About this task

Complete this task as part of setting up and deploying a new UDDI registry. The UDDI registry uses the data source to access the UDDI database.

Procedure

1. Optional: For network Apache Derby, create a Java 2 Connector (J2C) authentication data entry. This step is not required for embedded Apache Derby.
   a. Click **Security** > **Global security** > **[Authentication] Java Authentication and Authorization Service** > **J2C authentication data**.
   b. Click **New** to create a new J2C authentication data entry.
   c. Enter the following details:

      Alias A suitable short name, for example `UDDIAlias`.

      Userid

      The database user ID, for example `db2admin` for DB2, or `IBMUDDI` for Oracle, which is used to read and write to the UDDI registry database. For network Apache Derby, the user ID can be any value.

      Password
      The password that is associated with the user ID specified previously. For network Apache Derby, the password can be any value.

      Description
      A description of the user ID.

      Click **Apply**, then save the changes to the master configuration.

2. Create a JDBC provider, if a suitable one does not already exist, by using the following table to determine the provider type and implementation type for your chosen database.

Table 326. Provider types and implementation types. The table lists the correct provider type and implementation type for each database.

Database	Provider type	Implementation type
DB2	DB2 UDB for iSeries (Native)	Connection pool data source
Oracle	Oracle JDBC Driver	Connection pool data source
Embedded Apache Derby	Derby JDBC Driver	Connection pool data source
Network Apache Derby	Derby Network Server JDBC Driver provider	Connection pool data source
Microsoft SQL Server	DataDirect Connect JDBC Driver Microsoft SQL Server JDBC Driver	Connection pool data source

   For details about how to create a JDBC provider, see the topic about configuring a JDBC provider by using the administrative console.
3. Create the data source for the UDDI registry:
   a. Click **Resources** > **JDBC** > **JDBC Providers**.
   b. Select the scope of the JDBC provider that you selected or created earlier, that is, the level at which the JDBC provider is defined. For example, for a JDBC provider that is defined at the level of server1, select the following:

```
Node=Node01, Server=server1
```

      All the JDBC providers that are defined at the selected scope are displayed.
   c. Select the JDBC provider that you created earlier.
   d. Under **Additional Properties**, select **Data sources**. Do not select the **Data sources (WebSphere Application Server V4)** option.
   e. Click **New** to create a new data source.
   f. In the **Create a data source** wizard, enter the following data:

      Name A suitable name, for example `UDDI Datasource`.

      JNDI name
      Enter `datasources/uddids`. This is a mandatory field.

      You must not have any other data sources that use this Java Naming and Directory Interface (JNDI) name. If another data source uses this JNDI name, you must either remove it or change its JNDI name. For example, if you created a default UDDI node previously that uses an Apache Derby database, before you continue, use the uddiRemove.jacl script with the default option to remove the data source and the UDDI application instance.

      Component-managed authentication alias
      - For DB2, Oracle, or network Apache Derby, select the alias that you created in step 2. The alias is prefixed by the node name, for example MyNode/UDDIAlias.
      - For embedded Apache Derby, select `(none)`.

   g. Click **Next**.
   h. On the database-specific properties page of the wizard, enter the following data:
      - For DB2:

        Database name
        The name of the database, for example `*LOCAL`.
      - For Oracle:

URL The Uniform Resource Locator (URL) of the database from which the datasource obtains connections, for example `jdbc:oracle:oci8:@Oracle_database_name`.

- For Apache Derby (embedded or network):

  Database name
  The name of the database, for example:

`profile_root/databases/com.ibm.uddi/UDDI30`

  For network Apache Derby, ensure that the **Server name** and **Port number** values match the network server.

  Leave all other fields unchanged.

Use this Data Source in container-managed persistence (CMP)
Ensure that the check box is cleared.

i. Click **Next**, then check the summary and click **Finish**.

j. Click the data source to display its properties, and add the following information:

Description
A description of the data source.

Category
Enter `uddi`.

Data store helper class name
This value is provided automatically:

Table 327. Data store helper class names

Database	Data store helper class name
DB2	com.ibm.websphere.rsadapter.DB2AS400DataStoreHelper
Oracle 11g	com.ibm.websphere.rsadapter.Oracle11gDataStoreHelper
Embedded Apache Derby	com.ibm.websphere.rsadapter.DerbyDataStoreHelper
Network Apache Derby	com.ibm.websphere.rsadapter.DerbyNetworkServerDataStoreHelper

Mapping-configuration alias
Select `DefaultPrincipalMapping`.

k. Click **Apply**.

l. Select **Additional Properties** > **Custom Properties** > **libraries**.

m. Enter `IBMUDI30,IBMUDS30` in the **Value** field and click **OK**.

n. Save the changes to the master configuration.

4. Test the connection to your UDDI database by selecting the check box next to the data source and clicking **Test connection**. A message similar to `Test Connection for datasource UDDI Datasource on server server1 at node Node01 was successful` is displayed. If a different message is displayed, use the information in that message to investigate and resolve the problem.

What to do next

Continue with setting up and deploying your UDDI registry node.

Deploying the UDDI registry application:

You deploy a UDDI registry application as part of setting up a UDDI node. You can use a supplied script, the administrative console, or wsadmin scripting commands.

Before you begin

Before you deploy a UDDI registry application, you must create the database and data source for the UDDI registry.

About this task

Use this task as part of setting up a default UDDI node or setting up a customized UDDI node. You can deploy a UDDI registry application in two ways:

- You can use a script that performs all the necessary steps.

  This script deploys the UDDI registry to a server that you specify.
- You can use the administrative console. You deploy the UDDI registry application, the `uddi.ear` file, then complete additional steps, as described later in this topic. Alternatively, you can follow the same procedure using wsadmin scripting commands.

Procedure

1. Optional: To deploy a UDDI registry application using the supplied script:
   a. Start a Qshell session by entering the STRQSH command from the IBM i command line.
   b. Run the `uddiDeploy.jacl` wsadmin script as shown, from the *app_server_root*/bin directory.

```
wsadmin [-conntype none] [-profileName profile_name] -f uddiDeploy.jacl
        node_name server_name
```

   The attributes of the command are as follows:
   - `-conntype none` is optional, and is needed only if the application server is not running.
   - `-profileName` *profile_name* is optional, and is the name of the profile in which the UDDI application is deployed. If you do not specify a profile, the default profile is used.
   - *node_name* is the name of the WebSphere Application Server node on which the target server runs. The node name is case sensitive.
   - *server_name* is the name of the target server on which you want to deploy the UDDI registry, for example, server1. The server name is case sensitive.

   For example, to deploy UDDI on the node MyNode and the server server1, assuming that server1 is already started:

```
wsadmin -f uddiDeploy.jacl MyNode server1
```

2. Optional: To deploy a UDDI registry application using the administrative console, use the following steps.
   a. Install the UDDI application (the `uddi.ear` file) to the server that you require.
   b. Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***uddi_application*** > **[Detail Properties] Class loading and update detection**.
   c. Ensure that **Class loader order** is set to **Classes loaded with local class loader first (parent last)**.
   d. Ensure that **WAR class loader policy** is set to **Single class loader for application**.
   e. Click **Apply**, then save your changes to the master configuration.

What to do next

Continue setting up the UDDI node.

Initializing the UDDI registry node:

Use this topic to initialize a UDDI registry node after setup or migration.

Before you begin

You must have a UDDI registry node set up, either as a new node, or to use for migrating a UDDI registry Version 2 node.

About this task

You must set some of the properties of a UDDI registry node before you initialize the node. The UDDI registry node properties are in two categories:

- Mandatory node properties that must be set before the UDDI node can be initialized. You can set these properties as many times as you want before initialization. However, after the UDDI node is initialized, these properties are read-only for the lifetime of that UDDI node. It is very important to set these properties correctly.
- All other properties. You can set these properties before and after initialization.

You can configure these properties and initialize the node by using the UDDI administrative console or Java Management Extensions (JMX) management interface.

Procedure

1. Click **UDDI** > **UDDI Nodes** > ***UDDI_node_id*** to display the properties page for the UDDI registry node.
2. Set the mandatory node properties to suitable, and valid, values. These properties are indicated by the presence of an asterisk (*) next to the input field. The following list summarizes the properties. For more information on each property, see the context help of the administrative console.

   UDDI node ID
   This property must be a text string that begins with `uddi:` and that is unique to this UDDI node. The default value might be suitable, but ensure that it is unique to the UDDI node before you use it.

   UDDI node description
   This property is a text string that describes the node.

   Root key generator
   This property must be a text string that begins with `uddi:` and that is unique to this UDDI node. The default value might be suitable, but might contain text, such as `keyspace_id`, that you must modify to match your system. If you use the default value, ensure that it is unique to this UDDI node.

   Prefix for generated discoveryURLs
   This property must be a valid Uniform Resource Locator (URL).
3. If you are migrating from Version 2 of the UDDI registry, use the following table to complete the following steps:
   - Set any properties from the `uddi.properties` file that must remain the same as Version 2.
   - Set any properties from the `uddi.properties` file that you want to keep the same value, for example, dbMaxResultCount.

Table 328. Version 2 and Version 3 UDDI properties. The table lists the different UDDI properties for Version 2 and Version 3, along with additional information about each one.

Version 2 UDDI property (which is set in uddi.property file)	Version 3 UDDI property (which is set by using the administrative console or UDDI Administrative Interface)	Recommended Version 3 UDDI property setting
dbMaxResultCount	Maximum inquiry response set size	You can retain the value from Version 2, change the value, or use the default.
persister	No equivalent	Not applicable.

Table 328. Version 2 and Version 3 UDDI properties (continued). The table lists the different UDDI properties for Version 2 and Version 3, along with additional information about each one.

Version 2 UDDI property (which is set in uddi.property file)	Version 3 UDDI property (which is set by using the administrative console or UDDI Administrative Interface)	Recommended Version 3 UDDI property setting
defaultLanguage	Default language code	Retain the value from Version 2
operatorName	UDDI node ID	You must use a valid value for the UDDI node ID. This value is applied to your Version 2 data as it is migrated.
maxSearchKeys	Maximum search keys	You can retain the value from Version 2, change the value, or use the default.
getServletURLprefix	Prefix for generated discoveryURLs	Enter a valid value for your configuration, which is the same as the value used for Version 2.
getServletName	No equivalent	Not applicable.

4. Set any other properties, such as policy values, that you want to change from the default settings. For an explanation of policies and properties, see the topic about UDDI node settings. Remember that you can also change these properties later.
5. Click **Apply** to save the changes.

   Important: Ensure that the mandatory node properties are set to appropriate values and that you have saved them, because you cannot change them after initialization. If you do not save your changes before proceeding to the initialize step, you will have to delete and recreate the database.
6. After saving the changes, initialize the UDDI node by clicking **Initialize**, at the top of the pane.

   If you are migrating from Version 2 of the UDDI registry, the Version 2 data is migrated now. The initialization might take some time to complete; to track its progress, return to the node collection page and click the refresh icon at the top of the **Status** column. Alternatively, open a second administrative console window, and use the refresh icon in the same way. The UDDI node goes through the following states:
   a. Initialization pending.
   b. Initialization in progress.
   c. Migration in progress. This state occurs only if you are migrating.
   d. Value set creation in progress.
   e. Activated.

What to do next

If you migrated the node from a previous version, return to the steps in the procedure to migrate to Version 3 of the UDDI registry, to verify that the migration was successful. If you created a new node, follow the steps in “Using the UDDI registry installation verification test (IVT)” to verify that you have successfully set up the UDDI node.

Using the UDDI registry installation verification test (IVT)

You can use an installation verification test (IVT) to verify that you have successfully deployed a UDDI registry.

Before you begin

You must have set up and deployed a new UDDI registry.

Procedure

1. Open a browser window and enter the URL that accesses the UDDI registry user interface.

2. Under the **Quick Find** heading on the **Find** tab, select the **Business** radio button and enter a percent symbol (%) in the **Starting with** field.
3. Click **Find**. If you deployed your UDDI registry successfully, the detail frame shows the business entity that represents this UDDI node. You can click on the business entity to see its detail.

What to do next

As a further installation verification test, you can publish and find more UDDI entities by using the UDDI registry user interface. Alternatively, you can compile and run one or more of the UDDI registry samples that are available.

Changing the UDDI registry application environment after deployment

You can change the environment of the UDDI registry application after you deploy it. For example, you can evaluate a UDDI registry using one database, then put it into production using a different database.

About this task

After you deploy a UDDI registry application, you might want to change its environment. For example, you might complete initial evaluation of the UDDI registry by using an Apache Derby database, and then put the UDDI registry into production by using a DB2 database.

Procedure

1. Optional: To move from a default UDDI node to a customized UDDI node, delete the UDDI registry database and recreate it by completing one of the following tasks, ensuring that you do not use the default node options where specified:
   - “Creating a DB2 distributed database for the UDDI registry” on page 3484
   - “Creating a DB2 for i database for the UDDI registry” on page 3486
   - “Creating an Apache Derby database for the UDDI registry” on page 3487
   - “Creating an Oracle database for the UDDI registry” on page 3488

   Note: Any data that is saved in the default node (policies, properties, and user data) is lost when you delete the database. If you do not want to delete the database, create an entirely new customized UDDI node in a separate application server. The default UDDI node still exists for you to use for test purposes.
2. Optional: To change the database type for the UDDI registry, complete the following steps:
   a. Stop the UDDI registry application. Click **Applications** > **Application Types** > **WebSphere enterprise applications**, select the relevant check box, then click **Stop**.
   b. Either change the Java Naming and Directory Interface (JNDI) name of the existing data source from `datasources/uddids` to another value, or delete the data source. To display the data source properties, click **Resources** > **JDBC** > **JDBC providers** > ***database_type*** **JDBC Provider** > **[Additional Properties] Data sources** > ***uddi_datasource***.
   c. Create the new database by referring to one of the following topics:
      - “Creating a DB2 distributed database for the UDDI registry” on page 3484
      - “Creating a DB2 for i database for the UDDI registry” on page 3486
      - “Creating an Apache Derby database for the UDDI registry” on page 3487
      - “Creating an Oracle database for the UDDI registry” on page 3488
   d. To transfer your UDDI data, use the capabilities of the database products to export the data from the old database, and import it into the new one.
   e. Create the new data source. See “Creating a data source for the UDDI registry” on page 3489.
   f. Restart the UDDI registry application.
   g. Check that you can access your UDDI data, for example use the UDDI registry installation verification test, then delete the old database.

Creating a DB2 distributed database for the UDDI registry:

Complete this task if you want to use DB2 on the Windows, Linux, or UNIX operating systems as the database store for your UDDI registry data.

Before you begin

The following steps use a number of variables. Before you start, decide appropriate values to use for these variables. The variables, and suggested values, are:

DataBaseName
The name of the UDDI registry database. A suggested value is UDDI30. The UDDI information uses the suggested name of UDDI30, so if you use a different name, remember to substitute it when you see UDDI30 in the UDDI information.

DB2UserID
A DB2 user ID with administrative privileges.

DB2Password
The password for the DB2 user ID.

BufferPoolName
The name of a buffer pool for the UDDI registry database to use. A suggested value is uddibp, but you can use any name because the buffer pool is created as part of this task.

TableSpaceName
The name of a table space. A suggested value is uddits, but you can use any name.

TempTableSpaceName
The name of a temporary table space. A suggested value is udditstemp, but you can use any name because the temporary table space is created as part of this task.

If you want to create a remote database, refer first to the database product documentation about the relevant capabilities of the product.

About this task

You complete this task only once for each UDDI registry, as part of setting up and deploying a UDDI registry.

Procedure

1. Change the directory to *app_server_root*/UDDIReg/databaseScripts.
2. Start the DB2 Command Line Processor. Enter the following command at the command prompt:
   ```
   db2
   ```
3. Set up the DB2 environment variables. Enter the following command:
   ```
   set DB2CODEPAGE=1208
   ```
4. Create the DB2 database. Enter the following command:
   ```
   create database DataBaseName using codeset UTF-8 territory en
   ```
5. Configure the DB2 database. Enter the following commands:
   a.
   ```
   connect to DataBaseName user DB2UserID using DB2Password
   ```
   b.
   ```
   update db cfg for DataBaseName using applheapsz 2048
   ```
   c.
   ```
   update db cfg for DataBaseName using logfilsiz 8192
   ```
   d.
   ```
   connect reset
   ```

e.
```
terminate
```
f.
```
force application all
```
g.
```
terminate
```
h.
```
stop
```
i.
```
start
```

6. Restart the DB2 Command Line Processor. For all operating systems except Windows, enter the following command at the command prompt:
```
db2
```
7. Create further database structures. Enter the following commands:
   a.
   ```
   connect to DataBaseName user DB2UserID using DB2Password
   ```
   b.
   ```
   create regular tablespace uddits pagesize 32K managed by system using
   ('TableSpaceName') extentsize 64 prefetchsize 32 bufferpool BufferPoolName
   ```
   c.
   ```
   create system temporary tablespace TempTableSpacename pagesize 32K managed by
   system using ('TempTableSpacename') extentsize 32 overhead 14.06
   prefetchsize 32 transferrate 0.33 bufferpool BufferPoolName
   ```
8. Define the database structures that are needed to store the UDDI data.

   Exit the DB2 Command Line Processor and enter the following commands exactly as shown. Note that one step uses `-vf` rather than `-tvf`.
   a.
   ```
   db2 -tvf uddi30crt_10_prereq_db2.sql
   ```
   b.
   ```
   db2 -tvf uddi30crt_20_tables_generic.sql
   ```
   c.
   ```
   db2 -tvf uddi30crt_25_tables_db2udb.sql
   ```
   d.
   ```
   db2 -tvf uddi30crt_30_constraints_generic.sql
   ```
   e.
   ```
   db2 -tvf uddi30crt_35_constraints_db2udb.sql
   ```
   f.
   ```
   db2 -tvf uddi30crt_40_views_generic.sql
   ```
   g.
   ```
   db2 -tvf uddi30crt_45_views_db2udb.sql
   ```
   h.
   ```
   db2 -vf uddi30crt_50_triggers_db2udb.sql
   ```
   i.
   ```
   db2 -tvf uddi30crt_60_insert_initial_static_data.sql
   ```
9. Optional: To use the database as a default UDDI node, enter the following command:
   ```
   db2 -tvf uddi30crt_70_insert_default_database_indicator.sql
   ```
10. Issue the following commands:
    ```
    connect reset
    terminate
    ```
11. Issue the following commands:
    ```
    connect reset
    terminate
    ```

What to do next

Continue with setting up and deploying your UDDI registry node.

Creating a DB2 for i database for the UDDI registry:

Complete this task if you want to use DB2 for i as the database store for your UDDI registry data.

Before you begin

The default names of the UDDI registry schema in the SQL scripts listed in the following topic are IBMUDI30 and IBMUDS30. These names are the recommended values and are assumed throughout the UDDI information. To use different names, modify the SQL files listed, then substitute the new names when IBMUDI30 and IBMUDS30 are used in the information center.

About this task

You complete this task only once for each UDDI registry, as part of setting up and deploying a UDDI registry.

Procedure

1. Use IBM Navigator for i to run SQL scripts.
   a. Open IBM Navigator for i.
   b. Expand **My Connections** > **iSeriesName** > **Databases**.
   c. Select **iSeriesName**.
   d. Right-click **Run SQL Scripts...**.

   A **Run SQL Scripts** window opens.
2. Open the IBM i DB2 SQL files.
   a. Map a network drive to the root directory of your IBM i server integrated file system.
   b. In Windows Explorer, expand the `WAS_HOME/UDDIReg/databaseScripts` directory.
   c. Open the following SQL files with a text editor (for example, Windows Notepad):
      - uddi30crt_10_prereq_db2_iSeries.sql
      - uddi30crt_20_tables_generic_iSeries.sql
      - uddi30crt_25_tables_db2udb_iSeries.sql
      - uddi30crt_30_constraints_generic_iSeries.sql
      - uddi30crt_35_constraints_db2udb_iSeries.sql
      - uddi30crt_40_views_generic_iSeries.sql
      - uddi30crt_45_views_db2udb_iSeries.sql
      - uddi30crt_50_triggers_db2udb_iSeries.sql
      - uddi30crt_60_insert_initial_static_data_iSeries.sql
3. Copy the text to the **Run SQL Scripts** window.
   a. In the text editor of the file `uddi30crt_10_prereq_db2_iSeries.sql`, click **Edit** > **Select All**.
   b. Click **Edit** > **Copy**.
   c. In the **Run SQL Scripts** window, click **Edit** > **Paste**.
   d. Click **Run** > **All**.
   e. After the script completes running, select all the SQL text and delete it from the **Run SQL Scripts** window.
   f. Repeat the previous steps for all the SQL scripts listed in step 2.
4. Optional: If you want to use the database as a default UDDI node, complete the following steps:
   a. Open `uddi30crt_70_insert_default_database_indicator.sql` as described in step 2.
   b. Copy and run `uddi30crt_70_insert_default_database_indicator.sql` as described in step 3.

What to do next

Continue to set up and deploy your UDDI registry node.

Creating an Apache Derby database for the UDDI registry:

Complete this task to use an Apache Derby database as the database store for your UDDI registry. You can use an embedded or network Apache Derby database, and the database store can be local or remote.

Before you begin

The following steps use a number of variables. Before you start, decide appropriate values to use for these variables. The variables, and suggested values, are:

arg1 The path of the SQL files. On a standard installation, the path is *app_server_root*/UDDIReg/databasescripts.

arg2 The path to the location where you want to install the Apache Derby database.

For example, *profile_root*/databases/com.ibm.uddi.

arg3 The name of the Apache Derby database. A recommended value is UDDI30, and this name is assumed throughout the UDDI information. If you use another name, substitute that name when UDDI30 is used in the UDDI information.

arg4 An optional argument. Either use the value DEFAULT, or omit this argument. Specify DEFAULT to use the database as a default UDDI node. This argument is case sensitive.

If you want to create a remote database, refer first to the database product documentation about the relevant capabilities of the product.

About this task

You complete this task only once for each UDDI registry, as part of setting up and deploying a UDDI registry.

Procedure

1. Start a Qshell session. Enter the STRQSH command from the IBM i command line.
2. Create a UDDI Apache Derby database by using UDDIDerbyCreate.jar. Run the following Java -jar command from the *app_server_root*/UDDIReg/databaseScripts directory.

```
java -Djava.ext.dirs=app_server_root/derby/lib:app_server_root/java/jre/lib/ext -jar UDDIDerbyCreate.jar
arg1 arg2 arg3 arg4
```

   If the Apache Derby database already exists, you are asked if you want to re-create it. If you choose to re-create the database, the existing database is deleted and a new one is created in its place. If you choose not to re-create the database, the command exits and a new database is not created.

   Note: If the application server has already accessed the existing Apache Derby database, the uddiDeploy.jacl script cannot re-create the database. Use the uddiRemove.jacl script to remove the database, as described in the topic about removing a UDDI registry node, restart the server, and run the uddiDeploy.jacl script again.
3. If you are using a remote database, which requires network Apache Derby, or if you want to use network Apache Derby for other reasons, for example, to use Apache Derby with a cluster, configure the Apache Derby Network Server framework. For details, see the section about managing the Derby Network Server in the Derby Server and Administration Guide.

What to do next

Continue with setting up and deploying your UDDI registry node.

Creating an Oracle database for the UDDI registry:

Complete this task if you want to use Oracle as the database store for your UDDI registry data.

Before you begin

This task creates three new schemas: ibmuddi, ibmudi30 and ibmuds30. You cannot complete this task if schemas with these names exist already.

The following steps use a number of variables. Before you start, decide appropriate values to use for these variables. The variables, and suggested values, are:

OracleUserID
The Oracle user ID to use to create the database.

OraclePassword
The password for the Oracle user ID.

The Oracle database must be a remote database; you cannot create a local database. Refer first to the database product documentation about the relevant capabilities of the product.

About this task

You complete this task only once for each UDDI registry, as part of setting up and deploying a UDDI registry.

The supported versions of Oracle are Version 9i and Version 10g. Each version has the following restrictions:

Table 329. UDDI restrictions and Oracle versions. The table lists the Version 9i and Version 10g restrictions for different UDDI parameters.

	Version 9i restrictions		**Version 10g restrictions**	
discoveryURL (Business)	maximum 4000 bytes	UDDI specification 4096 characters	maximum 4000 bytes	UDDI specification 4096 characters
accessPoint (bindingTemplate)	maximum 4000 bytes	UDDI specification 4096 characters	maximum 4000 bytes	UDDI specification 4096 characters
instanceParms (tModelInstanceInfo)	maximum 4000 bytes	UDDI specification 8192 characters		
overviewURL (tModelInstanceInfo)	maximum 4000 bytes	UDDI specification 4096 characters		
Digital Signature	maximum 4000 bytes			

Procedure

1. Run the following commands:
   a.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_10_prereq_oracle.sql
```
   b.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_20_tables_generic.sql
```
2. Run one of the following commands, depending on the version of Oracle.
   - For Oracle Version 9i:

```
sqlplus OracleUserID/OraclePassword @ uddi30crt_25_tables_oracle_pre10g.sql
```

   - For Oracle Version 10g and later:

```
sqlplus OracleUserID/OraclePassword @ uddi30crt_25_tables_oracle.sql
```

3. Run the following commands:
   a.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_30_constraints_generic.sql
```
   b.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_35_constraints_oracle.sql
```
   c.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_40_views_generic.sql
```
   d.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_45_views_oracle.sql
```
   e.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_50_triggers_oracle.sql
```
   f.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_60_insert_initial_static_data.sql
```
4. Optional: To use the database as a default UDDI node, run the following command:
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_70_insert_default_database_indicator.sql
```

What to do next

Continue with setting up and deploying your UDDI registry node.

Removing a UDDI registry node

You can remove the UDDI registry application, delete the UDDI registry database, move a UDDI registry to another server or profile, or remove a UDDI registry node completely.

About this task

A UDDI registry node consists of the following elements:

- An enterprise application.
- A store of data that is referred to as the UDDI registry database and that uses a relational database management system.
- A way to connect the application to the data, that is, a data source and related elements.

All the data that relates to UDDI is stored in the UDDI database and therefore that data is separate from the UDDI application. Therefore, there are several options when you remove a UDDI registry node:

- You can remove a UDDI registry node from the application server without deleting the database. You delete only the UDDI application and any associated resources, such as the data source, and J2EE Connector Architecture (J2C) authentication data if it is used. You might do this for the following reasons:
  - You no longer want a UDDI facility on a particular application server. You can then move the UDDI registry node to a different application server.
  - You want to reinstall the application, for example to apply service changes or because the application has been corrupted.
- You can delete the UDDI registry database. If you do this, all UDDI data for that UDDI registry is lost. You might do this for the following reasons:
  - You want to use a different database product as the persistence store for the UDDI data.
  - You want to delete all the UDDI registry data and publish fresh data, for example after you complete a test cycle.
  - You want to initialize the UDDI registry node with new UDDI property settings, for example, to move from a default UDDI node to a customized UDDI node.
- You can move a UDDI registry to another server or profile.

  You might do this after you create a profile and you want to move the UDDI registry to the new profile.

- You can remove a UDDI registry node completely from an application server. You remove the UDDI registry application, the UDDI registry database, and the resources that are used to reference the UDDI registry database.

  You might do this to remove a UDDI registry that is used for testing after testing has finished.

To start a new UDDI registry node, you do not need to remove the UDDI application. Instead, you create a new replacement node by changing the data source that the UDDI application uses to access the new UDDI database.

Depending on what you want to do, complete one of the following steps.

Procedure

- To remove a UDDI registry node from the application server without deleting the database, complete the following:
  1. Start a Qshell session by entering the STRQSH command from the IBM i command line.
  2. Run the `uddiRemove.jacl` wsadmin script from the *app_server_root*/bin directory.

     The syntax of the command is as follows.

```
wsadmin [-profileName profile_name] -f uddiRemove.jacl
        node_name server_name [default]
```

     The attributes of the command are as follows:
     - `-profileName` *profile_name* is optional, and is the name of the profile in which the UDDI application is deployed. If you do not specify a profile, the default profile is used.
     - *node_name* and *server_name* are the names of the WebSphere Application Server node and the application server in which the UDDI application is deployed. These are the names that you specified when you deployed the UDDI application, for example when you ran the `uddiDeploy.jacl` script.
     - `default` is optional. Use this option only for the Apache Derby database and only if you ran the `uddiDeploy.jacl` script and used the default option to deploy the UDDI registry. This option removes the UDDI Apache Derby data source but does not remove the UDDI Apache Derby database.
  3. Optional: By default, output is displayed on screen. To direct the output to a log file, add the following to the end of the command, where *removeuddi*.log can be any name that you choose for the log file:

```
> removeuddi.log
```

     For example, to remove the UDDI application from server server1 that runs in node MyNode and send any messages to the file removeuddi.log:

```
wsadmin -profileName myProfile -f uddiRemove.jacl MyNode server1 > removeuddi.log
```

     Note: You can also remove the UDDI registry application by using the administrative console in the usual way, by selecting the application in the **Enterprise Applications** view and clicking **Uninstall**.
- To delete a UDDI registry database, complete the following steps. Remember that all UDDI data in the UDDI registry is deleted.
  1. Stop the server that hosts the UDDI registry application.
  2. Delete the database.
     - For DB2 for i, use either Navigator for i or a 5250 session to delete the IBMUDI30 and IBMUDS30 schemas.
     - For Oracle, delete the IBMUDDI, IBMUDI30 and IBMUDS30 schemas.
     - For Apache Derby, delete the directory tree that contains the UDDI database. By default, this directory tree is in the *profile_root*/databases/com.ibm.uddi/UDDI30 directory.
- To move a UDDI registry node to another server or profile, complete the following steps:

1. Ensure that the UDDI registry database remains accessible after the move. You might need to copy the database to a suitable new location. For example, if the database is remote, the new server must be able to access it. Also, the database might be deleted after the move. This situation occurs if you move the UDDI registry to a new profile and then delete the old profile, because any databases that were stored in the profile are also deleted. An example of such a database is an Apache Derby database that is created as part of creating default UDDI node.
2. Remove the UDDI registry application. See the step to remove a UDDI registry node from the application server.
3. Optional: Delete the data source and related objects.

   For the Apache Derby database, if you ran the `uddiRemove.jacl` script and used the default option to remove the UDDI registry application, the data source and related objects are deleted already and you do not need to complete this step. In all other situations, delete the following objects:
   - The UDDI data source that references the UDDI registry database, that is, the data source that was created when you set up the UDDI registry.
   - Any UDDI JDBC provider that was created if you did not reuse an existing JDBC provider.
   - Any J2C authentication data entry.
4. In the new server, if appropriate, create a J2C authentication data entry, and create a JDBC provider and a data source to reference the existing database. See the relevant steps in Setting up a customized UDDI node.
5. Deploy the UDDI registry application. See Deploying the UDDI registry application. If you use the supplied script, do not use the default option even if you used this option previously to set up a default UDDI node. Do not use the default option because an error might occur during deployment, or, in some circumstances, existing UDDI data might be overwritten.

   Note: The UDDI node name does not change. If the UDDI node name includes the node name and server name of the original server, after the move there is a mismatch between the UDDI node name, and the node name and server name of the new server. However, this mismatch does not affect the UDDI registry node function.
6. Check that the UDDI data can be accessed. If you are using a copy of the original UDDI registry database, you can now delete the original database. See the step to delete a UDDI registry database.

- To remove a UDDI registry node completely, complete the following steps:
  1. Remove the UDDI registry application. See the step to remove a UDDI registry node from the application server.
  2. Delete the UDDI registry database. See the step to delete a UDDI registry database.
  3. Optional: Delete the data source and related objects.

     For the Apache Derby database, if you ran the `uddiRemove.jacl` script and used the default option to remove the UDDI registry application, the data source and related objects are deleted already and you do not need to complete this step. In all other situations, delete the following objects:
     - The UDDI data source that references the UDDI registry database, that is, the data source that was created when you set up the UDDI registry.
     - Any UDDI JDBC provider that was created if you did not reuse an existing JDBC provider.
     - Any J2C authentication data entry.

What to do next

If you removed a UDDI registry node from the application server without deleting the database, you might want to reinstall the UDDI registry application.

Reinstalling the UDDI registry application

You can remove and reinstall an existing UDDI registry application to change the UDDI application code but continue to provide UDDI services with the existing UDDI database.

About this task

A UDDI registry node consists of the following elements:

- A Java EE application.
- A store of data that is referred to as the UDDI database. The UDDI database uses a relational database management system.
- A way to connect the application to the data (a data source and related elements).

All the data that relates to UDDI is stored in the UDDI database and therefore that data exists, regardless of the UDDI application. Therefore, you can remove a UDDI registry node from the application server without deleting the database, then reinstall the UDDI registry application. You might do this if an application is corrupted, or to apply service changes.

Procedure

1. Note any changes that you made to the installed UDDI application that you want to keep, for example changes to security role mappings, changes to the deployment descriptor (web.xml) in the v3soap.war, v3gui.war, v3soap.war, or soap.war files, or customization of the UDDI user interface (GUI). All such changes are lost during the reinstallation process, so you must reapply changes that you want to keep later.
2. Remove the existing UDDI application and reinstall it by running the uddiDeploy.jacl wsadmin script from the *app_server_root*/bin directory. Do not use the default option even if you used this option previously to set up a default UDDI node. If you use the default option, an error might occur during deployment, or, in some circumstances, existing UDDI data might be overwritten.

   Enter the following command at a command prompt:

```
wsadmin [-conntype none] [-profileName profile_name] -f uddiDeploy.jacl
       node_name server_name
```

   where:
   - `-conntype none` is optional, and is needed only if the application server is not running.
   - `-profileName` *profile_name* is optional, and is the name of the profile in which the UDDI application is deployed. If you do not specify a profile, the default profile is used.
   - *node_name* and *server_name* are the names of the WebSphere Application server node and the application server in which the UDDI application is deployed. These are the names that you specified when you ran the uddiDeploy.jacl script to install the UDDI application.

   Note: This procedure does not change the existing JDBC provider, data source and any J2EE Connector Architecture (J2C) authentication data entry. Your existing UDDI registry data, including UDDI entities, property settings, and policy settings, are also unaffected.
3. Optional: To direct the output to a log file, add the following option to the end of the command, where *log_name*.log can be any name that you choose for the log file:

```
> log_name.log
```

4. If you noted any changes in step 1, reapply them now.
5. For the reapplied changes to take effect, start or restart the application server.

Creating a DB2 distributed database for the UDDI registry

Complete this task if you want to use DB2 on the Windows, Linux, or UNIX operating systems as the database store for your UDDI registry data.

Before you begin

The following steps use a number of variables. Before you start, decide appropriate values to use for these variables. The variables, and suggested values, are:

DataBaseName
The name of the UDDI registry database. A suggested value is UDDI30. The UDDI information uses the suggested name of UDDI30, so if you use a different name, remember to substitute it when you see UDDI30 in the UDDI information.

DB2UserID
A DB2 user ID with administrative privileges.

DB2Password
The password for the DB2 user ID.

BufferPoolName
The name of a buffer pool for the UDDI registry database to use. A suggested value is uddibp, but you can use any name because the buffer pool is created as part of this task.

TableSpaceName
The name of a table space. A suggested value is uddits, but you can use any name.

TempTableSpaceName
The name of a temporary table space. A suggested value is udditstemp, but you can use any name because the temporary table space is created as part of this task.

If you want to create a remote database, refer first to the database product documentation about the relevant capabilities of the product.

About this task

You complete this task only once for each UDDI registry, as part of setting up and deploying a UDDI registry.

Procedure

1. Change the directory to *app_server_root*/UDDIReg/databaseScripts.
2. Start the DB2 Command Line Processor. Enter the following command at the command prompt:
   ```
   db2
   ```
3. Set up the DB2 environment variables. Enter the following command:
   ```
   set DB2CODEPAGE=1208
   ```
4. Create the DB2 database. Enter the following command:
   ```
   create database DataBaseName using codeset UTF-8 territory en
   ```
5. Configure the DB2 database. Enter the following commands:
   a.
   ```
   connect to DataBaseName user DB2UserID using DB2Password
   ```
   b.
   ```
   update db cfg for DataBaseName using applheapsz 2048
   ```
   c.
   ```
   update db cfg for DataBaseName using logfilsiz 8192
   ```
   d.
   ```
   connect reset
   ```
   e.
   ```
   terminate
   ```
   f.
   ```
   force application all
   ```
   g.
   ```
   terminate
   ```

h.
```
stop
```
i.
```
start
```
6. Restart the DB2 Command Line Processor. For all operating systems except Windows, enter the following command at the command prompt:
```
db2
```
7. Create further database structures. Enter the following commands:
   a.
   ```
   connect to DataBaseName user DB2UserID using DB2Password
   ```
   b.
   ```
   create regular tablespace uddits pagesize 32K managed by system using
   ('TableSpaceName') extentsize 64 prefetchsize 32 bufferpool BufferPoolName
   ```
   c.
   ```
   create system temporary tablespace TempTableSpacename pagesize 32K managed by
   system using ('TempTableSpacename') extentsize 32 overhead 14.06
   prefetchsize 32 transferrate 0.33 bufferpool BufferPoolName
   ```
8. Define the database structures that are needed to store the UDDI data.

   Exit the DB2 Command Line Processor and enter the following commands exactly as shown. Note that one step uses `-vf` rather than `-tvf`.
   a.
   ```
   db2 -tvf uddi30crt_10_prereq_db2.sql
   ```
   b.
   ```
   db2 -tvf uddi30crt_20_tables_generic.sql
   ```
   c.
   ```
   db2 -tvf uddi30crt_25_tables_db2udb.sql
   ```
   d.
   ```
   db2 -tvf uddi30crt_30_constraints_generic.sql
   ```
   e.
   ```
   db2 -tvf uddi30crt_35_constraints_db2udb.sql
   ```
   f.
   ```
   db2 -tvf uddi30crt_40_views_generic.sql
   ```
   g.
   ```
   db2 -tvf uddi30crt_45_views_db2udb.sql
   ```
   h.
   ```
   db2 -vf uddi30crt_50_triggers_db2udb.sql
   ```
   i.
   ```
   db2 -tvf uddi30crt_60_insert_initial_static_data.sql
   ```
9. Optional: To use the database as a default UDDI node, enter the following command:
```
db2 -tvf uddi30crt_70_insert_default_database_indicator.sql
```
10. Issue the following commands:
```
connect reset
terminate
```
11. Issue the following commands:
```
connect reset
terminate
```

What to do next

Continue with setting up and deploying your UDDI registry node.

Creating a DB2 for i database for the UDDI registry

Complete this task if you want to use DB2 for i as the database store for your UDDI registry data.

Before you begin

The default names of the UDDI registry schema in the SQL scripts listed in the following topic are IBMUDI30 and IBMUDS30. These names are the recommended values and are assumed throughout the

UDDI information. To use different names, modify the SQL files listed, then substitute the new names when IBMUDI30 and IBMUDS30 are used in the information center.

About this task

You complete this task only once for each UDDI registry, as part of setting up and deploying a UDDI registry.

Procedure

1. Use IBM Navigator for i to run SQL scripts.
   a. Open IBM Navigator for i.
   b. Expand **My Connections** > **iSeriesName** > **Databases**.
   c. Select **iSeriesName**.
   d. Right-click **Run SQL Scripts...**.

   A **Run SQL Scripts** window opens.
2. Open the IBM i DB2 SQL files.
   a. Map a network drive to the root directory of your IBM i server integrated file system.
   b. In Windows Explorer, expand the `WAS_HOME/UDDIReg/databaseScripts` directory.
   c. Open the following SQL files with a text editor (for example, Windows Notepad):
      - uddi30crt_10_prereq_db2_iSeries.sql
      - uddi30crt_20_tables_generic_iSeries.sql
      - uddi30crt_25_tables_db2udb_iSeries.sql
      - uddi30crt_30_constraints_generic_iSeries.sql
      - uddi30crt_35_constraints_db2udb_iSeries.sql
      - uddi30crt_40_views_generic_iSeries.sql
      - uddi30crt_45_views_db2udb_iSeries.sql
      - uddi30crt_50_triggers_db2udb_iSeries.sql
      - uddi30crt_60_insert_initial_static_data_iSeries.sql
3. Copy the text to the **Run SQL Scripts** window.
   a. In the text editor of the file `uddi30crt_10_prereq_db2_iSeries.sql`, click **Edit** > **Select All**.
   b. Click **Edit** > **Copy**.
   c. In the **Run SQL Scripts** window, click **Edit** > **Paste**.
   d. Click **Run** > **All**.
   e. After the script completes running, select all the SQL text and delete it from the **Run SQL Scripts** window.
   f. Repeat the previous steps for all the SQL scripts listed in step 2.
4. Optional: If you want to use the database as a default UDDI node, complete the following steps:
   a. Open `uddi30crt_70_insert_default_database_indicator.sql` as described in step 2.
   b. Copy and run `uddi30crt_70_insert_default_database_indicator.sql` as described in step 3.

What to do next

Continue to set up and deploy your UDDI registry node.

Creating an Apache Derby database for the UDDI registry

Complete this task to use an Apache Derby database as the database store for your UDDI registry. You can use an embedded or network Apache Derby database, and the database store can be local or remote.

Before you begin

The following steps use a number of variables. Before you start, decide appropriate values to use for these variables. The variables, and suggested values, are:

arg1 The path of the SQL files. On a standard installation, the path is *app_server_root*/UDDIReg/databasescripts.

arg2 The path to the location where you want to install the Apache Derby database.

For example, *profile_root*/databases/com.ibm.uddi.

arg3 The name of the Apache Derby database. A recommended value is UDDI30, and this name is assumed throughout the UDDI information. If you use another name, substitute that name when UDDI30 is used in the UDDI information.

arg4 An optional argument. Either use the value DEFAULT, or omit this argument. Specify DEFAULT to use the database as a default UDDI node. This argument is case sensitive.

If you want to create a remote database, refer first to the database product documentation about the relevant capabilities of the product.

About this task

You complete this task only once for each UDDI registry, as part of setting up and deploying a UDDI registry.

Procedure

1. Start a Qshell session. Enter the STRQSH command from the IBM i command line.
2. Create a UDDI Apache Derby database by using UDDIDerbyCreate.jar. Run the following Java -jar command from the *app_server_root*/UDDIReg/databaseScripts directory.

```
java -Djava.ext.dirs=app_server_root/derby/lib:app_server_root/java/jre/lib/ext -jar UDDIDerbyCreate.jar
arg1 arg2 arg3 arg4
```

   If the Apache Derby database already exists, you are asked if you want to re-create it. If you choose to re-create the database, the existing database is deleted and a new one is created in its place. If you choose not to re-create the database, the command exits and a new database is not created.

   Note: If the application server has already accessed the existing Apache Derby database, the uddiDeploy.jacl script cannot re-create the database. Use the uddiRemove.jacl script to remove the database, as described in the topic about removing a UDDI registry node, restart the server, and run the uddiDeploy.jacl script again.
3. If you are using a remote database, which requires network Apache Derby, or if you want to use network Apache Derby for other reasons, for example, to use Apache Derby with a cluster, configure the Apache Derby Network Server framework. For details, see the section about managing the Derby Network Server in the Derby Server and Administration Guide.

What to do next

Continue with setting up and deploying your UDDI registry node.

Creating an Oracle database for the UDDI registry

Complete this task if you want to use Oracle as the database store for your UDDI registry data.

Before you begin

This task creates three new schemas: ibmuddi, ibmudi30 and ibmuds30. You cannot complete this task if schemas with these names exist already.

The following steps use a number of variables. Before you start, decide appropriate values to use for these variables. The variables, and suggested values, are:

OracleUserID
The Oracle user ID to use to create the database.

OraclePassword
The password for the Oracle user ID.

The Oracle database must be a remote database; you cannot create a local database. Refer first to the database product documentation about the relevant capabilities of the product.

About this task

You complete this task only once for each UDDI registry, as part of setting up and deploying a UDDI registry.

The supported versions of Oracle are Version 9i and Version 10g. Each version has the following restrictions:

Table 330. UDDI restrictions and Oracle versions. The table lists the Version 9i and Version 10g restrictions for different UDDI parameters.

	Version 9i restrictions		**Version 10g restrictions**	
discoveryURL (Business)	maximum 4000 bytes	UDDI specification 4096 characters	maximum 4000 bytes	UDDI specification 4096 characters
accessPoint (bindingTemplate)	maximum 4000 bytes	UDDI specification 4096 characters	maximum 4000 bytes	UDDI specification 4096 characters
instanceParms (tModelInstanceInfo)	maximum 4000 bytes	UDDI specification 8192 characters		
overviewURL (tModelInstanceInfo)	maximum 4000 bytes	UDDI specification 4096 characters		
Digital Signature	maximum 4000 bytes			

Procedure

1. Run the following commands:
   a.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_10_prereq_oracle.sql
```
   b.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_20_tables_generic.sql
```
2. Run one of the following commands, depending on the version of Oracle.
   - For Oracle Version 9i:
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_25_tables_oracle_pre10g.sql
```
   - For Oracle Version 10g and later:
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_25_tables_oracle.sql
```
3. Run the following commands:
   a.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_30_constraints_generic.sql
```
   b.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_35_constraints_oracle.sql
```
   c.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_40_views_generic.sql
```
   d.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_45_views_oracle.sql
```
   e.
```
sqlplus OracleUserID/OraclePassword @ uddi30crt_50_triggers_oracle.sql
```

f.

```
sqlplus OracleUserID/OraclePassword @ uddi30crt_60_insert_initial_static_data.sql
```

4. Optional: To use the database as a default UDDI node, run the following command:

```
sqlplus OracleUserID/OraclePassword @ uddi30crt_70_insert_default_database_indicator.sql
```

What to do next

Continue with setting up and deploying your UDDI registry node.

Applying an upgrade to the UDDI registry

You can apply an interim fix, a fix pack, or a refresh pack to the UDDI registry.

Procedure

1. Apply the WebSphere Application Server interim fix, fix pack, or refresh pack to your application server, or servers, by using the WebSphere Application Server Update Installer. Repeat this process for each server that you want to apply the UDDI upgrade to. If you have not deployed a UDDI registry yet, no further action is required, because updates to the UDDI registry take effect when you first deploy UDDI into any of your application server profiles.
2. If you already deployed a UDDI registry to one or more application server profiles, to apply the upgrade, redeploy the UDDI application, as described in Reinstalling the UDDI registry application. The existing UDDI application is removed and the updated application is deployed.

What to do next

Some upgrades might require additional steps. Refer to the readme file for the upgrade to check whether there are additional steps for this upgrade.

Configuring SOAP API and GUI services for the UDDI registry

For SOAP application programming interface (API) and graphical user interface (GUI) UDDI services, you can configure whether the service is secure. For Version 1 and Version 2 SOAP API services, you can also configure the default pool size.

Before you begin

The UDDI registry application must be installed.

About this task

For the Version 1 and Version 2 SOAP interface, you can configure the following properties:

- **defaultPoolSize**. The number of SOAP parsers with which to initialize the parser pool for the SOAP interface. You can set this property independently for the Publish (uddipublish) and Inquiry (uddi) APIs. For example, if you expect more inquiries than publish requests through the SOAP interface, you can set a larger pool size for the Inquiry API. The default initial size for both APIs is 10.
- Whether the API is secure, that is, accessed using HTTPS, or insecure, that is, accessed using HTTP. The default is to use HTTPS for the Publish API and HTTP for the Inquiry API.

For the Version 3 SOAP interface, you can specify whether Publish, Custody Transfer, Security and Inquiry APIs are secure, that is, accessed using HTTPS, or insecure, that is, accessed using HTTP. The default is to use HTTPS for the Publish, Custody Transfer, and Security APIs, and HTTP for the Inquiry API.

For the Version 3 GUI interface, you can specify whether the Publish and Inquiry services are secure, that is, accessed using HTTPS, or insecure, that is, accessed using HTTP. The default is to use HTTPS for the Publish service and HTTP for the Inquiry service.

Procedure

- Optional: To configure Version 1 and Version 2 SOAP API services, use the following steps.
  1. Edit the active deployment descriptor, web.xml, for the Version 1 and Version 2 SOAP module, soap.war. The web.xml file is in the following directory:

profile_root/config/cells/*cell_name*/applications/
UDDIRegistry.*node_name*.*server_name*.ear/deployments/
UDDIRegistry.*node_name*.*server_name*/soap.war/WEB-INF

  2. To modify the defaultPoolSize parameter for the Version 1 or Version 2 Publish API, modify the param-value element in the servlet with servlet-name = uddipublish.
  3. To modify the defaultPoolSize parameter for the Version 1 or Version 2 Inquiry API, modify the param-value element in the servlet with servlet-name = uddi.
  4. To set whether the Publish service is secure or insecure for the Version 1 or Version 2 Publish API, modify the user data constraint transport guarantee. Find the security-constraint element with id = UDDIPublishTransportConstraint. Set the user-data-constraint transport-guarantee for that element to CONFIDENTIAL, that is, the service is secure and is accessed using HTTPS, or NONE, that is, the service is insecure and is accessed using HTTP.
  5. Stop and restart the application server for the changes to take effect.
- Optional: For the Version 3 SOAP interface, specify whether the Publish, Custody Transfer, Security, and Inquiry API services are secure or insecure by using the following steps. The default is to use HTTPS for the Publish, Custody Transfer, and Security APIs, and HTTP for the Inquiry API.
  1. Edit the active deployment descriptor, web.xml, for the Version 3 SOAP module, v3soap.war. The web.xml file is in the following directory:

profile_root/config/cells/*cell_name*/applications/
UDDIRegistry.*node_name*.*server_name*.ear/deployments/
UDDIRegistry.*node_name*.*server_name*/v3soap.war/WEB-INF

     Each type of service is represented by a <security-constraint> element in the web.xml file. Each <security-constraint> element includes the <display-name> element and <user-data-constraint> <transport-guarantee> element.
  2. For each service that you want to modify, search the web.xml file for the relevant <display-name> value (see the following table) to locate the <security-constraint> element for that service. Set the <user-data-constraint> <transport-guarantee> for that element to CONFIDENTIAL, that is, the service is secure and is accessed using HTTPS, or NONE, that is, the service is insecure and is accessed using HTTP.

Table 331. Display name values in web.xml for UDDI services. The table lists the different types of UDDI service and the value of the <security-constraint> <display-name> element for each one.

Type of UDDI service	Value of <security-constraint> <display-name> element
Publish	AxisServlet Publish Resource Collection
Custody transfer	AxisServlet CustodyTransfer Resource Collection
Security	AxisServlet Security Resource Collection
Inquiry	AxisServlet Inquiry Resource Collection

  3. Stop and restart the application server for the changes to take effect.
- Optional: For the Version 3 GUI interface, specify whether the Publish and Inquiry services are secure or insecure by using the following steps. The default is to use HTTPS for the Publish service and HTTP for the Inquiry service.
  1. Edit the active deployment descriptor, web.xml, for the Version 3 GUI module, v3gui.war. The web.xml file is in the following directory:

profile_root/config/cells/*cell_name*/applications/
UDDIRegistry.*node_name*.*server_name*.ear/deployments/
UDDIRegistry.*node_name*.*server_name*/v3gui.war/WEB-INF

  2. For each service that you want to modify, search the web.xml file for the relevant <user-data-constraint> value (see the following table). Set the <user-data-constraint>

<transport-guarantee> for that element to CONFIDENTIAL, that is, the service is secure and is accessed using HTTPS, or NONE, that is, the service is insecure and is accessed using HTTP.

Table 332. User data constraint ids in web.xml for UDDI services. The table lists the different types of UDDI service and the value of the <user-data-constraint id> element for each one.

Type of UDDI service	Value of <user-data-constraint id> element
Publish	UDDIPublishTransportConstraint
Inquiry	UDDIInquireTransportConstraint

3. Stop and restart the application server for the changes to take effect.

Managing the UDDI registry

You can use the WebSphere Application Server administrative console or the Java Management Extensions (JMX) management interface to manage all the policies and properties of the UDDI registry.

About this task

You can use JMX to monitor and configure UDDI registries programmatically, and use the UDDI registry administrative interface.

To manage UDDI nodes programmatically, you can use the following interfaces and tools:

- UDDI registry administrative (JMX) interface

  The UDDI registry administrative (JMX) interface provides a Java API that you can use to manage runtime configuration settings to control UDDI registry runtime behavior, such as setting the maximum number of results that UDDI users can receive for inquiry requests, or creating publish limits for UDDI publishers. Sample client code is provided for you to build on.
- User-defined value sets

  The UDDI Version 3 registry provides tools that you can use to manage your own categorization value sets, including loading value set data into a UDDI registry node. If you add custom value sets, UDDI entities can be categorized more specifically when they are published, so that clients can find specific data more efficiently.
- UDDI Utility Tools

  The UDDI Utility Tools is a suite of functions and a Java API that you can use to promote Version 2 entities from one UDDI registry to another while retaining entity keys. This capability is particularly useful for publishing canonical tModels with a predefined key.

To manage UDDI registries by using the WebSphere Application Server administrative console, start from the UDDI link in the navigation pane of the administrative console. If administrative security is enabled, you must log in to the administrative console and supply a valid user ID and password, to use the UDDI management functions. You can complete the following operations:

Procedure

- View and manage the status of all UDDI nodes in a cell.
- Initialize UDDI nodes with required settings.
- Configure general properties that affect UDDI runtime behavior.
- Manage UDDI policy settings.
- Create, view and update UDDI publishers.
- Create, view and update publisher tiers that limit how many UDDI entries can be published.
- View and manage the status of value sets.

Backing up and restoring the UDDI registry database

If you want to protect the data in your UDDI registry database, you can back up and restore the database by using the facilities of the database product that your UDDI node is on.

Procedure

- To back up an Apache Derby UDDI registry database, use the following steps:
  1. Ensure that the UDDI application is stopped, and therefore is not accessing the Apache Derby database.
  2. Ensure that no other application is using the Apache Derby UDDI30 database.
  3. Copy the UDDI30 directory by using the file system that the directory is in.
- To restore an Apache Derby UDDI registry database, replace the UDDI30 file structure with the backup copy. Remember that any updates made after the backup was taken are lost.
- To back up a UDDI registry database that does not use Apache Derby, use the appropriate backup and restore tools for the database. To use these tools, refer to the documentation for the database product.

UDDI node collection

You can manage the UDDI nodes in this cell. Each UDDI node represents an individual UDDI registry application. A UDDI node is displayed in this list only if its underlying UDDI application is started. The status of the UDDI node can indicate whether the node is activated (available to accept API requests), deactivated (not allowing user requests), or not initialized. UDDI nodes that are not initialized require some properties to be set before they can be initialized and activated.

To view this administrative console page, click **UDDI** > **UDDI Nodes**.

UDDI Node ID:

Specifies the identifier for the UDDI node.

To manage an individual UDDI node, click on the ***UDDI _node_id*** to display the UDDI node settings page, where you can manage its general properties, initialize it if the status is set to `Initialization Pending`, and access pages for managing policies, UDDI publishers, tiers and value sets.

Description:

Specifies the description of the UDDI node.

UDDI Application Location:

Specifies the server in which the UDDI registry application is deployed and running.

Status:

Specifies the status of the UDDI node.

The UDDI node can have one of the following statuses:

- `Not initialized`
- `Initialization pending`
- `Initialization in progress`
- `Migration in progress`
- `Migration pending`
- `Value set creation in progress`
- `Value set creation pending`
- `Activated`

- `Deactivated`

If the status of a node is `Initialization pending`, you must initialize the node before you can activate it. If you attempt to initialize the node and it remains in a pending state, an error occurred during migration or initialization.

To activate UDDI nodes that are deactivated, select them using the corresponding check boxes and click **Activate**. Similarly, to deactivate UDDI nodes, select them and click **Deactivate**.

Note: If you restart the UDDI application, or the application server, the UDDI node is always reactivated, even if the node was previously deactivated.

UDDI node settings:

You can configure the general properties for a UDDI node.

To view this administrative console page, click **UDDI** > **UDDI Nodes** > ***UDDI_node_id***.

The UDDI node detail page displays general properties for the UDDI node. Depending on the status of the node, you can edit some properties. Use the links on this page to view or change additional properties, such as Value sets, Tiers and UDDI Publishers. Use the Policy Groups link on this page to view or change UDDI node policy.

Unless the UDDI node is installed as a default UDDI node, you must set certain general properties before you can initialize the UDDI node. These required properties are indicated by an asterisk (*) next to the relevant fields. You can set these property values as many times as you want before you initialize the UDDI node. However, after initialization, these properties become read-only for the lifetime of that UDDI node. Therefore, it is important to set the required properties correctly. You can set other general properties of the UDDI node both before and after initialization.

After you set the general properties to appropriate values, click **OK** to save your changes and exit the page, or **Apply** to save your changes and remain on the same page. At this point, the changes are stored.

If the status of the UDDI node is “Not initialized”, an **Initialize** option is displayed. To initialize the UDDI node, ensure that you save any changes to the general properties by clicking **Apply** or **OK**, then click **Initialize**. This operation might take some time to complete.

UDDI node ID:

Specifies the unique identifier for a UDDI node in a UDDI registry. The node ID must be a valid UDDI key. The value is also the domain key for the UDDI node.

Required	Yes
Data type	String
Default	uddi:*cell_name*:*node_name*:*server_name*:node_id

UDDI node description:

Specifies the description of this UDDI node.

Required	Yes
Data type	String
Default	WebSphere UDDI registry default node

Root key generator:

Specifies the root key space of the registry. For registries that can become affiliate registries, you might want to specify a root key space in a partition below the root key generator of the parent root registry, for example, `uddi:thisregistry.com:keygenerator`.

Required	Yes
Data type	String
Default	uddi:*cell_name*:*node_name*:*server_name*:keyspace_id:keygenerator

Prefix for generated discoveryURLs:

Specifies the URL prefix that is applied to generated discoveryURLs in businessEntity elements, so that the discoveryURLs can be returned on HTTP GET requests. This property applies to UDDI version 2 API requests only. Set this prefix to a valid URL for your configuration, and do not change it unless absolutely necessary.

The format is `http://hostname:port/uddisoap/`, where `uddisoap` is the context root of the UDDI version 2 SOAP servlet.

Although this field is not required, you set it so that the required and valid URL is generated in response to version 2 GET requests. After you set the prefix, do not change it unless it becomes invalid following a later configuration change. If you change the prefix, any discoveryURLs that were generated by using the earlier prefix no longer work.

Required	No
Data type	String
Default	http://localhost:9080/uddisoap

Host name for UDDI node services:

Specifies the host name root that the UDDI node uses to model API services in its own node business entity. This value must be the fully qualified domain name, or IP address, of the network host.

The UDDI node provides web services that implement each of the UDDI API sets that it supports. The host name is used to generate access point URLs in the bindingTemplate elements for each of the services. The access point URL is generated by prefixing the host name value with a protocol, such as http, and suffixing it with the corresponding host port number. The access point URL must resolve to a valid URL.

Data type	String
Default	localhost

Host HTTP port:

Specifies the port number that is used to access UDDI node services with HTTP. This port number must match the WebSphere Application Server port for HTTP requests.

Data type	Integer
Default	9080

Host HTTPS port:

Specifies the port number that is used to access UDDI node services with HTTPS. This port number must match the WebSphere Application Server port for HTTPS requests.

Data type	Integer
Default	9443

Maximum inquiry result set size:

Specifies the maximum size of the result set that the registry processes for an inquiry API request.

If the result set exceeds this value, an E_resultSetTooLarge error is returned. If you set this value too low, and users use imprecise search criteria, it is more likely that an E_resultSetTooLarge error is returned. If you set this value higher, result sets are larger, but response times might increase.

Data type	Integer
Default	500
Range	0 to 1024

Maximum inquiry response set size:

Specifies the maximum number of results that are returned in each response for inquiry API requests. Do not set this value higher than the value of **Maximum inquiry result set size**.

If the result set contains more results than this value, the response includes only a subset of those results. The user can retrieve the remaining results by using the listDescription feature as described in the UDDI specification. If you set this value too low, the user must make more requests to retrieve the remainder of the result set.

Data type	Integer
Default	500
Range	0 to 1024

Maximum search names:

Specifies the maximum number of names that can be supplied in an inquiry API request. If you set higher values, the UDDI node can process more complex requests, but complex requests can increase the response times of the UDDI node significantly. Therefore, to avoid increasing UDDI node response times, set this value to 8 or less.

Data type	Integer
Default	5
Range	1 to 64

Maximum search keys:

Specifies the maximum number of keys that can be supplied in an inquiry API request. If you set higher values, the UDDI node can process more complex requests, but complex requests can increase the response times of the UDDI node significantly. Therefore, to avoid increasing UDDI node response times, set this value to 5 or less.

This value limits the number of references that can be specified in categoryBag, identifierBag, tModelBag and discoveryURLs elements.

In exceptional cases, the UDDI node might reject complex requests with too many keys, even if the value of maxSearchKeys is not exceeded.

Data type Integer
Default 5
Range 1 to 64

Key space requests require digital signature:

Specifies whether tModel:keyGenerator requests must be digitally signed.

Data type Boolean (check box)
Default False (cleared)

Use tier limits:

Specifies whether an approval manager is used to check publication tier limits. If you set this value to `false`, an unlimited number of UDDI entities can be published.

Data type Boolean (check box)
Default True (selected)

Use authInfo credentials if provided:

Specifies whether authInfo contents in UDDI API requests are used to validate users when WebSphere Application Server administrative security is off. If you select this option, the UDDI node uses the authInfo element in the request. If you clear this option, the UDDI node uses the default user name.

Data type Boolean (check box)
Default True (selected)

Authentication token expiry period:

Specifies the period, in minutes, after which an authentication token is invalidated and a new authentication token is required.

Set this value high enough to allow the registry to operate successfully, but be aware that high values can increase the risk of illegal use of authentication tokens.

Data type Integer
Default 30
Range 1 to 10080 minutes (10080 minutes = 1 week)

Automatically register UDDI publishers:

Specifies whether UDDI publishers are automatically registered and assigned to the default tier. Automatically registered UDDI publishers are given default entitlements.

Data type Boolean (check box)
Default True (selected)

Default user name:

Specifies the user name that is used for publish operations when WebSphere Application Server administrative security is off and **Use authInfo credentials if provided** is set to false.

Data type	String
Default	UNAUTHENTICATED

Default language code:

Specifies, for UDDI version 1 and version 2 requests, the default language code to be used for the xml:lang element, when it is not otherwise specified.

Data type	String
Default	en

Value set collection:

You can view and configure the value sets that are installed in a UDDI node.

To view this administrative console page, click **UDDI** > **UDDI Nodes** > ***UDDI_node_id*** > **Value Sets**.

Value sets in a UDDI node are either supported or not supported by policy. By default, new value sets are not supported. After you publish a value set tModel entity and load value set data, you can control whether other UDDI entities can reference this value set tModel entity by setting the Supported policy.

To enable support for one or more value sets, select the value sets by using the corresponding check boxes in the Select column, then click **Enable Support**. The Supported field for all the selected value sets is updated to a value of `true` to show the new status.

You might need to remove support for a value set before you remove the value set from the UDDI node. To remove support for a value set, select the corresponding check box, then click **Disable Support**. The corresponding Supported field is updated to a value of `false` to show the new status.

To view the attributes of a value set, click on the value set name in the list to display the Value set settings page.

Name:

Specifies the name of the tModel entity that represents this value set.

tModelkey:

Specifies the key for the tModel entity that represents this value set.

Supported:

Specifies whether this value set is supported by policy in this UDDI node, where `true` means supported, and `false` means not supported.

Value set settings:

You can view the attributes of a value set in a UDDI node.

To view this administrative console page, click **UDDI** > **UDDI Nodes** > ***UDDI_node_id*** > **Value Sets** > ***value_set_name***.

This page shows the values of the keyedReference elements in the tModel entity that represents this value set. This page also shows the Supported status of the value set. All properties are read-only. To change the Supported status, use the Value sets collection page.

Unvalidatable:

Specifies whether this value set is categorized as unvalidatable, as described in the UDDI specification. The value set tModel publisher sets this value, to indicate whether the value set is available for use by publish requests.

Checked:

Specifies whether this value set is categorized as checked, as described in the UDDI specification. When this value is true, UDDI entities that reference this value set are validated to ensure that their values are present in this value set.

Cached:

Specifies whether this value set is cached in this UDDI node.

Externally cacheable:

Specifies whether this value set is externally cacheable.

Externally validated:

Specifies whether this value set is externally validated.

Supported:

Specifies whether this value set is supported by policy in this UDDI node.

Last cached:

Specifies the date when this value set was last cached in the UDDI node.

Tier collection:

You can view a list of the available tiers for the UDDI node. You can create new tiers, modify tiers, set the default tier, and delete tiers.

To view this administrative console page, click **UDDI** > **UDDI Nodes** > ***UDDI_node_id*** > **Tiers**.

To view or change the properties of a tier, click on the tier name in the list to display the UDDI Tier settings page.

To create a tier, click **New**. The UDDI Tier settings page is displayed, where you can set properties for the new tier.

One tier in the collection is marked as the default tier, indicated by the word (`default`) next to the tier name. The default tier is assigned to UDDI publishers that are registered automatically when automatic user registration is turned on. To set the default tier, select the tier by using the corresponding check box in the Select column, then click **Set default**.

To delete a tier, select the tier by using the corresponding check box in the Select column, then click **Delete**. You cannot delete a tier that is marked as the default tier, or that is currently assigned to a UDDI publisher.

Name:

Specifies the name of the tier.

Description:

Specifies the description of the tier.

UDDI Tier settings:

You can configure the general properties of a UDDI publisher tier.

To view this administrative console page, click **UDDI** > **UDDI Nodes** > ***UDDI_node_id*** > **Tiers** > ***tier_name***.

Name:

Specifies the name of the tier.

Required	Yes
Data type	String
Default	No default
Range	1 to 255

Description:

Specifies a description of the purpose or usage of this tier.

Data type	String
Default	No default
Range	0 to 255

Maximum properties:

The data for each maximum property field has the following properties:

Required	Yes
Data type	Integer
Default	No default
Range	0 to 2147483647

Maximum businesses:

Specifies the maximum number of businesses that UDDI publishers in this tier can publish.

Maximum services per business:

Specifies the maximum number of services that UDDI publishers in this tier can publish for each business.

Maximum bindings per service:

Specifies the maximum number of bindings that UDDI publishers in this tier can publish for each service.

Maximum tModels:

Specifies the maximum number of tModels that UDDI publishers in this tier can publish.

Maximum publisher assertions:

Specifies the maximum number of publisher assertions that UDDI publishers in this tier can add.

UDDI Publisher collection:

You can view the users that are currently registered as UDDI publishers. You can create a UDDI publisher, register a user as a UDDI publisher, assign a UDDI publisher to a tier, and delete a UDDI publisher.

To view this administrative console page, click **UDDI** > **UDDI Nodes** > ***UDDI_node_id*** > **[Additional Properties] UDDI Publishers**.

To create a UDDI publisher, click **New**. The UDDI Publisher settings page is displayed, where you can set properties for the new UDDI publisher.

To register one or more existing WebSphere Application Server users as UDDI publishers, click **Create publishers**. The Create UDDI publishers page is displayed, where you can select users and modify their entitlements.

After users are registered as UDDI publishers, you can click on the user name to display the UDDI Publisher settings page and view or edit their entitlements.

You can assign multiple UDDI publishers to a tier without editing each UDDI publisher individually, by using the following steps:

1. Select the appropriate UDDI publishers by using the corresponding check boxes in the Select column.
2. From the tier list at the top of the collection table, select one of the tiers that is available on the UDDI node.
3. Click **Assign tier**.

To delete one or more UDDI publishers, select the UDDI publishers using the corresponding check boxes in the Select column, then click **Delete**.

User name:

Specifies the name of the UDDI publisher.

Tier:

Specifies the tier to which the UDDI publisher is assigned.

Create UDDI Publishers:

Use this page to register one or more existing WebSphere Application Server users as UDDI publishers.

To view this administrative console page, click **UDDI** > **UDDI Nodes >** *UDDI_node_id* **> [Additional Properties] UDDI Publishers** > **Create publishers**.

To register as UDDI publishers one or more users that are known to the application server, complete the following steps:

1. Enter a string to search for the required users. To find all users, use the * character.
2. Optionally, enter a number in the limit field to restrict the number of returned results.
3. Click **Search** to display a list of users that match the string.
4. Select the users that you want to register from the **Available** list and use the arrows to move them into the **Selected** list.
5. Use the entitlements listed under **General Properties** to give the UDDI publishers permission to undertake specific actions. Set the entitlements by selecting the check box next to each entitlement.

6. Select a tier for the users from the **Tier** list.
7. Click **OK** to register the users as UDDI publishers with the specified entitlements and tier.

Note: If you are using a Lightweight Directory Access Protocol (LDAP) user registry, the format of the name that is given to each UDDI Publisher is defined by the **User ID map** value in the LDAP advanced settings. To view the LDAP advanced settings, click **Security** > **Global security**, under **User account repository** select **Standalone LDAP registry** and click **Configure**, then under **Additional Properties** click **Advanced Lightweight Directory Access Protocol (LDAP) user registry settings**.

After a user has been registered as a UDDI publisher, you can edit their entitlements by clicking the user name.

Allowed to publish keyGenerator with derived key:

Specifies whether the UDDI publisher has permission to publish tModel: keyGenerator with a derived key.

The tModel:keyGenerator is a request for key space. An example of a legal derived key is uddi:tempuri.com:fish:buyingService where the key is based on the derivedKey "uddi:tempuri.com:fish". the string 'buyingService' is the key's key specific string (KSS).

Allowed to publish keyGenerator with domain keys:

Specifies whether the UDDI publisher has permission to publish tModel: keyGenerator with a domain key.

Allowed to publish keyGenerator:

Specifies whether the UDDI publisher has permission to publish tModel: keyGenerator.

If false, UDDI publishers cannot publish keyGenerators of any kind. In this situation all the entitlement settings are disregarded, regardless of how they are set.

Allowed to publish with UUID key:

Specifies whether the UDDI publisher has permission to publish elements with a UUID key.

Allowed to publish keyGenerator with UUID keys:

Specifies whether the UDDI publisher has permission to publish tModel: keyGenerator with a UUID key.

Tier:

Specifies the tier to which the UDDI publisher is assigned.

UDDI Publisher settings:

You can view and edit the entitlements and publication limits tier for a UDDI publisher, or create a new UDDI publisher.

To view this administrative console page, use one of the following options:

- To view and edit the properties of an existing UDDI publisher, click **UDDI** > **UDDI Nodes** > ***UDDI_node_id*** > **UDDI Publishers** > ***user_name***.
- To create a new UDDI publisher, click **UDDI** > **UDDI Nodes** > ***UDDI_node_id*** > **UDDI Publishers** > **New**.

User name:

Specifies the name of the UDDI publisher.

For a new UDDI publisher, enter the name of a user that is known to the application server. For an existing publisher, you cannot change the user name.

Allowed to publish keyGenerator with derived key:

Specifies whether the UDDI publisher has permission to publish a tModel:keyGenerator request with a derived key.

The tModel:keyGenerator request is a request for key space. An example of a legal derived key is uddi:tempuri.com:fish:buyingService, where the key is based on the derivedKey key uddi:tempuri.com:fish and the string buyingService is the key-specific string (KSS) for that key.

Data type Boolean
Default True (selected)

Allowed to publish keyGenerator with domain keys:

Specifies whether the UDDI publisher has permission to publish a tModel:keyGenerator request with a domain key.

Data type Boolean
Default True (selected)

Allowed to publish keyGenerator:

Specifies whether the UDDI publisher has permission to publish a tModel:keyGenerator request.

If you set this value to false, the UDDI publisher cannot publish keyGenerator requests of any kind. In this situation, the following settings are ignored, regardless of how they are set:

- **Allowed to publish keyGenerator with derived key**
- **Allowed to publish keyGenerator with domain keys**
- **Allowed to publish with UUID key**
- **Allowed to publish keyGenerator with UUID keys**

Data type Boolean
Default True (selected)

Allowed to publish with UUID key:

Specifies whether the UDDI publisher has permission to publish elements with a UUID key.

Data type Boolean
Default False (cleared)

Allowed to publish keyGenerator with UUID keys:

Specifies whether the UDDI publisher has permission to publish a tModel:keyGenerator request with a UUID key.

Data type Boolean
Default False (cleared)

Tier:

Specifies the tier to which the UDDI publisher is assigned.

Policy groups:

You can access the detailed settings information for every policy group that you can configure for a UDDI registry node.

To view this administrative console page, click **UDDI** > **UDDI Nodes** > ***UDDI_node_id***.

The page shows a list of the policy groups that can be acted upon. Click a specific group to open the page for the required group.

UDDI keying policy settings:

You can view or edit the UDDI keying settings for a UDDI registry.

To view this administrative console page, click **UDDI** > **UDDI Nodes** > ***UDDI_node_id*** > **Keying policies**.

Registry key generation:

Specifies whether publishers are allowed to publish key generator tModel entities. You can manage how publishers are allowed to publish key generator tModel entities by configuring the entitlements in the UDDI Publishers page.

Data type	Boolean
Default	True (selected)

Registry support of UUID keys:

Specifies whether publisher supplied uuidKeys keys are allowed in publish requests. You can manage how publishers are allowed to use uuidKeys keys by configuring the entitlements in the UDDI Publishers page.

Data type	Boolean
Default	False (cleared)

UDDI node API policy settings:

For UDDI Version 3, you can view or edit the API settings for a UDDI registry node.

To view this administrative console page, click **UDDI** > **UDDI Nodes** > ***UDDI_node_id*** > **API policies**.

Note: This information applies only to UDDI Version 3; you cannot change the API settings for Versions 1 and 2. In Versions 1 and 2, authentication tokens are required for publish requests, but not for inquiry requests. Versions 1 and 2 do not have custody transfer requests.

Authorization for inquiry:

Specifies whether authorization that uses the authInfo element is required for inquiry API requests. This setting is relevant only if the V3SOAP_Inquiry_User_Role role is set to Everyone and WebSphere Application Server administrative security is on.

If WebSphere Application Server administrative security is off, this setting is ignored. If WebSphere Application Server administrative security is on, but the V3SOAP_Inquiry_User_Role role is not set to Everyone, this setting is ignored.

If this option is selected, an authorization token is required to complete the request. If this option is cleared, an authorization token is not required. If this option is cleared and an authorization token is supplied, the token is ignored and the request is processed as if the default user that is defined in the UDDI node settings made the request.

Typically, UDDI registries are configured to not require authorization for inquiry API requests.

Data type Boolean
Default False (cleared)

Authorization for publish:

Specifies whether authorization that uses the authInfo element is required for publish API requests. This setting is relevant only if the V3SOAP_Publish_User_Role role is set to Everyone and WebSphere Application Server administrative security is on.

If WebSphere Application Server administrative security is off, this setting is ignored. If WebSphere Application Server administrative security is on, but the V3SOAP_Publish_User_Role role is not set to Everyone, this setting is ignored.

If this option is selected, an authorization token is required to complete the request. If this option is cleared, an authorization token is not required. If this option is cleared and an authorization token is supplied, the token is ignored and the request is processed as if the default user that is defined in the UDDI node settings made the request.

Typically, UDDI registries are configured to require authorization for publish API requests.

Data type Boolean
Default True (selected)

Authorization for custody transfer:

Specifies whether authorization that uses the authInfo element is required for custody transfer API requests. This setting is relevant only if the V3SOAP_CustodyTransfer_User_Role role is set to Everyone and WebSphere Application Server administrative security is on.

If WebSphere Application Server administrative security is off, this setting is ignored. If WebSphere Application Server administrative security is on, but the V3SOAP_CustodyTransfer_User_Role role is not set to Everyone, this setting is ignored.

If this option is selected, an authorization token is required to complete the request. If this option is cleared, an authorization token is not required. If this option is cleared and an authorization token is supplied, the token is ignored and the request is processed as if the default user that is defined in the UDDI node settings made the request.

Typically, UDDI registries are configured to require authorization for custody transfer API requests.

Data type Boolean
Default True (selected)

UDDI user policy settings:

You can view or edit the user policy settings for a UDDI registry node.

To view this administrative console page, click **UDDI** > **UDDI Nodes** > ***UDDI_node_id*** > **User policies**.

Allow transfer of ownership:

Specifies whether data ownership can be transferred between owners in the UDDI node. When this option is selected, data ownership can be transferred.

Data type	Boolean
Default	True (selected)

UDDI data custody policy settings:

You can view or edit the data custody settings for a UDDI registry node.

To view this administrative console page, click **UDDI** > **UDDI Nodes** > ***UDDI_node_id*** > **Data custody policies**.

Transfer token expiration period:

Specifies length of time, in minutes, allowed before a transfer token is no longer valid.

If you set this value too high, you might expose the UDDI registry to a risk of misuse.

Data type	Integer
Default	1440
Range	1 to 2147483647 (for all intents and purposes, unlimited)

UDDI value set policy settings:

You can view or edit the value set policy settings for a UDDI registry node.

To view this administrative console page, click **UDDI** > **UDDI Nodes** > ***UDDI_node_id*** > **Value set policies**.

Enable checked value sets:

Specifies whether checked value sets are supported. If you clear this option, publish requests of value set tModel entities that contain a checked keyedReference are rejected.

Data type	Boolean
Default	True (selected)

UDDI node miscellaneous settings:

You can view and edit settings for a UDDI node.

To view this administrative console page, click **UDDI** > **UDDI Nodes** > ***UDDI_node_id*** > **Miscellaneous policies**.

Node generates discoveryURLs:

Specifies whether a UDDI node can establish a policy on whether it generates discoveryURL URLs.

Data type	Boolean
Default	False (cleared)

Node supports HTTP Get Service:

Specifies whether the UDDI node supports an HTTP GET service for access to the XML representations of UDDI data structures.

Data type	Boolean
Default	True (selected)

URL prefix for V3 GET servlet:

Specifies the prefix for the URL to the Version 3 GET servlet that retrieves the XML representation of a published entity. This property applies to UDDI Version 3 API requests only.

The format of the prefix is http://hostname:port/uddiv3soap/, where uddiv3soap is the context root of the UDDI Version 3 SOAP servlet.

When a businessEntity entity is published, if **Node generates discovery URLs** is selected, the discoveryURL value is generated based on this prefix value. Otherwise, the discoveryURL value is empty.

The UDDI Version 3 specification recommends that you do not enable generation of discoveryURL URLs because they can affect the use of digital signatures. If you do enable generation of discoveryURL URLs, do not change the URL prefix later. Otherwise discoveryURL URLs that were generated using the earlier URL prefix no longer work.

Data type	URL
Default	http://localhost:9080/uddiv3soap/

UDDI registry administrative (JMX) interface

You can use the UDDI registry administrative interface to inspect and manage the runtime configuration of a UDDI application. You can manage the information about a UDDI node and its activation state, update properties and policies, set publish tier limits, register UDDI publishers, and control value set support.

You can read and invoke the operations of the UDDI registry administrative interface by using standard Java Management Extensions (JMX) interfaces. For more information about using JMX administrative programs, see the related links.

Each WebSphere Application Server UDDI registry application registers an MBean with an MBean identifier of UddiNode. Client applications can use this MBean to inspect and manage the runtime configuration of a UDDI application. Management activities include managing the activation state of a UDDI node, managing information about a UDDI node, updating properties and policies, setting publish tier limits, registering UDDI publishers, and controlling value set support.

You can read and invoke the UddiNode attributes and operations by using standard JMX interfaces. A UddiNodeProxy.java client utility class provides a ready-made application to connect to a UddiNode MBean and perform all the available operations. Example classes are also provided to drive UddiNodeProxy and demonstrate how to use the various UDDI management data types.

When WebSphere Application Server security is enabled, you can invoke the operations of the UddiNode MBean only if you are a user in an administrative role. Operations that make updates require the administrator or operator role. Administrator, operator, configurator and monitor roles can perform get operations.

Management of UDDI node states and attributes

You can use the UDDI registry administrative interface to manage the information about a UDDI node and its activation state.

UDDI nodes can be in one of several states, depending on the way the UDDI application is installed. The UddiNode MBean provides four read-only attributes:

- nodeID
- nodeState
- nodeDescription
- nodeApplicationName

The following MBean operations change the state of the UDDI node:

- activateNode
- deactivateNode
- initNode

nodeID

The node ID is the unique identifier for a UDDI node. If the UDDI application is installed as a default configuration, the node ID is generated automatically. If the UDDI application is installed manually, the administrator sets the node ID. The node ID must be a valid UDDI key.

```
String nodeID = uddiNode.getNode();

System.out.println("node ID: " + nodeId);
```

nodeState

The nodeState attribute can have one of the values in the following table:

Table 333. nodeState attribute values. The table lists different nodeState values along with the English text associated with each one.

nodeState value	English text associated with state
node.state.uninitialized	Not initialized
node.state.initialized	Initialized
node.state.initPending	Initialization pending
node.state.initInProgress	Initialization in progress
node.state.initMigrationPending	Migration pending
node.state.initMigration	Migration in progress
node.state.initValueSetCreationPending	Value set creation pending
node.state.initValueSetCreation	Value set creation in progress
node.state.activated	Activated
node.state.deactivated	Deactivated
node.state.unknown	Unknown

After a UDDI application is installed as a default configuration,, the UDDI node is in activated state, that is, ready to receive and process UDDI API requests. The node ID, root key generator, and some other properties are generated and you cannot change them.

After a UDDI application is installed manually, for example, because you want to specify the UDDI node ID and root key generator values, when the UDDI application starts, the UDDI node is in initPending state. In this state, you can update all writable values until you invoke the initNode

operation. The initNode operation loads base tModel entities and value set data, and writes all the configuration data to the database for the UDDI node. During initialization, the UDDI node is in initInProgress state. When initialization completes, the state changes momentarily to initialized and settles at activated. At this point, the state can be switched only between the activated and deactivated states, using the deactivateNode and activateNode MBean operations.

Each node state value is a message key that can be looked up in the messages.properties resource bundle. You can retrieve the attribute value by using the getNodeState method of the UddiNodeProxy class.

1. Invoke the getNodeState method:

```
String nodeStateKey = uddiNode.getNodeState();
```

2. Look up translated text from the resource bundle and produce it as output:

```
String messages = "com.ibm.uddi.v3.management.messages";

ResourceBundle bundle = ResourceBundle.getBundle(messages,Locale.ENGLISH);

String nodeStateText =  bundle.getString(nodeStateKey);

System.out.println("node state: " + nodeStateText);
```

nodeDescription

You can get the administrator-assigned description for the UDDI node by using the getNodeDescription method of the UddiNodeProxy class.

- Invoke the getNodeDescription method and produce output:

```
String nodeDescription = uddiNode.getNodeDescription();
System.out.println("node description: " + nodeDescription);
```

nodeApplicationName

You can use the nodeApplicationName attribute to discover where the UDDI application that corresponds to the UDDI node is installed. The value is a concatenation of the cell, node, and server names, separated by colons. To retrieve the application location, use the getApplicationId method of the UddiNodeProxy class.

- Invoke the getApplicationId method and produce output:

```
String nodeApplicationId = uddiNode.getApplicationId();

System.out.println("node application location: " + nodeApplicationId);
```

activateNode

Changes the state of the UDDI node to activated, if the UDDI node is currently deactivated.

- Invoke the activateNode operation:

```
uddiNode.activateNode();
```

deactivateNode

Changes the state of the UDDI node to deactivated, if the UDDI node is currently activated.

- Invoke the deactivateNode operation:

```
uddiNode.deactivateNode();
```

initNode

Initializes the UDDI node. When initialization completes, the UDDI node is in the activated state.

- Invoke the initNode operation:

```
 uddiNode.initNode();
```

Management of UDDI node configuration properties

You can use the UDDI registry administrative interface to manage the UDDI node runtime behavior by setting the configuration properties.

UDDI node runtime behavior is affected by the setting of several configuration properties. The UddiNode MBean provides the following operations to inspect and update the configuration properties:

- getProperties

- getProperty
- updateProperty
- updateProperties

In the samples for WebSphere Application Server, the ManagePropertiesSample class in the UDDI registry samples demonstrates these operations.

getProperties

Returns a collection of all configuration properties as ConfigurationProperty objects.

1. Invoke the getProperties operation:

```
List properties = uddiNode.getProperties();
```

2. Cast each collection member to the ConfigurationProperty object:

```
 if (properties != null) {
    for (Iterator iter = properties.iterator(); iter.hasNext();) {
       ConfigurationProperty property = (ConfigurationProperty) iter.next();
       System.out.println(property);
    }
 }
```

When you have the ConfigurationProperty objects, you can inspect attributes such as the ID, value, and type. You can determine whether the property is read-only or required for initialization, and get the name and description message keys. For example, if you invoke the toString method, results similar to the following example are returned:

```
ConfigurationProperty
id: operatorNodeIDValue
nameKey: property.name.operatorNodeIDValue
descriptionKey: property.desc.operatorNodeIDValue
type: java.lang.String
value: uddi:capnscarlet:capnscarlet:server1:default
unitsKey:
readOnly: true
required: true
usingMessageKeys: false
validValues: none
```

You can use the nameKey and descriptionKey values to look up the translated name and description for a given locale, using the messages.properties resource in the sample package.

getProperty

Returns the ConfigurationProperty object with the specified ID. Available property IDs are specified in PropertyConstants with descriptions of the purpose of the corresponding properties.

1. Invoke the getProperty operation:

```
ConfigurationProperty property =
uddiNode.getProperty(PropertyConstants.DATABASE_MAX_RESULT_COUNT);
```

2. To retrieve the value of the property, you can use the getValue method, which returns an Object, but in this case, the property is an integer type, so it is easier to retrieve the value by using the convenience method getIntegerValue:

```
int maxResults = property.getIntegerValue();
```

updateProperty

Updates the value of the ConfigurationProperty object with the specified ID. Available property IDs are specified in PropertyConstants with descriptions of the purpose of the corresponding properties. Although you can invoke the setter methods in a ConfigurationProperty object, the only value that is updated in the UDDI node is the value. To update a property, typically, use the following steps:

1. Create a ConfigurationProperty object and set its ID:

```
ConfigurationProperty defaultLanguage = new ConfigurationProperty();
defaultLanguage.setId(PropertyConstants.DEFAULT_LANGUAGE);
```

2. Set the value:

```
defaultLanguage.setStringValue("ja");
```

3. Invoke the updateProperty operation:

```
uddiNode.updateProperty(defaultLanguage);
```

updateProperties

Updates several ConfigurationProperty objects in a single request. Set up the ConfigurationProperty objects in the same way as for the updateProperty operation.

1. Add the updated properties to a list:

```
List updatedProperties = new ArrayList();

updatedProperties.add(updatedProperty1);
updatedProperties.add(updatedProperty2);
```

2. Invoke the updateProperties operation:

```
uddiNode.updateProperties(updatedProperties);
```

Management of UDDI node policies

You can use the UDDI registry administrative interface to manage policies that affect the UDDI API.

The UddiNode MBean provides the following operations to manage the policies that affect the behavior of the UDDI API:

- getPolicyGroups
- getPolicyGroup
- getPolicy
- updatePolicy
- updatePolicies

In the samples for WebSphere Application Server, the ManagePoliciesSample class in the UDDI registry samples demonstrates these operations.

getPolicyGroups

Returns a collection of all the policy groups as PolicyGroup objects.

1. Invoke the getPolicyGroups operation:

```
List policyGroups = uddiNode.getPolicyGroups();
```

2. Cast each collection member to PolicyGroup:

```
if (policyGroups != null) {
for (Iterator iter = policyGroups.iterator(); iter.hasNext();) {
   PolicyGroup policyGroup = (PolicyGroup) iter.next();
   System.out.println(policyGroup);
   }
}
```

Each policy group has an ID, name, and description key, which you can look up in the messages.properties resource in the sample package. Although the PolicyGroup class does have a getPolicies method, PolicyGroup objects that are returned by the getPolicyGroups operation do not contain any Policy objects. Because of this behavior, clients can determine the known policy groups, and their IDs, without retrieving the entire set of policies in one request. To retrieve the policies in a policy group, use the getPolicyGroup operation.

getPolicyGroup

Returns the PolicyGroup object with the supplied ID.

1. Convert the policy group ID to a string:

```
String groupId = Integer.toString(PolicyConstants.REG_APIS_GROUP);
```

2. Invoke the getPolicyGroup operation:

```
PolicyGroup policyGroup = uddiNode.getPolicyGroup(groupId);
```

getPolicy

Returns the Policy object for the specified ID. As with a configuration property, a Policy object has an ID, name and description keys, type, value, and indicators that specify whether the policy is read-only or required for node initialization.

1. Convert the policy ID to a string:

```
String policyId = Integer.toString(
   PolicyConstants.REG_AUTHORIZATION_FOR_INQUIRY_API);
```

2. Invoke the getPolicy operation:

```
Policy policy = uddiNode.getPolicy(policyId);
```

updatePolicy

Updates the value of the Policy object with the specified ID. Available policy IDs are specified in PolicyConstants with descriptions of the purpose of the corresponding policies. Although you can invoke the setter methods in a Policy object, the only value that is updated in the UDDI node is the value. To update a policy, typically, use the following steps:

1. Create a Policy object and set its ID:

```
Policy updatedPolicy = new Policy();
String policyId = Integer.toString(PolicyConstants.REG_SUPPORTS_UUID_KEYS);
updatedPolicy.setId(policyId);
```

2. Set the value:

```
updatedPolicy.setBooleanValue(true);
```

3. Invoke the updatePolicy operation:

```
uddiNode.updatePolicy(updatedPolicy);
```

updatePolicies

Updates several Policy objects in a single request. Set up the Policy objects in the same way as for the updatePolicy operation.

1. Add updated policies to a list:

```
List updatedPolicies = new ArrayList();

updatedPolicies.add(updatedPolicy1);
updatedPolicies.add(updatedPolicy2);
```

2. Invoke the updatePolicies operation:

```
uddiNode.updatePolicies(updatedPolicies);
```

Management of UDDI node tiers

You can use the UDDI registry administrative interface to set publish tier limits, which control the number of each type of UDDI entity that a publisher can save in the UDDI registry.

A tier has an ID, an administrator-defined name and description, and a set of limits, one for each type of entity. The UddiNode MBean provides the following operations to manage tiers:

- createTier
- getTierDetail
- getTierInfos
- getLimitInfos
- setDefaultTier
- updateTier
- deleteTier
- getUserCount

In the samples for WebSphere Application Server, the ManageTiersSample class in the UDDI registry samples demonstrates these operations.

createTier

Creates a new tier, with specified publish limits for each UDDI entity.

1. Set the tier name and description in a TierInfo object.

```
String tierName = "Tier 100";
String tierDescription = "A tier with all limits set to 100.";

TierInfo tierInfo = new TierInfo(null, tierName, tierDescription);
```

2. Define Limit objects for each UDDI entity:

```
List limits = new ArrayList();

Limit businessLimit = new Limit();
businessLimit.setIntegerValue(100);

businessLimit.setId(LimitConstants.BUSINESS_LIMIT);

Limit serviceLimit = new Limit();
serviceLimit.setIntegerValue(100);
serviceLimit.setId(LimitConstants.SERVICE_LIMIT);

Limit bindingLimit = new Limit();
bindingLimit.setIntegerValue(100);
bindingLimit.setId(LimitConstants.BINDING_LIMIT);

Limit tModelLimit = new Limit();
tModelLimit.setIntegerValue(100);
tModelLimit.setId(LimitConstants.TMODEL_LIMIT);

Limit assertionLimit = new Limit();
assertionLimit.setIntegerValue(100);

assertionLimit.setId(LimitConstants.ASSERTION_LIMIT);
limits.add(businessLimit);
limits.add(serviceLimit);
limits.add(bindingLimit);
limits.add(tModelLimit);
limits.add(assertionLimit);
```

3. Create the Tier object:

```
Tier tier = new Tier(tierInfo, limits);
```

4. Invoke the createTier operation and retrieve the created tier:

```
Tier createdTier = uddiNode.createTier(tier);
```

5. Inspect the generated tier ID of the created tier:

```
tierId = createdTier.getId();
System.out.println("created tier has ID: " + tierId);
```

getTierDetail

Returns the Tier object for the given tier ID. The Tier class has getter methods for the tier ID, tier name and description, as set by the administrator, and the collection of Limit objects, which specify how many of each UDDI entity type UDDI publishers that are allocated to the tier can publish. The isDefault method indicates whether the tier is the default tier, that is, the tier that is allocated to UDDI publishers when auto registration is enabled.

- Invoke the getTierDetail operation:

```
Tier tier = uddiNode.getTierDetail("2");
```

updateTier

Updates the tier contents with the supplied Tier object.

1. Update an existing Tier object, which might be newly instantiated, or returned by the getTierDetail or createTier operations. The following example retains the tier name, description, and all the limit values except the limit that is updated:

```
modifiedTier.setName(tier.getName());
modifiedTier.setDescription(tier.getDescription());

Limit tModelLimit = new Limit();
tModelLimit.setId(LimitConstants.TMODEL_LIMIT);
tModelLimit.setIntegerValue(50);

List updatedLimits = new ArrayList();
updatedLimits.add(tModelLimit);

modifiedTier.setLimits(updatedLimits);
```

2. Invoke the updateTier operation:

```
uddiNode.updateTier(modifiedTier);
```

getTierInfos

Returns a collection of lightweight tier descriptor objects (TierInfo) that contain the tier ID, tier name, tier description, and whether the tier is the default tier.

1. Invoke the getTierInfos operation:

```
List tierInfos = uddiNode.getTierInfos();
```

2. Output the content of each TierInfo object:

```
if (tierInfos != null) {

   for (Iterator iter = tierInfos.iterator(); iter.hasNext();) {
      TierInfo tierInfo = (TierInfo) iter.next();
      System.out.println(tierInfo);
   }
}
```

setDefaultTier

Specifies that the tier with the given tier ID is the default tier. The default tier is the tier that is allocated to UDDI publishers when auto registration is enabled. Typically, you set this to a tier with low publish limits to stop casual users from publishing too many entities.

- Invoke the setDefaultTier operation:

```
uddiNode.setDefaultTier("4");
```

deleteTier

Removes the tier with the given tier ID. Tiers can be removed only if they have no UDDI publishers assigned to them, and the tier is not the default tier.

1. Invoke the deleteTier operation:

```
uddiNode.deleteTier("4");
```

getUserCount

Returns the number of UDDI publishers that are assigned to the tier that is specified by the tier ID.

- Invoke the getUserCount operation:

```
Integer userCount = uddiNode.getUserCount("4");
System.out.println("users in tier 4: " + userCount.intValue());
```

getLimitInfos

Returns a collection of Limit objects that represent the limit values for each type of UDDI entity. Limits are used in Tier objects.

getLimitInfos

Returns collection of Limit objects representing the limit values for each type of UDDI entity. Limits are used in Tier objects.

1. Invoke the getLimitInfos operation:

```
List limits = uddiNode.getLimitInfos();
```

2. Output the ID and limit value for each Limit object:

```
for (Iterator iter = limits.iterator(); iter.hasNext();) {
   Limit limit = (Limit) iter.next();

   System.out.println("limit ID: " + limit.getId() + ", limit value: "
                      + limit.getIntegerValue());
}
```

Management of UDDI publishers

You can use the UDDI registry administrative interface to register UDDI publishers.

Managing UDDI publishers

The UddiNode MBean provides the following operations to manage UDDI publishers:

- createUddiUser
- createUddiUsers
- updateUddiUser
- deleteUddiUser

- getUddiUser
- getUserInfos
- getEntitlementInfos
- assignTier
- getUserTier
-

In the samples for WebSphere Application Server, the ManagePublishersSample class in the UDDI registry samples demonstrates these operations. An example is provided for each, making use of the UddiNodeProxy client class.

createUddiUser

Registers a single UDDI publisher in a specified tier with specified entitlements. The UddiUser class represents the UDDI publisher, and is constructed using a user ID, a TierInfo object that specifies the tier ID to allocate the UDDI publisher to, and a collection of Entitlement objects that specify what the UDDI publisher is permitted to do.

Tip: To allocate the UDDI publisher default entitlements, set the entitlements parameter to null.

1. Create the UddiUser object:

```
UddiUser user = new UddiUser("user1", new TierInfo("3"), null);
```

2. Invoke the createUddiUser operation:

```
uddiNode.createUddiUser(user);
```

createUddiUsers

Registers multiple UDDI publishers. The following example shows how to register seven UDDI publishers with default entitlements in one call.

1. Create TierInfo objects for the tiers that the publishers are allocated to:

```
TierInfo tier1 = new TierInfo("1");
TierInfo tier4 = new TierInfo("4");
```

2. Create UddiUser objects for each UDDI publisher, specifying the tier for each publisher:

```
UddiUser publisher1 = new UddiUser("Publisher1", tier4, null);
UddiUser publisher2 = new UddiUser("Publisher2", tier4, null);
UddiUser publisher3 = new UddiUser("Publisher3", tier4, null);
UddiUser publisher4 = new UddiUser("Publisher4", tier1, null);
UddiUser publisher5 = new UddiUser("Publisher5", tier1, null);
UddiUser cts1 = new UddiUser("cts1", tier4, null);
UddiUser cts2 = new UddiUser("cts2", tier4, null);
```

3. Add the UddiUser objects to a list:

```
List uddiUsers = new ArrayList();

uddiUsers.add(publisher1);
uddiUsers.add(publisher2);
uddiUsers.add(publisher3);
uddiUsers.add(publisher4);
uddiUsers.add(publisher5);
uddiUsers.add(cts1);
uddiUsers.add(cts2);
```

4. Invoke the createUddiUsers operation:

```
uddiNode.createUddiUsers(uddiUsers);
```

updateUddiUser

Updates a UDDI publisher with the details in the supplied UddiUser object. Typically, you use this operation to change the tier of one UDDI publisher or to update the entitlements of a UDDI publisher. Supply only the entitlements that you want to update; other available entitlements retain their existing values.

1. Create Entitlement objects with the appropriate permission. The entitlement IDs are found in EntitlementConstants.

```
Entitlement publishUuiDKeyGenerator =
   new Entitlement(PUBLISH_UUID_KEY_GENERATOR, true);
Entitlement publishWithUuidKey =
   new Entitlement(PUBLISH_WITH_UUID_KEY, true);
```

2. Add the Entitlement objects to a list:

```
List entitlements = new ArrayList();
entitlements.add(publishUuiDKeyGenerator);
entitlements.add(publishWithUuidKey);
```

3. Update a UddiUser object with the updated entitlements:

```
user.setEntitlements(entitlements);
```

4. Invoke the updateUddiUser operation:

```
uddiNode.updateUddiUser(user);
```

getUddiUser

Retrieves details about a UDDI publisher in the form of a UddiUser object. This specifies the UDDI publisher ID, information about the tier the UDDI publisher is assigned to and the entitlements of the UDDI publisher.

1. Invoke the getUddiUser operation:

```
UddiUser user1 = uddiNode.getUddiUser("user1");
```

2. Output the contents of the UddiUser object:

```
System.out.println("retrieved user: " + user1);
```

getUserInfos

Returns a collection of UserInfo objects. Each UserInfo object represents a UDDI publisher that is known to the UDDI node, and the tier that the UDDI publisher is allocated to. To get more details about a specific UDDI publisher, including the tier ID and entitlements, use the getUddiUser operation.

1. Invoke the getUserInfos operation:

```
List registeredUsers = uddiNode.getUserInfos();
```

2. Output the UserInfo objects:

```
System.out.println("retrieved registered users: ");
System.out.println(registeredUsers);
```

getEntitlementInfos

Returns a collection of Entitlement objects. Each entitlement is a property that controls whether a UDDI publisher has permission to undertake a specified action.

1. Invoke the getEntitlementInfos operation:

```
List entitlementInfos = uddiNode.getEntitlementInfos();
```

2. Specify where to find message resources:

```
String messages = "com.ibm.uddi.v3.management.messages";
ResourceBundle bundle = ResourceBundle.getBundle(messages, Locale.ENGLISH);
```

3. Iterate through the Entitlement objects, displaying the ID, name, and description:

```
for (Iterator iter = entitlementInfos.iterator(); iter.hasNext();) {
   Entitlement entitlement = (Entitlement) iter.next();

   StringBuffer entitlementOutput = new StringBuffer();

   String entitlementId = entitlement.getId();
   String entitlementName = bundle.getString(entitlement.getNameKey());
   String entitlementDescription =
                    bundle.getString(entitlement.getDescriptionKey());

   entitlementOutput.append("Entitlement id: ");
   entitlementOutput.append(entitlementId);
   entitlementOutput.append("\n  name: ");
   entitlementOutput.append(entitlementName);
   entitlementOutput.append("\n  description: ");
   entitlementOutput.append(entitlementDescription);

   System.out.println(entitlementOutput.toString());
}
```

deleteUddiUser

Removes the UDDI publisher with the specified user ID from the UDDI registry.

- Invoke the deleteUddiUser operation:

```
uddiNode.deleteUddiUser("user1");
```

assignTier

Assigns the UDDI publishers with the supplied IDs to the specified tier. This operationis useful when you want to restrict several UDDI publishers, for example by assigning them to a tier that does not allow publishing of any entities.

1. Create a list of publisher IDs:

```
List uddiUserIds = new ArrayList();

uddiUserIds.add("Publisher1");
uddiUserIds.add("Publisher2");
uddiUserIds.add("Publisher3");
uddiUserIds.add("Publisher4");
uddiUserIds.add("Publisher5");
uddiUserIds.add("cts1");
uddiUserIds.add("cts2");
```

2. Invoke the assignTier operation:

```
uddiNode.assignTier(uddiUserIds, "0");
```

getUserTier

Returns information about the tier that a UDDI publisher is assigned to. The returned TierInfo has getter methods for retrieving the tier ID, tier name, tier description, and whether the tier is the default tier.

1. Invoke the getUserTier operation:

```
TierInfo tierInfo = getUserTier("Publisher3");
```

2. Output the contents of the TierInfo object:

```
System.out.println(tierInfo);
```

Management of UDDI node value sets

You can use the UDDI registry administrative interface to inspect and manage the runtime configuration of a UDDI application. You can manage the information about a UDDI node and its activation state, update properties and policies, set publish tier limits, register UDDI publishers, and control value set support.

Value sets are represented in a UDDI registry as value set tModel entities, with a keyedReference UDDI type with the value categorization. Such value sets are backed with a set of valid values. For user-defined value sets, this data is loaded into the UDDI registry using UddiNode MBean operations, although it is more convenient to do this using the User defined value set tool.

Each value set can be controlled by policy as being supported or not supported. When a value set is supported by policy, it can be referenced in UDDI publish requests. The UddiNode MBean provides the following operations to manage value sets and their data:

- getValueSets
- getValueSetDetail
- getValueSetProperty
- updateValueSet
- updateValueSets
- loadValueSet
- changeValueSetTModelKey
- unloadValueSet
- isExistingValueSet

In the samples for WebSphere Application Server, the ManageValueSetsSample class in the UDDI registry samples demonstrates these operations.

getValueSets

Returns a collection of ValueSetStatus objects.

1. Invoke the getValueSets operation:

```
List valueSets = uddiNode.getValueSets();
```

2. Cast each element to ValueSetStatus and output contents:

```
for (Iterator iter = valueSets.iterator(); iter.hasNext();) {

   ValueSetStatus valueSetStatus = (ValueSetStatus) iter.next();
   System.out.println(valueSetStatus);
}
```

getValueSetDetail

Returns a ValueSetStatus object for the given value set tModel key.

1. Invoke the getValueSetDetail operation:

```
uddiNode.getValueSetDetail("uddi:uddi.org:ubr:categorization:naics:2002");
```

2. Retrieve and display the details:

```
String name = valueSetStatus.getName();
String displayName = valueSetStatus.getDisplayName();
boolean supported = valueSetStatus.isSupported();

System.out.println("name: " + name);
System.out.println("display name: " + displayName);
System.out.println("supported: " + supported);
```

3. Display the value set properties:

```
List properties = valueSetStatus.getProperties();

for (Iterator iter = properties.iterator(); iter.hasNext();) {

   ValueSetProperty property = (ValueSetProperty) iter.next();
   System.out.println(property);
}
```

getValueSetProperty

Returns a property of a value set as a ValueSetProperty object. This operation is mainly for the administrative console to render properties of a value set as a row in a table. For example, one such property is the keyedReference property, which indicates whether the value set is checked.

1. Invoke the getValueSetProperty operation:

```
uddiNode.getValueSetProperty("uddi:uddi.org:ubr:categorization:naics:2002",
   ValueSetPropertyConstants.VS_CHECKED);
```

2. Read and display the boolean value of the property:

```
boolean checked = valueSetProperty.getBooleanValue();

System.out.println("checked: " + checked);
```

updateValueSet

Updates the value set status. Only the supported attribute can be updated. All other setter methods are used by the UDDI application.

1. Create a ValueSetStatus object specifying the tModel key and the updated supported value:

```
ValueSetStatus updatedStatus = new ValueSetStatus();
updatedStatus.setTModelKey("uddi:uddi.org:ubr:categorization:naics:2002");
updatedStatus.setSupported(true);
```

2. Invoke the updateValueSet operation:

```
uddiNode.updateValueSet(updatedStatus);
```

updateValueSets

Updates the value set status for multiple value sets. Similarly to the updateValueSet operation, only the supported attribute is updated.

1. Populate the list with updated ValueSetStatus objects:

```
List valueSets = new ArrayList();

ValueSetStatus valueSetStatus = new ValueSetStatus();
valueSetStatus.setTModelKey("uddi:uddi.org:ubr:categorization:naics:2002");
```

```
valueSetStatus.setSupported(false);
valueSets.add(valueSetStatus);

valueSetStatus = new ValueSetStatus();
valueSetStatus.setTModelKey("uddi:uddi.org:ubr:categorizationgroup:wgs84");
valueSetStatus.setSupported(false);
valueSets.add(valueSetStatus);

valueSetStatus = new ValueSetStatus();
valueSetStatus.setTModelKey("uddi:uddi.org:ubr:identifier:iso6523:icd");
valueSetStatus.setSupported(false);
valueSets.add(valueSetStatus);
```

2. Invoke the updateValueSets operation:

```
uddiNode.updateValueSets(valueSets);
```

loadValueSet

Loads values for a value set from a UDDI registry Version 3 or Version 2 taxonomy data file on the local file system.

Note: There is also a loadValueSet operation that takes a ValueSetData object, but this is only for use by the user-defined value set tool.

1. Invoke the loadValueSet operation:

```
uddiNode.loadValueSet("/valuesets/myvalueset.txt",
   "uddi:cell:node:server:myValueSet");
```

changeValueSetTModelKey

Allocate any value set values that are allocated to one value set tModel to a new value set tModel.

- Invoke the changeValueSetTModelKey operation, specifying old and new tModel keys:

```
uddiNode.changeValueSetTModelKey(
"uddi:cell:node:server:myValueSet",
"uddi:cell:node:server:myNewValueSet");
```

unloadValueSet

Unloads values for a value set with the given tModel key.

- Invoke the unloadValueSet operation:

```
uddiNode.unloadValueSet("uddi:myValueSet");
```

isExistingValueSet

Determines whether value set data exists for the given tModel key.

1. Invoke the isExistingValueSet operation and display the result:

```
boolean exists = uddiNode.isExistingValueSet(
    "uddi:uddi.org:ubr:categorization:naics:2002");
System.out.println("NAICS 2002 is a value set: " + exists);
```

User-defined value set support in the UDDI registry

You can define multiple value sets and add custom value sets to the UDDI Version 3 registry. In UDDI Version 2, this feature was called custom taxonomy support.

The UDDI Version 3 registry provides the structure and modeling tools to find information in a registry effectively. Also, the verification of data in a UDDI registry is crucial to its mission of description, discovery and integration.

You can define multiple value sets to use UDDI. Therefore, multiple classification schemes can be overlaid on a single UDDI entity. Organizations can use this capability to extend the set of such systems that UDDI registries support. You are not restricted to a single system, but can employ several different classification systems simultaneously.

Default value sets are shipped with the product. The UDDI Version 3 registry provides tools to add custom, or user-defined, value sets. You can use such value sets to categorize UDDI entities more specifically when they are published, which enhances the capability of client to find specific data.

User-defined value sets can be either checked or unchecked. This is indicated by a keyedReference element in the categoryBag element of the tModel entity that represents a value set (a categorization tModel). These keyedReference elements have the tModel key for uddi-org:types and are added to the categoryBag to further describe the behavior of the categorization tModel, as follows:

checked
: Marking a tModel entity with this classification asserts that the entity represents a categorization, identifier, or namespace tModel entity that has a validation service to check that category values are present in a specified value set.

unchecked
: Marking a tModel entity with this classification asserts that the entity represents a categorization, identifier, or namespace tModel entity that does not have a validation service.

The following procedure describes how to add user-defined value sets, and display their allowed values in the UDDI user console value set tree display. Rational Application Developer has a Web Services Explorer user interface that also allows addition and display of custom checked value sets. The publisher of a value set categorization tModel entity might specify a display name for use in UDDI user console implementations.

Adding a user-defined value set

To add a user-defined value set to the UDDI registry, use the following procedure:

1. Publish a categorization tModel entity.
2. Load the user-defined value set data.
3. Enable support for the value set by using the administrative console.

To enable support for the value set, you must be a user in an administrative role. This means that you cannot add user-defined value sets to the UDDI registry without administrator permission.

The checked value set is referenced only when all steps of the procedure are complete. Value set data must be provided for validating checked value sets.

User consoles might use value set data for unchecked value sets, but it is not a requirement, and is usually used only for presentation of deprecated value sets, such as unspc-org:unspc, and for compatibility with earlier versions.

If the value set is checked, any publish requests that have a categoryBag element that contains keyedReference elements with the new categorization tModel are validated. If there is value set data corresponding to the categorization tModel entity in the registry database, only valid values are accepted. If there is no value set data in the database, all values are rejected and the publish request fails. If the categorization tModel entity is unchecked, all values are allowed, regardless of whether a corresponding value set is present in the UDDI registry database. The value set tModel entity is not available for use until the administrator enables support for it by using the administrative console or the JMX interface.

The following procedure provides a suggested approach to add a user-defined value set to the UDDI registry:

1. Publish the categorization tModel entity with the following values:

keyedReference element	**values**
uddi-org:categorization:types	keyValue = categorization
uddi-org:categorization:types	keyName = Checked value set and keyValue = checked or keyName = Unchecked value set and keyValue = unchecked

keyedReference element	values
uddi-org:categorization:general_keywords	supply the value set display name

2. Load the user-defined value set data into the UDDI registry database using the UDDIUserDefinedValueSet utility.
3. Use the administrative console to set the status of the value set to supported in the Value set settings. Alternatively, you can do this directly by using the JMX interface.

The SOAP and Enterprise JavaBeans (EJB) interfaces can use categorization tModel entities as soon as they are published. However, for the UDDI registry user console, the UDDI application must be restarted, because the console gathers the list of categorizations to use in the value set tree display when the application starts.

Publish a checked categorization tModel entity

You publish a checked categorization tModel entity as the first step in the procedure to add a user-defined value set to the UDDI registry.

This topic describes how to publish a checked categorization tModel entity with the keyName “Checked value set” for a user-defined value set to use.

Publish a tModel entity to the UDDI registry with a categoryBag element that contains the keyedReference elements shown in the following table.

Table 334. keyedReference elements for a checked categorization tModel entity. The table lists different tModelKey elements along with their KeyName, KeyValue and additional user notes.

tModelKey	KeyName	KeyValue	Notes
uddi:uddi-org:categorization:types	categorization	categorization	To choose this tModelKey in the UDDI registry user interface, select the category type **UDDI Types**. This element indicates that this tModel entity is a categorization tModel entity (required).
uddi:uddi-org:categorization:types	Checked value set	checked	To choose this tModelKey in the UDDI registry user interface, select the category type **UDDI Types**. This element indicates that use of the tModel entity is checked against a list of valid data (required). If this keyedReference element is omitted, or a value of unchecked is specified, this indicates that this categorization is unchecked.
uddi:uddi-org:categorization:general_keywords	urn:x-ibm:uddi:customTaxonomy:displayName	*user-defined Value Set displayName*	To choose this tModelKey in the UDDI registry user interface, select the category type **categorization: general_keywords**. This element indicates special use of the general keywords value set, with a proprietary uniform resource name (URN) as the keyName value, defines a name for the user-defined value set that is intended for use in user console implementations where the full tModel name might be too long. The value can be 1-255 characters (inclusive) long.

You can use the displayName value to give a value set a label that is meaningful to users, that is greater than 8 characters, and that is different to the published tModelName, which might be as long as 255 characters. The UDDI user console can display this label in a value set tree or in a drop-down list of available value sets. The following diagram shows an example:

Figure 50. Use of the display name in the UDDI user console

It is advisable to specify a unique name for urn:x-ibm:customTaxonomy:displayName to avoid confusion when it is displayed in user interfaces.

To publish a new categorization tModel that uses SOAP, use the following message:

```
<save_tModel generic="3.0" xmlns="urn:uddi-org:api_v3">
  <authInfo></authInfo>>
  <tModel tModelKey="">
    <name>Natural Foods tModel</name>
    <categoryBag>
      <keyedReference tModelKey="uddi:uddi.org:categorization:types"
        keyName="categorization" keyValue="categorization"/>
      <keyedReference tModelKey="uddi:uddi.org:categorization:types"
        keyName="Checked value set" keyValue="checked"/>
      <keyedReference tModelKey="uddi:uddi.org:categorization:general_keywords"
        keyName="urn:x-ibm:uddi:customTaxonomy:displayName"
        keyValue="Natural Foods"/>
    </categoryBag>
  </tModel>
</save_tModel>
```

Tip: To specify an unchecked categorization, change the keyName value from “Checked value set” to “Unchecked value set” and change the keyValue value from checked to unchecked. Alternatively, omit that keyedReference element completely.

Load user-defined value set data

You can use the UDDIUserDefinedValueSet utility to load value set data into the UDDI registry, assign existing value set data to another tModel entity, and unload existing value set data. You load value set data as a step in the procedure to add a user-defined value set to the UDDI registry.

Format of the value set data file

Value set data is identified by a unique code value, an optional description, and a parent code that specifies its relationship with other code values. Value set data must adhere to this format.

You must save the file in UTF-8 format.

Table 335. Value set data format. The table lists the different value set column names, shows their maximum character lengths and provides a description of each one.

Column name	Maximum length	Description of use
code	765	Unique value in the value set, which is used for validation
description	765	Typically used by UDDI user consoles and optionally used in the keyedReference element as the keyName value
parentcode	765	Indicates the existing code that is the logical parent of this code, and is used in tree displays

Typically, columns are delimited in the value set data file by number (#) characters, as shown in the following example:

```
00#Food#00
10#Fruit#00
101#Apples#10
102#Oranges#10
103#Pears#10
```

```
1031#Anjou#103
1032#Conference#103
1033#Bosc#103
104#Pomegranates#10
20#Vegetables#00
201#Carrots#20
202#Potatoes#20
203#Peas#20
204#Sprouts#20
```

In the example, Food is the description of the root node and it has the child nodes Fruit and Vegetables; the parentcode values of both these child nodes are the same as the code value of Food.

The value set data in the example file can then be rendered in a tree, as shown in the following example:

```
Food
  Fruit
    Apples
    Oranges
    Pears
      Anjou
      Conference
      Bosc
    Pomegranates
  Vegetables
    Carrots
    Potatoes
    Peas
    Sprouts
```

UDDIUserDefinedValueSet utility

You can use the UDDIUserDefinedValueSet utility to load value set data into the UDDI registry, assign existing value set data to another tModel entity, and unload existing value set data. The utility also supports custom taxonomy files that are used in UDDI Version 2.

This utility uses the UDDI registry JMX interface and therefore requires a number of connection parameters.

Usage:

```
UDDIUserDefinedValueSet '{'function'}' [options]
```

Functions:

```
-load <path> <key>         Load value set data from specified file
-newKey <oldKey> <newKey>  Move value set to a new tModel
-unload <key>              Unload existing value set
```

Options:

```
-properties <path>         Specify location of configuration file
-host <host name>          Application Server host
-port <port>               SOAP Lister port number
-node <node name>          Node running a UDDI server
-server <server name>      Server with UDDI deployed
-columnDelimiter <delim>   Character delimiter to denote field end
-stringDelimiter <delim>   Character delimiter to denote strings
```

Connector security parameters

```
-userName <name>
-password <password>
-trustStore <path>
-trustStorePassword <password>
-keyStore <name>
-keyStorePassword <password>
```

Ensure that the command window that you run the UDDIUserDefinedValueSet utility from uses a suitable code page and font to display the characters that are in the value set name. If you use an incorrect code page or font, a successful load might result in unclear messages, and it might be difficult to use the unload and newKey functions.

The UDDIUserDefinedValueSet script is in the *app_server_root*/bin directory.

If you do not supply any connection parameters, a connection is sought on the local host using the default application server SOAP port number.

Command arguments are not case sensitive.

Optionally, you can use the properties parameter to specify a configuration file. This configuration file determines optional properties that you can also specify on the command line. Properties that are specified on the command line override the values in the configuration file. These properties are largely JMX connection parameters and security parameters.

Typically, you use the stringDelimiter parameter when a description value contains the same character as the column delimiter character. For example, if the columnDelimiter parameter is set to a comma (,) and there is a value set description value of “Fruits, citrus”, to include this description in the value set data file, set the stringDelimiter parameter to quotation marks (") and enclose the description in quotes, for example, `"Fruits, citrus"`. Note that you must set a backslash (\) as an escape character to show that the literal character is used.

If you attempt to load a value set to a tModel entity that has existing value set data, a warning message is displayed. To override this warning, you can use the override argument. You also require this argument when you move value set data to a new tModel entity by using the newKey function when the tModel entity is checked, and when you unload value set data for a checked tModel entity.

Table 336. Command line arguments and properties. The table lists different command line arguments and their properties and contains a comment on each one.

Command line arguments and example data	Property and example data	Comments
-columnDelimiter #	column.delimiter=#	The column delimiter that is used in value set data files.
-stringDelimiter \"	string.delimiter=\"	The field delimiter. This value must be different from the column.delimiter value.
-host ibm.com	host=ibm.com	The host name of the system that is running the application server
-port 8880	port=8880	The SOAP port number of the application server.
-node ibmNode	node=ibmNode	The name of the node that runs the server with the UDDI registry.
-server server1	server=server1	The server that runs the UDDI registry.
-userName ibmuser	security.username=ibmuser	The user name. This value is required if WebSphere Application Server security is turned on.
-password mypassword	security.password=mypassword	The password.
-trustStore /TrustStoreLocation	security.truststore=/ TrustStoreLocation	The truststore file location.
-keyStore ibmkeystore	security.keystore=ibmkeystore	The keystore name.
-trustStorepassword trustpass	security.truststore.password=trustpass	The truststore password
-keyStorePassword keypass	security.keystore.password=keypass	The keystore password.

Usage examples

Load value set data for a tModel entity on the local UDDI registry, using the percent sign as a column marker in the valuesetdata.txt file.

Move value set data from one checked tModel entity to another on a UDDI registry in a network deployment configuration.

Unload a value set from a tModel entity from a server with security enabled. Supply the connection and security parameters in the file myproperties.properties, but supply the server and password arguments on the command line. Arguments that are supplied on the command line augment or override the arguments in the properties file.

Enable support for a user-defined value set

You can enable support for the value set by using the administrative console. You do this as part of the procedure to add a user-defined value set to the UDDI registry.

To enable support for the value set, you must be a user in an administrative role. This means that you cannot add user-defined value sets to the UDDI registry without administrator permission.

Use the following steps in the administrative console:

1. Click **UDDI** > **UDDI Nodes** > ***node_name*** > **[Additional properties] Value sets**.
2. Select the value set.
3. Click **Enable Support**.

Validation and error handling for user-defined value sets

The UDDI registry user console performs validation while a save tModel entity request is built, that is, before the publish occurs.

For example, if you try to add two customTaxonomy:displayName keyedReference elements, the following message is displayed:

```
Advice: Only one 'urn:x-ibm:uddi:customTaxonomy:displayName' key name is
allowed for the 'Other' taxonomy.
```

If a keyedReference element that contains a keyName value that starts with urn:x-ibm:uddi:customTaxonomy: is followed by anything other than displayName, the following message is displayed:

```
Advice: Only key name values of 'urn:x-ibm:uddi:customTaxonomy:displayName'
are supported.
```

For requests where the save_tModel entity message might have multiple tModel entities, if any one of the tModel entities is a categorization tModel entity and it fails validation, the request fails with a UDDIInvalidValueException plus additional information to explain the cause, and none of the tModel entities is published. For example:

```
E_invalidValue (20200) A value that was passed in a keyValue attribute did not
pass validation.  This applies to checked categorizations, identifiers and
other validated code lists. The error text will clearly indicate the key and
value combination that failed validation. Invalid 'customTaxonomy:dbKey'
keyValue [naics] in keyedReference. KeyValue already in use by
tModelKey[UUID:C0B9FE13-179F-413D-8A5B-5004DB8E5BB2]
```

UDDI Utility Tools

The UDDI Utility Tools is a suite of functions that you can use to migrate, move, or copy UDDI Version 2 entities, including child entities and their respective Version 2 entity keys, into a Version 3 UDDI registry.

To use the UDDI Utility Tools suite, run the UDDIUtilityTools.jar file. This file is in the *app_server_root*/UDDIReg/scripts directory. Alternatively, you can invoke all the functions of UDDI Utility Tools through the supplied public Java API.

The UDDI Utility Tools suite that is supplied in this release has the same functions as the version that is supplied in WebSphere Application Server Version 6.1. However, all UDDI Utility Tools functions in this release use the UDDI Version 2 API. Note that Version 2 API does not support publisher-assigned keys.

You can use the UDDI Utility Tools to export from Version 2 and 3 registries (supplying only the Version 2 representation of the UDDI entity key) and import into the Version 3 registry, using Version 2 API types.

Entities from a Version 3 registry are exported as Version 2 entities, so elements such as digital signatures are not present. See the topic about saving UDDI Version 3 entities with a supplied key for an example of how to use the Version 3 API to assign your own keys to Version 3 entities.

The UDDI Version 3 Publish API supports publisher-assigned keys, and to promote entities between Version 3 registries, you use normal API functions.

The UDDI Utility Tools suite also has the following uses:

- You can search and select entities from a source UDDI registry by specifying Version 2 keys or search criteria.
- You can publish canonical tModel entities in a UDDI registry, including child entities.
- You can persist UDDI (Version 2) entities in an intermediate XML representation so that you can customize and copy those entities to multiple target UDDI registries, by specifying Version 2 keys.
- You can update existing entities in a target UDDI registry, including child entities.
- You can delete selected entities from a target UDDI registry by specifying Version 2 keys.

The UDDI Utility Tools suite has five main functions:

Export
: The export function gets a list of UDDI entities from a specified registry and writes them to the UDDI entity definition file, using the specified entity types and keys. The entity type for each key can be business, service, bindingTemplate, or tModel. The entity definition file contains XML that exactly describes each of the specified entities, according to the UDDI Utility Tools schema, which includes the UDDI Version 2 schema. The UDDI entity definition file separates entities by type, and automatically detects and records tModel entities that the specified entities reference. You can use the “referenced tModels” section of the file to ensure that a target registry includes any referenced tModel entities before you import new entities to that registry.

Import
: The import function detects whether a list of UDDI entities already exist in the target registry and, if they do not, create a minimal entity, or stub, with the specified key. The UDDI entities can be supplied through a UDDI entity definition file, or programmatically in a container object. The entities are then published, updating the stubs with the supplied data, and overwriting or ignoring existing entities, as specified. Note that the original key is maintained throughout.

Promote
: The promote function combines the export and import steps such that the specified entities are extracted (by key) from the source registry and then imported into the target registry in a single logical step. Optionally, you can generate a UDDI entity definition file.

Delete The delete function deletes the specified entities from the target UDDI registry. The entities to delete are specified as an entity type, or a list of entity types, and keys, in the same way as for the export function.

Find matching entities
: The find matching entities function finds a set of entities that match the search criteria and generates a list of entity keys. The search criteria are UDDI Inquiry API objects for each of the various entity types. You can use the resulting list of entity keys as input to the export, promote, and delete functions.

  Note: This function is available through only the programmatic API.

  The following diagram shows relationship between the functions, their input and output, and the source and target UDDI registries:

UDDI Utility Tools prerequisites

Before you use the UDDI Utility Tools, ensure that the required .jar files are available.

Ensure that the following .jar files are available to the UDDI Utility Tools. You must specify the locations of the .jar files in the class path in the UDDI Utility Tools properties file:

UDDIUtilityTools.jar
This file is the UDDI Utility Tools .jar file and is in the *app_server_root*/UDDIReg/scripts directory.

com.ibm.uddi.jar
This file contains the UDDI4J classes and is in the *app_server_root*/plugins directory.

j2ee.jar
This file contains some required Java platform for enterprise applications classes, and is in the *app_server_root*/lib directory.

com.ibm.ws.runtime.jar
This file is the Apache SOAP implementation and is in the *app_server_root*/plugins directory.

DbDriver
This driver is needed for the UDDIUtilityTool to connect to your target database. See the following table for the values you must specify for your chosen database:

Table 337. DbDriver values for databases. The table details the values needed to connect to different databases.

	DB2	**Apache Derby**	**Oracle**
DBDriverLocation for class path	*DB2_HOME*/db2java.zip	*app_server_root*/derby/lib/derbyclient.jar	*ORACLE_HOME*/jdbc/lib/ojdbc6.jar
Driver	com.ibm.db2.jdbc.app.DB2Driver, or com.ibm.db2.jcc.DB2Driver for a remote DB2 database. You can also set up a local alias to the remote database by using the DB2 client.	com.ibm.db2.jcc.DB2Driver	oracle.jdbc.OracleDriver
URL	jdbc:db2://host:*database_name*	jdbc:db2j:net://host:1527/*database_name*	jdbc:oracle:thin:@host:1521:*database_name*

where:

- *app_server_root* is the directory location of WebSphere Application Server.
- *DB2_HOME* is the directory location of DB2, for example `c:\Program Files\SQLLIB\java12\`
- *ORACLE_HOME* is the directory location of Oracle, for example `c:\oracle\ora92\`
- *database_name* is the name of the database. For Apache Derby, ensure that *database_name* includes the path to the database, for example *profile_root*/databases/com.ibm.uddi/UDDI30

Notes:

- For Apache Derby, make the database network-enabled so that it can handle multiple connections. For further details, refer to the section about managing the Derby Network Server in the Derby Server and Administration Guide.
- For DB2, add DB2_HOME/sqllib/lib to your LD_LIBRARY_PATH and LIBPATH environment variables.

The Security provider configuration section in the configuration properties file shows the location of the default DummyClientTrustFile.jks file. If you use your own truststore, ensure that the location is placed here.

The UDDI Utility Tools use UDDI Version 2 SOAP Inquiry and Publish interfaces. These APIs are protected, as described in the topic about access control for UDDI registry interfaces. The UDDI Utility Tools also access the UDDI registry database through the database driver, and access to the database is controlled by the database management system.

UDDI Utility Tools configuration file

Configuration data for UDDI Utility Tools is in a configuration properties file, which describes the runtime environment, UDDI and database locations and access information, logging information, security configuration, entity definition file location, and other flags to control whether referenced entities can be imported, overwritten, or both.

A sample configuration properties file, UDDIUtilityTools.properties, is supplied with UDDI Utility Tools. By default, this file is in the *app_server_root*/UDDIReg/scripts directory. If you do not specify a properties path, by default, the configuration properties file is searched for in the current directory.

To set up and use the configuration file, use the following procedure:

1. Modify the sample configuration properties file:
   - Set the class path, which must include the current directory (.), the UDDIUtilityTools.jar, and all the dependent jars, as listed in "UDDI Utility Tools prerequisites" on page 3556. The class path must include the database driver JAR file, for example, db2java.zip.
   - If you are configuring a Java Secure Socket Extension (JSSE) provider, add the .jar file that contains the provider to the class path. To configure a JSSE provider, set the `jsse.provider` property. The default value is com.ibm.jsse.IBMJSSEProvider. To specify the Federal Information Processing Standard (FIPS) JSSE provider, set the `jsse.provider` property to com.ibm.fips.jsse.IBMJSSEFIPSProvider.
   - Set other properties as required. For details, see the comments in the sample UDDIUtilityTools.properties file.
   - Change localhost to the name of your server.
   - Change the port number 9080 to your internal HTTP port.
2. When you run UDDI Utility Tools, specify the modified configuration properties file.

The following example shows the sample configuration properties file.

```
############################################
# Runtime environment                      #
# (if invoking using java -jar...)         #
# "X Y" required around paths with spaces.  #
# Replace WAS_HOME with your WebSphere      #
# Application Server home path.            #
# db2java.zip is for DB2 - replace this with #
# appropriate database driver file.        #

# namespace prefix to use in definition file (export)
namespacePrefix=promote
```

UDDI entity definition file

The entity definition file contains XML that exactly describes each of the specified entities, according to the UDDI Utility Tools schema.

You can create a UDDI entity definition file in three ways:

- Use the export or promote functions in UDDI Utility Tools to generate a file.
- Modify a file that was generated by using the export function.
- Create a file manually.

The extension to the uddi:tModel type to add a deleted attribute is not currently used in UDDI Utility Tools.

The file is validated for form and compliance with the UDDI Utility Tools schema, shown here:

```
<?xml version="1.0" encoding="UTF-8" ?>
<xsd:schema id="uddiPromote" attributeFormDefault="unqualified"
 elementFormDefault="qualified" targetNamespace=
 "http://www.ibm.com/xmlns/prod/WebSphere/UDDIUtilityTools"
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:uddi="urn:uddi-org:api_v2"
xmlns="http://www.ibm.com/xmlns/prod/WebSphere/UDDIUtilityTools"
xmlns:promote="http://www.ibm.com/xmlns/prod/WebSphere/UDDIUtilityTools">

```

UDDI entity definition file example for canonical tModel entities

You can use UDDI Utility Tools to create new UDDI entities in a target UDDI registry. A typical example of this is to introduce a new canonical tModel entity that has a publicly known tModel key.

The following example entity definition file following shows the five main sections for tModels, businesses, services, bindings, and referencedTModels:

```
<?xml version="1.0" encoding="UTF-8"?>
<promote:uddiEntities xmlns="urn:uddi-org:api_v2" xmlns:promote=
 "http://www.ibm.com/xmlns/prod/WebSphere/UDDIUtilityTools">

  <!-- tModels -->
  <promote:tModels>

    <tModel tModelKey="uuid:ee3966a8-faa5-416e-9772-128554343571" >
      <name>http://schemas.xmlsoap.org/ws/2002/07/policytmodel</name>
      <description>WS-PolicyAttachment policy expression</description>
    </tModel>

    <tModel tModelKey="uuid:ad61de98-4db8-31b2-a299-a2373dc97212" >
      <name>uddi-org:wsdl:address</name>
 <description xml:lang="en">
This tModel is used to specify the URL fact that the address must be obtained
from the WSDL deployment file.
      </description>
      <overviewDoc>
        <overviewURL>
http://www.oasis-open.org/committees/uddi-spec/doc/tn/
uddi-spec-tc-tn-wsdl-v2.htm#Address
        </overviewURL>
      </overviewDoc>
    </tModel>

  </promote:tModels>

  <!-- businesses -->
  <promote:businesses>
  </promote:businesses>

  <!-- services -->
  <promote:services>
  </promote:services>

  <!-- bindings -->
  <promote:bindings>
  </promote:bindings>

  <!-- referenced tModels -->
  <promote:referencedTModels>
  </promote:referencedTModels>

</promote:uddiEntities>
```

UDDI Utility Tools at a command prompt

You can start UDDI Utility Tools at a command prompt. In some situations, there are prerequisites before you run the command.

Ensure that you are using the correct level of Java code by setting the PATH statement to include the Java code that is supplied with WebSphere Application Server. For example, from the command line, type:

Use one of the following approaches to start UDDI Utility Tools:

- Enter the following command and use a specified properties file that sets up class path and other parameters:

```
java - jar UDDIUtilityTools.jar {function} [options]
```

Note: Before you run UDDIUtilityTools.jar from the command line, ensure that you edit the UDDIUtilityTools.properties file. If you save this properties file in a different directory from the UDDIUtilityTools.jar file, specify the location of the properties file as part of the command line arguments.

- Enter the following command, where CommandLineProcessor is the class that processes command line arguments for UDDI Utility Tools, sets up the configuration and invokes the appropriate function:

```
java CommandLineProcessor
```

Usage of UDDIUtilityTools.jar:

```
java -jar UDDIUtilityTools.jar {function} [options]
```

Functions:

```
  -promote <entity source>   Promote entities between registries
  -export <entity source>    Extract entities from a registry to XML
  -delete <entity source>    Delete entities from a registry
  -import                    Create entities from XML to a registry

where <entity source> is one of:
  -tmodel|-business|-service|-binding <key> Specify a single entity type and key
  -keysFile | -f <filename>  Specify a file that contains entity types and keys
```

Options:

```
  -properties <filename>     Specify the path to a configuration file
  -overwrite | -o            Overwrite an entity if it already exists
  -log | -v                  Output verbose messages
  -definitionFile <filename> Specify the path to a UDDI entity definition file
  -importReferenced          Import entities that are referenced by source entities
```

The following command-line options override property settings in the configuration file:

- overwrite
- log
- definitionFile
- importReferenced

Examples

```
java -jar UDDIUtilityTools.jar -promote -keysFile /uddikeys.txt
```

Export a single business to the entity definition file that is specified in a properties file in the current directory.

```
java -jar UDDIUtilityTools.jar -export
-business 28B8B928-2B2E-4EC9-A647-1E40651E4752
```

Export a single business to the entity definition file that is specified in a properties file in the current directory and use a keys file to specify the entities to export.

```
java -jar UDDIUtilityTools.jar -export -keysFile /myKeyFiles/keyFile01.txt
```

Export a single business to the entity definition file that is specified in a properties file in the current directory and use a keys file to specify the entities to export. Also, display verbose output on the command line.

```
java -jar UDDIUtilityTools.jar -export -keysFile /myKeyFiles/keyFile02.txt -v
```

Import the contents of the default entity definition file that is specified in a UDDIUtilityTools.properties file in the current directory.

```
java -jar UDDIUtilityTools.jar -import
```

Import the contents of the default entity definition file that is specified in a UDDIUtilityTools.properties file in the current directory and import referenced tModel entities into the target registry.

```
java -jar UDDIUtilityTools.jar -import -importReferenced
```

Import the entities from an entity definition file at the specified location.

```
java -jar UDDIUtilityTools.jar -import -definitionFile /myEDFs/entities01.xml
```

Import the entities from the default entity definition file including referenced tModel entities. The overwrite options specifies that any entities, excluding referenced tModel entities that are found in the target registry, are overwritten.

```
java -jar UDDIUtilityTools.jar -import -overwrite -importReferenced
```

Promote a single service from a source to a target registry using the properties file at a specified location.

```
java -jar UDDIUtilityTools.jar -promote
-service 67961D67-330F-4F14-8210-E74A58E710F3
-properties /UUT/myUUTProps.properties
```

Promote a set of entities that is specified in a keys file.

```
java -jar UDDIUtilityTools.jar -promote -keysFile /myKeyFiles/keyFile03.txt
```

Promote a set of entities that is specified in a keys file and overwrite existing entities in the target registry.

```
java -jar UDDIUtilityTools.jar -promote -keysFile /myKeyFiles/keyFile04.txt
-overwrite
```

Promote a set of entities that is specified in a keys file, including referenced tModel entities.

```
java -jar UDDIUtilityTools.jar -promote -keysFile /myKeyFiles/keyFile05.txt
-importReferenced
```

Promote a set of entities that is specified in a keys file, but also create an entity definition file that contains the promoted entities.

```
java -jar UDDIUtilityTools.jar -promote -keysFile /myKeyFiles/keyFile06.txt
-definitionFile /myEDFs/entities02.xml
```

Logically delete a single tModel entity. You cannot physically delete tModel entities.

```
java -jar UDDIUtilityTools.jar -delete
-tModel UUID:1E2B9D1E-E53D-4D36-9D46-6CCC176C466A
```

Delete all the entities that are specified in the keys file. Except for tModel entities, all other entities are physically deleted from the target registry.

```
java -jar UDDIUtilityTools.jar -delete -keysFile /myKeyFiles/keyFile04.txt
```

A keys file example

The following example shows the keys to export, promote, or delete from the target registry:

```
#
# Keys of entities to be exported, promoted from source registry or deleted
# from target registry
#
# Note: keys must be comma separated and on SAME line
# Note: property names are case sensitive. ('tmodels=' are ignored)

businesses=97C77097-AC6C-4CA0-A6C4-452F7045C470,
4975E949-581F-4FCA-AD5F-E08280E05F9F
services=BB3864BB-1578-4833-8179-14391F14791F
bindings=
tModels=273F1727-7BFF-4FB5-A1FD-BA5C45BAFD9C
```

If the importReferenced property is set to `true`, the list of tModel entities in the referencedTModels section is imported to the target registry. If the referencedTModel is new, minimal entities are created. If the referencedTModel already exists, it is never overwritten, regardless of the overwrite property value. This approach prevents commonly referenced tModel entities, such as categorization tModel entities, from being updated unnecessarily.

If you want to update a referencedTModel, you must manually move the referencedTModel definition to the tModel entities section in the entity definition file and set overwrite to `true`.

UDDI Utility Tools log files:

The following examples show the contents of two log files that are produced by running UDDI Utility Tools. The examples include some comments in square brackets and in italics to highlight important points in the log file.

The following file is the messages.log file, which shows successful and unsuccessful operations for export, import, and delete functions:

```

```

Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

The following log file shows a typical trace log file entry for an export:

```
[29/07/04 17:39:57:531 BST] ********** Starting UDDI Utility Tools **********
[eyecatcher and timestamp indicate when tool is run]
[29/07/04 17:39:57:531 BST] > com.ibm.uddi.promoter.PromoterAPI.setUddiEntities()

```

UDDI Utility Tools through the API

UDDI Utility Tools provides a public API to functions to export, import, promote, find, and delete UDDI entities. To invoke these functions, use the PromoterAPI class.

Typically, you use these functions through the PromoterAPI class for the following uses:

- Create a Configuration object and populate it from a Properties object or from a configuration properties file.
- Create a PromoterAPI object, passing the Configuration object in the constructor.
- For keys based functions (export, delete, and promote), set the keys by supplying a UDDIEntityKeys object, the location of the keys file, or, for one entity, by specifying an entity type and a key value.

- Invoke the corresponding method for the function required: exportEntities, promoteEntities(boolean), importEntities, deleteEntities, or extractKeysFromInquiry(FindTModel, FindBusiness, FindService, FindBinding, FindRelatedBusinesses).

The samples for WebSphere Application Server include sample code for UDDI Utility Tools that demonstrates use of the API classes.

Note: The low-level UDDI Utility Tools API classes and methods, such as BusinessStub and ServiceStub, are deprecated in WebSphere Application Server Version 6.0. These APIs are replaced with the high-level PromoterAPI interface in the com.ibm.uddi.promoter package. Refer to the API documentation for details.

Save UDDI Version 3 entities with a supplied key

The following example shows how to save a Version 3 business entity with a defined key. You might do this after you use UDDI Utility Tools to export from a Version 3 registry, because entities from a Version 3 registry are exported as Version 2 entities, so elements such as digital signatures are not present.

```
<?xml version="1.0" encoding="UTF-8"?>
<Envelope xmlns="http://schemas.xmlsoap.org/soap/envelope/">
  <Body>
    <save_business xmlns="urn:uddi-org:api_v3">
      <authInfo>a399c4a3-6387-47cd-a1bd-91f7bb91bdd7</authInfo>
      <businessEntity businessKey="uddi:mycompany-p1.com:computers">
        <name xml:lang="en">WithKey</name>
      </businessEntity>
    </save_business>
  </Body>
</Envelope>
```

UDDI Utility Tools limitations and resolutions

For some limitations with the UDDI Utility Tools, there are actions to resolve each issue.

- You attempt to run UDDI Utility Tools, but you get the following error:

```
java.lang.noClassDefFoundError: com/ibm/uddi/promoter/CommandLineProcessor
```

  - Ensure that you have edited the supplied properties file, `UDDIUtilityTools.properties` and that the file contains appropriate values for your environment. For details of the files that are required on the classpath, and an example properties file, see the topics about UDDI Utility Tools prerequisites and the UDDI Utility Tools configuration file.
  - Ensure that you use the level of Java code that is supplied with WebSphere Application Server.
- PublisherAssertions are not supported and are not promoted.

  To resolve this issue, after you promote the businesses that are related, recreate the publisherAssertion relationship.
- Referenced businesses in service projections are not added automatically to the entity definition file in the same manner as referenced tModel entities.

  To resolve this issue, add the referenced business that owns the projected service to the entity definition file. If the business is not present in the target registry, place it before the owning business of the service in the entity definition file.
- Cycle detection for service projections are not detected in the same manner as for referenced tModel entities.

  To resolve this issue, if a circular reference is present between two or more service projections, break the cycle by removing one of the projections temporarily, perform the import, and update the changed entity to establish the cycle again in the target registry.
- The tModel entities that are deleted, in the logical sense, in the source registry are imported and promoted as undeleted in the target registry. This is because, in the UDDI Version 2 specification, the deleted state of tModel entities is not exposed as API calls.

  To resolve this issue, after importing the tModel entity, perform a delete, using the UDDI Utility Tools delete function, or any other UDDI registry API access method.

- BindingTemplates that are referenced by hostingRedirectors are not added automatically to the entity definition file in the same manner as referenced tModel entities.

  To resolve this issue, add the referenced bindingTemplate to the entity definition file.
- Businesses that are referenced by an owningBusiness keyedReference are not added automatically to the entity definition file.

  To resolve this issue, import the referenced business into the target registry before importing the tModel that references it.
- With an embedded Apache Derby database, the import and promote functions are not supported when referencing a target registry.

  To resolve this issue, make the embedded Apache Derby database network-enabled. For information about configuring network Apache Derby, refer to the section about managing the Derby Network Server in the Derby Server and Administration Guide.

  The export and delete functions when referencing a source registry with an embedded Apache Derby database are supported.
- Some combinations of command-line arguments are not validated and prevented. For example, it is possible to specify `-import` with `-keysFile` *`path_to_file`* in the same command, although the `-keysFile` option is ignored.

Chapter 40. Administering Work area

This page provides a starting point for finding information about work areas, a WebSphere extension for improving developer productivity.

Work areas provide a capability much like that of global variables. They enable efficient sharing of information across a distributed application.

For example, you might want to add profile information as each customer enters your application. By placing this information in a work area, it is available throughout your application, eliminating the need to hand-code a solution or to read and write information to a database.

Managing the UserWorkArea partition

Managing the UserWorkArea partition

Before you begin

For an application to take advantage of work areas, the work area service must be enabled for both clients and servers. On a server the service is disabled by default. On the client, the service is enabled by default.

For an application to take advantage of the default partition, the UserWorkArea partition, this partition must be enabled by enabling the work area service for both clients and servers. The work area service on a server is disabled by default and the work area service on a client is enabled by default. Note that rather than using this default work area partition, a user can create their own work area partition using the Work area partition service.

About this task

Applications can set maximum sizes on each work area that is sent or received. By default, the maximum size of a work area that is sent by a client and received, then possibly resent, by a server is 32,768 bytes. The maximum size that you can specify is determined by the maximum value expressible in the Java Integer data type, 2,147,483,647. The smallest maximum size that you can specify is 1. Using a maximum size of 1 byte effectively means that no requests associated with the work area can leave the system or enter another system. A value of 0 means that no limit is imposed. A value of -1 means that the default value is to be honored. The default value is also used if an invalid value or a malformed property is specified. You can change this size as described in this topic.

Procedure

1. Enable or disable the use of the UserWorkArea partition on a server: The work area service is disabled by default on servers but enabled by default on the client
   a. Start the administrative console.
   b. Select **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **Business Process Services** > **Work area service**.
   c. Select or clear the **Startup** check box. This specifies whether or not the server should automatically start the work area service when the server starts.
   d. Save the new configuration and restart the server to apply the new configuration.
2. Enable (or disable) the UserWorkArea partition on a client: Set the com.ibm.websphere.workarea.enabled property to TRUE or FALSE before starting the client. For example, to disable the work area service, when invoking the launchClient script found in the *app_server_root*/`bin` directory, add the following system property to the launchClient invocation:

   ```
   -CCDcom.ibm.websphere.workarea.enabled=false
   ```

Alternatively, this property can be set in a property file that is used by the launchClient script. Refer to the Running a Java EE client application with launchClient article for additional information.

3. Manage the size of the work areas that this server can send and the number of work areas that this server can accept.
   a. Start the administrative console.
   b. Select **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **Business Process Services** > **Web container**.
      - To change the send size or receive size on the work area service (namely the "UserWorkArea" partition):
        – Select **Work area service**.
      - To change the send size or receive size on a user defined partition:
        – Select **Work area partition service**.
        – Select a partition.
   c. Enter a new value in the **Maximum send size** field to modify the size of the work area that this server can send, or enter a new value in the **Maximum receive size** field to modify the size of the work area that this server can accept.
   d. Save the new configuration and restart the server to apply the new configuration.
4. Change the size of the work area that can be sent by a client. This step only applies to the UserWorkArea partition on the client. To set the maximum send or receive size on a user defined partition, you must set these values when creating the partition on the client. For more information on creating a partition on a client, see the client section in the Configuring work area partitions topic. To change the size of the work area that can be sent by a client, set the com.ibm.websphere.workarea.maxSendSize property to the desired number of bytes before starting the client. You can set the maximum send size as follows:
   - Set the maximum send size when invoking the launchClient invocation script found in the `$WAS_HOME/bin` directory. For example, to set the maximum size to 10,000 bytes, add the following system properties to the launchClient invocation as needed:
     `-CCDcom.ibm.websphere.workarea.maxSendSize=10000`
   - Set the maximum send size propery, com.ibm.websphere.workarea.maxSendSize, in a property file that is used by the launchClient script. Refer to the Running a Java EE client application with launchClient article for additional information.

   Because the UserWorkArea partition is defined as unidirectional, for example, context only propagates on outbound calls and not on the return of those calls, the maximum receive size is ignored.

Accessing the UserWorkArea partition

About this task

The work area service provides a JNDI binding to an implementation of the UserWorkArea interface under the name `java:comp/websphere/UserWorkArea`. This is the default work area partition, namly the "UserWorkArea" partition. It is created and bound into JNDI naming automatically, as long as it is enabled as defined in Enabling the work area service (UserWorkArea partition). Applications that need to access UserWorkArea partition can perform a lookup on that JNDI name, as shown in the following code example:

Example

```
import com.ibm.websphere.workarea.*;
import javax.naming.*;

public class SimpleSampleServlet {
  ...

  InitialContext jndi = null;
  UserWorkArea userWorkArea = null;
  try {
```

```
    jndi = new InitialContext();
    userWorkArea = (UserWorkArea)jndi.lookup(
       "java:comp/websphere/UserWorkArea");
  }
  catch (NamingException e) { ... }
}
```

Rather than using this default work area partition, a user has the option to create their own work area partition using the Work area partition service.

What to do next

The next step is to use the begin method to create a new work area and associate it with the calling thread, as described in the Beginning a new work area article.

Managing local work with a work area

Managing local work with a work area

Before you begin

Be sure that your client has a reference to the UserWorkArea interface, as described in the Accessing the UserWorkArea partition topic, or a reference to a user defined partition, as defined in the Accessing a user defined work area partition topic. The following steps use the UserWorkArea partition as an illustration. However a user defined partition can be used in the exact same way.

About this task

In a business application that uses work areas, server objects typically retrieve the work area properties and use them to guide local work.

Procedure

1. Retrieve the name of the active work area to determine whether the calling thread is associated with a work area.

   Applications use the getName method on the UserWorkArea interface to retrieve the name of the current work area. If the thread is not associated with a work area, the getName method returns null. In the following code example, the name of the work area corresponds to the name of the class in which the work area was begun.

   ```
   public class SimpleSampleBeanImpl implements SessionBean {

       ...

       public String [] test() {
          // Get the work-area reference from JNDI.
          ...

          // Retrieve the name of the work area. In this example,
          // the name is used to identify the class in which the
          // work area was begun.
          String invoker = userWorkArea.getName();
          ...
       }
   }
   ```

2. Overriding work area properties. Server objects can override client work area properties by creating their own, nested work area. Refer to the Overriding work area properties article for more information.
3. Retrieve properties from a work area by using the get method.

   The get method is intentionally lightweight; there are no declared exceptions to handle. If there is no active work area, or if there is no such property set in the current work area, the get method returns null.

Important: The get method can raise a NotSerializableError in the relatively rare scenario in which CORBA clients set composed data types and invoke enterprise-bean interfaces.

The following example shows the retrieval of the site-identifier and priority properties by the SimpleSampleBean. Notice that one property was set into an outer work area by the client and the other property was set into the nested work area by the server-side bean; the nesting is transparent to the retrieval of the properties.

```
public class SimpleSampleBeanImpl implements SessionBean {

    public String [] test() {
      ...

      // Begin a nested work area.
      userWorkArea.begin("SimpleSampleBean");
      try {
        userWorkArea.set("company",
                         SimpleSampleCompany.London_Development);
      }
      catch (NotOriginator e) {
      }

      SimpleSampleCompany company =
         (SimpleSampleCompany) userWorkArea.get("company");
      SimpleSamplePriority priority =
         (SimpleSamplePriority) userWorkArea.get("priority");
       ...
   }
}
```

4. Optional: Retrieve a list of all the keys visible from a work area.

   The UserWorkArea interface provides the retrieveAllKeys method for retrieving a list of all the keys visible from a work area. This method takes no arguments and returns an array of strings. The retrieveAllKeys method returns null if there is no work area associated with the thread. If there is an associated work area that does not contain any properties, the method returns an array of size 0.

5. Query the mode of a work area property using the getMode method.

   The UserWorkArea interface provides the getMode method determine the mode of a specific property. This method takes the property's key as an argument and returns the mode as a PropertyModeType object. If the specified key does not exist in the work area, the method returns PropertyModeType.normal, indicating that the property can be set and removed without error.

6. Optional: Delete a work area property.

   The UserWorkArea interface provides the remove method to delete a property from the current scope of a work area. If the property was initially set in the current scope, removing it deletes the property. If the property was initially set in an enclosing work area, removing it deletes the property until the current scope is completed. When the current work area is completed, the deleted property is restored.

   The remove method takes the property's key as an argument. Only properties with the modes normal and read-only can be removed. Attempting to remove a fixed property creates the PropertyFixed exception. Attempting to remove properties in work areas that originated in other processes creates the NotOriginator exception.

Example

The server side of the SimpleSample application example, which is included in the Developing applications that use work areas topic, accepts remote invocations from clients. With each remote call, the server also gets a work area from the client if the client has created one. The work area is propagated transparently. None of the remote methods includes the work area on its argument list.

In the example application, the server objects use the work area interface for demonstration purposes only. For example, the SimpleSampleBean intentionally attempts to write directly to an imported work area, which creates the NotOriginator exception. Likewise, the bean intentionally attempts to mask the read only

SimpleSampleCompany, which triggers the PropertyReadOnly exception. The SimpleSampleBean also nests a work area and successfully overrides the priority property before invoking the SimpleSampleBackendBean. A true business application would extract the work area properties and use them to guide the local work. The SimpleSampleBean mimics this by writing a message that function is denied when a request emanates from a sales environment.

Work area service settings

Use this page to manage the work area service.

The work area service manages the scope and implicit propagation of application context. The work area service panel in the administrative console configures the UserWorkArea partition only and has no effect on the work area partition service panel.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **Business Process Services** > **Work area service**.

For additional information about work area, see the com.ibm.websphere.workarea package in the Application Programming Interfaces (API) documentation. The generated API documentation is available in the information center table of contents from the path **Reference** > **>Programming interfaces** > **APIs - Application Programming Interfaces**.

Enable service at server startup:

Specifies whether the server attempts to start the work area service.

Selected
When the application server starts, it attempts to start the work area service automatically.

Cleared
The server does not try to start the work area service. If work areas are used on this application server, the system administrator must start the service manually or select this property and then restart the server.

Maximum send size:

Specifies the maximum size of data that can be sent within a single work area.

Data type	Integer
Units	Bytes
Default	10000
Range	-1, 0 (no limit) and 1 to 2147483647

The following values are also used to define the maximum send size.

-1	Default.
0	No limit.

Maximum receive size:

Specifies the maximum size of data that a single work area can receive.

Data type	Integer
Units	Bytes
Default	10000
Range	-1, 0 (no limit) and 1 to 2147483647

The following values are also used to define the maximum receive size.

-1	Default.
0	No limit.

Enable Web service propagation:

Specifies whether the work area is propagated on Web service requests. This option is disabled by default.

Overriding work area properties

About this task

Work areas are inherently associated with the process that creates them. In the sample application, the client begins a work area and sets into it the site-identifier and priority properties. This work area is propagated to the server when the client makes a remote invocation.

Applications nest work areas in order to temporarily override properties imported from a client process. The nesting mechanism is automatic; invoking begin on the UserWorkArea interface from within the scope of an existing work area creates a nested work area that inherits the properties from the enclosing work area. Properties set into the nested work area are strictly associated with the process in which the work area was begun; the nested work area must be completed within the process that created them. If a work area is not completed by the creating process, the work-area facility terminates the work area when the process exits. After a nested work area is completed, the original view of the enclosing work area is restored. However, the view of the complete set of work areas associated with a thread cannot be decomposed by downstream processes.

Applications set properties into a work area using property modes in ensure that a particular property is fixed (not removable) or read-only (not overrideable) within the scope of the given work area.

Example

In the following code example, the server-side sample bean attempts to write directly to the imported work area; because the UserWorkArea partition is not defined to be bidirectional, this action is not permitted, and the NotOriginator exception is thrown. When the UserWorkArea partition is not defined as bidirectional, the sample bean must begin its own work area in order to override any imported properties, as shown in the second code example. If a work area in a user defined partition is used and is defined as bidirectional, this bean can set context into the work area before beginning another work area. This context set in the bidirectional case propagates back to the caller. Refer to the Work area partition service article for additional information.

```
public class SimpleSampleBeanImpl implements SessionBean {

   public String [] test() {
     ...
     String invoker = userWorkArea.getName();

     try {
       userWorkArea.set("key", "value");
     }
     catch (NotOriginator e) {
     }
     ...
  }
}
```

The following code example demonstrates beginning a nested work area, using the name of the creating class to identify the nested work area.

```
public class SimpleSampleBeanImpl implements SessionBean {

   public String [] test() {
      ...
      String invoker = userWorkArea.getName();
      try {
        userWorkArea.set("key", "value");
      }
      catch (NotOriginator e) {
      }

      // Begin a nested work area. By using the name of the creating
      // class as the name of the work area, we can avoid having
      // to explicitly set the name of the creating class in
      // the work area.
      userWorkArea.begin("SimpleSampleBean");

      ...
   }
}
```

In the example application, the client sets the site-identifier property as read-only; that guarantees that the request is always associated with the client's company identity. A server cannot override that value in a nested work area. In the following code example, the SimpleSampleBean attempts to change the value of the site-identifier property in the nested work area it created.

```
public class SimpleSampleBeanImpl implements SessionBean {

  public String [] test() {
      ...

      String invoker = userWorkArea.getName();
      try {
        userWorkArea.set("key", "value");
      }
      catch (NotOriginator e) {
      }

      // Begin a nested work area.
      userWorkArea.begin("SimpleSampleBean");

      try {
        userWorkArea.set("company",
                         SimpleSampleCompany.London_Development);
      }
      catch (NotOriginator e) {
      }
      ...
  }
}
```

retrieveAllKeys method

About this task

The UserWorkArea interface provides the retrieveAllKeys method for retrieving a list of all the keys visible from a work area. This method takes no arguments and returns an array of strings. The retrieveAllKeys method returns null if there is no work area associated with the thread. If there is an associated work area that does not contain any properties, the method returns an array of size 0.

For additional information about work area, see the com.ibm.websphere.workarea package in the API documentation. The generated API documentation is available in the information center table of contents from the path **Reference** > **APIs - Application Programming Interfaces**.

Managing local work with a work area

Managing local work with a work area

Before you begin

Be sure that your client has a reference to the UserWorkArea interface, as described in the Accessing the UserWorkArea partition topic, or a reference to a user defined partition, as defined in the Accessing a user defined work area partition topic. The following steps use the UserWorkArea partition as an illustration. However a user defined partition can be used in the exact same way.

About this task

In a business application that uses work areas, server objects typically retrieve the work area properties and use them to guide local work.

Procedure

1. Retrieve the name of the active work area to determine whether the calling thread is associated with a work area.

   Applications use the getName method on the UserWorkArea interface to retrieve the name of the current work area. If the thread is not associated with a work area, the getName method returns null. In the following code example, the name of the work area corresponds to the name of the class in which the work area was begun.

   ```
   public class SimpleSampleBeanImpl implements SessionBean {

       ...

       public String [] test() {
          // Get the work-area reference from JNDI.
          ...

          // Retrieve the name of the work area. In this example,
          // the name is used to identify the class in which the
          // work area was begun.
          String invoker = userWorkArea.getName();
          ...
      }
   }
   ```

2. Overriding work area properties. Server objects can override client work area properties by creating their own, nested work area. Refer to the Overriding work area properties article for more information.
3. Retrieve properties from a work area by using the get method.

   The get method is intentionally lightweight; there are no declared exceptions to handle. If there is no active work area, or if there is no such property set in the current work area, the get method returns null.

   Important: The get method can raise a NotSerializableError in the relatively rare scenario in which CORBA clients set composed data types and invoke enterprise-bean interfaces.

   The following example shows the retrieval of the site-identifier and priority properties by the SimpleSampleBean. Notice that one property was set into an outer work area by the client and the other property was set into the nested work area by the server-side bean; the nesting is transparent to the retrieval of the properties.

   ```
   public class SimpleSampleBeanImpl implements SessionBean {

       public String [] test() {
         ...

         // Begin a nested work area.
   ```

```
        userWorkArea.begin("SimpleSampleBean");
        try {
          userWorkArea.set("company",
                           SimpleSampleCompany.London_Development);
        }
        catch (NotOriginator e) {
        }

        SimpleSampleCompany company =
           (SimpleSampleCompany) userWorkArea.get("company");
        SimpleSamplePriority priority =
           (SimpleSamplePriority) userWorkArea.get("priority");
         ...
    }
}
```

4. Optional: Retrieve a list of all the keys visible from a work area.

   The UserWorkArea interface provides the retrieveAllKeys method for retrieving a list of all the keys visible from a work area. This method takes no arguments and returns an array of strings. The retrieveAllKeys method returns null if there is no work area associated with the thread. If there is an associated work area that does not contain any properties, the method returns an array of size 0.

5. Query the mode of a work area property using the getMode method.

   The UserWorkArea interface provides the getMode method determine the mode of a specific property. This method takes the property's key as an argument and returns the mode as a PropertyModeType object. If the specified key does not exist in the work area, the method returns PropertyModeType.normal, indicating that the property can be set and removed without error.

6. Optional: Delete a work area property.

   The UserWorkArea interface provides the remove method to delete a property from the current scope of a work area. If the property was initially set in the current scope, removing it deletes the property. If the property was initially set in an enclosing work area, removing it deletes the property until the current scope is completed. When the current work area is completed, the deleted property is restored.

   The remove method takes the property's key as an argument. Only properties with the modes normal and read-only can be removed. Attempting to remove a fixed property creates the PropertyFixed exception. Attempting to remove properties in work areas that originated in other processes creates the NotOriginator exception.

Example

The server side of the SimpleSample application example, which is included in the Developing applications that use work areas topic, accepts remote invocations from clients. With each remote call, the server also gets a work area from the client if the client has created one. The work area is propagated transparently. None of the remote methods includes the work area on its argument list.

In the example application, the server objects use the work area interface for demonstration purposes only. For example, the SimpleSampleBean intentionally attempts to write directly to an imported work area, which creates the NotOriginator exception. Likewise, the bean intentionally attempts to mask the read only SimpleSampleCompany, which triggers the PropertyReadOnly exception. The SimpleSampleBean also nests a work area and successfully overrides the priority property before invoking the SimpleSampleBackendBean. A true business application would extract the work area properties and use them to guide the local work. The SimpleSampleBean mimics this by writing a message that function is denied when a request emanates from a sales environment.

Work area service settings

Use this page to manage the work area service.

The work area service manages the scope and implicit propagation of application context. The work area service panel in the administrative console configures the UserWorkArea partition only and has no effect on the work area partition service panel.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **Business Process Services** > **Work area service**.

For additional information about work area, see the com.ibm.websphere.workarea package in the Application Programming Interfaces (API) documentation. The generated API documentation is available in the information center table of contents from the path **Reference** > **>Programming interfaces** > **APIs - Application Programming Interfaces**.

Enable service at server startup

Specifies whether the server attempts to start the work area service.

Selected
When the application server starts, it attempts to start the work area service automatically.

Cleared
The server does not try to start the work area service. If work areas are used on this application server, the system administrator must start the service manually or select this property and then restart the server.

Maximum send size

Specifies the maximum size of data that can be sent within a single work area.

Data type	Integer
Units	Bytes
Default	10000
Range	-1, 0 (no limit) and 1 to 2147483647

The following values are also used to define the maximum send size.

-1	Default.
0	No limit.

Maximum receive size

Specifies the maximum size of data that a single work area can receive.

Data type	Integer
Units	Bytes
Default	10000
Range	-1, 0 (no limit) and 1 to 2147483647

The following values are also used to define the maximum receive size.

-1	Default.
0	No limit.

Enable Web service propagation

Specifies whether the work area is propagated on Web service requests. This option is disabled by default.

Overriding work area properties

About this task

Work areas are inherently associated with the process that creates them. In the sample application, the client begins a work area and sets into it the site-identifier and priority properties. This work area is propagated to the server when the client makes a remote invocation.

Applications nest work areas in order to temporarily override properties imported from a client process. The nesting mechanism is automatic; invoking begin on the UserWorkArea interface from within the scope of an existing work area creates a nested work area that inherits the properties from the enclosing work area. Properties set into the nested work area are strictly associated with the process in which the work area was begun; the nested work area must be completed within the process that created them. If a work area is not completed by the creating process, the work-area facility terminates the work area when the process exits. After a nested work area is completed, the original view of the enclosing work area is restored. However, the view of the complete set of work areas associated with a thread cannot be decomposed by downstream processes.

Applications set properties into a work area using property modes in ensure that a particular property is fixed (not removable) or read-only (not overrideable) within the scope of the given work area.

Example

In the following code example, the server-side sample bean attempts to write directly to the imported work area; because the UserWorkArea partition is not defined to be bidirectional, this action is not permitted, and the NotOriginator exception is thrown. When the UserWorkArea partition is not defined as bidirectional, the sample bean must begin its own work area in order to override any imported properties, as shown in the second code example. If a work area in a user defined partition is used and is defined as bidirectional, this bean can set context into the work area before beginning another work area. This context set in the bidirectional case propagates back to the caller. Refer to the Work area partition service article for additional information.

```
public class SimpleSampleBeanImpl implements SessionBean {

   public String [] test() {
     ...
     String invoker = userWorkArea.getName();

     try {
       userWorkArea.set("key", "value");
     }
     catch (NotOriginator e) {
     }
     ...
  }
}
```

The following code example demonstrates beginning a nested work area, using the name of the creating class to identify the nested work area.

```
public class SimpleSampleBeanImpl implements SessionBean {

   public String [] test() {
      ...
      String invoker = userWorkArea.getName();
      try {
        userWorkArea.set("key", "value");
      }
      catch (NotOriginator e) {
      }

      // Begin a nested work area. By using the name of the creating
```

```
      // class as the name of the work area, we can avoid having
      // to explicitly set the name of the creating class in
      // the work area.
      userWorkArea.begin("SimpleSampleBean");

      ...
   }
}
```

In the example application, the client sets the site-identifier property as read-only; that guarantees that the request is always associated with the client's company identity. A server cannot override that value in a nested work area. In the following code example, the SimpleSampleBean attempts to change the value of the site-identifier property in the nested work area it created.

```
public class SimpleSampleBeanImpl implements SessionBean {

  public String [] test() {
      ...

      String invoker = userWorkArea.getName();
      try {
        userWorkArea.set("key", "value");
      }
      catch (NotOriginator e) {
      }

      // Begin a nested work area.
      userWorkArea.begin("SimpleSampleBean");

      try {
        userWorkArea.set("company",
                         SimpleSampleCompany.London_Development);
      }
      catch (NotOriginator e) {
      }
      ...
  }
}
```

retrieveAllKeys method

About this task

The UserWorkArea interface provides the retrieveAllKeys method for retrieving a list of all the keys visible from a work area. This method takes no arguments and returns an array of strings. The retrieveAllKeys method returns null if there is no work area associated with the thread. If there is an associated work area that does not contain any properties, the method returns an array of size 0.

For additional information about work area, see the com.ibm.websphere.workarea package in the API documentation. The generated API documentation is available in the information center table of contents from the path **Reference** > **APIs - Application Programming Interfaces**.

Appendix. Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This topic describes the conventions in use for WebSphere Application Server.

Default product locations - IBM i

These file paths are default locations. You can install the product and other components in any directory where you have write access. You can create profiles in any valid directory where you have write access. Multiple installations of WebSphere Application Server products or components require multiple locations.

app_client_root
The default installation root directory for the Application Client for IBM WebSphere Application Server is the `/QIBM/ProdData/WebSphere/AppClient/V8/client` directory.

app_client_user_data_root
The default Application Client for IBM WebSphere Application Server user data root is the `/QIBM/UserData/WebSphere/AppClient/V8/client` directory.

app_client_profile_root
The default Application Client for IBM WebSphere Application Server profile root is the `/QIBM/UserData/WebSphere/AppClient/V8/client/profiles/`*`profile_name`* directory.

app_server_root
The default installation root directory for WebSphere Application Server - Express is the `/QIBM/ProdData/WebSphere/AppServer/V8/Express` directory.

java_home

Table 338. Root directories for supported Java Virtual Machines.

This table shows the root directories for all supported Java Virtual Machines (JVMs).

JVM	Directory
32–bit IBM Technology for Java	`/QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit`
64–bit IBM Technology for Java	`/QOpenSys/QIBM/ProdData/JavaVM/jdk60/64bit`

plugins_profile_root
The default Web Server Plug-ins profile root is the `/QIBM/UserData/WebSphere/Plugins/V8/webserver/profiles/`*profile_name* directory.

plugins_root
The default installation root directory for Web Server Plug-ins is the `/QIBM/ProdData/WebSphere/Plugins/V8/webserver` directory.

plugins_user_data_root
The default Web Server Plug-ins user data root is the `/QIBM/UserData/WebSphere/Plugins/V8/webserver` directory.

product_library
product_lib
This is the product library for the installed product. The product library for each Version 8.0 installation on the system contains the program and service program objects (similar to `.exe`, `.dll`, `.so` objects) for the installed product. The product library name is `QWAS8`*x* (where *x* is A, B, C, and so on). The product library for the first WebSphere Application Server Version 8.0 product installed on the system is `QWAS8A`. The *`app_server_root`*`/properties/product.properties` file contains the value for the product library of the installation, `was.install.library`, and is located under the *`app_server_root`* directory.

profile_root
The default directory for a profile named *profile_name* for WebSphere Application Server - Express is the `/QIBM/UserData/WebSphere/AppServer/V8/Express/profiles/`*`profile_name`* directory.

shared_product_library
The shared product library, which contains all of the objects shared by all installations on the system, is `QWAS8`. This library contains objects such as the product definition, the subsystem description, the job description, and the job queue.

user_data_root
The default user data directory for WebSphere Application Server - Express is the `/QIBM/UserData/WebSphere/AppServer/V8/Express` directory.

The `profiles` and `profileRegistry` subdirectories are created under this directory when you install the product.

web_server_root
The default web server path is /www/*web_server_name*.

Notices

References in this publication to IBM products, programs, or services do not imply that IBM intends to make these available in all countries in which IBM operates. Any reference to an IBM product, program, or service is not intended to state or imply that only IBM's product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any of IBM's intellectual property rights may be used instead of the IBM product, program, or service. Evaluation and verification of operation in conjunction with other products, except those expressly designated by IBM, is the user's responsibility.
