IBM WebSphere Application Server - Express for IBM i, Version 8.0

Administering WebSphere applications

Note

Before using this information, be sure to read the general information under “Notices” on page 3583.

Compilation date: July 25, 2011

Contents

How to send your comments xv

Changes to serve you more quickly xvii

Chapter 1. Administering ActivitySessions 1
Administering applications that use ActivitySessions 1
Enabling or disabling the ActivitySession service 1
Configuring the default ActivitySession timeout for an application server 2
ActivitySession service settings 2

Chapter 2. Administering Application profiling 5
Managing application profiles 5

Chapter 3. Administering Asynchronous beans 7
Administering asynchronous beans 7
Configuring timer managers 7
Configuring work managers 10

Chapter 4. Administering the batch environment 15
Administering the batch environment 15
Job scheduler and grid endpoint considerations 15
Configuring the job scheduler 17
Configuring WebSphere grid endpoints 22
batch jobs and their environment 24
Administrative roles and privileges 33
Administrative console help 33
Custom properties at different scopes 37
Batch administrator examples 40

Chapter 5. Administering Client applications 47
Deploying client applications 47
Deploying applet client code 47
Running an ActiveX client application 48
Deploying and running a Java EE client application 51
Running the IBM Thin Client for Enterprise JavaBeans (EJB) 155
Running Java thin client applications 157
Managing resources for Java EE client applications 160
Updating data source and data source provider configurations with the Application Client Resource Configuration Tool 160
Updating URLs and URL provider configurations for application clients 160
Updating mail session configurations for application clients 161
Updating Java Message Service provider, connection factories, and destination configurations for application clients 161
Updating WebSphere MQ as a Java Message Service provider, and its JMS resource configurations, for application clients 162
Updating resource environment entry and resource environment provider configurations for application clients 162
Removing application client resources 163
clientUpgrade script 164

Chapter 6. Administering Communications Enabled Applications 167
Administering communications enabled applications 167
Configuring services for communications enabled applications 167

Configuring communications enabled applications in a cluster . . . 169

Chapter 7. Administering Data access resources . . . 171
Deploying data access applications . . . 171
Available resources . . . 173
Map data sources for all 1.x CMP beans . . . 173
Map default data sources for modules containing 1.x entity beans . . . 175
Map data sources for all 2.x CMP beans settings . . . 176
Map data sources for all 2.x CMP beans . . . 178
Installing a resource adapter archive . . . 180
Installing resource adapters embedded within applications . . . 181
Install RAR . . . 182
Deploying SQLJ applications . . . 182
Deploying SQLJ applications that use container-managed persistence (CMP) . . . 184
Deploying SQLJ applications that use bean-managed persistence, servlets, or sessions beans 186
Customizing and binding profiles for Structured Query Language in Java (SQLJ) applications 188
Using embedded SQLJ with the DB2 for z/OS Legacy driver . . . 196
Directory conventions . . . 199
Administering data access applications . . . 201
Configuring Java EE Connector connection factories in the administrative console . . . 202
Establishing custom finder SQL dynamic enhancement server-wide . . . 234
Establishing custom finder SQL dynamic enhancement on a set of beans . . . 234
CMP connection factories collection . . . 235
Configuring resource adapters . . . 237
Updating a stand-alone resource adapter archive . . . 243
Mapping resource manager connection factory references to resource factories . . . 247
Managing messages with message endpoints . . . 248
Configuring a JDBC provider and data source . . . 251
Configuring connection validation timeout . . . 335
Resource references . . . 336
Mapping-configuration alias . . . 339
Select a J2C authentication alias . . . 340
Considerations for isolated resource providers . . . 341
Implicitly set client information . . . 341
Enabling client information tracing with the administrative console . . . 343
About Apache Derby . . . 344
Managing resources through JCA lifecycle management operations . . . 345

Chapter 8. Administering Dynamic caching . . . 349
Administering the dynamic cache service . . . 349
Using the dynamic cache service . . . 349
Disabling template-based invalidations during JSP reloads . . . 377
Dynamic cache provider for the JPA 2.0 second level cache . . . 378

Chapter 9. Administering EJB applications . . . 383
Deploying EJB 3.x enterprise beans . . . 383
EJB module settings . . . 383
Directory conventions . . . 383
Deploying EJB modules . . . 385
EJB 3.0 and EJB 3.1 deployment overview . . . 386
EJBDEPLOY relationships – troubleshooting tips . . . 388
Directory conventions . . . 388
Administering entity beans . . . 389
Enterprise beans back up and recovery best practices . . . 389
Managing EJB containers . . . 390
EJB containers . . . 391

EJB container settings . . . 392
EJB container system properties . . . 393
Changing enterprise bean types to initialize at application start time using the administrative console . . . 397
Changing applications to WebSphere "version specific" setRollbackOnly behavior . . . 398
EJB cache settings . . . 400
Container interoperability . . . 400
Configuring a timer service . . . 402
Caching data for a timer service . . . 403
Configuring the timer service using scripting . . . 406
EJB timer service settings . . . 408
Managing message-driven beans . . . 411
Managing messages with message endpoints . . . 412
Managing message listener resources for message-driven beans . . . 414
Administering applications that use the Java Persistence API . . . 431
Configure JPA to work in your environment . . . 431
Configuring OpenJPA caching to improve performance . . . 447

Chapter 10. Administering Internationalization service . . . 451
Task overview: Globalizing applications . . . 451
Globalization . . . 451
Working with locales and character encodings . . . 453
Language versions offered by this product . . . 454
Globalization: Resources for learning . . . 455
Task overview: Internationalizing interface strings (localizable-text API) . . . 455
Identifying localizable text . . . 456
Creating message catalogs . . . 456
Composing language-specific strings . . . 457
Preparing the localizable-text package for deployment . . . 465
Task overview: Internationalizing application components (internationalization service) . . . 467
Internationalization service . . . 468
Assembling internationalized applications . . . 468
Using the internationalization context API . . . 473
Administering the internationalization service . . . 492

Chapter 11. Administering Mail, URLs, and other Java EE resources . . . 499
Configuring mail providers and sessions . . . 499
Mail provider collection . . . 501
Mail provider settings . . . 501
Protocol providers collection . . . 502
Protocol providers settings . . . 502
Mail session collection . . . 502
Mail session configuration settings . . . 503
Administering URLs . . . 505
URL provider collection . . . 505
URL provider settings . . . 506
URL configurations collection . . . 506
URL configuration settings . . . 507
Administering resource environment entries . . . 508
Configuring new resource environment entries to map logical environment resource names to physical names . . . 508

Chapter 12. Administering Messaging resources . . . 515
Managing messaging with the default messaging provider . . . 515
Configuring resources for the default messaging provider . . . 516
Interoperating with a WebSphere MQ network . . . 545

Enabling WebSphere Application Server Version 5.1 JMS usage of messaging resources in later versions of the product . . . 583
Configuring the messaging engine selection process for JMS applications . . . 593
Managing messages and subscriptions for default messaging JMS destinations . . . 595
Using JMS from stand-alone clients to interoperate with service integration resources . . . 596
Using JMS from a third party application server to interoperate with service integration resources 605

Chapter 13. Managing messaging with the WebSphere MQ messaging provider . . . 717
JMS provider settings . . . 717
Scope . . . 718
Name . . . 718
Description . . . 719
Classpath . . . 719
Native library path . . . 719
Update resource adapter . . . 719
External initial context factory . . . 719
External provider URL . . . 720
Disable WebSphere MQ . . . 720
Additional properties . . . 720
Resource adapter properties . . . 721
Connection pool properties . . . 722
Max connections . . . 722
Connection concurrency . . . 722
Reconnection retry count . . . 722
Reconnection retry interval . . . 722
Additional properties . . . 722
Installing WebSphere MQ to interoperate with WebSphere Application Server . . . 722
Configuring the WebSphere MQ messaging provider with native libraries information . . . 723
Maintaining the WebSphere MQ resource adapter . . . 724
Listing JMS resources for the WebSphere MQ messaging provider . . . 727
JMS providers collection . . . 728
Activation specification collection . . . 729
Connection factory collection . . . 730
Queue connection factory collection . . . 731
Topic connection factory collection . . . 732
Queue collection . . . 732
Topic collection . . . 733
Configuring JMS resources for the WebSphere MQ messaging provider . . . 734
Creating an activation specification for the WebSphere MQ messaging provider . . . 736
Configuring an activation specification for the WebSphere MQ messaging provider . . . 738
Migrating a listener port to an activation specification for use with the WebSphere MQ messaging provider . . . 758
Creating a connection factory for the WebSphere MQ messaging provider . . . 759
Configuring a unified connection factory for the WebSphere MQ messaging provider . . . 761
Configuring a queue connection factory for the WebSphere MQ messaging provider . . . 789
Configuring a topic connection factory for the WebSphere MQ messaging provider . . . 813
Configuring a queue for the WebSphere MQ messaging provider . . . 840
Configuring a topic for the WebSphere MQ messaging provider . . . 852
Configuring custom properties for WebSphere MQ messaging provider JMS resources . . . 862
WebSphere MQ messaging provider custom properties . . . 863
Configuring custom properties for WebSphere MQ messaging provider JMS resources . . . 864
Configuring properties for the WebSphere MQ resource adapter . . . 866
Configuring custom properties for the WebSphere MQ resource adapter . . . 867
Disabling WebSphere MQ functionality in WebSphere Application Server . . . 868
WMQAdminCommands command group for the AdminTask object . . . 870
createWMQActivationSpec command . . . 871

deleteWMQActivationSpec command . . . 882
listWMQActivationSpecs command . . . 883
modifyWMQActivationSpec command . . . 884
showWMQActivationSpec command . . . 886
createWMQConnectionFactory command . . . 888
deleteWMQConnectionFactory command . . . 898
listWMQConnectionFactories command . . . 899
modifyWMQConnectionFactory command . . . 900
showWMQConnectionFactory command . . . 902
createWMQTopic command . . . 904
deleteWMQTopic command . . . 908
listWMQTopics command . . . 909
modifyWMQTopic command . . . 910
showWMQTopic command . . . 911
manageWMQ command . . . 913
showWMQ command . . . 916
migrateWMQMLP command . . . 917
createWMQQueue command . . . 919
deleteWMQQueue command . . . 922
listWMQQueues command . . . 923
modifyWMQQueue command . . . 924
showWMQQueue command . . . 926
Mapping of administrative console panel names to command names and WebSphere MQ names 927

Chapter 14. Managing messaging with a third-party or (deprecated) V5 default messaging provider . . . 933
Managing messaging with a third-party JCA 1.5-compliant messaging provider . . . 933
Configuring an activation specification for a third-party JCA resource adapter . . . 934
Configuring an administered object for a third-party JCA resource adapter . . . 938
Managing messaging with a third-party non-JCA messaging provider . . . 941
Defining a third-party non-JCA messaging provider . . . 941
Listing JMS resources for a third-party non-JCA messaging provider . . . 946
Configuring JMS resources for a third-party non-JCA messaging provider . . . 952
Maintaining (deprecated) Version 5 default messaging resources . . . 959
JMS provider settings . . . 959
Listing Version 5 default messaging resources . . . 963
Configuring Version 5 default messaging resources . . . 968

Chapter 15. Managing message-driven beans . . . 993
Managing messages with message endpoints . . . 993
Managing message listener resources for message-driven beans . . . 995
Configuring the message listener service . . . 996
Administering listener ports . . . 1004

Chapter 16. Administering Naming and directory . . . 1015
Configuring namespace bindings . . . 1015
Name space binding collection . . . 1017
Specify binding type settings . . . 1017
String binding settings . . . 1019
EJB binding settings . . . 1020
CORBA object binding settings . . . 1021
Indirect lookup binding settings . . . 1022
Configuring name servers . . . 1023
Name server settings . . . 1023

Chapter 17. Administering Object pools . . . 1025

Using object pools 1025
Object pool managers 1026
Object pool managers collection 1028
Object pool service settings 1030
Object pools: Resources for learning 1031
MBeans for object pool managers and object pools 1031

Chapter 18. Administering Object Request Broker (ORB) 1033
Administering Object Request Brokers 1033
Object Request Broker service settings 1033
Object Request Broker custom properties 1036
Character code set conversion support for the Java Object Request Broker service 1045

Chapter 19. Administering OSGi Applications 1047
Updating bundle versions for an EBA asset 1048
Updating bundle versions for an EBA asset using the editAsset command. 1049
Maintaining an OSGi composition unit 1051
Updating an OSGi composition unit 1052
Adding or removing extensions for an OSGi composition unit 1055
Modifying the configuration of an OSGi composition unit 1063
Checking the bundle download status of an EBA asset. 1076
Checking the update status of an OSGi composition unit 1077
Administering bundle repositories. 1078
Moving bundles from an OSGi application to a bundle repository 1079
Administering bundles in the internal bundle repository. 1080
Administering links to external bundle repositories 1088
Interacting with the OSGi bundle cache 1095
Exporting and importing a deployment manifest file 1097
Exporting a deployment manifest 1097
Importing a deployment manifest 1100
Default messaging provider, JMS resources 1104

Chapter 20. OSGiApplicationCommands: OSGi Applications administrative commands for the AdminTask object 1105
addExternalBundleRepository command 1105
addLocalRepositoryBundle command 1106
addOSGiExtension command 1107
addOSGiExtensions command. 1108
exportDeploymentManifest command 1109
importDeploymentManifest command 1110
listExternalBundleRepositories command 1111
listLocalRepositoryBundles command 1112
listOSGiExtensions command 1113
modifyExternalBundleRepository command 1114
removeExternalBundleRepository command 1115
removeLocalRepositoryBundle command 1115
removeLocalRepositoryBundles command 1117
removeOSGiExtension command 1118
removeOSGiExtensions command 1119
showExternalBundleRepository command. 1120
showLocalRepositoryBundle command. 1121

Chapter 21. Administering Portlet applications 1123
Portlet container settings and custom properties 1123
Portlet container settings 1123
Portlet container custom properties 1123

Portlet and PortletApplication MBeans 1124

Chapter 22. Administering Scheduler service 1127
Installing default scheduler calendars 1127
Scheduler calendars 1127
Installing default scheduler calendars 1128
Example: Using default scheduler calendars 1130
Managing schedulers 1130
Managing schedulers 1130
Scheduler daemon 1130
Example: Stopping and starting scheduler daemons using Java Management Extensions API 1131
Example: Dynamically changing scheduler daemon poll intervals using Java Management Extensions API. 1131
Configuring schedulers 1132
Creating the database for schedulers 1141

Chapter 23. Administering application security 1159
Setting up, enabling and migrating security 1159
Migrating, coexisting, and interoperating – Security considerations 1159
Enabling security 1172
Configuring multiple security domains 1218
Multiple security domains. 1222
Creating new multiple security domains 1238
Deleting multiple security domains 1241
Copying multiple security domains 1241
Configuring inbound trusted realms for multiple security domains 1245
Configure security domains 1245
External realm name 1251
Trust all realms 1251
Security domains collection 1252
Authentication cache settings 1252
Authenticating users 1254
Selecting a registry or repository 1254
Selecting an authentication mechanism 1411
Integrating third-party HTTP reverse proxy servers 1433
Single sign-on for authentication 1437
Implementing single sign-on to minimize web user authentications 1441
Configuring administrative authentication 1515
Java Authentication and Authorization Service 1516
Using the Java Authentication and Authorization Service programming model for web authentication 1519
Performing identity mapping for authorization across servers in different realms 1532
Security attribute propagation 1544
Propagating security attributes among application servers. 1549
Configuring the authentication cache 1560
Configuring Common Secure Interoperability Version 2 (CSIV2) inbound and outbound communication settings 1561
Authentication protocol for EJB security 1593
Using Microsoft Active Directory for authentication 1600
Authorizing access to resources 1614
Authorization technology 1615
Authorizing access to Java EE resources using Tivoli Access Manager 1644
Authorizing access to administrative roles 1679
Fine-grained administrative security 1688
Creating a fine-grained administrative authorization group using the administrative console 1694
Editing a fine-grained administrative authorization group using the administrative console 1696

Fine-grained administrative security in heterogeneous and single-server environments 1699
Securing communications 1700
Secure communications using Secure Sockets Layer (SSL) 1700
Creating a Secure Sockets Layer configuration. 1741
Creating a CA client in SSL 1790
Deleting a CA client in SSL 1791
Viewing or modifying a CA client in SSL 1791
Creating a keystore configuration for a preexisting keystore file. 1792
Creating a self-signed certificate 1801
Creating a certificate authority request 1805
Extracting a signer certificate from a personal certificate 1818
Retrieving signers from a remote SSL port 1822
Adding a signer certificate to a keystore 1824
Adding a signer certificate to the default signers keystore 1826
Exchanging signer certificates 1828
Configuring certificate expiration monitoring 1830
Key management for cryptographic uses 1834
Creating a key set configuration 1835
Creating a key set group configuration 1840
Auditing the security infrastructure 1847
Enabling the security auditing subsystem 1848
Creating security auditing event type filters 1853
Configuring security audit subsystem failure notifications 1861
Configuring the default audit service providers for security auditing 1864
Configuring a third party audit service providers for security auditing 1868
Configuring audit event factories for security auditing 1869
Protecting your security audit data 1872
Using the audit reader 1878

Chapter 24. Administering Service integration 1883
Enabling or disabling service integration notification events 1883
Administering service integration buses 1884
Configuring buses 1884
Operating buses 1941
Managing service integration buses with administrative commands 1943
Administering messaging engines 1943
Configuring messaging engines 1944
Starting a messaging engine 1951
Stopping a messaging engine 1951
Displaying the runtime properties of a messaging engine 1952
Displaying the runtime properties of a service integration bus link 1952
Managing messaging engines with administrative commands 1953
Administering message stores 1953
Administering file stores 1953
Administering data stores 1957
Avoiding message store errors when creating a messaging engine 1968
Avoiding errors when creating a messaging engine with a file store or a data store by using the wsadmin tool 1969
Administering bus destinations. 1970
Configuring bus destinations 1970
Managing bus destinations with administrative commands 1999
Configuring message points. 1999
Managing messages on message points 2001
Administering durable subscriptions 2002
Administering mediations. 2005
Securing mediations 2005

Configuring mediations 2007
Configuring mediation points 2018
Managing mediations with administrative commands 2020
Operating mediations at mediation points 2020
Administering messages on mediation points 2023
Example: Using mediations to trace, monitor and log messages 2024

Chapter 25. Administering Session Initiation Protocol (SIP) applications 2437
Deploying SIP applications 2437
Deploying SIP applications through the console 2437
Deploying SIP applications through scripting 2438
Administering SIP applications 2439
Configuring the SIP container 2439
Configuring SIP application routers 2462
Configuring multihomed hosting 2481
Configuring multiple proxy servers using a load balancer in a multihomed environment 2484

Chapter 26. Administering Startup beans 2487
Using startup beans 2487
Enabling startup beans in the administrative console 2488
Startup beans service settings 2488

Chapter 27. Administering Transactions 2491
Administering the transaction service 2491
Configuring transaction properties for an application server 2491
Managing active and prepared transactions 2505
Managing transaction logging for optimum server availability 2510
Displaying transaction recovery audit messages 2514
Delaying the cancelling of transaction timeout alarms 2515
Removing entries from the transaction partner log 2515

Chapter 28. Administering web applications 2517
Deploying JavaServer Pages and JavaServer Faces files 2517
JSP class loading settings 2517
JavaServer Pages (JSP) runtime reloading settings 2518
JSP and JSF option settings 2523
JSP run time compilation settings 2524
Provide options to compile JavaServer Pages settings 2525
Administering web applications 2527
Modifying the default web container configuration 2527
Configuring JSP engine parameters 2556
Backing up and recovering servlets 2570
Backing up and recovering JavaServer Pages files 2571
Administering RRD applications 2572
Asynchronous request dispatching settings 2573
Asynchronous request dispatching settings 2574
Asynchronous request dispatching settings 2574
Administering RRD applications 2575
Remote request dispatcher 2575
Configuring HTTP sessions 2576
Configuring session management by level 2576
Configuring session tracking 2579
Configuring session tracking for Wireless Application Protocol (WAP) devices 2588
Configuring for database session persistence 2588
Configuring write contents 2593
Configuring write frequency 2594

Chapter 29. Administering web services 2595
Planning to use web services 2595
Deploying web services 2596
Deploying web services applications onto application servers 2596
Using a third-party JAX-WS web services engine 2601
Deploying web services client applications 2603
Making deployed web services applications available to clients 2604
Running an unmanaged web services JAX-RPC client 2618
Running an unmanaged web services JAX-WS client 2619
Testing web services-enabled clients 2621
Administering deployed web services applications 2622
Overview of service and endpoint listeners 2623
Administration of service and endpoint listeners 2624
Viewing service providers at the cell level using the administrative console 2624
Viewing service providers at the application level using the administrative console. 2626
Viewing the detail of a service provider and managing policy sets using the administrative console 2628
Managing policy sets and bindings for service providers at the application level using the administrative console 2634
Viewing WSDL documents for service providers using the administrative console 2640
Viewing service clients at the cell level using the administrative console 2641
Viewing service clients at the application level using the administrative console. 2642
Viewing detail of a service client and managing policy sets using the administrative console 2643
Managing policy sets and bindings for services references using the administrative console 2649
Managing policy sets and bindings for service clients at the application level using the administrative console 2656
Viewing web services deployment descriptors in the administrative console 2662
Configuring the scope of a JAX-RPC web services port 2663
Suppressing the compensation service. 2665
Managing policy sets using the administrative console 2666
Viewing policy sets using the administrative console. 2667
Creating policy sets using the administrative console 2668
Importing policy sets using the administrative console 2675
Modifying policy sets using the administrative console 2678
Deleting policy sets using the administrative console 2679
Defining and managing policy set bindings 2680
Attaching a policy set to a service artifact. 2710
Managing policies in a policy set using the administrative console. 2711
Exporting policy sets using the administrative console 2759
Application policy sets collection 2760
Application policy set settings 2761
Search attached applications collection 2762
Web services policy sets 2763
Overview of migrating policy sets and bindings. 2768

Chapter 30. Administering web services - bus-enabled web services 2771
Enabling web services through the service integration bus 2771
Installing and configuring the SDO repository 2772
Configuring web services for a service integration bus 2777
Administering the bus-enabled web services resources. 2789
Creating a new WS-Security binding 2815
Creating a new WS-Security configuration 2820
Passing SOAP messages with attachments through the service integration bus. 2824

Chapter 31. Administering web services - Invocation framework (WSIF) 2955
Administering WSIF. 2955
Enabling a WSIF client to invoke a web service through JMS 2955

wsif.properties file - Initial contents 2959

Chapter 32. Administering web services - Notification (WS-Notification) 2961
Using WS-Notification for publish and subscribe messaging for web services 2961
Accomplishing common WS-Notification tasks 2962
Configuring WS-Notification resources 2985

Chapter 33. Administering web services - Policy (WS-Policy) 3099
Using WS-Policy to exchange policies in a standard format 3099
Configuring a service provider to share its policy configuration 3099
Configuring the client policy to use a service provider policy 3107
Configuring security for a WS-MetadataExchange request 3115

Chapter 34. Administering web services - Reliable messaging (WS-ReliableMessaging) . . . 3117
Administering reliable web services 3117
Configuring a WS-ReliableMessaging policy set by using the administrative console 3117
Attaching and binding a WS-ReliableMessaging policy set to a web service application by using the administrative console 3122
Configuring endpoints to only support clients that use WS-ReliableMessaging 3125
Providing transactional recoverable messaging through WS-ReliableMessaging. 3126
WS-ReliableMessaging - administrative console panels 3127

Chapter 35. Administering web services - RESTful services 3145
Planning JAX-RS web applications 3145
Planning to use JAX-RS to enable RESTful services 3145
Defining the resources in RESTful applications. 3146
Defining the URI patterns for resources in RESTful applications 3147
Defining resource methods for RESTful applications. 3149
Defining the HTTP headers and response codes for RESTful applications. 3151
Defining media types for resources in RESTful applications 3152
Defining parameters for request representations to resources in RESTful applications 3155
Defining exception mappers for resource exceptions and errors 3158
Deploying JAX-RS web applications. 3159

Chapter 36. Administering web services - Security (WS-Security) 3163
Deploying applications that use SAML 3163
Propagating SAML tokens 3163

How to send your comments

Your feedback is important in helping to provide the most accurate and highest quality information.

- To send comments on articles in the WebSphere Application Server Information Center
  1. Display the article in your Web browser and scroll to the end of the article.
  2. Click on the **Feedback** link at the bottom of the article, and a separate window containing an e-mail form appears.
  3. Fill out the e-mail form as instructed, and click on **Submit feedback** .
- To send comments on PDF books, you can e-mail your comments to: **wasdoc@us.ibm.com** or fax them to 919-254-5250.

  Be sure to include the document name and number, the WebSphere Application Server version you are using, and, if applicable, the specific page, table, or figure number on which you are commenting.

When you send information to IBM, you grant IBM a nonexclusive right to use or distribute the information in any way it believes appropriate without incurring any obligation to you.

Changes to serve you more quickly

Print sections directly from the information center navigation

PDF books are provided as a convenience format for easy printing, reading, and offline use. The information center is the official delivery format for IBM WebSphere Application Server documentation. If you use the PDF books primarily for convenient printing, it is now easier to print various parts of the information center as needed, quickly and directly from the information center navigation tree.

To print a section of the information center navigation:

1. Hover your cursor over an entry in the information center navigation until the **Open Quick Menu** icon is displayed beside the entry.
2. Right-click the icon to display a menu for printing or searching your selected section of the navigation tree.
3. If you select **Print this topic and subtopics** from the menu, the selected section is launched in a separate browser window as one HTML file. The HTML file includes each of the topics in the section, with a table of contents at the top.
4. Print the HTML file.

For performance reasons, the number of topics you can print at one time is limited. You are notified if your selection contains too many topics. If the current limit is too restrictive, use the feedback link to suggest a preferable limit. The feedback link is available at the end of most information center pages.

Under construction!

The Information Development Team for IBM WebSphere Application Server is changing its PDF book delivery strategy to respond better to user needs. The intention is to deliver the content to you in PDF format more frequently. During a temporary transition phase, you might experience broken links. During the transition phase, expect the following link behavior:

- Links to Web addresses beginning with http:// work
- Links that refer to specific page numbers within the same PDF book work
- The remaining links will *not* work. You receive an error message when you click them

Thanks for your patience, in the short term, to facilitate the transition to more frequent PDF book updates.

Chapter 1. Administering ActivitySessions

This page provides a starting point for finding information about ActivitySessions, a WebSphere extension for reducing the complexity of commitment rules and limitations that are associated with one-phase commit resources.

Use ActivitySessions to extend the scope and group multiple local transactions. With this capability, you can commit these transactions based on either deployment criteria or through explicit program logic. More introduction...

Administering applications that use ActivitySessions

You can enable or disable the ActivitySession service, and configure the default ActivitySession timeout for an application server.

About this task

You can specify whether or not the ActivitySession service is started automatically for an application server.

You can configure the default ActivitySession timeout for an application server, after which any started ActivitySessions are completed automatically by the ActivitySession service.

Procedure

- Configure the default ActivitySession timeout for an application server.
- Enable or disable the ActivitySession service.

Enabling or disabling the ActivitySession service

You can specify whether or not the ActivitySession service is started automatically for an application server.

About this task

To specify whether or not the ActivitySession service is started automatically for an application server, you can use the administrative console to configure the ActivitySession **Enable service at server startup** property.

Procedure

1. In the navigation pane of the administrative console, click **Servers** > **Server Types** > **WebSphere application servers**.
2. Click the name of the application server that you want to configure. This displays the properties for the application server in the content pane.
3. Click **[Container Settings] Business Process Services** > **ActivitySession Service** The ActivitySession service properties are displayed.
4. Select or clear the **Enable service at server startup** property as needed:
   Selected
   The ActivitySession service is started when the application server is started. Applications that specify use of ActivitySessions in their deployment descriptors can run on the application server.
   Cleared
   [Default] The ActivitySession service is not started when the application server is started. Applications that specify use of ActivitySessions in their deployment descriptors cannot start on the application server.

Any attempt to start an application that uses ActivitySessions is rejected and a message issued:

```
WACS0043E: Error found starting an application.  application_name specified an
ActivitySession attribute that is not allowed when the ActivitySession service
is not enabled
```

If this happens during server startup, the server continues to start without the application.

5. Click **OK**.
6. Save your changes to the master configuration.
7. To have the changed configuration take effect, stop then restart the application server.

Configuring the default ActivitySession timeout for an application server

Use this task to configure the default ActivitySession timeout for an application server, after which any started ActivitySessions are completed automatically by the ActivitySession service.

About this task

The ActivitySession timeout is used to reset any ActivitySession whose remote client has failed to complete the ActivitySession in a timely fashion. You can configure the initial default timeout separately for each application server, and you can override the timeout programmatically by using the setSessionTimeout method of the UserActivitySession interface. If an ActivitySession that contains a transaction reaches the timeout, the transaction's timeout is accelerated so that it is timed out (and rolled back) immediately before the ActivitySession is reset.

To configure the default ActivitySession timeout for an application server, you can use the administrative console.

Procedure

1. In the navigation pane of the administrative console, click **Servers** > **Server Types** > **WebSphere application servers**.
2. Click the name of the application server that you want to configure. This displays the properties for the application server in the content pane.
3. Click **[Container Settings] Business Process Services** > **ActivitySession Service** The ActivitySession service properties are displayed.
4. Ensure that **Enable service at server startup** is selected. You must enable the service for the timeout to have an effect.
5. In the **Default timeout** field, set the default ActivitySession timeout in seconds.
   - -1 indicates that ActivitySessions never time out
   - 0 indicates that the default timeout, 300 seconds, applies
   - Other values are an integer number of seconds
6. Click **OK**.
7. Save your changes to the master configuration.
8. For the changed configuration take effect, stop then restart the application server.

ActivitySession service settings

Use this page to configure the properties of the ActivitySession service. The ActivitySession service is a unit-of-work service to coordinate one-phase resources or to extend the activation and passivation of an enterprise bean.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > *server_name* > **[Container Settings] Business Process Services** > **ActivitySession service**.

Enable service at server startup

Specifies whether the application server attempts to start the ActivitySession service when the server next starts up.

Default
Cleared

Range

Cleared
The server does not try to start the ActivitySession service. If ActivitySessions are to be used in applications that run on this server, the system administrator must select this property then restart the server.

Selected
When the application server starts, it attempts to start the ActivitySession service automatically.

Default timeout

Specifies the default timeout for an activity session. A server automatically completes an activity session if a remote client has failed to complete the activity session within this time period.

The initial default timeout can be configured separately for each application server, and can be overridden programmatically by the UserActivitySession interface (setSessionTimeout).

Data type
Integer

Units
Seconds

Default
300 (5 minutes)

Range
-1 through 1000000000 seconds

- -1 indicates that ActivitySessions never timeout
- 0 indicates that the default timeout applies
- Other values are an integer number of seconds

Chapter 2. Administering Application profiling

This page provides a starting point for finding information about application profiling, a WebSphere extension for defining strategies to dynamically control concurrency, prefetch, and read-ahead.

Application profiling and access intent provide a flexible method to fine-tune application performance for enterprise beans without impacting source code. Different enterprise beans, and even different methods in one enterprise bean, can have their own intent to access resources. Profiling the components based on their access intent increases performance in the application server run time.

Managing application profiles

Using the administrative console, you can add tasks to or remove tasks from application profiles.

Procedure

1. Start the administrative console.
2. Select **Applications > Enterprise Applications >** *application_name* **> Application Profiles >** *profile_name* **> Tasks**.
3. On the Tasks collection page, you can add new tasks to the profile, delete tasks, edit current task settings, and so on.

   Note that, within the scope of an application, no task can be configured on more than one application profile. In such a situation, your application cannot be restarted until you correct the configuration.
4. Save your configuration.
5. Restart the application in order for your changes to take effect.

Chapter 3. Administering Asynchronous beans

This page provides a starting point for finding information about asynchronous beans.

Asynchronous beans and asynchronous scheduling facilities offer performance enhancements for resource-intensive tasks by enabling single tasks to run as multiple tasks.

Administering asynchronous beans

Configuring timer managers

A timer manager acts as a thread pool for application components that use asynchronous beans. Use the administrative console to configure timer managers. The timer manager service is enabled by default.

Before you begin

If you are not familiar with timer managers, review the conceptual section, Timer managers, in the Asynchronous beans topic.

About this task

You can define multiple timer managers for each cell. Each timer manager is bound to a unique place in Java Naming and Directory Interface (JNDI).

Important: The timer manager service is only supported from within the Enterprise Java Beans (EJB) container or web container. Looking up and using a configured timer manager from a Java Platform, Enterprise Edition (Java EE) application client container is not supported.

Procedure

1. Start the administrative console.
2. Select **Resources > Asynchronous beans > Timer managers**.
3. Specify a **Scope** value and click **New**.
4. Specify the following required properties:
   Scope The scope of the configured resource. This value indicates the location for the configuration file.
   Name The display name for the timer manager.
   JNDI Name
   The Java Naming and Directory Interface (JNDI) name for the timer manager. This name is used by asynchronous beans that must look up the timer manager. Each timer manager must have a unique JNDI name within the cell.
   Number of Timer Threads
   The maximum number of threads that are used for timers.
5. [Optional] Specify a **Description** and a **Category** for the timer manager.
6. [Optional] Select the **Service Names** (Java EE contexts) on which you want this timer manager to be made available. Any asynchronous beans that use this timer manager then inherit the selected Java EE contexts from the component that creates the bean. The list of selected services also is known as the "sticky" context policy for the timer manager. Selecting more services than required might impede performance.
7. [Optional] Select **Custom Properties > New**. Other optional fields include:
   Name lateTimerTime
   Value Number of seconds
   Description
   Specify a description

Type Select java.lang.String

The lateTimerTime custom property is the number of seconds beyond which a late-firing timer causes an informational message to be logged. The informational message is logged once per timer manager. The default value is 5 seconds and a value of 0 disables this property.

8. Save your configuration.

Results

The timer manager is now configured and ready for access by application components that must manage the start of asynchronous code.

Timer manager collection

Use this page to view the configuration properties of timer managers, which enable applications to schedule future timer notifications and to receive timer notification callbacks to application-specified listeners within a Java 2 Platform, Enterprise Edition (J2EE) environment. The timer manager binds to the Java Naming and Directory Interface (JNDI) name space.

A timer manager contains a pool of threads bound into JNDI.

To view this administrative console page, click **Resources** > **Asynchronous beans** > **Timer managers**.

Name:

Specifies the name by which the timer manager is known for administrative purposes.

Data type String

JNDI Name:

Specifies the JNDI name used to look up the timer manager in the name space.

Data type String

Scope:

Specifies the scope of the configured resource. This value indicates the location for the configuration file.

Description:

Specifies a description of this timer manager for administrative purposes.

Data type String

Category:

Specifies a string that can be used to classify or group this timer manager.

Data type String

Timer manager settings:

Use this page to modify timer manager settings. Timer managers enable applications to schedule future timer notifications and to receive timer notification callbacks to application-specified listeners within a Java Platform, Enterprise Edition (Java EE) environment. The timer manager binds to the Java Naming and Directory Interface (JNDI) name space.

A timer manager contains a pool of threads bound into JNDI.

To view this administrative console page, click **Resources** > **Asynchronous beans** > **Timer managers** *timermanager_name*.

Scope:

Specifies the scope of the configured resource. This value indicates the location for the configuration file.

Name:

Specifies the name by which the timer manager is known for administrative purposes.

Data type String

JNDI name:

Specifies the JNDI name used to look up the timer manager in the namespace.

Data type String

Description:

Specifies a description of this timer manager for administrative purposes.

Data type String

Category:

Specifies a string that can be used to classify or group this timer manager.

Data type String

Service names:

Specifies a list of services to make available to this timer manager.

Asynchronous beans can inherit Java EE context information by enabling one or more Java EE service contexts on the timer manager resource in the product administrative console or by setting the serviceNames attribute of the TimerManagerInfo configuration object. When specifying the serviceNames attribute each enabled service should be separated by a semicolon, for example, `security;UserWorkArea;com.ibm.ws.i18n`. When a Java EE service context is enabled, it propagates the context from the scheduling thread to the target thread. If not enabled, the target thread does not inherit the context of the scheduling thread and a default context is applied. Any related Java EE context that is already present on the thread is suspended before any new Java EE context is applied.

The context information of each selected service is propagated to each timer that is created using this timer manager. Selecting services that are not needed can negatively impact performance.

Work area	Use the administrative console or the `UserWorkArea` service name to enable work area partitions. When enabled, the work area context for every work area partition that exists on the scheduling thread is available on the target thread. This feature is optional.
Security	Use the administrative console or the `security` service name to enable the Java Authentication and Authorization Service (JAAS) subject. When this feature and administrative security are enabled, the JAAS subject that is present on the scheduling thread is applied to the target thread. If not enabled, the target thread is run anonymously without a JAAS subject on the thread. This feature is optional.
Internationalization	Use the administrative console or the `com.ibm.ws.i18n` service name to enable the internationalization context information. When the internationalization context and the Internationalization service is enabled, the internationalization context that exists on the scheduling thread is available on the target thread. This feature is optional.

Number of timer threads:

Specifies the maximum number of threads that are used for timers.

Data type	Integer

Configuring work managers

A work manager acts as a thread pool for application components that use asynchronous beans. Use the administrative console to configure work managers.

Before you begin

If you are not familiar with work managers, refer to the Work managers conceptual topic.

About this task

The work manager service is always enabled. In previous versions of the product, the work manager service could be disabled using the administration console or configuration service. The work manager service configuration objects are still present in the configuration service, but the enabled attribute is ignored.

You can define multiple work managers for each cell. Each work manager is bound to a unique place in the Java Naming and Directory Interface (JNDI) namespace.

Important: The work manager service is only supported from within the Enterprise Java Beans (EJB) Container or web container. Looking up and using a configured work manager from a Java Platform, Enterprise Edition (Java EE) application client container is not supported.

Procedure

1. Start the administrative console.
2. Select **Resources > Asynchronous beans > Work managers**.
3. Specify a **Scope** value and click **New**.
4. Specify the required properties for work manager settings.

Scope The scope of the configured resource. This value indicates the location for the configuration file.

Name The display name for the work manager.

JNDI Name

The Java Naming and Directory Interface (JNDI) name for the work manager. This name is used by asynchronous beans that must look up the work manager. Each work manager must have a unique JNDI name within the cell.

Number of Alarm Threads

The maximum number of threads to use for processing alarms. A single thread is used to monitor pending alarms and dispatch them. An additional pool of threads is used for dispatching the threads. All alarm managers on the asynchronous beans associated with this work manager share this set of threads. A single alarm thread pool exists for each work manager, and all of the asynchronous beans associated with the work manager share this pool of threads.

Minimum Number Of Threads

The number of threads to be kept in the thread pool, created as needed.

Maximum Number Of Threads

Note: The maximum number of threads to be created in the thread pool. The maximum number of threads can be exceeded temporarily if the **Growable** check box is selected. These additional threads are discarded when the work on the thread completes.

Thread Priority

The priority to assign to all threads in the thread pool.

Every thread has a priority. Threads with higher priority are run before threads with lower priority. For more information about how thread priorities are used, see the Javadoc for the setPriority method of the java.lang.Thread class in the Java Standard Edition specification.

5. [Optional] Specify a **Description** and a **Category** for the work manager.
6. [Optional] Select the **Service Names** (**Java** EE contexts) on which you want this work manager to be made available. Any asynchronous beans that use this work manager then inherit the selected Java EE contexts from the component that creates the bean. The list of selected services also is known as the "sticky" context policy for the work manager. Selecting more services than are required might impede performance.

   Other optional fields include:

   Work timeout

   Specifies the number of milliseconds to wait before a scheduled work object is released. If a value is not specified, then the timeout is disabled.

   Work request queue size

   Specifies the size of the work request queue. The work request queue is a buffer that holds scheduled work objects and can be a value of 1 or greater. The thread pool pulls work from this queue. If you do not specify a value or the value is 0, the queue size is managed automatically. When the queue size is managed automatically, it is computed as the larger of (*maximum_number_of_threads*) or 20. If this value computes to a zero value, a queue size of 1 is used. Large values can consume significant system resources.

   Work request queue full action

   Specifies the action taken when the thread pool is exhausted, and the work request queue is full. This action starts when you submit non-daemon work to the work manager. If set to FAIL, the work manager API methods creates an exception instead of blocking.
7. [Optional] Select **Custom Properties > New**. Other optional fields include:

   Name lateWorkTime

   Value Number of seconds

   Description

   Specify a description

   Type Select java.lang.String

The lateWorkTime custom property is the number of seconds beyond which late-starting work must cause an informational message to be logged. The informational message is logged once per work manager. The default value is 60 seconds and a value of 0 disables this property.
Name lateAlarmTime
Value Number of seconds
Description
Specify a description
Type Select java.lang.String

The lateAlarmTime custom property is the number of seconds beyond which a late-firing alarm must cause an informational message to be logged. The informational message is logged once per work manager. The default value is 5 secondsand a value of 0 disables this property.

8. Save your configuration.

Results

The work manager is now configured and ready for access by application components that must manage the start of asynchronous code.

Work manager collection

Use this page to view the collection properties of work managers, which contain a pool of threads bound into the Java Naming and Directory Interface.

To view this administrative console page, click **Resources > Asynchronous beans > Work managers**.

Name:

Specifies the name by which the work manager is known for administrative purposes.

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name used to look up the work manager in the namespace.

Data type String

Scope:

Specifies the scope of the configured resource. This value indicates the location for the configuration file.

Description:

Specifies the description of this work manager for administrative purposes.

Category:

Specifies a category name that is used to classify or group this work manager.

Work manager settings:

Use this page to modify work manager settings. Work managers contain a pool of threads that are bound into Java Naming and Directory Interface.

To view this administrative console page, click **Resources > Asynchronous beans > Work managers >** *workmanager_name*.

Scope:

Specifies the scope of the configured resource. This value indicates the location for the configuration file.

Name:

Specifies the name by which the work manager is known for administrative purposes.

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name used to look up the work manager in the namespace.

Description:

Specifies the description of this work manager for administrative purposes.

Category:

Specifies a string that you can use to classify or group this work manager.

Work timeout:

Specifies the number of milliseconds to wait before attempting to release a unit of work. The timeout interval begins when the unit of work starts, rather than when the unit of work is submitted.

Default	0
Range	0 to int.maxvalue

Work request queue size:

Specifies the size of the work request queue.

Note: The work request queue is a buffer that holds scheduled work objects and can be a value of 1 or greater. The thread pool pulls work from this queue. If you do not specify a value or the value is 0, the queue size is managed automatically. When the queue size is managed automatically, it is computed as the larger of (*maximum_number_of_threads*) or 20. Large values can consume significant system resources.

Default 0

Work request queue full action:

Specifies the action taken when the thread pool is exhausted, and the work request queue is full. This action starts when you submit non-daemon work to the work manager.

If set to FAIL, the work manager API methods creates an exception instead of blocking.

Default BLOCK
Range FAIL

Service names:

Specifies a list of services to make available to this work manager.

Asynchronous beans can inherit J2EE context information by enabling one or more J2EE service contexts on the work manager resource in the WebSphere administrative console or by setting the serviceNames attribute of the WorkManagerInfo configuration object. When specifying the serviceNames attribute each enabled service should be separated by a semicolon. For example: `security;UserWorkArea;com.ibm.ws.i18n`. When a J2EE service context is enabled, it propagates the context from the scheduling thread to the target thread. If not enabled, the target thread does not inherit the context of the scheduling thread and a default context is applied. Any related J2EE context that is already present on the thread is suspended before any new J2EE context is applied.

The context information of each selected service is propagated to each work or alarm that is created using this work manager. Selecting services that are not needed can negatively impact performance.

Application profile (deprecated) Use the administrative console or the AppProfileService service name to enable the application profile tasks. Application profile context is not supported and not available for J2EE 1.4 applications. For J2EE 1.3 applications, the application profile context is deprecated and is only available when Application Profile Service 5.x Compatibility Mode is enabled and both the scheduling thread and target thread are J2EE 1.3 applications. When enabled, all application profile tasks that are available on the scheduling thread are available on the target thread. The scheduled work that runs in a J2EE 1.4 application does not get the application profiling task of the scheduling thread. This feature is optional.

Work area Use the administrative console or the UserWorkArea service name to enable work area partitions. When enabled, the work area context for every work area partition that exists on the scheduling thread is available on the target thread. This feature is optional.

Security Use the administrative console or the security service name to enable the Java Authentication and Authorization Service (JAAS) subject. When this feature and administrative security are enabled, the JAAS subject that is present on the scheduling thread is applied to the target thread. If not enabled, the target thread is run anonymously without a JAAS subject on the thread. This feature is optional.

Internationalization Use the administrative console or the `com.ibm.ws.i18n` service name to enable the internationalization context information. When the internationalization context and the Internationalization service is enabled, the internationalization context that exists on the scheduling thread is available on the target thread. This feature is optional.

Thread pool properties:

Specifies the priority of the threads available in this work manager.

Number of alarm threads Specifies the desired maximum number of threads used for alarms.

Minimum number of threads Specifies the minimum number of threads available in this work manager.

Maximum number of threads Specifies the maximum number of threads available in this work manager.

Thread priority Specifies the priority of the threads available in this work manager.

Growable Specifies whether the number of threads in this work manager can be increased.

Chapter 4. Administering the batch environment

You can administer the batch environment using the job scheduler, which is used to submit jobs and determine where to run them, and manage batch jobs using the job management console.

In a batch environment, many applications must complete batch work that is computational and resource intensive. Batch work might take hours or even days to finish. The batch work can use large amounts of memory or processing power while it runs.

Administering the batch environment

You can configure the batch environment and manage batch jobs.

Job scheduler and grid endpoint considerations

Configuring the batch environment includes configuring the job scheduler and grid endpoints. The job scheduler accepts job submissions and determines where to run them. Configurations for the job scheduler includes the selection of the deployment target, datasource JNDI name, database schema name, and endpoint job log location to be configured for the schedule. Batch applications are hosted in grid endpoints.

Batch environment planning for transactional batch applications and compute-intensive applications

When planning your batch environment, consider certain factors that can help you design your environment to best suit your needs.

Before you build your environment, carefully consider the goals that you want to accomplish. For example, you can configure your batch environment in an existing cell or build a new cell. Also, you must decide what relational database to use, the security you need, and what your availability requirements are. The following sections contain information about each of these considerations.

New or existing cell

You can choose to configure your batch environment in an existing WebSphere® Application Server cell or you can build a new cell entirely. Your choice depends on whether you want a new environment isolated from any existing WebSphere Application Server environment, or whether you want to add the capabilities of batch to an existing environment.

On the application server nodes where you want the job scheduler and batch container functions, use the administrative console to activate the functions. No action is necessary on the deployment manager node.

Job types

There are two job types. They are hosted in the WebSphere Application Server environment.

1. Transactional batch

   Runs transactional batch applications that are written in Java and implement a WebSphere Application Server programming model. They are packaged as Enterprise Archive (EAR) files and are deployed to the batch container hosted in an application server or cluster.

   The transactional batch programming model provides a container-managed checkpoint/restart mechanism that enables batch jobs to be restarted from the last checkpoint if interrupted by a planned or unplanned outage.
2. Compute-intensive

Runs compute-intensive applications that are written in Java and implement a WebSphere Application Server programming model. They are packaged as Enterprise Archive (EAR) files and are deployed to the batch container hosted in an application server or cluster.

The compute-intensive programming model provides a lightweight execution model based on the common framework

For all batch environments, you must deploy the job scheduler on a WebSphere Application Server server or cluster. To set up an environment to host transactional batch or compute-intensive job types, you must deploy the batch container to at least one WebSphere Application Server server or cluster. The transactional batch, compute-intensive applications, or both are installed on the same WebSphere Application Server server or cluster.

Relational database

The job scheduler and batch container both require access to a relational database. The relational database used is JDBC connected. Access to the relational database is through the underlying WebSphere Application Server connection management facilities. The relational databases supported are the same as those relational databases supported by WebSphere Application Server, including DB2®, Oracle, and others.

The simple file-based Apache Derby database is automatically configured for you by default so that you can quickly get a functioning environment up and running. However, do not use the Derby database for production use. Moreover, the default Derby database does not support a clustered job scheduler, nor a clustered batch container.

A highly available environment includes both a clustered job scheduler, and one or more clustered batch containers. Clustering requires a network database. Use production grade databases such as DB2for this purpose. Network Derby works also, but lacks the robustness necessary for production purposes. Do not use the network version in production.

Note: Application JPA settings always override the settings on this page.

Security considerations

Security for the batch environment is based on the following techniques:

1. WebSphere authentication for access to job scheduler interfaces. Users defined to the active WebSphere security registry can authenticate and gain access to the Web, command line, and programmatic interfaces of the job scheduler.
2. Role-based security for permission rights to job. Authenticated users must be assigned to the appropriate roles in order to perform actions against jobs. There are two roles:
   - lrsubmitter - Users in the lrsubmitter role can submit and operate on their own jobs, but on no others.
   - lradmin - Users in the lradmin role can submit jobs and operate on their own job or the jobs of anyone else.

   These roles are assigned through the job scheduler configuration page in the administrative console.

High availability considerations

Use clustering for high availability of batch components. Deploy and operate on clusters using the job scheduler and batch container.

Use typical application clustering techniques with the job scheduler to ensure that it is highly available. The job scheduler supports multiple methods of access to its APIs: Web application, command line, web service, and Enterprise JavaBeans (EJB). Ensuring that highly available network access to a clustered job

scheduler depends on which job scheduler API access method. The batch container is made highly available by deploying it to a cluster. The job scheduler automatically recognizes the batch container is clustered and takes advantage of it to ensure a highly available execution environment for the batch jobs that run there.

Configuring the job scheduler

The job scheduler accepts job submissions and determines where to run them. As part of managing jobs, the job scheduler stores job information in an external job database. Configurations for the job scheduler includes the selection of the deployment target, data source JNDI name, database schema name, and endpoint job log location to be configured for the scheduler.

Before you begin

See the topic about creating a non-default job scheduler and grid endpoint database.

About this task

Stand-alone application servers or clusters can host the job scheduler. The first time a server or cluster is selected to host the grid scheduler, an embedded Apache Derby database is automatically created, and configured to serve as the scheduler database if the default data source JNDI name jdbc/lrsched is selected.

The job scheduler can be configured using the administrative console or by scripting. To configure the job scheduler using the scripting language, use the link to the job scheduler configuration administrative tasks provided in the related links at the bottom of this topic. To configure the job scheduler using the administrative console, see the following procedure.

Procedure

1. Choose the environment to host the job scheduler. Use a stand-alone server for test environments. The stand-alone server can use the default Derby database. Use a cluster host for production environments. Although Derby is used as the default job scheduler database, you might want to use your own database. See the topic on creating a job scheduler and grid endpoint database for more information.
2. Log on to the administrative console.
3. Expand **System Administration** > **Job Scheduler**. The job scheduler panel opens.
4. In the **Scheduler hosted by** list, select the deployment target.
5. Type the database schema name. The default is LRSSCHEMA.
6. Select the data source JNDI name from the list. If the default of jdbc/lrsched is selected, the default embedded Derby job scheduler database is created.
7. Type the directory where the job scheduler and the batch execution environment write the job logs. The default is ${GRID_JOBLOG_ROOT}/joblogs.
8. Click **OK** and save the configuration.
9. If administrative security is enabled, enable application security and secure the job scheduler. See the topic on securing the job scheduler for more information. Only authorized users who are granted the lrmonitor, lrsubmitter, and lradmin roles, or a combination of the roles, through the administrative console are allowed access to the job management console.

Creating the job scheduler and grid endpoint database

You can create a database for the job scheduler and grid endpoint if you do not use the default Apache Derby database. The job scheduler stores job information in a relational database while the grid endpoint uses the database to track the progress of a batch job.

Before you begin

When you install the product, one Derby Java Database Connectivity (JDBC) provider is created. The Derby JDBC provider contains two data sources. One is the default Derby data source, JNDI name jdbc/lrsched, that points to the default Derby job scheduler database. The other, JNDI name jdbc/pgc, is the batch execution environment data source. If you decide to use the default data source you do not need to create the job scheduler database. The default Derby database for the job scheduler is created when the job scheduler host (deployment target) is selected through the administrative console. The default Derby database for the endpoint is created when a batch application is first installed on a node. Embedded Derby databases cannot be shared by multiple processes and are unsuitable for environments where the job scheduler must move from one node to another. For example, the job scheduler must move from one node to another in high availability scenarios.

About this task

The product supports Derby, DB2, and Oracle databases. You can use the following steps to configure the job scheduler and grid endpoint database if you decide to use a database other than the Derby database. When you create the database manually, the job scheduler and grid endpoint can use the same database.

Procedure

1. Select the correct file based on the type of database that you are going to use.

   The product provides DDL files except for DB2 on the z/OS® operating system. Use the DDL files to define the job scheduler database in the `<WAS_install_root>/util/Batch` directory. The DDL files for creating the job scheduler database are named `CreateLRSCHEDTablesXxx.ddl` where *Xxx* indicates the type of database manager that the scripts are intended for. These same DDL files are used for the grid endpoint.
2. See the documentation of your database vendor for details on customizing scripts and using the database tools to run it.

What to do next

After creating the database, complete the following steps.

1. Define the XA JDBC provider for the database through the administrative console.

   Consult the JDBC provider documentation for more information about defining a new JDBC provider.
2. Create the data source using the JDBC provider through the administrative console.

   Define the data source at the cell level. Doing so guarantees that the database is available for each application server that hosts the job scheduler.
3. Verify that the database has been created by testing the connection on the data source that you created in the previous step.
4. Configure the job scheduler by selecting the JNDI name of the newly created data source in the job scheduler panel.
5. Specify the JNDI name of the data source that you created in a previous step as the value of the GRID_ENDPOINT_DATASOURCE variable.

Verifying the job scheduler installation

This topic describes how to verify that the job scheduler is installed correctly. The job scheduler is a system application and cannot be seen in the Enterprise Application panel in the administrative console.

Before you begin

Privileges for the job scheduler differ, depending on the various roles. Roles include monitor, operator, configurator, and administrator. If you are a user with either a monitor or an operator role, you can only view the job scheduler information. If you have the role of configurator or administrator, you have all the configuration privileges for the job scheduler.

Procedure

1. Verify that the job scheduler is installed correctly by restarting the application server or cluster members where the job scheduler is configured.

   If the application server or cluster members on which the job scheduler is installed have the started icon in the status field, the job scheduler is usually running. However, the job scheduler might have a problem and not start. You can verify whether the job scheduler started by checking the log files.
2. After the server is restarted, access the job management console through a web browser by typing `http://job_scheduler_server_host:grid_host/jmc`.

   The *grid_host* port is the WC_defaulthost port under the server that you chose for the job scheduler. To find the *grid_host* port, go to your server in the administrative console, expand ports, and look for WC_defaulthost.

   If you cannot access the job management console, check the appropriate log. If you specified a server in the web address, check the server log. If you specified a cluster member in the web address, check the cluster member log.

Securing the job scheduler using roles

You can secure the job scheduler by mapping users and groups to specific security roles.

Before you begin

Users who are assigned the lradmin role have the authority to perform all job scheduler application actions on all jobs regardless of job ownership, while users who are assigned with the lrsubmitter role can only act on jobs that are owned by the submitters themselves.

Note: To start lrcmd.sh | .bat on an HTTPS port, you must configure SSL on the scheduler server. Following the steps in part three of the series, location in the following DeveloperWorks topic, Build Web services with transport-level security using Rational® Application Developer V7, Part 3: Configure HTTPS. In order to access topics, you must be a registered user for DeveloperWorks. If you have not registered as a user for DeveloperWorks, follow the instructions on the IBM® registration page.

About this task

This sample task assumes that the job scheduler is configured. From the administrative console:

Procedure

1. Click **Security > Secure administration, applications, and infrastructure**.
2. Select administrative security and application security.
3. Configure User account repository by specifying one of the available realm definitions.
4. After you have configured WebSphere Application Server Security, click **Apply** to save your configuration.
5. Expand **System administration > Job scheduler > Security role to user/group mapping**.
6. Select the roles to be configured.
7. Click **Look up users** if one or more users are to be assigned the target role, or click **Look up groups** if role assignment is at the group level.
8. Select the user or group to be assigned to the target role.
9. Click **OK** and save the configuration.
10. Restart the cell.

What to do next

With security enabled, provide a valid user ID and password for job actions that are performed through the command- line interface. Submit a job action through the command-line interface with the user name and password information. See the following example:

```
<install_root>/bin/lrcmd.[bat|sh]
-cmd=<name_of_command> <command_arguments> [-host=<host> -port=<port>]
-userid=<user_ID> -password=<password>
```

where:

- `<host>` is the job scheduler server host name. If not specified, the default is `localhost`.
- `<port>` is the scheduler server HTTP (HTTPS) port. If not specified, the default is 80.

See the following example:

```
D:\IBM\WebSphere\AppServer\bin\lrcmd
-cmd=submit -xJCL=D:\IBM\WebSphere\AppServer\samples\Batch\
postingSampleXJCL.xml -port=9445 -host=wasxd01.ibm.com
-userid=mylradmin -password=w2g0u1tf
```

Job scheduler WebSphere variables:

Use WebSphere variables to modify the job scheduler configuration. You can configure the amount of time that the job scheduler waits before signaling a problem with the endpoint and waits between polling the endpoint.

GRID_ENDPOINT_MISSED_HEART_BEAT_TOLERANCE_INTERVAL:

Define this WebSphere variable to configure the amount of time in milliseconds that the job scheduler waits between polls of the endpoint heartbeat before signaling a problem.

Table 1. GRID_ENDPOINT_MISSED_HEART_BEAT_TOLERANCE_INTERVAL. The table includes the scope, valid values, and default for the WebSphere variable.

Scope	Valid values	Default
Cell, job scheduler node, or job scheduler server level	Time in milliseconds	5 minutes

GRID_ENDPOINT_HEART_BEAT_POLL_INTERVAL:

Define this WebSphere variable to configure the amount of time in milliseconds the job scheduler waits between polls of the endpoint heartbeat.

Table 2. GRID_ENDPOINT_HEART_BEAT_POLL_INTERVAL. The table includes the scope, valid values, and default for the WebSphere variable.

Scope	Valid values	Default
Cell, job scheduler node, or job scheduler server level	Time in milliseconds	1 minute

Administrative roles and privileges:

Roles and privileges vary depending on your administrative role and the component.

Administrative roles and privileges

For definitions of administrative roles in WebSphere Application Server and how to assign them, see Authorizing access to administrative roles.

Table 3. Administrative roles and privileges. The table lists each component for the graphical user interface (GUI) and what privileges the component has for the monitor, operator, configurator, and administrator privileges.

GUI	Monitor privileges	Operator privileges	Configurator privileges	Administrator privileges
Job scheduler	View the information.	View the information.	Has all privileges.	Has all privileges.

Running batch jobs under user credentials:

This topic explains how to allow batch jobs to run under credentials of the user when WebSphere security is enabled.

About this task

The RUN_JOBS_UNDER_USER_CREDENTIAL variable allows users to enable or disable batch jobs to run under credentials of the user. When the job is dispatched to the endpoint, the batch container switches the credentials of the server to the credentials of the user. The credentials of the server are in the job step thread.

Note:

RUN_JOBS_UNDER_USER_CREDENTIAL can be created at any scope level and accepts values **true** or **false**. The default is false, which means that batch jobs run under server credentials.

When Java 2 Security is enabled, your batch applications must grant the following two permissions in the WebSphere Application Server.policy file of the application:

- permission com.ibm.websphere.security.WebSphereRuntimePermission "SecOwnCredentials"
- permission com.ibm.websphere.security.WebSphereRuntimePermission "ContextManager.getServerCredential"

The following steps describe how to create the custom property to enable or disable batch jobs to run under the credentials of a user after logging on to the administrative console:

Procedure

1. Click **Environment > WebSphere Variables**
2. Select a configuration scope, then click **New**. The general properties panel opens.
3. Type **RUN_JOBS_UNDER_USER_CREDENTIAL** in the Name field.
4. Type True or False to enable or disable jobs to run under user credential.
5. Click **OK**, then click **Save**.

What to do next

Stop and start the server where the batch execution environment is installed.

Roles and privileges for securing the job scheduler:

This topic describes the lradmin and lrsubmitter roles and privileges for securing the job scheduler.

Authority for different roles

You can secure the job scheduler application by enabling global security and application security. Application security secures the job management console. The job scheduler application uses a

combination of both declarative and instance-based security approaches to secure jobs and commands, where only users who are assigned with the lradmin or lrsubmitter role have the authority to perform grid operations in a security-enabled environment.

As illustrated in the following table, users who are assigned with the lradmin role have the authority to perform all job scheduler application actions on all jobs regardless of job ownership, while users who are assigned with the lrsubmitter role can only act on jobs that are owned by the submitters themselves. The **X** character represents authority in the following table.

Table 4. Authoritative roles. The table lists client commands and indicates with an **X** *character whether the lradmin role or the lrsubmitter role have authority for those commands.*

Client commands	lradmin role	lrsubmitter role
`submit -xJCL=<file>`	**X**	**X**
`submit -job=<job name>`	**X**	**X**
`submit -job=<job name> -add or replace`	**X**	N/A This is an admin command.
`cancel -jobid=<jobid>`	**X**	**X** (only jobs owned)
`purge -jobid=<jobid>`	**X**	**X** (only jobs owned)
`output -jobid=<jobid>`	**X**	**X** (only jobs owned)
`restart -jobid=<jobid>`	**X**	**X** (only jobs owned)
`remove -job=<jobname>`	**X**	N/A This is an admin command.
`suspend -jobid=<jobid>`	**X**	**X** (only jobs owned)
`resume -jobid=<jobid>`	**X**	**X** (only jobs owned)
`status (showAll)`	**X**	N/A This is an admin command.
`status -jobid=<jobid>`	**X**	**X** (only jobs owned)
`getBatchJobRC -jobid=<jobid>`	**X**	**X** (only jobs owned)
`help`	**X**	**X**

Configuring WebSphere grid endpoints

This topic explains how to set up a WebSphere grid endpoint.

Procedure

1. Install a batch application on a server or cluster using the administrative console.
2. If the application is the first batch application installed on the server or cluster, restart the server or cluster.

Results

The WebSphere grid endpoints are automatically set up. By installing the application on the deployment target, the common batch container is automatically deployed on the server or cluster selected using the default Apache Derby data source jdbc/pgc. The default file-based Derby data source can be used only when using the batch function on a stand-alone application server. If you have a WebSphere Application Server Network Deployment environment, you must use a network database.

If you use the default Derby data source, no further action is required. If you use a different data source, complete the following steps to make the data source available to the WebSphere grid endpoints.

1. From the administrative console, go to **Environment > WebSphere Variables**.
2. Select **Cell scope** from the list.

3. Edit the GRID_ENDPOINT_DATASOURCE variable to point to the JNDI lookup name of the job scheduler data source.
4. Save your configuration.
5. Restart all endpoints.

Creating the job scheduler and grid endpoint database

You can create a database for the job scheduler and grid endpoint if you do not use the default Apache Derby database. The job scheduler stores job information in a relational database while the grid endpoint uses the database to track the progress of a batch job.

Before you begin

When you install the product, one Derby Java Database Connectivity (JDBC) provider is created. The Derby JDBC provider contains two data sources. One is the default Derby data source, JNDI name jdbc/lrsched, that points to the default Derby job scheduler database. The other, JNDI name jdbc/pgc, is the batch execution environment data source. If you decide to use the default data source you do not need to create the job scheduler database. The default Derby database for the job scheduler is created when the job scheduler host (deployment target) is selected through the administrative console. The default Derby database for the endpoint is created when a batch application is first installed on a node. Embedded Derby databases cannot be shared by multiple processes and are unsuitable for environments where the job scheduler must move from one node to another. For example, the job scheduler must move from one node to another in high availability scenarios.

About this task

The product supports Derby, DB2, and Oracle databases. You can use the following steps to configure the job scheduler and grid endpoint database if you decide to use a database other than the Derby database. When you create the database manually, the job scheduler and grid endpoint can use the same database.

Procedure

1. Select the correct file based on the type of database that you are going to use.

   The product provides DDL files except for DB2 on the z/OS operating system. Use the DDL files to define the job scheduler database in the `<WAS_install_root>/util/Batch` directory. The DDL files for creating the job scheduler database are named `CreateLRSCHEDTablesXxx.ddl` where *Xxx* indicates the type of database manager that the scripts are intended for. These same DDL files are used for the grid endpoint.
2. See the documentation of your database vendor for details on customizing scripts and using the database tools to run it.

What to do next

After creating the database, complete the following steps.

1. Define the XA JDBC provider for the database through the administrative console.

   Consult the JDBC provider documentation for more information about defining a new JDBC provider.
2. Create the data source using the JDBC provider through the administrative console.

   Define the data source at the cell level. Doing so guarantees that the database is available for each application server that hosts the job scheduler.
3. Verify that the database has been created by testing the connection on the data source that you created in the previous step.
4. Configure the job scheduler by selecting the JNDI name of the newly created data source in the job scheduler panel.
5. Specify the JNDI name of the data source that you created in a previous step as the value of the GRID_ENDPOINT_DATASOURCE variable.

Endpoint WebSphere variables

Use WebSphere variables to modify the endpoint configuration. You can do such things as enable jobs to run under user credentials and configure the schema name of the grid endpoint database.

RUN_JOBS_UNDER_USER_CREDENTIAL:

Define this WebSphere variable so that jobs can run under user credentials.

Table 5. RUN_JOBS_UNDER_USER_CREDENTIAL. The table includes the scope, valid values, and default for the WebSphere variable.

Scope	Valid values	Default
Cell, endpoint node, or endpoint server level	• true Jobs are run under user credentials • false Jobs are run under server credentials	false

GRID_ENDPOINT_HEART_BEAT_INTERVAL:

Define this WebSphere variable to configure the amount of time between heartbeat transmissions from the grid endpoint to the job scheduler.

Table 6. GRID_ENDPOINT_HEART_BEAT_INTERVAL. The table includes the scope, valid values, and default for the WebSphere variable.

Scope	Valid values	Default
Cell, endpoint node, or endpoint server level	Time in milliseconds	30 seconds

GRID_ENDPOINT_DATASOURCE:

Define this WebSphere variable to configure the grid endpoint data source Java Naming and Directory Interface (JNDI) name.

Table 7. GRID_ENDPOINT_DATASOURCE. The table includes the scope, valid values, and default for the WebSphere variable.

Scope	Valid values	Default
Cell, endpoint node, or endpoint server level	Grid endpoint data source JNDI name	jdbc/pgc

batch jobs and their environment

The product provides ways of managing the scheduling and execution control of background activities in a grid computing environment.

The various ways that you can manage your batch environment include using the job management console, analyzing job logs, specifying job classes, and by using classification rules.

Through the job management console, you can:

- Submit jobs
- Monitor job execution
- Perform operational actions against jobs

- View job logs

Job logs

A job log is a file that contains a detailed record of the execution details of a job. It is composed of both system and application messages. Job logs are stored on the endpoints where the job runs and on the application server that hosts the job scheduler.

Job logs are viewable through the job management console and from the command line.

Job management console

The job management console is a stand-alone web interface that you can use to perform job operations such as submit, monitor, schedule, and manage.

The job management console is for managing jobs. This console provides controlled access when security is enabled.

Only authorized users who are granted the lrsubmitter role, the lradmin role, or both roles through the administrative console can be allowed access to the job management console.

Through the job management console, you can:

- Submit jobs.
- Monitor job execution.
- Perform operational actions against jobs.
- View job logs.

To access the job management console:

1. Configure the job scheduler.
2. Ensure that the job scheduler is running.

   If the application server or cluster members on which the job scheduler is installed have the started icon in the status field, the job scheduler is usually running. However, the job scheduler might have a problem and not start. You can verify whether the job scheduler started by checking the log files.
3. In a browser, type the web address: `http://<job scheduler server host>:<port>/jmc`.
4. If an on-demand router (ODR) is defined in the cell, type the web address: `http://<odr host>:80/jmc`.
5. If you cannot access the job management console, check the appropriate log. If you specified a server in the web address, check the server log. If you specified a cluster member in the web address, check the cluster member log.

To access the field help for the job management console, click **?** in the upper right corner of every job management panel.

Command-line interface

The command-line interface interacts with the job scheduler to submit and manipulate a batch job. It is located in the *was_root*/bin directory as the lrcmd.sh or lrcmd.bat script and can be started from any location in the WebSphere cell.

Use the lrcmd script to perform the following commands:

Table 8. lrcmd commands. The table includes arguments, a description, and additional information for the lrcmd command.

Command	Arguments	Description	Additional Information
Display usage information for lrcmd.	None	The command displays usage information for the lrcmd command.	Example: lrcmd

Table 8. lrcmd commands (continued). The table includes arguments, a description, and additional information for the lrcmd command.

Command	Arguments	Description	Additional Information
Submit a job to the job scheduler.	-cmd=submit -xJCL=<xjcl_filename> [-host=<host>] [-port=<port>], or -cmd=submit -job=<job_name> [-startDate=<startDate> - startTime=<startTime>] [-host=<host>] [-port=<port>]	When an XML Job Control Language (xJCL) file is specified, -xJCL=<xjcl_filename> specifies the path of the xJCL to be submitted from the file system and optionally saved. Optional arguments: • Use -host=<host> as the on-demand router (ODR) host name or job scheduler server host name. If not specified, the default is localhost. • Use -port=<port> as the ODR HTTP Proxy address or job scheduler server HTTP port. If not specified, the default is 80. Both variations of the command return a job ID for the submitted job.	Examples: • lrcmd -cmd=submit -xJCL=myxjcl.xml -host=myhost -port=81 • lrcmd -cmd=submit -xJCL=myxjcl.xml • lrcmd -cmd=submit -job=myjob
Cancel a previously submitted job.	-cmd=cancel -jobid=<jobid> [-<host>] [-port=<port>]	This command cancels the start of a previously submitted job, or cancels the execution of a running job. Use -jobid=<jobid> as the job ID assigned to the job by the job scheduler. The job ID is returned by the lrcmd -cmd=submit command that initially submitted the job. The -cmd=status command can also be used to identify the job ID for a particular job. Optional arguments: • Use -host=<host> as the ODR host name or job scheduler server host name. If not specified, the default is localhost. • Use -port=<port> as the ODR HTTP Proxy address or job scheduler server HTTP port. If not specified, the default is 80.	Example: lrcmd -cmd=cancel -jobid=myjob:2 -host=myLRShost -port=9083
Restart a job.	-cmd=restart -jobid=<jobid> [-host=<host>] [-port=<port>]	This command restarts the start of a job. Only jobs in restartable state can be restarted. Use -jobid=<jobid> as the job ID assigned to the job by the job scheduler. The job ID is returned by the lrcmd -cmd=submit command that initially submitted the job. The -cmd=status command can also be used to identify the job ID for a particular job. Optional arguments: • Use -host=<host> as the ODR host name or job scheduler server host name. If not specified, the default is localhost. • Use -port=<port> as the ODR HTTP Proxy address or job scheduler server HTTP port. If not specified, the default is 80.	Only a batch job associated with batch applications can be restarted. When a batch job is canceled using the -cmd=cancel command, its state is changed to restartable. When the job is restarted, processing resumes from the last successfully committed checkpoint. Example: lrcmd -cmd=restart -jobid=myjob:2 -host=myLRShost -port=9081

Table 8. lrcmd commands (continued). The table includes arguments, a description, and additional information for the lrcmd command.

Command	Arguments	Description	Additional Information

Purge job information.	`-cmd=purge`
	`-job=<jobid>`
	`[-host=<host>] [-port=<port>]`
		This command purges job information from the job scheduler and grid endpoints.
		
		The job scheduler maintains information about a job after the job has completed. The purge command permanently deletes job information from the job scheduler and grid endpoint databases. The command also purges the job log of the job.
		
		Use `-jobid=<jobid>` as the job ID assigned to the job by the job scheduler. The job ID is returned by the `lrcmd -cmd=submit` command that initially submitted the job. The -cmd=status command can also be used to identify the job ID for a particular job.
		
		Optional arguments:
		• Use `-host=<host>` as the ODR host name or job scheduler server host name. If not specified, the default is localhost.
		• Use `-port=<port>` as the ODR HTTP Proxy address or job scheduler server HTTP port. If not specified, the default is 80.
			The job scheduler maintains information about a job after the job has completed. The purge command permanently deletes job information from the job scheduler and grid endpoint databases. The command also purges the job log of the job.
			
			Example:
			
			`lrcmd -cmd=purge -jobid=myjob:2`

Show the status of a batch job.	`-cmd=status`
	
	or
	
	`-cmd=status`
	`-jobid=<jobid>`
	`[-host=<host>] [-port=<port>]`
		This command displays status information about one or more jobs in the job scheduler database.
		
		Optional argument: `-job=<jobid>`, if specified, indicates that only job information for the specified job is displayed.
			Examples:
			• `lrcmd -cmd=status host=myODRHost -port=83`
			• `lrcmd -cmd=submit -xJCL=myxjcl.xml` (returns job ID LongRunningScheduler:17)
			• `lrcmd -cmd=status -jobid=LongRunningScheduler:17`

Suspend a job.	`-cmd=suspend`
	`-jobid=<jobid>`
	`-seconds=<seconds>`
	`[-host=<host>] [-port=<port>]`
		This command suspends the start of a grid batch job for the specified number of seconds. Unless manually resumed (with `lrcmd -cmd=resume`, for example), the job automatically resumes running after the specified number of seconds.
		
		Use `-jobid=<jobid>` as the job ID assigned to the job by the job scheduler. The job ID is returned by the lrcmd -cmd=submit command that initially submitted the job. The `-cmd=status` command can also be used to identify the job ID for a particular job.
		
		Optional arguments:
		
		Use `-seconds=<seconds>` to indicate the number of seconds that the job start is suspended. If not specified, the default value of 15 seconds is used. If `-seconds=0` is specified, the job does not start until manually resumed.
		• Use `-host=<host>` as the ODR host name or job scheduler server host name. If not specified, the default is localhost.
		• Use `-port=<port>` as the ODR HTTP Proxy address or job scheduler server HTTP port. If not specified, the default is 80.
			Examples:
			
			`lrcmd -cmd=submit -xJCL=myxjcl.xml` (returns job ID myjob:23). After job myjob:23 has begun execution, it can be suspended for five minutes (for example), with: `lrcmd -cmd=suspend -jobid=myjob:23 -seconds=300 -port=81 -host=myODRHost`
			
			Execution of the job can be resumed before the 5 minutes expires with: `lrcmd -cmd=resume -jobid=myjob:23`

Table 8. lrcmd commands (continued). The table includes arguments, a description, and additional information for the lrcmd command.

Command	Arguments	Description	Additional Information
Resume start of a previously suspended job.	`-cmd=resume -jobid=<jobid> [-host=<host>] [-port=<port>]`	This command resumes start of a previously suspended batch job. Use `-jobid=<jobid>` as the job ID assigned to the job by the job scheduler. The job ID is returned by the lrcmd -cmd=submit command that initially submitted the job. The -cmd=status command can also be used to identify the job ID for a particular job.	See description of -cmd=suspend.
Display the output for a job.	`-cmd=output -jobid=<jobid> [-host=<host>] [-port=<port>]`	Displays the output generated by the job scheduler and grid endpoint during the execution of the specified job. Use `-jobid=<jobid>` as the ID assigned to the job by the job scheduler. The job ID is returned by the lrcmd -cmd=submit command that initially submitted the job. The -cmd=status command can also be used to identify the job ID for a particular job.	(none)
Display the return code of a batch job.	`-cmd=getBatchJobRC -jobid=<jobid> [-host=<host>] [-port=<port>]`	Displays the overall return code produced by a grid batch job. Use `-jobid=<jobid>` as the ID assigned to the job by the job scheduler. The job ID is returned by the lrcmd -cmd=submit command that initially submitted the job. The -cmd=status command can also be used to identify the job ID for a particular job. • Use `-host=<host>` as the ODR host name or job scheduler server host name. If not specified, the default is localhost. • Use `-port=<port>` as the ODR HTTP Proxy address or job scheduler server HTTP port. If not specified, the default is 80.	(none)

Table 9. lrcmd commands. The table includes arguments, a description, and additional information for the lrcmd command.

Command	Arguments	Description	Additional information
Display usage information for lrcmd.	None	This command displays usage information for the `lrcmd` command.	Example: `lrcmd`
Stop the execution of a previously submitted job.	`-cmd=stop [-jobid=<job_id> [-host=<host>] [-port=<port>]`	This command stops the execution of a previously submitted job when a checkpoint occurs. Use `-jobid=<jobid>` as the job ID assigned to the job by the job scheduler Optional arguments: • Use `-host=<host>` as the ODR host name or job scheduler server host name. If not specified, the default is localhost. • Use `-port=<port>` as the ODR HTTP Proxy address or job scheduler server HTTP port. If not specified, the default is 80.	Examples: • `lrcmd -cmd=stop -jobid=MyApp:1 -port=80 -host=myodrhost.com` • `lrcmd -cmd=stop -jobid=MyApp:1 -port=9080 -host=mygshost.com -userid=myname -password=mypassword`

Table 9. lrcmd commands (continued). The table includes arguments, a description, and additional information for the lrcmd command.

Command	Arguments	Description	Additional information
Show the symbolic variables that are referenced in the job definition xJCL.	`-cmd=getSymbolicVariables -xJCL=<xjcl_file> [-<host>] [-port=<port>]`	This command shows the symbolic variables which are referenced in the job definition xJCL. Use `-jobid=<jobid>` as the job ID assigned to the job by the job scheduler Optional arguments: • Use `-XJCL=<xjcl_file>` to specify the path of the job definition xJCL file which describes the grid job. • Use `-job=<job_name>` to specify the job name, which is a key in the job repository of the job scheduler. • Use `-host=<host>` as the ODR host name or job scheduler server host name. If not specified, default is localhost. • Use `-port=<port>` as the ODR HTTP Proxy address or job scheduler server HTTP port. If not specified, the default is 80.	Examples: • `lrcmd -cmd=getSymbolicVariables -xJCL=C:\myXJCL -port=9080 -host=mygshost.com` • `lrcmd -cmd=getSymbolicVariables -job=MyJob -port=80 -host=myodrhost.com -userid=myname -password=mypassword`
Save the job log.	`-cmd=saveJobLog -jobid=<job_id> [-host=<host>] [-fileName=<fileName>]`	This command saves the job log associated with the requested job identifier to the local file system. Use `-jobid=<job_id>` as the job ID assigned to the job by the job scheduler. The job ID is returned by the lrcmd -cmd=submit command that initially submitted the job. The Use `-fileName=<fileName>` to indicate the name of a file on the local file system where the compressed job log data is to be saved. The file is replaced if it exists. The file name `<fileName>`might not contain embedded blanks. Optional arguments: • Use `-host=<host>` as the ODR host name or job scheduler server host name. If not specified, the default is localhost. • Use `-port=<port>` as the ODR HTTP Proxy address or job scheduler server HTTP port. If not specified, the default is 80.	Examples: • `lrcmd -cmd=saveJobLog -jobid=MyApp:1 -fileName=/tmp/myZippedJobLog -port=80 -host=myodrhost.com` • `lrcmd -cmd=saveJobLog -jobid=MyApp:1 -fileName=/tmp/mySavedJobLog -port=9080 -host=mygshost.com -userid=myname -password=mypassword`
Get job log.	`-cmd=getJobLog -jobid=<job_id>`	Displays the job log associated with the requested job identifier. Use `-jobid=<job_id>` as the job ID assigned to the job by the job scheduler. The job ID is returned by the lrcmd -cmd=submit command that initially submitted the job. Optional arguments: • Use `-host=<host>` as the ODR host name or job scheduler server host name. If not specified, the default is localhost. • Use `-port=<port>` as the ODR HTTP Proxy address or job scheduler server HTTP port. If not specified, the default is 80.	Examples: • `lrcmd -cmd=getJobLog -jobid=MyApp:1 -port=80 -host=myodrhost.com` • `lrcmd -cmd=getJobLog -jobid=MyApp:1 -port=9080 -host=mygshost.com -userid=myname -password=mypassword`

Table 9. lrcmd commands (continued). The table includes arguments, a description, and additional information for the lrcmd command.

Command	Arguments	Description	Additional information
Purge job log	`-cmd=getJobLog -jobid=<job_id> -logTimeStamp=<logTimeStamp>`	Removes the job log associated with the requested job identifier and log time stamp. A job log entry remains in, for example: /opt/IBM/WebSphere/AppServer/profiles/scheduler/joblogs/PostingsSampleEar_99/14022007_164535/part.0.log. The entry tracks the reason why the job log was removed. • Use `-jobid=<job_id>` as the job ID assigned to the job by the job scheduler. The job ID is returned by the lrcmd -cmd=submit command that initially submitted the job. • Use -logTimeStamp=<logTimeStamp to indicate the time stamp, the subdirectory name, which identifies the job log to be removed. The time stamp is returned by -cmd=getLogMetaData. • Use `-userid=<user_id>` to specify the user ID required when the job scheduler server is running in secure mode. • Use `-password=<password>` to specify the password required when the job scheduler server is running in secure mode.	Examples: • `lrcmd -cmd=getLogMetaData -jobid=PostingsSampleEar:99 -port=80 -host=myodrhost.com -userid=myname -password=mypassword` • `lrcmd -cmd=purgeJobLog -jobid=PostingsSampleEar:99 -port=80 -logTimeStamp=14022007_164535 -host=myodrhost.com -userid=myname -password=mypassword`
Display the job log metadata for the requested job identifier.	`-cmd=getLogMetaData -jobid=<job_id>`	The job log metadata indicates the log time stamps associated with the requested job identifier. The metadata or time stamp identifies a unique instance of the job. Logs from multiple different jobs with the same job number can exist. Use `-jobid=<job_id>` as the job ID assigned to the job by the job scheduler. The job ID is returned by the lrcmd -cmd=submit command that initially submitted the job.	Examples: • `lrcmd -cmd=getLogMetaData -jobid=MyApp:1 -port=80 -host=myodrhost.com` • `lrcmd -cmd=getLogMetaData -jobid=MyApp:1 -port=9080 -host=mygshost.com`
Display the job log part list.	`-cmd=getLogPartList -jobid=<job_id> -logTimeStamp=<logTimeStamp>`	Displays the job log part list associated with the requested job identifier and log time stamp. Use the command getLogMetaData to return a timestamp to use with `-logTimeStamp=<timestamp>`. Use `-jobid=<job_id>` as the job ID assigned to the job by the job scheduler. The job ID is returned by the lrcmd -cmd=submit command that initially submitted the job.	Examples: • `lrcmd -cmd=getLogPartList -jobid=MyApp:1 -logTimeStamp=20102006_155529 -port=80 -host=myodrhost.com` • `lrcmd -cmd=getLogPartList -jobid=MyApp:1 -logTimeStamp=20102006_155529 -port=9080 -host=myodrhost.com -userid=myname -password=mypassword`
Display the job log part.	`-cmd=getLogPart -jobid=<job_id> -logTimeStamp=<logTimeStamp> -logPart=<logPart>`	Displays the job log part associated with the requested job identifier, log time stamp, and log part. Use `-jobid=<job_id>` as the job ID assigned to the job by the job scheduler. The job ID is returned by the lrcmd -cmd=submit command that initially submitted the job. Use `-logTimeStamp=<logTimeStamp>`to indicate the time stamp (the subdirectory name), which identifies the job log whose part list information is to be returned. The time stamp is returned by -cmd=getLogMetaData. Use `-logPart=<logPart>` to indicate the portion of the job log associated with the requested job identifier and time stamp to be returned. The log part information is returned by -cmd=getLogPartList.	Examples: • `lrcmd -cmd=submit -xJCL=myxjcl.xml -host=myhost -port=80` (returns a job identifier of PostingsSampleEar:99) • `lrcmd -cmd=getLogMetaData -jobid=PostingsSampleEar:99` (returns the timestamp 14022007_164535) • `lrcmd -cmd=getLogPart -jobid=PostingsSampleEar:99 -logTimeStamp=14022007_164535 -logPart=part.1.log`

Table 9. lrcmd commands (continued). The table includes arguments, a description, and additional information for the lrcmd command.

Command	Arguments	Description	Additional information
Display the size of the job log associated with the requested job identifier.	`-cmd=getLogSize -jobid=<job_id> -logTimeStamp=<logTimeStamp>`	This command returns the size of the job login bytes. Use -jobid=<job_id> as the job ID assigned to the job by the job scheduler. The job ID is returned by the lrcmd -cmd=submit command that initially submitted the job. Use `-logTimeStamp=<logTimeStamp>` to indicate the time stamp; that is, the subdirectory name, which identifies the job log whose part list information is to be returned. The time stamp is returned by -cmd=getLogMetaData.	Examples: • `lrcmd -cmd=getLogSize -jobid=MyApp:1 -logTimeStamp=20102006_155529 -port=80 -host=myodrhost.com` • `lrcmd -cmd=getLogSize -jobid=MyApp:1 -logTimeStamp=20102006_155529 -port=9080 -host=myodrhost.com -userid=myname -password=mypassword`
Return the age of the job log in the seconds since it was last modified.	`-cmd=getLogAge -jobid=<job_id> -logTimeStamp=<logTimeStamp>`	Displays the age of the • `lrcmd -cmd=getLogAge -jobid=MyApp:1 -logTimeStamp=20102006_155529 -port=80 -host=myodrhost.com` • `lrcmd -cmd=getLogAge -jobid=MyApp:1 -logTimeStamp=20102006_155529 -port=9080 -host=myodrhost.com -userid=myname -password=mypassword` Job log associated with the requested job identifier. Use `-jobid=<jobid>` as the ID assigned to the job by the job scheduler. The job ID is returned by the lrcmd -cmd=submit command that initially submitted the job. The -cmd=status command can also be used to identify the job ID for a particular job. Use `-logTimeStamp=<logTimeStamp>` to indicate the time stamp; that is, the subdirectory name, which identifies the job log whose part list information is to be returned. The time stamp is returned by -cmd=getLogMetaData.	Examples: • `lrcmd -cmd=getLogAge -jobid=MyApp:1 -logTimeStamp=20102006_155529 -port=80 -host=myodrhost.com` • `lrcmd -cmd=getLogAge -jobid=MyApp:1 -logTimeStamp=20102006_155529 -port=9080 -host=myodrhost.com -userid=myname -password=mypassword`

Example of retrieving output of a batch job:

```
lrcmd -cmd=output -jobid=mybatchjob:63 -host=myLRSHost -port=9081
```

```
CWLRB4940I: com.ibm.websphere.batch.wsbatch : -cmd=output -jobid=mybatchjob:63

CWLRB5000I: Wed Jun 15 17:55:36 EDT 2005 : com.ibm.websphere.batch.wsbatch : response to output

CWLRB1740I: [Wed Jun 15 17:55:36 EDT 2005] Job [mybatchjob:63] is in job setup.
CWLRB1760I: [Wed Jun 15 17:55:37 EDT 2005] Job [mybatchjob:63] is submitted for execution.
CWLRB2420I: [Wed Jun 15 17:55:37 EDT 2005] Job [mybatchjob:63] Step [Step1] is in step setup.
CWLRB2440I: [Wed Jun 15 17:55:38 EDT 2005] Job [mybatchjob:63] Step [Step1] is dispatched.
CWLRB2460I: [Wed Jun 15 17:55:38 EDT 2005] Job [mybatchjob:63] Step [Step1] is in step breakdown.
CWLRB2600I: [Wed Jun 15 17:55:38 EDT 2005] Job [mybatchjob:63] Step [Step1] completed normally rc=0.
CWLRB2420I: [Wed Jun 15 17:55:39 EDT 2005] Job [mybatchjob:63] Step [Step2] is in step setup.
CWLRB2440I: [Wed Jun 15 17:55:39 EDT 2005] Job [mybatchjob:63] Step [Step2] is dispatched.
CWLRB2460I: [Wed Jun 15 17:55:40 EDT 2005] Job [mybatchjob:63] Step [Step2] is in step breakdown.
CWLRB2600I: [Wed Jun 15 17:55:40 EDT 2005] Job [mybatchjob:63] Step [Step2] completed normally rc=4.
End
```

Job logs

A job log is a file that contains a detailed record of the execution details of a job. System messages from the batch container and output from the job executables are collected. By examining job logs, you can see the life cycle of a batch job, including output from the batch applications themselves.

A job log is composed of the following three types of information:

1. xJCL - A job log contains a copy of the xJCL used to run the job, including xJCL substitution values.

2. System messages - A set of system messages that communicate the major life cycle events corresponding to the job. The following system events are recorded in a job log:
   - Begin and end of a job
   - Begin and end of a step
   - Begin and end of a checkpoint
   - Open, close, and checkpoint of a batch data stream
   - Checkpoint algorithm invocation / results
   - Results algorithm invocation / results
3. Application messages - A set of messages written to standard out and standard error by a job step program.

Job logs are viewable through the job management console. Since information is added dynamically to the job log while the job is running, you can view the latest information by selecting Refresh from the job log view. Jobs logs are viewable only if the owning scheduler is active. In addition, if the endpoint running the job is unavailable, a partial job log is the result.

Output of a job log

Job log output is collected on the job scheduler node, and on the grid execution endpoint node. The output is collected in a directory which has the format:

`${GRID_JOBLOG_ROOT}/joblogs/<job-directory>/<timeStamp-directory>`

where

`${GRID_JOBLOG_ROOT}/joblogs` - The base directory for all job logs on the node. It is configurable through the endpoint job log location attribute of the job scheduler panel from the administration console. The default value for `${GRID_JOBLOG_ROOT}` is `${user.install.root}`.

`<job-directory>` Is generated at run time from the job name. For example, if the job ID assigned by the job scheduler is `PostingsSampleEar:99`, then the generated directory name is `PostingsSampleEar_99`

`<timeStamp-directory>`- Is generated at run time from the current date. It is in the format ddmmyyy_hhmmss, where dd is the day of the month, mm is a month (00 - 11), and yyyy is the year. hh is the hour of the day (00 - 23), mm is the minute of the hour (00 - 59) and ss is the seconds of the minutes (00 - 59). For example, a timestamp directory with the name 14022007_164535 means that the job began processing on 14 Mar 2007, at 16:45:35.

For example, job output from job PostingsSampleEar:99 might be collected in the directory `/opt/IBM/WebSphere/AppServer/profiles/scheduler/joblogs/PostingsSampleEar_99/14022007_164535`.

Output on the scheduler node contains an echo of the job xJCL (before and after symbolic variable substitution, if any, is performed) and job dispatch information. Job log output from the job scheduler is collected in the job log directory in the file named part.0.log. Output on the execution endpoint node contains both application output and grid endpoint runtime messages. This output includes any application generated output directed to the System.out and System.err output streams. Job log output from the grid endpoint is collected in the job log directory in files with names such as part.1.log and part.2.log. However, if the job scheduler and grid endpoint are installed on the same application server, job log output from both the scheduler and the grid endpoint is collected in the job log directory in the file named part.0.log. Each of the log parts contains approximately 1000 records. The following example shows the contents of part.1.log:

```
System.out: [03/13/07 08:25:32:708 EDT] Tue Mar 13 08:25:32 EDT 2007: SimpleCI application starting...
System.out: [03/13/07 08:25:32:708 EDT] -->Will loop processing a variety of math functions for approximately 30.0 seconds!
System.out: [03/13/07 08:26:02:752 EDT] Tue Mar 13 08:26:02 EDT 2007: SimpleCI application complete!
System.out: [03/13/07 08:26:02:753 EDT] -->Actual Processing time = 30.043 seconds!
CWLRB5764I: [03/13/07 08:26:03:069 EDT] Job SimpleCIEar:44 ended
```

Administrative roles and privileges

Roles and privileges vary depending on your administrative role and the component.

Administrative roles and privileges

For definitions of administrative roles in WebSphere Application Server and how to assign them, see Authorizing access to administrative roles.

Table 10. Administrative roles and privileges. The table lists each component for the graphical user interface (GUI) and what privileges the component has for the monitor, operator, configurator, and administrator privileges.

GUI	Monitor privileges	Operator privileges	Configurator privileges	Administrator privileges
Job scheduler	View the information.	View the information.	Has all privileges.	Has all privileges.

Administrative console help

This reference information describes settings that you can view and configure on the pages of the product administrative console and elsewhere. Custom properties are documented separately. Custom properties are name-value pairs that you can enter on specific console pages if you know what to specify.

To open the information center table of contents to the location of this reference information, click **Show in Table of Contents** ( ) on your information center border. For example, if you found this page from the information center search or from an internet search engine, such as Google, click **Show in Table of Contents** ( ) to make the information center show you the location of this page in the information center navigation tree. You can then browse the contents that are indented under this navigation entry.

Custom property collection for the job scheduler

Use this page to view and manage arbitrary name-value pairs of data, where the name is a property key and the value is a string value that is used to set internal system configuration properties.

The administrative console contains several custom properties pages that work similarly. To view one of these administrative pages, click a custom properties link.

Name:

Specifies the name (or key) for the property.

Each property name must be unique. If the same name is used for multiple properties, the value specified for the first property that has that name is used. Do not start your property names with *was.* because this prefix is reserved for properties that are predefined in WebSphere Application Server.

Value:

Specifies the value that is paired with the specified name.

Description:

Provides information about the name and value pair.

Custom property settings for the job scheduler

Use this page to configure arbitrary name-value pairs of data, where the name is a property key and the value is a string value that can be used to set internal system configuration properties. You can define a new property to configure a setting beyond what is available in the administrative console.

To view this administrative console page, click **System administration** > **Job scheduler** > **Custom Properties**.

Name:

Specifies the name (or key) for the property.

Each property name must be unique. If the same name is used for multiple properties, the value specified for the first property that has that name is used. Do not start your property names with *was.* because this prefix is reserved for properties that are predefined in WebSphere Application Server.

Data type String

Value:

Specifies the value that is paired with the specified name.

Data type String

Description:

Provides information about the name and value pair.

Data type String

Job scheduler configuration

Use this page to set up persistence of job information to the external job database. Configuration settings include the deployment target of the job scheduler, the data source, the database schema name, and the endpoint job log location.

To view this administrative console page, click **System administration** > **Job scheduler**.

Use this page to add custom properties, map security roles to users and groups for the job scheduler, and view the grid endpoints.

Users in the lrsubmitter role can submit and manage their own jobs. Users in the lradmin role can perform any action against any job.

Scheduler hosted by:

Specifies the deployment target where the grid scheduler is hosted / running.

Database schema name:

Specifics the database schema name for the grid scheduler database.

Data source JNDI name:

Specifies the data source Java Naming and Directory Interface (JNDI) where grid jobs are stored.

Endpoint job log location:

Specifies a location on the endpoints where the job log is created.

WebSphere grid endpoints

View servers or clusters that host grid applications and the data source Java Naming and Directory Interface (JNDI) names used by the WebSphere grid endpoints.

To view this administrative console page, click **System administration** > **Job Scheduler** > **WebSphere grid endpoints**.

Name:

Specifies the name of the WebSphere grid endpoint.

Datasource JNDI name:

Specifies the data source JNDI name used by the WebSphere grid endpoint.

Welcome to the job management console

The job management console is a stand-alone web interface for users to perform job operations.

To view this job management console page, click **Help** from the Welcome page of the job management console.

You must be granted the lrsubmitter role, the lradmin role, or both roles through the administrative console to access the job management console.

Depending on role privileges, users can perform various job operations. The job management console provides controlled access when security is enabled.

View jobs

Use the page to view the list of all jobs submitted to the job scheduler and to view information about the jobs.

To view this job management console page, click **Job Management** > **View jobs**.

To apply action on the jobs, select the jobs and the action, then click **Apply**.

Use the filter function to filter and sort jobs. Click the Show filter function icon , enter the filter criteria, then click **Go**.

To refresh this panel, click **View Jobs** in the navigation or click the icon in the Status column.

Privileges in the job management console vary, depending on assigned roles. For this console page, a user can do the following actions:

- Manage jobs that the user owns with the lrsubmitter role.
- Manage jobs from all users with the lradmin role.

There are multiple types of actions to take, depending on the job type and state. From this console page, users with the lrsubmitter or lradmin roles can complete actions such as cancel, purge, restart, remove, suspend, or resume a job.

Job ID:

Specifies the link to the job. To view the job log, click the link of the job ID.

Submitter:

Specifics the ID of the user who submitted the job.

Last update:

Specifies the date when the job was last updated.

State:

Shows the state of the job.

Node:

Specifies the node where the job is located.

Application server:

Specifies the application server where the job is located.

View job log

Use this page to view job log information of all jobs submitted to the job scheduler, and to download a job log to your local system.

To view this job management console page, click **Job Management** > **View jobs** > ***job name***.

Use this panel to view job log information, or to download the log file to your local system.

Privileges in the job management console vary, depending on assigned roles. For this console page, a user can do the following actions:

- Manage jobs that the user owns with the lrsubmitter role.
- Manage jobs from all users with the lradmin role.

Refresh:

Click to refresh the screen.

Download:

Click to download this job log to your local system.

Back:

Click to return to the view job panel.

Submit a job

Use this page to submit a job by specifying the job definition. The job definition can originate from the local file system.

To view this job management console page, click **Job Management** > **Submit a job**.

Privileges in the job management console vary, depending on assigned roles. For this console page, users with the lrsubmitter role or the lradmin role can submit jobs.

Local file system:

Specify the path of the job definition to submit as a new job.

Use the **Browse** button to locate and specify the full path of a local file.

Substitution properties:

Select to update the values of the substitution properties for the job.

If a job has substitution properties without values, you must specify them.

Custom properties at different scopes

Custom properties are unique settings in the administrative console. They are name-value pairs that you can enter on specific administrative console pages. Use the documentation for the specific custom property to determine where the property must be set.

Setting cell-wide custom properties

You can configure a cell-wide custom property using the following steps:

1. In the administrative console, select **System administration** > **Cell** > **Custom properties** > **New**.
2. Provide a name and value for the custom property.
3. Click **OK**.

Setting custom properties at other levels

Some custom properties can be set at other levels than the cell level. If the custom property documentation specifies another scope at which the custom property must be set, the steps are similar, but you first go to the indicated level before you set the custom property.

1. Go to the indicated configuration object.
2. Click **Custom properties** > **New**.
3. Provide a name and value for the custom property.
4. Click **OK**.

Job scheduler custom properties

Custom properties modify the job scheduler configuration. You can use these settings to tune the job scheduler behavior beyond the settings that are in the administrative console.

You can use the custom properties page to define the following job scheduler custom properties:

- "MaxConcurrentDispatchers"
- "UseHTTPSConnection"
- "RECORD_SMF_SUBTYPES" on page 38

MaxConcurrentDispatchers:

Define this custom property if jobs are being dispatched slowly when large numbers of jobs are submitted. By default, MaxConcurrentDispatchers is set to 100. MaxConcurrentDispatchers is an optional custom property.

Table 11. MaxConcurrentDispatchers custom property values. The table includes the scope, valid values, and default for the custom property.

Scope	Valid values	Default
Job scheduler	Integer value greater than 0	100

UseHTTPSConnection:

Define this custom property if you want to enable HTTP SSL connections between the job scheduler and the common batch container. By default, HTTP SSL connections are disabled. UseHTTPSConnection is an optional custom property.

Table 12. UseHTTPSConnection custom property values. The table includes the scope, valid values, and default for the custom property.

Scope	Valid values	Default
Job scheduler	• true Enables HTTP SSL connections • false Disables HTTP SSL connections	false (disabled)

RECORD_SMF_SUBTYPES:

Define this property to indicate which SMF 120 record subtype you want to use to record job usage data. By default, SMF 120 subtype 20 records are used. RECORD_SMF_SUBTYPES is an optional custom property.

Table 13. RECORD_SMF_SUBTYPES custom property values. The table includes the scope, valid values, and default for the custom property.

Scope	Valid values	Default
Job scheduler cell	• 20 Use SMF120 subtype 20 records. • 9 Use SMF120 subtype 9 records. **Note:** SMF120 subtype 9 support for batch jobs is available on WebSphere® Application Server Version 8 or later. Earlier versions are not supported. If you specify 9 on an earlier version, the job scheduler issues a message. The message notifies you that SMF120 subtype 9 is not supported on the earlier version of WebSphere Application Server. The job scheduler reverts to SMF120 subtype 20 records. **Note:** SMF 120 subtype 9 support for batch jobs requires that SMF 120 subtype 9 recording for asynchronous beans is enabled on the endpoint server. SMF 120 subtype 9 support for asynchronous beans is available on WebSphere Application Server Version 8.0.0.1 or later. Earlier versions are not supported. If you specify `RECORD_SMF_SUBTYPES=9` on an earlier version, the job scheduler issues a message. The message indicates that SMF 120 subtype 9 records are not supported on earlier versions of WebSphere Application Server. The job scheduler reverts to SMF 120 subtype 20 records. **Note:** If you specify `RECORD_SMF_SUBTYPES=9` without also enabling SMF 120 subtype 9 recording for asynchronous beans in the endpoint server, the endpoint server issues a message. The message indicates that SMF 120 subtype 9 recording for asynchronous beans is not enabled. No SMF120 subtype 9 job usage records are collected. • ALL Use both SMF120 subtype 20 and SMF120 subtype 9 records.	20

Batch administrator examples

Batch administrator examples are examples of code snippets, command syntax, and configuration values that are relevant to performing administrative and deployment tasks in the batch environment.

The samples in this section consist of xJCL samples and XML schemas for batch jobs, native jobs, and compute-intensive jobs.

xJCL sample for a batch job

The following sample illustrates a batch job, which demonstrates that you can invoke existing session beans from within job steps.

```
<job name="PostingsSampleEar" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">

        <jndi-name>ejb/com/ibm/websphere/samples/PostingsJob</jndi-name>

    <step-scheduling-criteria>
  <scheduling-mode>sequential</scheduling-mode>
 </step-scheduling-criteria>

    <checkpoint-algorithm name="${checkpoint}">
  <classname>com.ibm.wsspi.batch.checkpointalgorithms.${checkpoint}</classname>
  <props>
   <prop name="interval" value="${checkpointInterval}" />
  </props>
 </checkpoint-algorithm>

    <results-algorithms>
  <results-algorithm name="jobsum">
   <classname>com.ibm.wsspi.batch.resultsalgorithms.jobsum</classname>
  </results-algorithm>
 </results-algorithms>

    <substitution-props>
        <prop name="wsbatch.count" value="5" />
        <prop name="checkpoint" value="timebased" />
        <prop name="checkpointInterval" value="15" />
        <prop name="postingsDataStream" value="${was.install.root}${file.separator}temp${file.separator}postings" />
    </substitution-props>

    <job-step name="Step1">

        <jndi-name>ejb/DataCreationBean</jndi-name>

        <!-- apply checkpoint policy to step1 -->
        <checkpoint-algorithm-ref name="${checkpoint}" />

        <results-ref name="jobsum"/>

  <batch-data-streams>
   <bds>

                <logical-name>myoutput</logical-name>

                <impl-class>com.ibm.websphere.samples.PostingOutputStream</impl-class>

                <props>
```

```
                  <prop name="FILENAME" value="${postingsDataStream}" />

   </props>
  </bds>
 </batch-data-streams>

       <props>

           <prop name="wsbatch.count" value="${wsbatch.count}" />
 </props>
</job-step>

<job-step name="Step2">

       <step-scheduling condition="OR">
  <returncode-expression step="Step1" operator="eq" value="0" />
           <returncode-expression step="Step1" operator="eq" value="4" />
 </step-scheduling>

       <jndi-name>ejb/PostingAccountData</jndi-name>
 <checkpoint-algorithm-ref name="${checkpoint}" />
 <results-ref name="jobsum"/>

 <batch-data-streams>
  <bds>

              <logical-name>myinput</logical-name>
   <impl-class>com.ibm.websphere.samples.PostingStream</impl-class>

              <props>
    <prop name="FILENAME" value="${postingsDataStream}" />
   </props>

  </bds>
 </batch-data-streams>
</job-step>

        <job-step name="Step3">
      <step-scheduling>
          <returncode-expression step="Step2" operator="eq" value="4" />
      </step-scheduling>

      <jndi-name>ejb/OverdraftAccountPosting</jndi-name>
      <checkpoint-algorithm-ref name="${checkpoint}" />
      <results-ref name="jobsum" />

     <batch-data-streams>
          <bds>

             <logical-name>dbread</logical-name>
              <impl-class>com.ibm.websphere.samples.OverdraftInputStream</impl-class>
         </bds>
     </batch-data-streams>
  </job-step>
</job>
```

XML schema for a compute intensive job

The following example shows the XML schema for a compute-intensive job:

```
<?xml version="1.0" encoding="UTF-8"?>
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema">
```

```
<xsd:element name="classname" type="xsd:string" />
<xsd:element name="jndi-name" type="xsd:string" />

<xsd:element name="required-capability">
   <xsd:complexType>
       <xsd:attribute name="expression" type="xsd:string" use="required" />
   </xsd:complexType>
</xsd:element>

<xsd:element name="substitution-props">
   <xsd:complexType>
       <xsd:sequence>
           <xsd:element ref="prop" minOccurs="0" maxOccurs="unbounded"/>

```

Chapter 5. Administering Client applications

This page provides a starting point for finding information about application clients and client applications. Application clients provide a framework on which application code runs, so that your client applications can access information on the application server.

For example, an insurance company can use application clients to help offload work on the server and to perform specific tasks. Suppose an insurance agent wants to access and compile daily reports. The reports are based on insurance rates that are located on the server. The agent can use application clients to access the application server where the insurance rates are located. More introduction...

Deploying client applications

Deploying a client application depends on installing appropriate supporting files on the client machine, usually some configuring actions, and adding the program files for the client application. When the client application has been deployed, the application can run.

About this task

The steps required to deploy and run a client application depend on the type of client and the programming model used.

You can install an application client JAR file using the administrative console, wsadmin AdminApp install, or update commands. Install the client module only on a Version 8.0 deployment target (such as server, cluster, and so on).

Complete one or more of the following tasks:

Procedure

- Deploy the client application
- Run an ActiveX client application
- Deploy and run a Java EE client application
- Run the IBM Thin Client for Enterprise JavaBeans

Deploying applet client code

Applet clients are capable of communicating over the HTTP protocol and the RMI-IIOP protocol.

Before you begin

Applet clients have the following setup requirements:

- These clients are available on the Windows platforms. Check the prerequisites page for information on platform support and product prerequisites.
- The browser installation precedes the client code installation.

About this task

Unlike typical applets that are on web servers or WebSphere Application Servers and can only communicate over the HTTP protocol, applet clients can communicate over the HTTP protocol and the RMI-IIOP protocol. This additional capability gives the applet direct access to enterprise beans.

The applet container is the web browser and the Java plug-in combination. You must first install the Application Client for WebSphere Application Server so that the browser recognizes the IBM product Java plug-in.

Procedure

1. Install the Application Client for WebSphere Application Server.
2. Configure required Java runtime parameters.
   a. Click **Start** > **Control panel** .
   b. Select the IBM Control Panel for Java
   c. On the Advanced tab, enter the following parameter values in the Java Runtime Parameters field.

```
-Xmx512M
-Djava.security.policy=<app_client_root>\properties\client.policy
-Dwas.install.root=<app_client_root>
-Djava.ext.dirs=<app_client_root>\java\jre\lib\ext;
<app_client_root>\lib;
<app_client_root>\plugins;
<app_client_root>\lib\ext;
<app_client_root>\installedConnectors\
-Djava.class.path=<app_client_root>\properties
-Dcom.ibm.CORBA.ConfigURL=file:<app_client_root>\properties\sas.client.props
-Dcom.ibm.SSL.ConfigURL=file:<app_client_root>\properties\ssl.client.props
```

   Note: These parameter entries are automatically placed into the WebSphere Application Server control panel for the Java plug-in user who installed the WebSphere Application Server Application Client provided you are using a Java SE Development Kit (JDK) prior to JDK 1.5. If the applet is being run by a user other than the person who installed the client, then that user must enter the parameter entries.

   For JDK 1.5 and later, this automatic parameter feature is removed.

   - The Java Runtime Parameters field is similar to the command prompt when using command line options. Therefore, you can enter most options available from the command prompt (for example, -cp, classpath, and others) in this field as well.

3. Configure use of secure sockets layer (SSL) for secure access to resources. By default, the applet client is configured to have security enabled. If you have administrative security turned on at the server from which you are accessing resources, then you can use SSL when needed. If you decide that the security requirements for applet client applications differ from other types of client applications, then you can create special copies of client property files for applets to use.

Running an ActiveX client application

To run an ActiveX client application that is to use the ActiveX to Enterprise Java Beans (EJB) bridge, you must perform some initial configuration to set appropriate environment variables and to enable the ActiveX to EJB bridge to find its `XJB.JAR` file and the Java run time. This initial configuration sets up the environment within which the ActiveX client application can run.

About this task

To perform the required configuration, complete one or more of the following tasks:

Procedure

1. Start an ActiveX application and configure service programs.
2. Start an ActiveX application and configuring non-service programs

Starting an ActiveX application and configuring service programs

To run an ActiveX service program such as Active Server Page (ASP) that is to use the ActiveX to the Enterprise Java Bean (EJB) bridge, some initial configuration (to set appropriate environment variables and to enable the ActiveX to EJB bridge to find its `XJB.JAR` file and the Java run time) is necessary. This configuration sets up the environment within which the ActiveX service program can run.

Before you begin

The XJB.JClassFactory must find the Java run time dynamic link library (DLL) when initializing. In a service program such as Internet Information Server you cannot specify a path for its processes independently; you must set the process paths in the system PATH variable. This limitation means that you can only have a single Java virtual machine (JVM) version available on a machine using ASP.

About this task

To add the Java Runtime Environment (JRE) directories to your system path, complete one of the following task.

Procedure

On Windows XP systems, complete the following steps:
1. Open the Control Panel, then double-click the **System** icon.
2. Click the **Advanced** tab on the System Properties window.
3. Click **Environment Variables**.
4. Edit the Path variable in the System Variables window.
5. Add the following information to the beginning of the path that is displayed in the Variable Value field:

   `C:\WebSphere\AppClient\Java\jre\bin;C:\WebSphere\AppClient\Java\jre\bin\classic;`

   where `C:\WebSphere\AppClient` is the directory in which you installed the Java client in the WebSphere product.
6. Click **OK** in the Edit System Variable window to apply the changes.
7. Click **OK** in the Environment Variables window.
8. Click **OK** in the System Properties window.
9. Restart Windows XP.

What to do next

After you change the system PATH variable you must reboot the Internet Information Server machine so that Internet Information Server can see the change.

Starting an ActiveX application and configuring non-service programs

To run an ActiveX program initiated from an icon or command line (a non-service program) that is to use the ActiveX to the Enterprise Java Beans (EJB) bridge, you must perform some initial configuration to set appropriate environment variables and to enable the ActiveX to EJB bridge to find its `XJB.JAR` file and the Java run-time environment. This uses a batch file to set up the environment within which the ActiveX program can run.

About this task

To perform the required configuration, complete the following steps:

Procedure

1. Edit the `setupCmdLineXJB.bat` file to specify appropriate values for the environment variables required by the ActiveX to EJB bridge. For more information about these environment variables, see ActiveX to EJB bridge, environment and configuration. For more information about creating a JVM for an ActiveX program, see ActiveX to EJB bridge, initializing the Java virtual machine (JVM). After the ActiveX program has created an XJB.JClassFactory object and called the XJBInit() method, the JVM is initialized and ready for use.
2. Start the ActiveX client application by using one of the following methods:
   - Use the `launchClientXJB.bat` file to start the application. For example:

     `launchClientXJB MyApplication.exe` *parm1 parm2*

or

```
launchClientXJB MyApplication.vbp
```

- Use the `setupCmdLineXJB.bat` file to create an environment in which to run the application, then start the application from within that environment.

setupCmdLineXJB.bat, launchClientXJB.bat and other ActiveX batch files

This topic provides reference information about the aids that client applications and client services can use to access the ActiveX to EJB bridge. These enable the ActiveX to Enterprise JavaBeans (EJB) bridge to find its `XJB.JAR` file and the Java run-time environment.

Location

The include file is located in the *was_client_home*`\aspIncludes` directory. You can include the file into your Active Server Pages (ASP) application with the following syntax in your ASP page:

```
<--  #include virtual ="/WSASPIncludes/setupASPXJB.inc" -->
```

This syntax assumes that you have created a virtual directory in Internet Information Server called `WSASPIncludes` that points to the *was_client_home*`\aspIncludes` directory.

Usage notes

The following batch files are provided for client applications to use the ActiveX to EJB bridge:

- **setupCmdLineXJB.bat**

  Sets the client environment variables.
- **launchClientXJB.bat**

  Calls the `setupCmdLineXJB.bat` file and launches the application you specify as its arguments; for example:

  ```
  launchClientXJB.bat myapp.exe parm1 parm2
  ```

  or

  ```
  launchClientXJB MyApplication.vbp
  ```
- **Active Server Pages (ASP) include file**

  An include file is provided for ASP users to automatically set the following page-level (local) environment variables:
  - **com_ibm_websphere_javahome**. Path to the Java run-time directory installed with the WebSphere advanced server client.
  - **com_ibm_websphere_washome**. Path to the WebSphere advanced server client directory.
  - **com_ibm_websphere_namingfactory**. Sets the Java java.naming.factory.initial system property.
  - **com_ibm_websphere_computername**. (Optional) Name of the computer where the WebSphere Advanced Server Client is installed. If you intend to talk to a single specific computer, you are recommended to change this value to become the server name that you intend to access.
- **System settings**

  To enable the ActiveX to EJB bridge to access the Java run-time dynamic link library (DLL), the following directories must exist in the system PATH environment variable:

  was_client_home`\java\jre\bin;`*was_client_home*`\java\jre\bin\classic`

  Where *was_client_home* is the name of the directory where you installed the WebSphere Application Server client (for example, `C:\WebSphere\AppClient`).

  Note: This technique enables only one Java run time to activate on a machine, therefore all client services on that machine must use the same Java run time. Client applications do not have this limitation because they each have their own private, non-system scope.

Deploying and running a Java EE client application

You can use the launchClient command to run a Java Enterprise Edition (EE) client application in an Application Client installation or in a WebSphere Application Server node. Alternatively, you can use Java Web Start on a remote client machine to download and run a Java EE client application, including Thin client application, with a single click from a web browser on that machine.

Procedure

1. Deploy and run a Java EE client application for use with the launchClient command.

   After deploying a Java EE client application onto a machine with an Application Client installation or in a WebSphere Application Server node, you can start the application by using the launchClient command on that machine.

   a. Deploy the Java EE client application

   b. Start the Java EE client application

2. Deploy and run a Java EE client application by using Java Web Start.

   a. Prepare the Java EE client application ready to be deployed by remote action.

   b. Use Java Web Start on a remote client machine to download and run the Java EE client application.

Deploying a Java EE client application

Deploying a Java EE client application onto the client machines where it is to run includes distributing the EAR file for the client application and configuring resource references for use by the client application.

Before you begin

To run a deployed Java EE client application, the application needs access to a Application Client installation or a WebSphere Application Server installation.

For information about installing the Application Client on a client machine, refer to the Installing Application Client for WebSphere Application Server topic.

Attention: Application Client for WebSphere Application Server ships only with the 32-bit WebSphere Application Server.

About this task

Use this topic only if you later want to use the want to launchClient command to run the Java client application on an Application Client installation or in a WebSphere Application Server node.

If you want to download and run a Java EE client application remotely, you can use the Java Web Start to deploy the application onto the remote client machine with a single click from a Web browser on the client machine. For information about using Java Web Start to deploy Java EE client applications, see “Downloading and running a Java EE client application by using Java Web Start”.

Procedure

1. Distribute the EAR file.

   The client machines configured to run a client application must have access to the EAR file.

   - If all the machines in your environment share the same image and platform, run the Application Client Resource Configuration Tool (ACRCT) on one machine to configure the external resources, then distribute the configured EAR file to the other machines.
   - If your environment is set up with a variety of client installations and platforms, run the ACRCT for each unique configuration.
   - You can either distribute an EAR file to the correct client machines, or make it available on a network drive.

- Distributing EAR files is the responsibility of the system and network administrator.

2. Configure the resources for the application client. This generally involves using the Application Client Resource Configuration Tool (ACRCT) to configure references for the resources that the application is to use, including resource adapters, resource providers, data sources, and Java Message Service resources. These configurations are stored in the client JAR file within the application EAR file. The client runtime uses these configurations to resolve and create an instance of the resources for the client application.

   For some types of resources, other actions are needed; for example, to install a resource adapter and define environment variable needed to start the client application. More information about the actions for different types of resources is given in other configuring resources topics.

   If you plan to deploy the client application on z/OS, run the ACRCT on Windows. You can also run the ACRCT for distributed platforms locally.

   If the client application defines the local resources, but the resources are installed in a different location, run the ACRCT (clientConfig command) on the local machine to change the configuration in the EAR file. For example, the EAR file can contain a DB2 resource, configured as `C:\DB2`. If, however, you installed DB2 in the `D:\Program Files\DB2` directory, use the ACRCT to create a local version of the EAR file.

What to do next

After deploying the Java EE client application, use the launchClient command to run the client application.

Starting the Application Client Resource Configuration Tool and opening an EAR file:

You can perform many tasks by starting the Application Client Resource Configuration Tool (ACRCT). Many of these tasks also involve then opening an EAR file.

Before you begin

Attention: This task only applies to Java Platform, Enterprise Edition (Java EE) application clients.

About this task

Use these steps to start the Application Client Resource Configuration Tool. When you start the tool, one of the most common tasks that you perform is opening and modifying the components of EAR files.

Procedure

1. Open a command prompt and change to the *app_server_root*`\bin` directory.
2. Run the `clientConfig.bat` file.
3. Open an EAR file within the Application Client Resource Configuration Tool (ACRCT):
   a. Click **File** > **Open**.
   b. Select the file then click **Open**.
4. Save your changes to the file and close the tool:
   a. Click **File** > **Save**.
   b. Click **File** > **Exit**.

Deploying a resource adapter for a Java EE client application:

A Java EE client application can use a resource adapter to connect to an enterprise information system (EIS). To use a resource adapter, you need to install it, configure it, and configure related resources.

About this task

The resource adapter support provided for Java EE client applications is a subset of the support provided for application servers. A client resource adapter is used in a non-managed environment and must conform to the J2EE Connector Architecture Specification Version 1.5 or higher. Only outbound connections to the EIS are supported through the ManagedConnectionFactory interfaces. The inbound messaging support (from the EIS), life cycle management, and work management aspects of the specification are not supported on the client.

When running Java EE application clients, the launchClient script specifies a system property called **com.ibm.ws.client.installedConnector**, which is set to the same value as the *CLIENT_CONNECTOR_INSTALL_ROOT* variable. This is the default location for installed resource adapters and can be overridden for each launchClient call by specifying the **-CCD** parameter. When the client container is activated, all resource adapter subdirectories under the specified default location for the resource adapters directory are added to the classpath. This action allows the client application to use the resource adapters without using the ACRCT to specify any of the client resources.

Procedure

1. Install the resource adapter archive (RAR) file

   For a client application to use a resource adapter, the RAR file must be installed in the directory specified by the environment variable, CLIENT_CONNECTOR_INSTALL_ROOT, defined when the setupCmdLine script runs. The launchClient tool, Application Client Resource Configuration Tool (ACRCT) and clientRAR tool all use this variable to find the default location of all installed resource adapters.

   To install a RAR file for a client application, use the clientRAR tool.
2. Configure the resource adapter and its resources for the client application Use the Application Client Resource Configuration Tool (ACRCT) to define the resource adapter, connection factories, and administered objects in the EAR file for the client application. The client application uses this configuration to resolve and create an instance of the resource adapter and the other resources.
   a. Configure the resource adapter
   b. Configure a connection factory
   c. Configure administered objects

clientRAR tool:

This topic describes the command line syntax for the client resource adapter installation tool.

If this tool is used to add or delete resource adapters on the server, then only the client can use the resource adapter. If the resource adapter is installed on the server using the wsadmin tool or the administrative console, then do not use the clientRAR tool remove it. Only resource adapters that are installed using the clientRAR tool should be removed using the clientRAR tool.

The command line invocation syntax for the `clientRAR` tool follows:

```
clientRAR [-help | -?] [-CRDcom.ibm.ws.client.installedConnectors=<dir>] <task> <archive>

where
-help, -?
Print the usage information.
-CRDcom.ibm.ws.client.installedConnectors
The directory where resource adapters are installed.
This will override the system property of the same name
(com.ibm.ws.client.installedConnectors).

<task>
The task to perform: add - install, delete - uninstall.
```

```
<archive>
if task=add then this is the fully qualified name of the resource adapter archive file.
If task=delete then this is the filename of the resource adapter archive to be uninstalled.
```

The following examples demonstrate correct syntax.

Configuring resource adapters for the client:

Use the Application Client Resource Configuration Tool (ACRCT) to configure resource adapters for the client.

Procedure

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure new resource adapters. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new resource adapters from the tree.
4. Expand the JAR file to view its contents.
5. Right-click the Resource Adapters folder, and click **New**.
6. Configure the resource adapter settings in the resulting property dialog.
7. Click **OK**.
8. Click **File > Save** on the menu bar to save your changes.

Resource adapters for the client:

A resource adapter is a system-level software driver that a Java application uses to connect to an enterprise information system (EIS). A resource adapter plugs into an application client and provides connectivity between the EIS and the enterprise application.

Important: This topic is not relevant to the WebSphere MQ resource adapter. WebSphere MQ classes are picked up automatically by the client container (for both stand alone and with a WebSphere Application Server installation).

The resource adapter support for the Java EE client applications is a subset of the support for the server. For any resource adapter installed using the clientRAR tool, the client resource adapter is used in a non-managed environment and must conform to the Java EE Connector Architecture Specification Version 1.5 or higher. Only outbound connections to the EIS are supported through the ManagedConnectionFactory interfaces. The inbound messaging support (from the EIS), life cycle management, and work management aspects of the specification are not supported on the client.

For a client application to use a resource adapter, it must be installed in the directory specified by the environment variable, CLIENT_CONNECTOR_INSTALL_ROOT, defined when the setupCmdLine script runs. The launchClient tool, Application Client Resource Configuration Tool (ACRCT) and clientRAR tool all use this variable to find the default location of all installed resource adapters. To install a resource adapter in the client, use the clientRAR tool. Once the resource adapter is installed, it must be configured using the ACRCT. The client configuration tool adds the resource adapter configuration to the EAR file. Then, connection factories and administered objects are defined.

When running Java EE application clients, the `launchClient` script specifies a system property called `com.ibm.ws.client.installedConnector`, which is set to the same value as the `CLIENT_CONNECTOR_INSTALL_ROOT` variable. This is the default location for installed resource adapters and can be overridden for each `launchClient` call by specifying the `-CCD` parameter. When the client container is activated, all resource adapter subdirectories under the specified default location for the resource adapters directory are added to the classpath. This action allows the client application to use the resource adapters without using the ACRCT to specify any of the client resources.

Using resource adapters is a new mechanism for easily extending client applications.

Resource adapter settings:

Use this panel to view or change the configuration properties of the resource adapter. These configuration properties control how resource adapters are created.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Adapter**. Right-click **Resource Adapter** and click **New**. The following fields appear on the **General** tab.

Name:

The name by which this Resource Adapter is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the Resource Adapters across the product administrative domain.

Data type String

Description:

A description of this resource adapter for administrative purposes within IBM WebSphere Application Server.

Data type String

Class Path:

Any additional class path. The path to the resource adapter directory is automatically added.

Data type String
Default The path to your Resource Adapter directory.

Native Path:

The native path where the Resource Adapter is located. Enter any additional native class path here.

Data type String

Resource Adapter Name:

A mandatory field that points to an installed resource adapter subdirectory. The entry does not represent the full directory name for the resource adapter. The full directory name is the installed resource adapter path, plus the resource adapter name.

Data type String

Installed Resource Adapter Path:

The directory where resource adapters are installed. If you do not complete this field, then the default takes effect.

If you specify the value, `${CONNECTOR_INSTALL_ROOT}`, then this value replaces the value of the `CLIENT_CONNECTOR_INSTALL_ROOT` variable on the machine on which the client application runs. This action allows the application to run easily on different machines, where the client installation might be in different locations.

Data type String
Default ${CONNECTOR_INSTALL_ROOT}

Configuring new connection factories for resource adapters for the client:

Use the Application Client Resource Configuration Tool (ACRCT) to configure new connection factories for resource adapters for the client.

About this task

Complete this task to configure new connection factories for resource adapters.

Procedure

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure new connection factories. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new connection factories from the tree.
4. Expand the JAR file to view its contents.
5. Click the Resource Adapters folder.
6. Expand the resource adapter for which you want to create connection factories.
7. Right-click the Connection Factories folder and click **New**.
8. Configure the connection factory properties in the resulting property dialog.
9. Click **OK**.
10. Click **File > Save** on the menu bar to save your changes.

Resource adapter connection factory settings:

Use this panel to view or change the configuration properties of the selected resource adapter connection factory.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Adapters**. Right-click the **Connection Factories** folder, and click **New**. The following fields appear on the **General** tab.

Name:

The name by which this connection factory is known for administrative purposes within WebSphere Application Server. The name must be unique within the resource adapter connection factories across the product administrative domain.

Data type String

Description:

An optional description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI Name:

The JNDI name that is used to match this resource adapter connection factory definition to the deployment descriptor. This entry should be a `resource-ref` name.

Data type String

User Name:

The **User Name** used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly when getting a connection. If this field is used, then the Properties field `UserName` is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User Name** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly when getting a connection.

Data type String

Password:

Specifies an encrypted password. If you complete this field, then the **Password** field in the Properties box is ignored.

If you specify a value for the **UserName** property, you must also specify a value for the **Password** property.

Data type String

Re-Enter Password:

Confirms the password.

Type:

A drop-down list of all the `connectionFactoryInterfaces` as defined for the factories in the Resource Adapter Archive.

For each **Type**, there is a set of properties specified in the Properties box. This set of properties is constructed by retrieving the properties from each connection definition object. For any existing connection factories that are displayed for updating, this list of properties is overlaid with the properties specified for the objects. When the **Type** field is changed, the properties also change to reflect the correct properties for that type.

Data type String

Configuring administered objects for resource adapters for the client:

This section helps you configure new administered objects for the client.

Before you begin

Before you configure new administered objects, you must complete the following prerequisites:

1. Install the Resource Adapter Archive file (RAR) using the clientRAR tool.
2. Configure the resource adapter for the `.ear` file, using the Application Client Resource Configuration Tool (ACRCT) tool.

About this task

Complete this task to configure new administered objects for installed resource adapters.

Procedure

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure new administered objects. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new administered objects from the tree.
4. Expand the JAR file to view its contents.
5. Click the **Resource Adapters** folder.
6. Expand the resource adapter for which you want to create administered objects.
7. Right-click the **Administered Objects** folder and click **New**.
8. Configure the administered object properties in the resulting property dialog.
9. Click **OK**.
10. Click **File > Save** on the menu bar to save your changes.

Administered objects settings:

Use this panel to view or change the configuration properties of the selected administered objects.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Adapters** > *resource_adapter_instance*. Right-click **Administered Objects** and click **New**. The following fields appear on the **General** tab.

The settings for administered objects are handled similarly to connection factories. When updating administered objects, use the same panels that you used to create administered objects.

Name:

The name by which this administered object is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the resource adapter administered objects across the product administrative domain.

Data type String

Description:

An optional description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI Name:

This entry is a `resource-env-ref` name, a `message-destination-ref` name (if the `message-destination-ref` has no link), or a `message-destination` link.

Data type String

Type:

A drop-down list of all the administered object class-interface pairs as defined for the admin objects in the Resource Adapter Archive (RAR) file.

For each **Type**, there is a set of properties specified in the Properties box. This set of properties is constructed by retrieving the properties from each administered object definition. For any existing administered objects that are displayed for updating, this list of properties is overlaid with the properties specified for the objects. When the **Type** field is changed, the properties also change to reflect the correct properties for that type.

Data type String

Enabling client use of data sources:

If a Java EE client application accesses a database directly, you must provide the database drivers on the client machine, and configure the data source provider (JDBC provider) and data sources. Instead of accessing the database directly, it is recommended that your client application access the database through an enterprise bean.

About this task

WebSphere Application Server and the Application Client for WebSphere Application Server do not provide client database drivers to be used directly from a Java EE client application. You can contact your database vendor to get client database driver code and licenses.

Data sources configured on the server and looked up on the client do not participate in global transactions.

Instead of accessing the database directly, it is recommended that your client application access the database through an enterprise bean. This technique eliminates the need to have database drivers on the client machine, because the database access is handled by the enterprise bean running on WebSphere Application Server. It also enables the client application to take advantage of the pooling and additional database functions provided by the server.

For a current list of data source providers that are supported on WebSphere Application Server, see the WebSphere Application Server prerequisite website.

Procedure

1. For direct access from a client to the database, install the client database drivers on the client machine. For information about installing database drivers, see the documentation provided by your database vendor.
2. Configure a data source provider and a data source for the client application Use the Application Client Resource Configuration Tool (ACRCT) to define the data source provider and a data source in the EAR file for the client application. The client application uses this configuration to resolve and create an instance of the data source provider and data source.
   a. Configure a new data source provider. This provider describes the JDBC database implementation for your client application.
   b. Configuring a new data source This describes the client properties of the database your client application uses.

Configuring new data source providers (JDBC providers) for application clients:

You can create new data source providers, also known as JDBC providers, for your application client using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

During this task, you create new data source providers, also known as JDBC providers, for your application client. In a separate administrative task, install the Java code for the required data source provider on the client machine on which the application client resides.

About this task

Use this task to connect application clients to relational databases.

Procedure

1. Start the Application Client Resource Configuration Tool (ACRCT) and open the EAR file for which you want to configure the new data source provider. The EAR file contents display in a tree view.
2. Select the JAR file in which you want to configure the new data source provider from the tree.
3. Expand the JAR file to view its contents.
4. Click the Data Source Providers folder. Do one of the following:
   - Right-click the folder and click **New Provider**.
   - Click **Edit > New** on the menu bar.
5. Configure the data source provider properties in the resulting property dialog.
6. Click **OK** when you finish.
7. Click **File > Save** on the menu bar to save your changes.

Example

You can configure data source provider and data source settings.

- Configuring data source provider and data source settings

The following code examples illustrates how to use configure data source provider and data source settings:

```
<resources.jdbc:JDBCProvider xmi:id="JDBCProvider_1" name="jdbcProvider:name"
description="jdbcProvider:description" implementationClassName="jdbcProvider:
ImplementationClass">
<classpath>jdbcProvider:classPath</classpath>
<factories xmi:type="resources.jdbc:WAS40DataSource" xmi:id="WAS40DataSource_1"
name="jdbcFactory:name" jndiName="jdbcFactory:jndiName"
description="jdbcFactory:description" databaseName="jdbcFactory:databasename">
<propertySet xmi:id="J2EEResourcePropertySet_13">
<resourceProperties xmi:id="J2EEResourceProperty_13" name="jdbcFactory:customName"
value="jdbcFactory:customValue"/>
<resourceProperties xmi:id="J2EEResourceProperty_14" name="user"
value="jdbcFactory:user"/>
<resourceProperties xmi:id="J2EEResourceProperty_15" name="password"
value="{xor}NTs9PBk+PCswLSZlMT4yOg==/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_14">
<resourceProperties xmi:id="J2EEResourceProperty_16" name="jdbcProvider:customName"
value="jdbcProvider:customeValue"/>
</propertySet>
</resources.jdbc:JDBCProvider>
```

- Required fields:
  - Data Source Provider Properties page: name

  - Data Source Properties page: name, jndiName
- Special cases:
  - The user name and password fields have no equivalent XMI tags. You must specify these fields in the custom properties.
  - The password is encrypted when you use the Application Client Resource Configuration Tool (ACRCT). If you do not use the ACRCT the field cannot be encrypted.

Example: Configuring data source provider and data source settings:

You can configure data source provider and data source settings.

The purpose of this article is to help you to configure data source provider and data source settings.
- Required fields:
  - Data Source Provider Properties page: name
  - Data Source Properties page: name, jndiName
- Special cases:
  - The user name and password fields have no equivalent XMI tags. You must specify these fields in the custom properties.
  - The password is encrypted when you use the Application Client Resource Configuration Tool (ACRCT). If you do not use the ACRCT the field cannot be encrypted.
- Example:

```
<resources.jdbc:JDBCProvider xmi:id="JDBCProvider_1" name="jdbcProvider:name"
description="jdbcProvider:description" implementationClassName="jdbcProvider:
ImplementationClass">
<classpath>jdbcProvider:classPath</classpath>
<factories xmi:type="resources.jdbc:WAS40DataSource" xmi:id="WAS40DataSource_1"
name="jdbcFactory:name" jndiName="jdbcFactory:jndiName"
description="jdbcFactory:description" databaseName="jdbcFactory:databasename">
<propertySet xmi:id="J2EEResourcePropertySet_13">
<resourceProperties xmi:id="J2EEResourceProperty_13" name="jdbcFactory:customName"
value="jdbcFactory:customValue"/>
<resourceProperties xmi:id="J2EEResourceProperty_14" name="user"
value="jdbcFactory:user"/>
<resourceProperties xmi:id="J2EEResourceProperty_15" name="password"
value="{xor}NTs9PBk+PCswLSZlMT4yOg==">
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_14">
<resourceProperties xmi:id="J2EEResourceProperty_16" name="jdbcProvider:customName"
value="jdbcProvider:customeValue"/>
</propertySet>
</resources.jdbc:JDBCProvider>
```

Data source provider settings for application clients:

Use this page to create a data source under a JDBC provider which provides the specific JDBC driver implementation class.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right-click **Data Source Providers** > and click **New**. The following fields appear on the **General** tab:

Name:

Specifies the display name for the data source.

For example you can set this field to *Test Data Source*.

Data type String

Description:

Specifies a text description for the resource.

Data type	String

Class Path:

A list of paths or `.jar` file names which together form the location for the resource provider classes.

Implementation class:

Use this setting to perform database specific functions.

Data type	String
Default	Dependent on JDBC driver implementation class

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Configuring new data sources for application clients:

Learn how to create date sources for application clients.

About this task

During this task, you create new data sources for your application client.

Procedure

1. Click the data source provider for which you want to create a data source in the tree. Take one of the following actions as needed:
   - Configure a new data source provider.
   - Click an existing data source provider.
2. Expand the data source provider to view its Data Sources folder.
3. Click the data source folder. Take one of the following actions as needed:
   - Right click the data source folder and click **New Factory**.
   - Click **Edit > New** on the menu bar.
4. Configure the data source properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Data source properties for application clients:

Use this page to create or modify the data sources.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Data Source Providers** > *Data source provider instance*. Right-click **Data Sources** and click **New**. The following fields are displayed on the **General** tab:

Name:

Specifies the display name of this data source.

Data type String

Description:

Specifies a text description of the data source.

Data type String

JNDI Name:

The application client run time uses this field to retrieve configuration information.

Database Name:

The name of the database to which you want to connect.

User:

Use the user ID with the Password property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the User ID property, then you must also specify a value for the Password property. The connection factory User ID and Password properties are used if the calling application does not provide a user ID and password explicitly.

Password:

Use the password with the User ID property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the Password property, then you must also specify a value for the User ID property.

Re-Enter Password:

Confirms the password.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Configuring mail providers and sessions for application clients:

You can edit the configurations of mail sessions and providers for your application clients using the Application Client Resource Configuration Tool (ACRCT).

About this task

Use the Application Client Resource Configuration Tool (ACRCT) to edit the configurations of mail sessions and providers for your application clients to use.

Procedure

1. Start the ACRCT.
2. Open an EAR file.
3. Locate the mail objects in the tree that is displayed for the EAR file. For example, if your file contains mail sessions, expand **Resources** > ***application*.jar** > **Mail Providers** > ***java_mail_provider_instance*** > **Mail Sessions**.

   In this example, ***java_mail_provider_instance*** is a particular mail provider.

Results

The mail session instances are located in the JavaMail Sessions folder.

Example

You can configure mail provider and mail session settings.

- Configuring mail provider and mail session settings for application clients

The following code examples illustrates how to configure mail provider and mail session settings for application clients:

```
<resources.mail:MailProvider xmi:id="builtin_mailprovider" name="Built-in Mail Provider" description="The built-in mail provider">
  <factories xmi:type="resources.mail:MailSession"
             xmi:id="MailSession_1207766754834" name="MailSession"
             jndiName="mail/session" description="Sample mail session" category="Sample"
             mailTransportHost="smtp.coldmail.com" mailTransportUser="transportUser"
             mailTransportPassword="{xor}Lz4sLChvLTs="
             mailFrom="smith@coldmail.com" mailStoreHost="imap.coldmail.com" mailStoreUser="storeUser"
             mailStorePassword="{xor}Lz4sLChvLTs="
             debug="true" strict="true"
             mailTransportProtocol="builtin_smtp" mailStoreProtocol="builtin_imap">
    <propertySet xmi:id="J2EEResourcePropertySet_1207766778585">
      <resourceProperties xmi:id="J2EEResourceProperty_1207766778585" name="key" type="java.lang.String" value="value" required="false"/>
    </propertySet>
  </factories>
  <protocolProviders xmi:id="builtin_smtp" protocol="smtp" classname="com.sun.mail.smtp.SMTPTransport" type="TRANSPORT"/>
  <protocolProviders xmi:id="builtin_pop3" protocol="pop3" classname="com.sun.mail.pop3.POP3Store" type="STORE"/>
  <protocolProviders xmi:id="builtin_imap" protocol="imap" classname="com.sun.mail.imap.IMAPStore" type="STORE"/>
  <protocolProviders xmi:id="builtin_smtps" protocol="smtps" classname="com.sun.mail.smtp.SMTPSSLTransport" type="TRANSPORT"/>
  <protocolProviders xmi:id="builtin_pop3s" protocol="pop3s" classname="com.sun.mail.pop3.POP3SSLStore" type="STORE"/>
  <protocolProviders xmi:id="builtin_imaps" protocol="imaps" classname="com.sun.mail.imap.IMAPSSLStore" type="STORE"/>
</resources.mail:MailProvider>
```

- Required fields:
  - Mail Provider Properties page: name, and at least one protocol provider
  - Mail Session Properties page: name, jndiName, outgoing server and protocol, and/or incoming server and protocol
- Special cases:
  - If you use the ACRCT tool, the password field will be encrypted. You cannot encrypt the password field if you do not use the ACRCT tool.

Mail provider settings for application clients:

Use this page to implement the JavaMail API and create mail sessions.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right-click **Mail Providers** > and click **New**. The following fields appear on the **General** tab:

Name:

The name of the JavaMail resource provider.

Description:

An optional description for the resource provider.

Class Path:

Specifies a list of paths or JAR file names which together form the location for the resource provider classes.

Protocol:

Specifies the name of the protocol.

Classname:

Specifies the name of the class implementing the protocol. Leave this field blank if you want to use the default implementation.

Type:

This menu contains the following two values: `TRANSPORT` or `STORE`.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Mail session settings for application clients:

Use this page to configure mail session properties.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Mail Providers** > *mail provider instance*. Right-click **Mail Sessions** and click **New**. The following fields appear on the **General** tab:

Name:

Represents the administrative name of the JavaMail session object.

Description:

Provides an optional description for your administrative records.

JNDI Name:

The application client run time uses this field to retrieve configuration information.

Mail Transport Host:

Specifies the server to connect to when sending mail.

Mail Transport Protocol:

Specifies the transport protocol to use when sending mail.

Mail Transport User:

Specifies the user ID to use when the mail transport host requires authentication.

Mail Transport Password:

Specifies the password to use when the mail transport host requires authentication.

Enable strict Internet address parsing:

Specifies whether the recipient addresses must be parsed strictly in compliance with RFC 822, which is a specifications document issued by the Internet Architecture Board.

This setting is not generally used for most mail applications. RFC 822 syntax for parsing addresses effectively enforces a strict definition of a valid email address. If you select this setting, JavaMail will adhere to RFC 822 syntax and reject recipient addresses that do not parse into valid email addresses (as defined by the specification). If you do not select this setting, JavaMail will not adhere to RFC 822 syntax and will accept recipient addresses that do not comply with the specification. By default, this setting is deselected. You can view the RFC 822 specification at the following URL for the World Wide Web Consortium (W3C): http://www.w3.org/Protocols/rfc822/.

Re-Enter Password:

Confirms the password.

Mail From:

Specifies the mail originator.

Mail Store Host:

Specifies the mail account host (or "domain") name.

Mail Store User:

Specifies the user ID of the mail account.

Mail Store Password:

Specifies the password of the mail account.

Re-Enter Password:

Confirms the password.

Mail Store Protocol:

Specifies the protocol to be used when receiving mail.

Mail Debug:

When `true`, JavaMail interaction with mail servers, along with these mail session properties are printed to the `stdout` file.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Example: Configuring mail provider and mail session settings for application clients:

You can configure mail provider and mail session settings. This topic provides the required fields, special cases, and an example.

The purpose of this topic is to help you configure mail provider and mail session settings.

- Required fields:
  - Mail Provider Properties page: name, and at least one protocol provider
  - Mail Session Properties page: name, jndiName, outgoing server and protocol, and/or incoming server and protocol
- Special cases:
  - If you use the ACRCT tool, the password field will be encrypted. You cannot encrypt the password field if you do not use the ACRCT tool.
- Example:

```
<resources.mail:MailProvider xmi:id="builtin_mailprovider" name="Built-in Mail Provider" description="The built-in mail provider">
  <factories xmi:type="resources.mail:MailSession"
             xmi:id="MailSession_1207766754834" name="MailSession"
             jndiName="mail/session" description="Sample mail session" category="Sample"
             mailTransportHost="smtp.coldmail.com" mailTransportUser="transportUser"
             mailTransportPassword="{xor}Lz4sLChvLTs="
             mailFrom="smith@coldmail.com" mailStoreHost="imap.coldmail.com" mailStoreUser="storeUser"
             mailStorePassword="{xor}Lz4sLChvLTs="
             debug="true" strict="true"
             mailTransportProtocol="builtin_smtp" mailStoreProtocol="builtin_imap">
    <propertySet xmi:id="J2EEResourcePropertySet_1207766778585">
      <resourceProperties xmi:id="J2EEResourceProperty_1207766778585" name="key" type="java.lang.String" value="value" required="false"/>
    </propertySet>
  </factories>
  <protocolProviders xmi:id="builtin_smtp" protocol="smtp" classname="com.sun.mail.smtp.SMTPTransport" type="TRANSPORT"/>
  <protocolProviders xmi:id="builtin_pop3" protocol="pop3" classname="com.sun.mail.pop3.POP3Store" type="STORE"/>
  <protocolProviders xmi:id="builtin_imap" protocol="imap" classname="com.sun.mail.imap.IMAPStore" type="STORE"/>
  <protocolProviders xmi:id="builtin_smtps" protocol="smtps" classname="com.sun.mail.smtp.SMTPSSLTransport" type="TRANSPORT"/>
  <protocolProviders xmi:id="builtin_pop3s" protocol="pop3s" classname="com.sun.mail.pop3.POP3SSLStore" type="STORE"/>
  <protocolProviders xmi:id="builtin_imaps" protocol="imaps" classname="com.sun.mail.imap.IMAPSSLStore" type="STORE"/>
</resources.mail:MailProvider>
```

Configuring new mail sessions for application clients:

You can use the Application Client Resource Configuration Tool (ACRCT) to configure new mail sessions for your application client.

Before you begin

During this task, you configure new mail sessions for your application client. The mail sessions are associated with the pre-configured default mail provider supplied by the product.

Procedure

1. Start the Application Client Resource Configuration Tool (ACRCT) and open the EAR file. The EAR file contents are displayed in a tree view.
2. Select the JAR file in which you want to configure the new JavaMail session.
3. Expand the JAR file to view its contents.
4. Click **Mail Providers > Mail Provider > Mail Sessions**. Complete one of the following actions:
   - Right click the Mail Sessions folder and select **New Factory**.
   - Click **Edit > New** on the menu bar.
5. Configure the Mail Session properties in the displayed fields.
6. Click **OK**.
7. Click **File > Save** on the menu bar to save your changes.

Configuring new URL providers for application clients:

You can create URL providers and URLs for your client application using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

During this task, you create URL providers and URLs for your client application. In a separate administrative task, you must install the Java code for the required URL provider on the client machine on which the client application resides.

About this task

Procedure

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure the new URL provider. The EAR file contents display in a tree view.
3. Select the JAR file in which you want to configure the new URL provider from the tree.
4. Expand the JAR file to view the contents.
5. Click the folder called URL Providers. Complete one of the following actions:
   - Right click the folder and select **New**.
   - Click **Edit > New** on the menu bar.
6. Configure the URL provider properties in the resulting property dialog.
7. Click **OK**.
8. Click **File > Save** on the menu bar to save your changes.

Example

- Configuring URL and URL provider settings for application clients

This code example illustrates how to configure URL and URL provider settings for application clients:

```
<resources.url:URLProvider xmi:id="URLProvider_1" name="urlProvider:name"
description="urlProvider:description"
streamHandlerClassName="urlProvider:streamHandlerClass"
protocol="urlProvider:protocol">
<classpath>urlProvider:classpath</classpath>
<factories xmi:type="resources.url:URL" xmi:id="URL_1" name="urlFactory:name"
jndiName="urlFactory:jndiName" description="urlFactory:description"
spec="urlFactory:url">
<propertySet xmi:id="J2EEResourcePropertySet_18">
<resourceProperties xmi:id="J2EEResourceProperty_20" name="urlFactory:customName"
value="urlFactory:customValue"/>
</propertySet>
```

```
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_19">
<resourceProperties xmi:id="J2EEResourceProperty_21" name="urlProvider:customName"
value="urlProvider:customValue"/>
</propertySet>
</resources.url:URLProvider>
```

- Required fields:
  - URL Properties page: name, jndiName, url
  - URL Provider Properties page: name

URLs for application clients:

A *Uniform Resource Locator* (URL) is an identifier that points to an electronically accessible resource, such as a directory file on a machine in a network, or a document stored in a database.

URLs appear in the format *scheme*:*scheme_information*.

You can represent a *scheme* as `http`, `ftp`, `file`, or another term that identifies the type of resource and the mechanism by which you can access the resource.

In a web browser location or address box, a URL for a file available using HyperText Transfer Protocol (HTTP) starts with `http:`. An example is `http://www.ibm.com`. Files available using File Transfer Protocol (FTP) start with `ftp:`. Files available locally start with `file:`.

The *scheme_information* commonly identifies the Internet machine making a resource available, the path to that resource, and the resource name. The scheme_information for HTTP, FTP and File generally starts with two slashes (//), then provides the Internet address separated from the resource path name with one slash (/). For example,

`http://www.ibm.com/software/webservers/appserv/library.html`.

For HTTP and FTP, the path name ends in a slash when the URL points to a directory. In such cases, the server generally returns the default index for the directory.

URL providers for the Application Client Resource Configuration Tool:

A URL provider implements the function for a particular URL protocol, such as HyperText Transfer Protocol (HTTP). This provider, comprised of a pair of classes, extends the java.net.URLStreamHandler and java.net.URLConnection classes.

Configuring URL providers and sessions using the Application Client Resource Configuration Tool:

You can edit the configurations of URL providers and URLs to be used by your application clients using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

Use the Application Client Resource Configuration Tool (ACRCT) to edit the configurations of URL providers and URLs to be used by your application clients.

About this task

Procedure

1. Start the ACRCT.
2. Open an EAR file.

3. Locate the URL objects in the tree that displays. For example, if your file contains URL providers and URLs, expand **Resources > *application* > .jar > URL Providers > *url_provider_instance***
   where *url_provider_instance* is a particular URL provider.
4. If you expand the tree further, you will also see the URLs folders containing the URL instances for each URL provider instance.

URL settings for application clients:

Use this page to implement the function for a particular URL protocol, such as Hyper Text Transfer Protocol (HTTP).

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **URL Providers** > *URL provider instance*. Right-click **URLs** and click **New**. The following fields appear on the **General** tab.

This provider, comprised of classes, extends the `java.net.URLStreamHandler` and `java.net.URLConnection` classes.

Name:

The administrative name for the URL.

Description:

This is an optional description of the URL for your administrative records.

JNDI Name:

The application client run time uses this field to retrieve configuration information.

URL:

A Uniform Resource Locator (URL) name that points to an Internet or intranet resource. For example: `http://www.ibm.com`.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

URL provider settings for application clients:

Use this page create new URL providers.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right click **URL Providers**, and click **New**. The following fields appear on the **General** tab.

A URL provider implements the function for a particular URL protocol, such as Hyper Text Transfer Protocol (HTTP). This provider, comprised of classes, extends the `java.net.URLStreamHandler` and `java.net.URLConnection` classes.

Name:

Administrative name for the URL.

Description:

Optional description of the URL, for your administrative records.

Class Path:

A list of paths or JAR file names which together form the location for the resource provider classes.

Protocol:

Protocol supported by this stream handler. For example, `nntp`, `smtp`, `ftp`, and so on.

To use the default protocol, leave this field blank.

Stream handler class:

Fully qualified name of a User-defined Java class that extends the `java.net.URLStreamHandler` for a particular URL protocol, such as FTP.

To use the default stream handler, leave this field blank.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Example: Configuring URL and URL provider settings for application clients:

You can configure URL and URL provider settings. This topic provides the required fields and an example.

The purpose of this article is to help you to configure URL and URL provider settings.

- Required fields:
  - URL Properties page: name, jndiName, url
  - URL Provider Properties page: name
- Example:

```
<resources.url:URLProvider xmi:id="URLProvider_1" name="urlProvider:name"
description="urlProvider:description"
streamHandlerClassName="urlProvider:streamHandlerClass"
protocol="urlProvider:protocol">
<classpath>urlProvider:classpath</classpath>
<factories xmi:type="resources.url:URL" xmi:id="URL_1" name="urlFactory:name"
jndiName="urlFactory:jndiName" description="urlFactory:description"
spec="urlFactory:url">
<propertySet xmi:id="J2EEResourcePropertySet_18">
<resourceProperties xmi:id="J2EEResourceProperty_20" name="urlFactory:customName"
value="urlFactory:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_19">
```

```
<resourceProperties xmi:id="J2EEResourceProperty_21" name="urlProvider:customName"
value="urlProvider:customValue"/>
</propertySet>
</resources.url:URLProvider>
```

Configuring new URLs with the Application Client Resource Configuration Tool:

You can use URLs for your client application using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

During this task, you create URLs for your client application.

About this task

Procedure

1. Click the URL provider for which you want to create a URL in the tree. Complete one of the following:
   - Configure a new URL provider.
   - Click an existing URL provider.
2. Expand the URL provider to view the URLs folder.
3. Click the URL folder. Complete one of the following actions:
   - Right click the folder and click **New**.
   - Click **Edit -> New** on the menu bar.
4. Configure the URL properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File > Save** in the menu bar to save your changes.

Configuring Java messaging client resources:

To configure Java messaging client resources, you create new JMS provider configurations for your application client. The application client can use a messaging service through the Java Message Service APIs. A JMS provider provides two kinds of J2EE factories. One is a *JMS connection factory*, and the other is a *JMS destination factory*.

Before you begin

In a separate administrative task, install the Java Message Service (JMS) client on the client machine where the application client resides. The messaging product vendor must provide an implementation of the JMS client. For more information, see your messaging product documentation.

Attention: When completing this task, you can either create a new messaging provider, or you can use an existing one.

Procedure

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure the new JMS provider. The EAR file contents are in the displayed tree view.
3. Select the JAR file in which you want to configure the new JMS provider from the tree.
4. Expand the JAR file to view its contents.
5. Optionally right-click **Messaging Providers** and select **New**, if you want to create and use a new messaging provider.
6. Configure the JMS provider properties in the resulting property dialog.

7. Click **OK**.
8. Click **File > Save**.

Asynchronous messaging in WebSphere Application Server using JMS:

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) programming interface. The JMS interface provides a common way for Java programs (clients and Java Platform, Enterprise Edition (Java EE) applications) to create, send, receive, and read asynchronous requests as JMS messages.

This topic provides a generic overview of asynchronous messaging using the JMS support provided by WebSphere Application Server.

The base support for asynchronous messaging using the JMS API provides the common set of JMS interfaces and associated semantics that define how a JMS client can access the facilities of a JMS provider. This support enables WebSphere product Java EE applications, as JMS clients, to exchange messages asynchronously with other JMS clients, by using JMS destinations (queues or topics). A Java EE application can use JMS queue destinations for point-to-point messaging and JMS topic destinations for publish and subscribe messaging. A Java EE application can explicitly poll for messages on a destination, and then retrieve messages for processing by business logic beans (enterprise beans).

With the base JMS and XA support, the Java EE application uses standard JMS calls to process messages, including any responses or outbound messaging. An enterprise bean can handle responses acting as a sender bean, or within the enterprise bean that receives the incoming messages. Optionally, this process can use two-phase commit within the scope of a transaction. This level of function for asynchronous messaging is called *bean-managed messaging*, and gives an enterprise bean complete control over the messaging infrastructure, for example, connection and session pool management. The common container has no role in bean-managed messaging.

WebSphere Application Server also supports automatic asynchronous messaging using message-driven beans (a type of enterprise bean defined in the Enterprise JavaBeans (EJB) 2.0 specification) and JMS listeners (part of the JMS application server facilities). Messages are automatically retrieved from JMS destinations, optionally within a transaction, then sent to the message-driven bean in a Java EE application, without the application having to explicitly poll JMS destinations.

Java Message Service providers for clients:

Client applications can use messaging resources from three main types of Java Message Service (JMS) providers in WebSphere Application Server: The WebSphere Application Server default messaging provider (which uses service integration as the provider), the WebSphere MQ messaging provider (which uses your WebSphere MQ system as the provider) and third-party messaging providers (which use another company's product as the provider).

IBM WebSphere Application Server supports asynchronous messaging through the use of a JMS provider and its related messaging system. JMS providers must conform to the JMS specification version 1.1. To use message-driven beans the JMS provider must support the optional Application Server Facility (ASF) function defined within that specification, or support an inbound resource adapter as defined in the JCA specification version 1.5.

Default messaging provider

If you mainly want to use messaging between applications in WebSphere Application Server, perhaps with some interaction with a WebSphere MQ system, the default messaging provider is the natural choice. This provider is based on service integration technologies and is fully integrated with the WebSphere Application Server runtime environment.

WebSphere MQ messaging provider

If your business also uses WebSphere MQ, and you want to integrate WebSphere Application

Server messaging applications into a predominately WebSphere MQ network, choose the WebSphere MQ messaging provider, which allows you to define resources for connecting to any queue manager on the WebSphere MQ network.

Third-party messaging provider
You can configure any third-party messaging provider that supports the JMS Version 1.1 unified connection factory. You might want to do this, for example, because of existing investments.

Note: In WebSphere Application Server 7.0, the Version 5 default messaging provider is deprecated.

Note: For backwards compatibility with earlier releases, WebSphere Application Server Version 7 supports the (deprecated) Version 5 default messaging provider and the Version 6 WebSphere MQ messaging provider. This support enables your applications that still use these resources to communicate with Version 5 and Version 6 nodes in Version 7 mixed cells.

WebSphere applications can use messaging resources provided by any of these JMS providers. However the choice of provider is most often dictated by requirements to use or integrate with an existing messaging system. For example, you may already have a messaging infrastructure based on WebSphere MQ. In this case you may either connect directly using the included support for WebSphere MQ as a JMS provider, or configure a service integration bus with links to a WebSphere MQ network and then access the bus through the default messaging provider.

Configuring new JMS providers with the Application Client Resource Configuration Tool:

You can create new Java Message Service (JMS) provider configurations for the Application Client. The Application Client makes use of a messaging service through the JMS interfaces.

About this task

During this task, you create new Java Message Service (JMS) provider configurations for the Application Client. The Application Client makes use of a messaging service through the JMS interfaces. A JMS provider provides two kinds of Java Platform, Enterprise Edition (Java EE) resources. One is a JMS connection factory, and the other is a JMS destination.

In a separate administrative task, you must install the JMS client on the client machine where your particular application client resides. The messaging product vendor must provide an implementation of the JMS client. For more information, see your messaging product documentation.

Procedure

1. Start the Application Client Resource Configuration Tool and open the EAR file for which you want to configure the new JMS provider. The EAR file contents are displayed in a tree view.
2. From the tree, select the JAR file in which you want to configure the new JMS provider.
3. Expand the JAR file to view its contents.
4. Right-click **Messaging Providers**. Complete one of the following actions:
   - Right click the folder and select **New**.
   - On the menu bar, click **Edit > New**.
5. In the resulting property dialog, configure the JMS provider properties.
6. Click **OK** when finished.
7. Click **File > Save** on the menu bar to save your changes.

Example

The following code example illustrates how to configure JMS Provider, JMS Connection Factory and JMS Destination settings for application clients.

```
<resources.jms:JMSProvider xmi:id="JMSProvider_3" name="genericJMSProvider:name"
description="genericJMSProvider:description"
externalInitialContextFactory="genericJMSProvider:contextFactoryClass"
externalProviderURL="genericJMSProvider:providerUrl">
<classpath>genericJMSProvider:classpath</classpath>
<factories xmi:type="resources.jms:GenericJMSDestination"
xmi:id="GenericJMSDestination_1" name="jmsDestination:name"
jndiName="jmsDestination:jndiName" description="jmsDestination:description"
externalJNDIName="jmsDestination:externalJndiName" type="QUEUE">
<propertySet xmi:id="J2EEResourcePropertySet_15">
<resourceProperties xmi:id="J2EEResourceProperty_17" name="jmsDestination:customName"
value="jmsDestination:customValue"/>
</propertySet>
</factories>
<factories xmi:type="resources.jms:GenericJMSConnectionFactory"
xmi:id="GenericJMSConnectionFactory_1" name="jmsCF:name" jndiName="jmsCF:jndiName"
description="jmsCF:description" userID="jmsCF:user" password="{xor}NTIsHBllMT4yOg=="
externalJNDIName="jmsCF:externalJndiName" type="QUEUE">
<propertySet xmi:id="J2EEResourcePropertySet_16">
<resourceProperties xmi:id="J2EEResourceProperty_18" name="jmsCF:customName"
value="jmsCF:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_17">
<resourceProperties xmi:id="J2EEResourceProperty_19"
name="genericJMSProvider:customName" value="genericJMSProvider:customValue"/>
</propertySet>
</resources.jms:JMSProvider>
```

Required fields include:
- JMS Provider Properties page: name, and at least one protocol provider
- JMS Connection Factory Properties page: name, jndiName, destination type
- JMS Destination Properties page: name, jndiName, destination type

Special cases:
- The destination type must be QUEUE, or TOPIC.

JMS provider settings for application clients:

Use this page to configure properties of the Java Message Service (JMS) provider, if you want to use a JMS provider other than the default messaging provider or the WebSphere MQ as a JMS provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file. Right click **Messaging Providers**, and click **New**. The following fields appear on the **General** tab.

Name:

The name by which the JMS provider is known for administrative purposes.

Data type String

Description:

A description of the JMS provider, for administrative purposes.

Data type String

Class Path:

A list of paths or `.jar` file names which together form the location for the resource provider classes.

Context factory class:

The Java class name of the initial context factory for the JMS provider.

For example, for an LDAP service provider the value has the form: `com.sun.jndi.ldap.LdapCtxFactory`.

Data type String

Provider URL:

The JMS provider URL for external JNDI lookups.

For example, an LDAP URL for a JMS provider has the form: `ldap://hostname.company.com/contextName`.

Data type String

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Default Provider connection factory settings:

Use this panel to view or change the configuration properties of the selected JMS connection factory for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server. These configuration properties control how connections are created between the JMS provider and the service integration bus that it uses

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Connection Factories** and click **New**. The following fields appear on the **General** tab.

Settings that have a default value display the appropriate value. Any settings that have fixed values have a drop down menu.

Name:

The name of the connection factory.

Data type String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI Name:

The JNDI name that is used to match this Resource Adapter connection factory definition to the deployment descriptor. This entry is a `resource-ref` name.

Data type String

User Name:

The **User Name** used with the **Password** property for connecting to an application.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly. If a user name and password are specified, then an authentication alias is created for the factory where the password is encrypted.

Data type String

Password:

The password used to authenticate connection to an application.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

Data type String

Re-Enter Password:

Confirms the password.

Bus Name:

The name of the bus to which the connection factory connects.

Data type String

Client Identifier:

The name of the client. Required for durable topic subscriptions.

Data type String

Nonpersistent Messaging Reliability:

The reliability applied to nonpersistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus** destination. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default
ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Persistent Message Reliability:

The reliability applied to persistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus destination**. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default
ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Durable Subscription Home:

The name of the durable subscription home.

Data type String

Share durable subscriptions:

Controls whether or not durable subscriptions are shared across connections with members of a server cluster.

Normally, only one session at a time can have a TopicSubscriber for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers.

Data type Selection list
Default In cluster
Range

In cluster
Allows sharing of durable subscriptions when connections are made from within a server cluster.

Always shared
Durable subscriptions can be shared across connections.

Never shared
Durable subscriptions are never shared across connections.

Read Ahead:

Controls the read-ahead optimization during message delivery.

Default	Default
Range	Default, AlwaysOn and AlwaysOff

Target:

The name of the Workload Manager target group containing the messaging engine.

Data type	String

Target Type:

The type of Workload Manager target group that contains the messaging engine.

Default	BusMember
Range	BusMember, Custom, ME

Target Significance:

The priority of significance for the target specified.

Default	Preferred
Range	Preferred, Required

Target Inbound Transport Chain:

The name of the protocol that resolves to a group of messaging engines.

Data type	String

Provider Endpoints:

The list of comma separated endpoints used to connect to a bootstrap server.

Type a comma-separated list of endpoint triplets with the syntax: host:port:protocol.

Example	`merlin:7276:BootstrapBasicMessaging,Gandalf:5557:BootstrapSecureMessaging` where `BootstrapBasicMessaging` corresponds to the remote protocol InboundBasicMessaging (JFAP-TCP/IP).
Default	• If the host name is not specified, then the default `localhost` is used as a default value. • If the port number is not specified, then `7276` is used as a default value. • If the chain name is not specified, a predefined chain, such as `BootstrapBasicMessaging`, is used as a default value.

Connection Proximity:

The proximity that the messaging engine should have to the requester.

Default Bus
Range Bus, Host, Cluster, Server

Temporary Queue Name Prefix:

The prefix to apply to the names of temporary queues. This name is a maximum of 12 characters.

Data type String

Temporary Topic Name Prefix:

The prefix to apply to the names of temporary topics. This name is a maximum of 12 characters.

Data type String

Default Provider queue connection factory settings:

Use this panel to view or change the configuration properties of the selected JMS queue connection factory for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server. These configuration properties control how connections are created between the JMS provider and the service integration bus that it uses

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Queue Connection Factories** and click **New**. The following fields appear on the **General** tab.

Settings that have a default value display the appropriate value. Any settings that have fixed values have a drop down menu.

Name:

The name of the queue connection factory.

Data type String

Description:

A description of this queue connection factory for administrative purposes within WebSphere Application Server.

Data type String

JNDI Name:

The JNDI name that is used to match this queue connection factory definition to the deployment descriptor. This entry is a `resource-ref` name.

Data type String

User Name:

The **User Name** used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly. If this field is used, then the Properties field `UserName` is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User Name** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly. If a user name and password are specified, then an authentication alias is created for the factory where the password is encrypted.

Data type String

Password:

The password used to create an encrypted. If you complete this field, then the Password field in the Properties box is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

Data type String

Re-Enter Password:

Confirms the password.

Bus Name:

The name of the bus to which the queue connection factory connects.

Data type String

Client Identifier:

The client identifier. Required for durable topic subscriptions.

Data type String

Nonpersistent Messaging Reliability:

The reliability applied to nonpersistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus** destination. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Persistent Message Reliability:

The reliability applied to persistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus destination**. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Read Ahead:

Controls the read-ahead optimization during message delivery.

Default Default
Range Default, AlwaysOn and AlwaysOff

Target:

The name of the Workload Manager target group containing the messaging engine.

Data type String

Target Type:

The type of Workload Manager target group that contains the messaging engine.

Default BusMember
Range BusMember, Custom, Destination, ME

Target Significance:

The priority of significance for the target specified.

Default Preferred
Range Preferred, Required

Target Inbound Transport Chain:

The name of the protocol that resolves to a group of messaging engines.

Data type String

Provider Endpoints:

The list of comma separated endpoints used to connect to a bootstrap server.

Type a comma-separated list of endpoint triplets with the syntax: host:port:protocol.

Example `localhost:7777:BootstrapBasicMessaging`

where

`BootstrapBasicMessaging` corresponds to the remote protocol InboundBasicMessaging (JFAP-TCP/IP).

Default

- If the host name is not specified, then the default `localhost` is used as a default value.
- If the port number is not specified, then `7276` is used as a default value.
- If the chain name is not specified, a predefined chain, such as `BootstrapBasicMessaging`, is used as a default value.

Connection Proximity:

The proximity that the messaging engine should have to the requester.

Default Bus, Cluster, Server
Range Bus, Host

Temporary Queue Name Prefix:

The prefix to apply to the names of temporary queues. This name is a maximum of 12 characters.

Data type String

Default Provider topic connection factory settings:

Use this panel to view or change the configuration properties of the selected JMS topic connection factory for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server. These configuration properties control how connections are created between the JMS provider and the service integration bus that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Topic Connection Factories** and click **New**. The following fields appear on the **General** tab.

Settings that have a default value display that appropriate value. Any settings that have fixed values have a drop down menu.

Name:

The name of the topic connection factory.

Data type String

Description:

A description of this topic connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI Name:

The JNDI name that is used to match this topic connection factory definition to the deployment descriptor. This entry is a `resource-ref` name.

Data type String

User Name:

The **User Name** used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly. If this field is used, then the Properties field `UserName` is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

The connection factory **User Name** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly. If a user name and password are specified, then an authentication alias is created for the factory where the password is encrypted.

Data type String

Password:

The password used to create an encrypted. If you complete this field, then the Password field in the Properties box is ignored.

If you specify a value for the **User Name** property, you must also specify a value for the **Password** property.

Data type String

Re-Enter Password:

Confirms the password.

Bus Name:

The name of the bus to which the topic connection factory connects.

Data type String

Client Identifier:

The name of the client. This field is required for durable topic subscriptions.

Data type String

Nonpersistent Messaging Reliability:

The reliability applied to nonpersistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus** destination. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Persistent Message Reliability:

The reliability applied to persistent JMS messages sent using this connection factory.

If you want different reliability delivery options for individual JMS destinations, you can set this property to **As bus destination**. The reliability is then defined by the Reliability property of the bus destination to which the JMS destination is assigned.

Default ReliablePersistent

Range

None There is no message reliability for nonpersistent messages. If a nonpersistent message cannot be delivered, it is discarded.

Best effort nonpersistent
Messages are never written to disk, and are thrown away if memory cache overruns.

Express nonpersistent
Messages are written asynchronously to persistent storage if memory cache overruns, but are not kept over server restarts.

Reliable nonpersistent
Messages can be lost if a messaging engine fails, and can be lost under normal operating conditions.

Reliable persistent
Messages can be lost if a messaging engine fails, but are not lost under normal operating conditions.

Assured persistent
Highest degree of reliability where assured message delivery is supported.

As Bus destination
Use the delivery option configured for the bus destination.

Durable Subscription Home:

The name of the durable subscription home.

Data type String

Share durable subscriptions:

Controls whether or not durable subscriptions are shared across connections with members of a server cluster.

Normally, only one session at a time can have a TopicSubscriber for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers.

Data type Selection list
Default In cluster
Range

In cluster
Allows sharing of durable subscriptions when connections are made from within a server cluster.

Always shared
Durable subscriptions can be shared across connections.

Never shared
Durable subscriptions are never shared across connections.

Read Ahead:

Controls the read-ahead optimization during message delivery.

Default	Default
Range	Default, AlwaysOn and AlwaysOff

Target:

The name of the Workload Manager target group containing the messaging engine.

Data type	String

Target Type:

The type of Workload Manager target group that contains the messaging engine.

Default	BusMember
Range	BusMember, Custom, ME

Target Significance:

The priority of significance for the target specified.

Default	Preferred
Range	Preferred, Required

Target Inbound Transport Chain:

The name of the protocol that resolves to a group of messaging engines.

Data type	String

Provider Endpoints:

The list of comma separated endpoints used to connect to a bootstrap server.

Type a comma-separated list of endpoint triplets with the syntax: host:port:protocol.

Example	`localhost:7777:BootstrapBasicMessaging` where `BootstrapBasicMessaging` corresponds to the remote protocol InboundBasicMessaging (JFAP-TCP/IP).
Default	• If the host name is not specified, then the default `localhost` is used as a default value. • If the port number is not specified, then `7276` is used as a default value. • If the chain name is not specified, a predefined chain, such as `BootstrapBasicMessaging`, is used as a default value.

Connection Proximity:

The proximity that the messaging engine should have to the requester.

Default Bus
Range Bus, Host, Cluster, Server

Temporary Topic Name Prefix:

The prefix to apply to the names of temporary topics. This name is a maximum of 12 characters.

Data type String

Default Provider queue destination settings:

Use this panel to view or change the configuration properties of the selected JMS queue destination for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Queue Destinations**. Click **New**. The following fields appear on the **General** tab.

Name:

The name of the queue destination factory. You must complete this field.

Data type String

Description:

A description of this queue destination for administrative purposes within WebSphere Application Server.

Data type String

JNDI Name:

The JNDI name used to match this definition to a deployment descriptor `resource-env-ref` name.

Data type String

Queue Name:

The name of the queue.

Data type String

Delivery Mode:

The delivery mode for messages sent to this destination.

Data type String
Range Application, Persistent or NonPersistent

Default Application

Time to Live:

The default length of time from its dispatch time that a message sent to this destination should be retained by the system, where **0** indicates that time to live value does not expire. Value from the producer is used if the Time to Live field is not completed.

Data type Integer
Units Milliseconds

Priority:

The priority for messages sent to this destination. The value from the producer is used if not completed.

Data type Integer
Range 0 to 9 with **0** as the lowest priority and **9** as the highest priority

Read Ahead:

Used to control read-ahead optimization during message delivery.

Data type String
Range AsConnection, AlwaysOn and AlwaysOff
Default AsConnection

Default Provider topic destination settings:

Use this panel to view or change the configuration properties of the selected JMS topic destination for use with the internal product Java Message Service (JMS) provider that is installed with WebSphere Application Server.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Default Provider**. Right-click **Topic Destinations**, and click **New**. The following fields appear on the **General** tab.

Name:

The name of the topic destination entry.

Data type String

Description:

A description of the entry.

Data type String

JNDI Name:

The JNDI name used to match this definition to a deployment descriptor `resource-env-ref` name.

Data type String

Topic Space:

The name of the topic space. This field is required.

Data type String
Default DEFAULT_TOPIC_SPACE

Topic Name:

The name of the topic. This field is required.

Data type String

Delivery Mode:

The default mode for messages sent to this destination.

Data type String
Range Application, Persistent or NonPersistent
Default Application

Time to Live:

The default length of time from its dispatch time that a message sent to this destination should be retained by the system, where **0** indicates that time to live value does not expire. Value from the producer is used if not completed.

Data type Long
Units Milliseconds

Priority:

The priority for messages sent to this destination. Value from producer is used if not completed.

Data type Integer
Range 0 to 9 with **0** as the lowest priority and **9** as the highest priority

Read Ahead:

Used to control read-ahead optimization during message delivery.

Data type String
Range AsConnection, AlwaysOn and AlwaysOff
Default AsConnection

V5 default messaging provider queue connection factory settings for application clients:

Use this panel to browse or change the configuration properties of the selected JMS queue connection factory for point-to-point messaging for use by WebSphere Application Server version 5 applications. These configuration properties control how connections are created between the JMS provider and the default messaging system that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Provider** > **Version 5 Default Provider**. Right-click **Queue Connection Factories** and click **New**. The following fields appear on the **General** tab.

A queue connection factory is used to create JMS connections to queue destinations. The queue connection factory is created by the internal WebSphere Application Server product JMS provider. A V5 default messaging provider queue connection factory has the following properties:

Name:

The name by which this queue connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

JNDI Name:

The application client run time uses this field to retrieve configuration information.

User ID:

The User ID used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a User ID and password explicitly, for example, if the calling application uses the method createQueueConnection(). The JMS client flows the `userid` and `password` to the JMS server.

Data type String

Password:

The password used, with the **User ID** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Re-Enter Password:

Confirms the password.

Node:

The WebSphere node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

Data type String

Application Server:

Enter the name of the application server. This name is not the host name of the machine, but the name of the configured application server.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

V5 default messaging provider topic connection factory settings for application clients:

Use this panel to view or change the configuration properties of the selected topic connection factory for use with the internal product Java Message Service (JMS) provider. These configuration properties control how connections are created between the JMS provider and the messaging system that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Version 5 Default Provider**. Right click **Topic Connection Factories** and click **New**. The following fields appear on the **General** tab.

A V5 default messaging provider topic connection factory has the following properties.

Name:

The name by which this queue connection factory is known for administrative purposes within WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere Application Server administrative domain.

Data type String

Description:

A description of this topic connection factory for administrative purposes within WebSphere Application Server.

Data type String

JNDI Name:

The application client run time uses this field to retrieve configuration information.

User ID:

The user ID used, with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a `userid` and `password` explicitly, for example, if the calling application uses the method createTopicConnection(). The JMS client flows the `userid` and `password` to the JMS server.

Data type	String

Password:

The password used, with the **User ID** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Data type	String

Re-Enter Password:

Confirms the password.

Node:

The WebSphere Application Server node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

Data type	Enum
Range	Pull-down list of nodes in the WebSphere Application Server administrative domain.

Application Server:

Enter the name of the application server. This name is not the host name of the machine, but the name of the configured application server.

Port:

Which of the two ports that connections use to connect to the JMS Server. The QUEUED port is for full-function JMS publish/subscribe support, the DIRECT port is for nonpersistent, nontransactional, nondurable subscriptions only.

Note: Message-driven beans cannot use the direct listener port for publish or subscribe support. Therefore, any topic connection factory configured with the Port set to `Direct` cannot be used with message-driven beans.

Data type	Enum
Default	QUEUED

Range

QUEUED
The listener port used for full-function JMS compliant, publish or subscribe support.

DIRECT
The listener port used for direct TCP/IP connection (nontransactional, nonpersistent, and nondurable subscriptions only) for publish or subscribe support.

The TCP/IP port numbers for these ports are defined on the product internal JMS server.

Client ID:

The JMS client identifier used for connections to the MQSeries® queue manager.

Data type String

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

V5 default messaging provider queue destination settings for application clients:

Use this panel to view or change the configuration properties of the selected queue destination for use with product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Version 5 Default Provider**. Right click **Queue Destinations** and click **New**. The following fields are displayed on the **General** tab.

A queue destination is used to configure the properties of a JMS queue. A V5 default messaging provider queue destination has the following properties.

Name:

The name by which the queue is known for administrative purposes within WebSphere Application Server.

Data type String

Description:

A description of the queue, for administrative purposes.

Data type String

JNDI Name:

The application client run time uses this field to retrieve configuration information.

Persistence:

Whether all messages sent to the destination are persistent, nonpersistent, or have their persistence defined by the application.

Data type Enum
Default APPLICATION_DEFINED
Range
Application defined
Messages on the destination have their persistence defined by the application that put them onto the queue.
Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
Persistent
Messages on the destination are persistent.
Nonpersistent
Messages on the destination are not persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property.

Data type Enum
Default APPLICATION_DEFINED
Range
Application defined
The priority of messages on this destination is defined by the application that put them onto the destination.
Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
Specified
The priority of messages on this destination is defined by the **Specified priority** property. *If you select this option, you must define a priority on the **Specified priority** property.*

Specified Priority:

If the **Priority** property is set to `Specified`, type here the message priority for this queue, in the range 0 (lowest) through 9 (highest).

If the **Priority** property is set to `Specified`, messages sent to this queue have the priority value specified by this property.

Data type Integer
Units Message priority level
Range 0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or whether messages on the queue expire (have an unlimited expiry timeout).

Data type Enum

Default APPLICATION_DEFINED

Range

Application defined
The expiry timeout for messages in this queue is defined by the application that put them onto the queue.

Specified
The expiry timeout for messages in this queue is defined by the **Specified expiry** property.If you select this option, you must define a time out on the **Specified expiry** property.

Unlimited
Messages in this queue have no expiry timeout, and those messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to `Specified`, specify the number of milliseconds (greater than 0) after which messages on this queue expire.

Data type Integer

Units Milliseconds

Range Greater than or equal to 0

- 0 indicates that messages never timeout.
- Other values are an integer number of milliseconds.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

V5 default messaging provider topic destination settings for application clients:

Use this panel to view or change the configuration properties of the selected topic destination for use with the internal product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **Version 5 Default Provider**. Right click **Topic Destinations** and click **New**. The following fields appear on the **General** tab.

A topic destination is used to configure the properties of a JMS topic for the associated JMS provider. A V5 default messaging provider topic has the following properties.

Name:

The name by which the topic is known for administrative purposes.

Data type String

Description:

A description of the topic, for administrative purposes within WebSphere Application Server.

Data type String

JNDI Name:

The application client run-time environment uses this field to retrieve configuration information.

Topic Name: The name of the topic as defined to the JMS provider.

Data type String

Persistence:

Whether all messages sent to the destination are persistent, nonpersistent, or have their persistence defined by the application.

Data type Enum
Default APPLICATION_DEFINED
Range

Application defined
Messages on the destination have their persistence defined by the application that put them onto the queue.

Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

Persistent
Messages on the destination are persistent.

Nonpersistent
Messages on the destination are not persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property.

Data type Enum
Default APPLICATION_DEFINED
Range

Application defined
The priority of messages on this destination is defined by the application that put them onto the destination.

Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

Specified
The priority of messages on this destination is defined by the **Specified priority** property.*If you select this option, you must define a priority on the **Specified priority** property.*

Specified Priority:

If the **Priority** property is set to `Specified`, specify the message priority for this queue, in the range 0 (lowest) through 9 (highest).

If the **Priority** property is set to `Specified`, messages sent to this queue have the priority value specified by this property.

Data type	Integer
Units	Message priority level
Range	0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or messages on the queue never expire (have an unlimited expiry timeout).

Data type	Enum
Default	APPLICATION_DEFINED
Range	**Application defined** The expiry timeout for messages on this queue is defined by the application that put them onto the queue. **Specified** The expiry timeout for messages on this queue is defined by the **Specified expiry** property. *If you select this option, you must define a timeout on the **Specified expiry** property.* **Unlimited** Messages on this queue have no expiry timeout, so those messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to `Specified`, type here the number of milliseconds (greater than 0) after which messages on this queue expire.

Data type	Integer
Units	Milliseconds
Range	Greater than or equal to 0 • 0 indicates that messages never time out. • Other values are an integer number of milliseconds.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

WebSphere MQ Provider queue connection factory settings for application clients:

Use this panel to view or change the configuration properties of the selected queue connection factory for use with the WebSphere MQ Java Message Service (JMS) provider. These configuration properties control how connections are created between the JMS provider and WebSphere MQ.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file and click **Messaging Providers** > **WebSphere MQ Provider**. Right click **Queue Connection Factories**, and click **New**. The following fields are displayed on the **General** tab.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the *Using Java* section of the WebSphere MQ information center.
- In WebSphere MQ, names can have a maximum of 48 characters, except for channels which have a maximum of 20 characters.

A queue connection factory for the JMS provider has the following properties.

Name:

The name by which this queue connection factory is known for administrative purposes within WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type String

Description:

A description of this connection factory for administrative purposes within WebSphere Application Server.

Data type String
Default Null

JNDI Name:

The application client run time uses this field to retrieve configuration information.

User ID:

The user ID used, with the password property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the user ID property, you must also specify a value for the password property.

The connection factory user ID and password properties are used if the calling application does not provide a user ID and password explicitly; for example, if the calling application uses the method createQueueConnection(). The JMS client flows the user ID and password to the JMS server.

Data type String

Password:

The password used, with the user ID property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the user ID property, you must also specify a value for the password property.

Data type String
Default Null

Re-Enter Password:

Confirms the password.

Queue Manager:

The name of the WebSphere MQ queue manager for this connection factory.

Connections created by this factory connect to that queue manager.

Data type	String

Enter Hostname and Port Information:

This radio button is selected by default and, if selected, enables the host and port properties and disables the connection name list property.

Data type	Radio button
Default	Selected

Host:

The name of the host on which the WebSphere MQ queue manager runs for client connection only.

Data type	String
Default	Null
Range	A valid TCP/IP host name

Port:

The TCP/IP port number used for connection to the WebSphere MQ queue manager, for client connection only.

This port must be configured on the WebSphere MQ queue manager.

Data type	Integer
Default	Null
Range	A valid TCP/IP port number, configured on the WebSphere MQ queue manager.

Enter Connection Name List Information:

If selected, this radio button enables the connection name list property and disables the host and port name properties. Select this radio button if you want to connect to a multi-instance queue manager.

Data type	Radio button
Default	Cleared

Connection Name List:

A comma-separated list of host and port information which can be used to connect to a multi-instance queue manager.

The format of the list is:
`host[(port)],[host[(port)]]`

where port is optional and defaults to 1414 if it is not set. For example:
`hostname1,hostname2(1415)`

For further information about multi-instance queue managers, see the WebSphere MQ information center.

This property must only be used for connecting to a multi-instance queue manager. It must not be used for connecting to a list of distinct queue managers as that can result in transaction integrity issues.

Channel:

The name of the channel used for connection to the WebSphere MQ queue manager, for client connection only.

Data type	String
Default	Null
Range	1 through 20 ASCII characters

Transport type:

Specifies whether the WebSphere MQ client connection or JNDI bindings are used for connection to the WebSphere MQ queue manager. The external JMS provider controls the communication protocols between JMS clients and JMS servers. Tune the transport type when you are using non-ASF nonpersistent, nondurable, nontransactional messaging or when you want to satisfy security issues and the client is local to the queue manager node.

Data type	Enum
Units	Not applicable
Default	BINDINGS
Range	**BINDINGS** JNDI bindings are used to connect to the queue manager. BINDINGS is a shared memory protocol and can only be used when the queue manager is on the same node as the JMS client and poses security risks that must be addressed through the use of EJB roles. **CLIENT** WebSphere MQ client connection is used to connect to the queue manager. CLIENT is a typical TCP-based protocol. **DIRECT** For WebSphere MQ Event Broker using DIRECT mode. DIRECT is a lightweight sockets protocol used in nontransactional, nondurable, and nonpersistent Publish/Subscribe messaging. DIRECT only works for clients and message-driven beans using the non-ASF protocol. **QUEUED** QUEUED is a standard TCP protocol.

Recommended

Queue connection factory transport type

BINDINGS is faster by 30% or more, but it requires correctly set up EJB roles to guarantee security. If you have security concerns and need to use CLIENT then you should make appropriate use of SSL to secure the connection to the queue manager.

Topic connection factory transport type

DIRECT is the fastest type and must be used where possible. Use BINDINGS when you want to satisfy additional security tasks and the queue manager is local to the JMS client. QUEUED is the fallback for all other cases. WebSphere MQ 5.3 before CSD2 with the DIRECT setting can lose messages when used with message-driven beans and under load. This loss also happens with client-side applications unless the broker maxClientQueueSize is set to 0. You can set this value to 0 with the command:

```
#wempschangeproperties WAS_nodeName_server1
 -e default -o DynamicSubscriptionEngine -n
 maxClientQueueSize -v 0 -x executionGroupUUID
```

where executionGroupUUID can be found by starting the broker and looking in the Event Log/Applications for event 2201. This value is usually ffffffff-0000-0000-000000000000.

Note: The WebSphere MQ 5.3 JMS cannot be used within WebSphere Application Server Version 6.1 because WebSphere Application Server Version 6.1 has a Java 5 runtime. Therefore, cross-memory connections cannot be established with WebSphere MQ 5.3 queue managers. This can result in a performance degradation if you were previously using WebSphere MQ 5.3 and BINDINGS for your connections and move to CLIENT network connections in migrating to WebSphere Application Server Version 6.1.

Client ID:

The JMS client identifier used for connections to the WebSphere MQ queue manager.

Data type String

CCSID:

The coded character set identifier for use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

Data type String

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *System Administration* and *Application Programming Reference* sections of the WebSphere MQ information center.

Message Retention:

Select this check box to specify that unwanted messages are to be left on the queue. Otherwise, unwanted messages are handled according to their disposition options.

Data type Enum
Units Not applicable
Default Cleared

Range

Selected
Unwanted messages are left on the queue.

Cleared
Unwanted messages are handled according to their disposition options.

Temporary model:

The name of the model definition used to create temporary connection factories if a connection factory does not already exist.

Data type String
Range 1 through 48 ASCII characters

Temporary queue prefix:

The prefix used for dynamic queue naming.

Data type String

Fail if quiesce:

Specifies whether applications return from a method call if the queue manager has entered a controlled failure.

Data type Check box
Default Selected

Local Server Address:

Specifies the local server address.

Data type String

Polling Interval:

Specifies the interval, in milliseconds, between scans of all receivers during asynchronous message delivery

Data type Integer
Units Milliseconds
Default 5000

Rescan interval:

Specifies the interval in milliseconds between which a topic is scanned to look for messages that have been added to a topic out of order.

This interval controls the scanning for messages that have been added to a topic out of order with respect to a WebSphere MQ browse cursor.

Data type Integer
Units Milliseconds

Default 5000

SSL cipher suite:

Specifies the cipher suite to use for SSL connection to WebSphere MQ.

Set this property to a valid cipher suite provided by your JSSE provider. The value must match the CipherSpec specified on the SVRCONN channel as the **Channel** property.

You must set this property, if you set the **SSL Peer Name** property.

SSL certificate store:

Specifies a list of zero or more Certificate Revocation List (CRL) servers used to check for SSL certificate revocation. If you specify a value for this property, you must use WebSphere MQ JVM at Java 2 version 1.4.

The value is a space-delimited list of entries of the form:
`ldap://hostname:[port]`

A single slash (/) follows this value. If *port* is omitted, the default LDAP port of 389 is assumed. At connect-time, the SSL certificate presented by the server is checked against the specified CRL servers. For more information about CRL security, see the information about "Working with Certificate Revocation Lists" in the *Security* section of the WebSphere MQ information center.

SSL peer name:

For SSL, a *distinguished name* skeleton that must match the name provided by the WebSphere MQ queue manager. The distinguished name is used to check the identifying certificate presented by the server at connection time.

If this property is not set, such certificate checking is performed.

The SSL peer name property is ignored if **SSL Cipher Suite** property is not specified.

This property is a list of attribute name and value pairs separated by commas or semicolons. For example:
`CN=QMGR.*, OU=IBM, OU=WEBSPHERE`

The example given checks the identifying certificate presented by the server at connect-time. For the connection to succeed, the certificate must have a Common Name beginning QMGR., and must have at least two Organizational Unit names, the first of which is IBM and the second WEBSPHERE. Checking is not case-sensitive.

For more details about distinguished names and their use with WebSphere MQ, see the information about "Distinguished Names" in the WebSphere MQ information center.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This connection pooling is independent from any WebSphere MQ connection pooling. You must configure the connection and session pool properties appropriately for your applications, otherwise you might not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Data type Check box
Default Selected

Client reconnect options:

Specifies whether a client mode connection reconnects automatically, or not, in the event of a communications or queue manager failure. This property is ignored unless the connection factory is being used in a thin or managed client environment.

Data type Drop-down list
Default DISABLED
Range

DISABLED
The client reconnection does not automatically occur.

ASDEF The value from the DefRecon attribute from the channels stanza of the client configuration file is used. If there is no DefRecon value specified then this setting has the same effect as a value of DISABLED.

RECONNECT
Reconnection occurs to any queue manager consistent with the value of the queue manager attribute, which might be a different queue manager from that to which the connection was originally connected.

QMGR Reconnection only occurs to the queue manager to which the connection was originally connected.

For more information about automatic client reconnection, see the WebSphere MQ information center.

Client reconnect timeout:

The maximum number of seconds that a client mode connection spends attempting to automatically reconnect to a queue manager after a communications or queue manager failure. This parameter is ignored unless the connection factory is being used in a thin or managed client environment. Whether this parameter is used or not depends on the value of the client reconnect options parameter.

Data type Integer
Units Seconds
Default 1800
Range A value greater than zero and up to 2147483647

For more information about automatic client reconnection, see the WebSphere MQ information center.

WebSphere MQ Provider topic connection factory settings for application clients:

Use this panel to view or change the configuration properties of the selected topic connection factory for use with the WebSphere MQ Java Message Service (JMS) provider. These configuration properties control how connections are created between the JMS provider and WebSphere MQ.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **WebSphere MQ Provider**. Right-click **Topic Connection Factories** and click **New**.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ product JMS resources. For more information about configuring WebSphere MQ JMS resources, see the *Using Java* section of the WebSphere MQ information center.
- In WebSphere MQ, names can have a maximum of 48 characters, except for channels which have a maximum of 20 characters.

MA0C broker: When creating a WebSphere Application Server Version 6 topic connection factory for the MA0C broker, consider the following attribute values:

BrokerControlQueue
This value is fixed at SYSTEM.BROKER.CONTROL.QUEUE for the MA0C broker and is the queue the broker reads from.

BrokerVersion
Set this value to BASIC for the MA0C broker.

ClientID
Set this value to whatever you like for the MA0C broker (the value is string and is merely an identifier for your client application).

XA Enabled
Set this value to TRUE or FALSE for the MA0C broker (the setting you use is a performance enhancement flag - you probably want to set this value to 'true' most of the time).

BrokerMessage Selection
This value is fixed at CLIENT for the MA0C broker because the broker relies on client side message selection.

Direct Broker Authorization Type
This value is not required by the MA0C broker.

A topic connection factory for the WebSphere MQ JMS provider has the following properties.

Name:

The name by which this topic connection factory is known for administrative purposes within WebSphere Application Server. The name must be unique within the JMS provider.

Data type String

Description:

A description of this topic connection factory for administrative purposes within WebSphere Application Server.

Data type String

JNDI Name:

The Java Naming and Directory Interface (JNDI) name that is used to bind the topic connection factory into the application server name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String
Units En_US ASCII characters
Range 1 through 45 ASCII characters

User ID:

The user ID used, with the password property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the user ID property, you must also specify a value for the password property.

The connection factory user ID and password properties are used if the calling application does not provide a user ID and password explicitly, for example, if the calling application uses the method createTopicConnection(). The JMS client flows the user ID and password to the JMS server.

Data type String

Password:

The password used, with the user ID property, for authentication if the calling application does not provide a user ID and password explicitly.

If you specify a value for the user ID property, you must also specify a value for the password property.

Data type String

Re-Enter Password:

Confirms the password.

Queue Manager:

The name of the WebSphere MQ queue manager for this connection factory. Connections created by this connection factory connect to this queue manager.

Data type String

Enter Hostname and Port Information:

This radio button is selected by default and, if selected, enables the host and port properties and disables the connection name list property.

Data type Radio button
Default Selected

Host:

The name of the host on which the WebSphere MQ queue manager runs for client connections only.

Data type	String
Range	A valid TCP/IP host name

Port:

The TCP/IP port number used for connection to the WebSphere MQ queue manager, for client connection only.

This port must be configured on the WebSphere MQ queue manager.

Data type	Integer
Range	A valid TCP/IP port number, configured on the WebSphere MQ queue manager.

Enter Connection Name List Information:

If selected, this radio button enables the connection name list property and disables the host and port name properties. Select this radio button if you want to connect to a multi-instance queue manager.

Data type	Radio button
Default	Cleared

Connection Name List:

A comma-separated list of host and port information which can be used to connect to a multi-instance queue manager.

The format of the list is:

```
host[(port)],[host[(port)]]
```

where port is optional and defaults to 1414 if it is not set. For example:

```
hostname1,hostname2(1415)
```

For further information about multi-instance queue managers, see the WebSphere MQ information center.

This property must only be used for connecting to a multi-instance queue manager. It must not be used for connecting to a list of distinct queue managers as that can result in transaction integrity issues.

Channel:

The name of the channel used for client connections to the WebSphere MQ queue manager, for client connection only.

Data type	String
Range	1 through 20 ASCII characters

Transport Type:

Whether WebSphere MQ client connection or JNDI bindings are used for connection to the WebSphere MQ queue manager.

Data type Enum
Default BINDINGS
Range
CLIENT
WebSphere MQ client connection is used to connect to the WebSphere MQ queue manager.
BINDINGS
JNDI bindings are used to connect to the WebSphere MQ queue manager.

Client ID:

The JMS client identifier used for connections to the WebSphere MQ queue manager.

Data type String

CCSID:

The coded character set identifier to use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs that WebSphere MQ supports. See the properties for the topic destination for more details.

Data type String
Units Integer
Range 1 through 65535

Broker Control Queue:

The name of the broker control queue to which all command messages (except publications and requests to delete publications) are sent.

Data type String
Units En_US ASCII characters
Range 1 through 48 ASCII characters

Broker Queue Manager:

The name of the WebSphere MQ queue manager that provides the Publisher and Subscriber message broker.

Data type String
Units En_US ASCII characters
Range 1 through 48 ASCII characters

Broker Publish Queue:

The name of the broker input queue that receives all publication messages for the default stream.

The name of the broker's input queue (stream queue) that receives all publication messages for the default stream. Applications can also send requests to delete publications on the default stream to this queue.

Data type String
Units En_US ASCII characters
Range 1 through 48 ASCII characters

Broker Subscribe Queue:

The name of the broker queue from which nondurable subscription messages are retrieved.

The name of the broker queue from which nondurable subscription messages are retrieved. The subscriber specifies the name of the queue when it registers a subscription.

Data type String
Units En_US ASCII characters
Range 1 through 48 ASCII characters

Broker CCSubQ:

The name of the broker queue from which nondurable subscription messages are retrieved for a ConnectionConsumer request. This property applies only for use of the web container.

Data type String
Units En_US ASCII characters
Range 1 through 48 ASCII characters

Broker Version:

Whether the message broker is provided by the WebSphere MQ MA0C SupportPac or newer versions of WebSphere family message broker products.

Data type Enum
Default Advanced
Range

Advanced
The message broker is provided by newer versions of WebSphere family message broker products (WebSphere MQ Integrator and WebSphere MQ Publish and Subscribe).

Basic
The message broker is provided by the WebSphere MQ MA0C SupportPac (WebSphere MQ - Publish and Subscribe).

Cleanup level:

The level of cleanup provided by the publish or subscribe cleanup utility.

Data type Enum
Default SAFE
Range

ASPROP

NONE

STRONG

Cleanup interval:

The interval, in milliseconds, between background executions of the publish/subscribe cleanup utility.

Data type Integer
Units Milliseconds
Default 6000

Message selection:

Where broker message selection is performed.

Data type Enum
Default BROKER
Range

BROKER
Message selection is performed at the broker location.

Message CLIENT
Message selection is performed at the client location.

Publish acknowledge interval:

The interval, in number of messages, between publish requests that require acknowledgment from the broker.

Data type Integer
Default 25

Sparse subscriptions:

Enables sparse subscriptions.

Data type Check box
Default Cleared

Status refresh interval:

The interval, in milliseconds, between transactions to refresh the publish or subscribe status.

Data type Integer
Default 6000

Subscription store:

Where WebSphere MQ stores data relating to active JMS subscriptions.

Data type Enum
Default MIGRATE
Range

MIGRATE

QUEUE

BROKER

Multicast:

Whether this connection factory uses multicast transport.

Data type Enum
Default NOT USED
Range

NOT USED
This connection factory does not use multicast transport.

ENABLED
This connection factory always uses multicast transport.

ENABLED_IF_AVAILABLE
This connection factory uses multicast transport.

ENABLED_RELIABLE
This connection factory uses reliable multicast transport.

ENABLED_RELIABLE_IF_AVAILABLE
This connection factory uses reliable multicast transport if available.

Direct authentication:

Whether to use direct broker authorization.

Data type Enum
Default NONE
Range

NONE Direct broker authorization is not used.

PASSWORD
Direct broker authorization is authenticated with a password.

CERTIFICATE
Direct broker authorization is authenticated with a certificate.

Proxy Host Name:

The host name of a proxy to be used for communication with WebSphere MQ.

Data type String

Proxy Port:

The port number of a proxy to be used for communication with WebSphere MQ.

Data type Integer
Default 0

Fail if quiesce:

Whether applications return from a method call if the queue manager has entered a controlled failure.

Data type	Check box
Default	Selected

Local Server Address:

The local server address.

Data type	String

Polling Interval:

The interval, in milliseconds, between scans of all receivers during asynchronous message delivery.

Data type	Integer
Units	Milliseconds
Default	5000

Rescan interval:

The interval in milliseconds between which a topic is scanned to look for messages that have been added to a topic out of order.

The rescan interval controls the scanning for messages that have been added to a topic out of order with respect to a WebSphere MQ browse cursor.

Data type	Integer
Units	Milliseconds
Default	5000

SSL cipher suite:

The cipher suite to use for SSL connection to WebSphere MQ.

Set this property to a valid cipher suite provided by your JSSE provider. The value must match the CipherSpec specified on the SVRCONN channel as the **Channel** property.

You must set this property, if you set the **SSL Peer Name** property.

SSL certificate store:

A list of zero or more Certificate Revocation List (CRL) servers that are used to check for SSL certificate revocation. If you specify a value for this property, you must use WebSphere MQ JVM at Java 2 version 1.4.

The value is a space-delimited list of entries of the form:
`ldap://hostname:[port]`

A single slash (/) follows this value. If *port* is omitted, the default LDAP port of 389 is assumed. At connect-time, the SSL certificate presented by the server is checked against the specified CRL servers. For more information about CRL security, see the information about “Working with Certificate Revocation Lists” in the *Security* section of the WebSphere MQ information center.

SSL peer name:

For SSL, a *distinguished name* skeleton that must match the name provided by the WebSphere MQ queue manager. The distinguished name is used to check the identifying certificate presented by the server at connection time.

If this property is not set, such certificate checking is performed.

The SSL peer name property is ignored if **SSL Cipher Suite** property is not specified.

This property is a list of attribute name and value pairs separated by commas or semicolons. For example:

```
CN=QMGR.*, OU=IBM, OU=WEBSPHERE
```

The example given checks the identifying certificate presented by the server at connect-time. For the connection to succeed, the certificate must have a Common Name beginning QMGR., and must have at least two Organizational Unit names, the first of which is IBM and the second WEBSPHERE. Checking is not case-sensitive.

For more details about distinguished names and their use with WebSphere MQ, see the information about "Distinguished Names" in the Security section of the WebSphere MQ information center.

Connection pool:

An optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This connection pooling is independent from any WebSphere MQ connection pooling. You must configure the connection and session pool properties appropriately for your applications, otherwise you might not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Data type	Check box
Default	Selected

Client reconnect options:

Specifies whether a client mode connection reconnects automatically, or not, in the event of a communications or queue manager failure. This property is ignored unless the connection factory is being used in a thin or managed client environment.

Data type	Drop-down list
Default	DISABLED

Range

DISABLED
The client reconnection does not automatically occur.

ASDEF The value from the DefRecon attribute from the channels stanza of the client configuration file is used. If there is no DefRecon value specified then this setting has the same effect as a value of DISABLED.

RECONNECT
Reconnection occurs to any queue manager consistent with the value of the queue manager attribute, which might be a different queue manager from that to which the connection was originally connected.

QMGR Reconnection only occurs to the queue manager to which the connection was originally connected.

For more information about automatic client reconnection, see the WebSphere MQ information center.

Client reconnect timeout:

The maximum number of seconds that a client mode connection spends attempting to automatically reconnect to a queue manager after a communications or queue manager failure. This parameter is ignored unless the connection factory is being used in a thin or managed client environment. Whether this parameter is used or not depends on the value of the client reconnect options parameter.

Data type	Integer
Units	Seconds
Default	1800
Range	A value greater than zero and up to 2147483647

For more information about automatic client reconnection, see the WebSphere MQ information center.

WebSphere MQ Provider queue destination settings for application clients:

Use this panel to view or change the configuration properties of the selected queue destination for use with the WebSphere MQ product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file and click **Messaging Providers** > **WebSphere MQ Provider**. Right-click **Queue Destinations** and click **New**. The following fields are displayed on the **General** tab.

Note:
- The property values that you specify must match the values that you specified when configuring JMS resources for WebSphere MQ. For more information about configuring JMS resources for WebSphere MQ, see *Using Java* in the WebSphere MQ information center.
- In WebSphere MQ, names can have a maximum of 48 characters.

A queue for use with the WebSphere MQ product JMS provider has the following properties.

Name:

The name by which the queue is known for administrative purposes within WebSphere Application Server.

Data type String

Description:

A description of the queue, for administrative purposes within WebSphere Application Server.

Data type String

JNDI Name:

The application client runtime environment uses this field to retrieve configuration information.

Persistence:

Whether all messages sent to the destination are persistent, nonpersistent or have their persistence defined by the application.

Data type Enum
Default APPLICATION_DEFINED
Range

Application defined
Messages on the destination have their persistence defined by the application that put them onto the queue.

Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

Persistent
Messages on the destination are persistent.

Nonpersistent
Messages on the destination are not persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property.

Data type Enum
Units Not applicable
Default APPLICATION_DEFINED
Range

Application defined
The priority of messages on this destination is defined by the application that put them onto the destination.

Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

Specified
The priority of messages on this destination is defined by the **Specified priority** property. *If you select this option, you must define a priority on the **Specified priority** property.*

Specified Priority:

If the **Priority** property is set to `Specified`, specify the message priority for this queue, in the range 0 (lowest) through 9 (highest).

Data type Integer
Units Message priority level
Range 0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout value for this queue is defined by the application or the by **Specified expiry** property or whether messages on the queue never expire (have an unlimited expiry time out).

Data type Enum
Units Not applicable
Default APPLICATION_DEFINED
Range
Application defined
The expiry timeout for messages on this queue is defined by the application that put them onto the queue.
Specified
The expiry timeout for messages on this queue is defined by the **Specified expiry** property. If you select this option, you must define a timeout on the **Specified expiry** property.
Unlimited
Messages on this queue have no expiry timeout and those messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to `Specified`, type here the number of milliseconds (greater than 0) after which messages on this queue expire.

Data type Integer
Units Milliseconds
Range Greater than or equal to 0
- 0 indicates that messages never time out
- Other values are an integer number of milliseconds

Base Queue Name:

The name of the queue to which messages are sent, on the queue manager specified by the **Base queue manager name** property.

Data type String

Base Queue Manager Name:

The name of the WebSphere MQ queue manager to which messages are sent.

This queue manager provides the queue specified by the **Base queue name** property.

Data type String
Units En_US ASCII characters
Range A valid WebSphere MQ Queue Manager name, as 1 through 48 ASCII characters

CCSID:

The coded character set identifier to use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ queue manager. See the WebSphere MQ messaging provider queue and topic advanced properties settings for more details.

Data type String

Integer encoding:

If native encoding is not enabled, select whether integer encoding is normal or reversed.

Data type Enum
Default NORMAL
Range
NORMAL
Normal integer encoding is used.
REVERSED
Reversed integer encoding is used.

For more information about encoding properties, see *Using Java* in the WebSphere MQ information center.

Decimal encoding:

If native encoding is not enabled, select whether decimal encoding is normal or reversed.

Data type Enum
Default NORMAL
Range
NORMAL
Normal decimal encoding is used.
REVERSED
Reversed decimal encoding is used.

For more information about encoding properties, see *Using Java* in the WebSphere MQ information center.

Floating point encoding:

If native encoding is not enabled, select the type of floating point encoding.

Data type Enum
Default IEEENORMAL
Range
IEEENORMAL
IEEE normal floating point encoding is used.
IEEEREVERSED
IEEE reversed floating point encoding is used.
S390 S390 floating point encoding is used.

For more information about encoding properties, see *Using Java* in the WebSphere MQ information center.

Native encoding:

Indicates that the queue destination uses native encoding (appropriate encoding values for the Java platform) when you select this check box.

Data type Enum
Default Cleared
Range **Cleared**
Native encoding is not used, so specify the following properties for integer, decimal and floating point encoding.
Selected
Native encoding is used (to provide appropriate encoding values for the Java platform).

For more information about encoding properties, see *Using Java* in the WebSphere MQ information center.

Target client:

Whether the receiving application is JMS compliant or is a traditional WebSphere MQ application.

Data type Enum
Default WebSphere MQ
Range **WebSphere MQ**
The target is a traditional WebSphere MQ application that does not support JMS.
JMS The target application supports JMS.

Message body:

Specifies whether an application processes the RFH version 2 header of a WebSphere MQ message as part of the JMS message body.

Data type Drop-down list
Default UNSPECIFIED
Range **UNSPECIFIED**
When sending messages, the WebSphere MQ messaging provider does or does not generate and include an RFH version 2 header, depending on the value of the Append RFH version 2 headers to messages sent to this destination property. When receiving messages, the WebSphere MQ messaging provider acts as if the value is set to JMS.
JMS When sending messages, the WebSphere MQ messaging provider automatically generates an RFH version 2 header and includes it in the WebSphere MQ message. When receiving messages, the WebSphere MQ messaging provider sets the JMS message properties according to values in the RFH version 2 header (if these value are present); it does not present the RFH version 2 header as part of the JMS message body.
MQ When sending messages, the WebSphere MQ messaging provider does not generate an RFH version 2 header. When receiving messages, the WebSphere MQ messaging provider presents the RFH version 2 header as part of the JMS message body.

ReplyTo destination style:

Specifies the format of the JMSReplyTo field.

Data type Drop-down list
Default DEFAULT

Range

DEFAULT
The default value is equivalent to the information in the RFH version 2 header.

MQMD Use the value supplied in the MQMD. This populates the reply to queue manager field with the value from the MQMD, equivalent to the default behaviour of WebSphere MQ Version 6.0.2.4 and 6.0.2.5.

RFH2 Use the value supplied in the RFH version 2 header. If the sending application set a JMSReplyTo value, then that value is used.

MQMD read enabled:

Specifies whether an application can read the values of MQMD fields from JMS messages that have been sent or received using the WebSphere MQ messaging provider.

Data type Check box

Default Cleared

Range

Cleared
Applications cannot read the values of the MQMD fields.

Selected
Applications can read the values of the MQMD fields.

MQMD write enabled:

Specifies whether an application can write the values of MQMD fields to JMS messages that will be sent or received using the WebSphere MQ messaging provider.

Data type Check box

Default Cleared

Range

Cleared
Applications cannot write the values of the MQMD fields.

Selected
Applications can write the values of the MQMD fields.

MQMD message context:

Defines the message context options specified when sending messages to a destination.

Data type Drop-down list

Default DEFAULT

Range

DEFAULT
The MQOPEN API call and the MQPMO structure specify no explicit message context options.

SET_IDENTITY_CONTEXT
The MQOPEN API call specifies the message context option MQOO_SET_IDENTITY_CONTEXT, and the MQPMO structure specifies MQPMO_SET_IDENTITY_CONTEXT.

SET_ALL_CONTEXT
The MQOPEN API call specifies the message context option MQOO_SET_ALL_CONTEXT, and the MQPMO structure specifies MQPMO_SET_ALL_CONTEXT.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

WebSphere MQ Provider topic destination settings for application clients:

Use this panel to view or change the configuration properties of the selected topic destination for use with the WebSphere MQ product Java Message Service (JMS) provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > **WebSphere MQ Provider**. Right click **Topic Destinations**, and click **New**. The following fields are displayed on the **General** tab.

Note:

- The property values that you specify must match the values that you specified when configuring JMS resources for WebSphere MQ. For more information about configuring JMS resources for WebSphere MQ, see *Using Java* in the WebSphere MQ information center.
- In WebSphere MQ, names can have a maximum of 48 characters.

A topic destination is used to configure the properties of a JMS topic for the associated JMS provider. A topic for use with the WebSphere MQ product JMS provider has the following properties.

Name:

The name by which the topic is known for administrative purposes within WebSphere Application Server.

Data type String

Description:

A description of the topic for administrative purposes within WebSphere Application Server.

Data type String

JNDI Name:

The application client runtime environment uses this field to retrieve configuration information.

Persistence:

Whether all messages sent to the destination are persistent, nonpersistent, or have their persistence defined by the application.

Data type Enum
Default APPLICATION_DEFINED
Range
Application defined
Messages on the destination have their persistence defined by the application that put them in the queue.
Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
Persistent
Messages on the destination are persistent.
Nonpersistent
Messages on the destination are not persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property.

Data type Enum
Default APPLICATION_DEFINED
Range
Application defined
The priority of messages on this destination is defined by the application that put them in the destination.
Queue defined
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
Specified
The priority of messages on this destination is defined by the **Specified priority** property. If you select this option, you must define a priority for the **Specified priority** property.

Specified Priority:

If the **Priority** property is set to `Specified`, specify the message priority for this queue, in the range 0 (lowest) through 9 (highest).

If the **Priority** property is set to `Specified`, messages sent to this queue have the priority value specified by this property.

Data type Integer
Units Message priority level
Range 0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or by the **Specified expiry** property, or whether messages on the queue never expire (have an unlimited expiry timeout).

Data type Enum
Default APPLICATION_DEFINED
Range
Application defined
The expiry timeout for messages on this queue is defined by the application that put them in the queue.
Specified
The expiry timeout for messages in this queue is defined by the **Specified expiry** property. If you select this option, you must define a timeout value for the **Specified expiry** property.
Unlimited
Messages on this queue have no expiry timeout, and these messages never expire.

Specified Expiry:

If the **Expiry timeout** property is set to `Specified`, type the number of milliseconds (greater than 0) after which messages on this queue expire.

Data type Integer

Units Milliseconds
Range Greater than or equal to 0
- 0 indicates that messages never time out.
- Other values are an integer number of milliseconds.

Base Topic Name:

The name of the topic to which messages are sent.

Data type String

CCSID:

The coded character set identifier to use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs that WebSphere MQ supports.

Data type String
Units Integer
Range 1 through 65535

Integer encoding:

If native encoding is not enabled, select whether integer encoding is normal or reversed.

Data type Enum
Default NORMAL
Range
NORMAL
Normal integer encoding is used.
REVERSED
Reversed integer encoding is used.

For more information about encoding properties, see *Using Java* in the WebSphere MQ information center.

Decimal encoding:

If native encoding is not enabled, select whether decimal encoding is normal or reversed.

Data type Enum
Default NORMAL
Range
NORMAL
Normal decimal encoding is used.
REVERSED
Reversed decimal encoding is used.

For more information about encoding properties, see *Using Java* in the information WebSphere MQ center.

Floating point encoding:

If native encoding is not enabled, select the type of floating point encoding.

Data type Enum

Default IEEENORMAL

Range

IEEENORMAL
IEEE normal floating point encoding is used.

IEEEREVERSED
IEEE reversed floating point encoding is used.

S390 S/390® floating point encoding is used.

For more information about encoding properties, see *Using Java* in the WebSphere MQ information center.

Native encoding:

Indicates that the queue destination uses native encoding (appropriate encoding values for the Java platform) when you select this check box.

Data type Enum

Default Cleared

Range

Cleared
Native encoding is not used, so specify the previous properties for integer, decimal and floating point encoding.

Selected
Native encoding is used (to provide appropriate encoding values for the Java platform).

For more information about encoding properties, see *Using Java* in the WebSphere MQ information center.

BrokerDurSubQueue:

The name of the broker queue from which durable subscription messages are retrieved.

The subscriber specifies the name of the queue when it registers a subscription.

Data type String

Units En_US ASCII characters

Range 1 through 48 ASCII characters

BrokerCCDurSubQueue:

The name of the broker queue from which durable subscription messages are retrieved for a ConnectionConsumer. This property applies only for use of the web container.

Data type String

Units En_US ASCII characters

Range 1 through 48 ASCII characters

Target Client:

Whether the receiving application is JMS compliant or is a traditional WebSphere MQ application.

Data type Enum

Default WebSphere MQ

Range **WebSphere MQ**
The target is a traditional WebSphere MQ application that does not support JMS.
JMS The target application supports JMS.

Message body:

Specifies whether an application processes the RFH version 2 header of a WebSphere MQ message as part of the JMS message body.

Data type Drop-down list
Default UNSPECIFIED
Range **UNSPECIFIED**
When sending messages, the WebSphere MQ messaging provider does or does not generate and include an RFH version 2 header, depending on the value of the Append RFH version 2 headers to messages sent to this destination property. When receiving messages, the WebSphere MQ messaging provider acts as if the value is set to JMS.
JMS When sending messages, the WebSphere MQ messaging provider automatically generates an RFH version 2 header and includes it in the WebSphere MQ message. When receiving messages, the WebSphere MQ messaging provider sets the JMS message properties according to values in the RFH version 2 header (if these value are present); it does not present the RFH version 2 header as part of the JMS message body.
MQ When sending messages, the WebSphere MQ messaging provider does not generate an RFH version 2 header. When receiving messages, the WebSphere MQ messaging provider presents the RFH version 2 header as part of the JMS message body.

ReplyTo destination style:

Specifies the format of the JMSReplyTo field.

Data type Drop-down list
Default DEFAULT
Range **DEFAULT**
The default value is equivalent to the information in the RFH version 2 header.
MQMD Use the value supplied in the MQMD. This populates the reply to queue manager field with the value from the MQMD, equivalent to the default behaviour of WebSphere MQ Version 6.0.2.4 and 6.0.2.5.
RFH2 Use the value supplied in the RFH version 2 header. If the sending application set a JMSReplyTo value, then that value is used.

Multicast:

Whether this connection factory uses multicast transport.

Data type Enum
Default AS_CF

Range

AS_CF This connection factory uses multicast transport.

DISABLED
This connection factory does not use multicast transport.

NOT_RELIABLE
This connection factory always uses multicast transport.

RELIABLE
This connection factory uses multicast transport when the topic destination is not reliable.

ENABLED
This connection factory uses reliable multicast transport.

MQMD read enabled:

Specifies whether an application can read the values of MQMD fields from JMS messages that have been sent or received using the WebSphere MQ messaging provider.

Data type Check box
Default Cleared
Range

Cleared
Applications cannot read the values of the MQMD fields.

Selected
Applications can read the values of the MQMD fields.

MQMD write enabled:

Specifies whether an application can write the values of MQMD fields to JMS messages that will be sent or received using the WebSphere MQ messaging provider.

Data type Check box
Default Cleared
Range

Cleared
Applications cannot write the values of the MQMD fields.

Selected
Applications can write the values of the MQMD fields.

MQMD message context:

Defines the message context options specified when sending messages to a destination.

Data type Drop-down list
Default DEFAULT
Range

DEFAULT
The MQOPEN API call and the MQPMO structure specify no explicit message context options.

SET_IDENTITY_CONTEXT
The MQOPEN API call specifies the message context option MQOO_SET_IDENTITY_CONTEXT, and the MQPMO structure specifies MQPMO_SET_IDENTITY_CONTEXT.

SET_ALL_CONTEXT
The MQOPEN API call specifies the message context option MQOO_SET_ALL_CONTEXT, and the MQPMO structure specifies MQPMO_SET_ALL_CONTEXT.

Generic JMS connection factory settings for application clients:

Use this panel to view or change the configuration properties of the selected Java Message Service (JMS) connection factory for use with the associated JMS provider. These configuration properties control how connections are created between the JMS provider and the messaging system that it uses.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > *new_JMS_Provider_instance*. Right-click **Connection Factories**, and click **New**. The following fields are displayed on the **General** tab.

A Java Message Service (JMS) connection factory creates connections to JMS destinations. The JMS connection factory is created by the associated JMS provider. A JMS connection factory for a generic JMS provider (other than the internal default messaging provider or WebSphere MQ as a JMS provider) has the following properties:

Name:

The name by which this JMS connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the associated JMS provider.

Data type String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

JNDI Name:

The application client run time uses this field to retrieve configuration information.

User ID:

Indicates the user ID used with the **Password** property, for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

The connection factory **User ID** and **Password** properties are used if the calling application does not provide a userid and password explicitly; for example, if the calling application uses the method createQueueConnection(). The JMS client flows the `userid` and `password` to the JMS server.

Data type String

Password:

The password used with the **User ID** property for authentication if the calling application does not provide a `userid` and `password` explicitly.

If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.

Data type String
Default Null

Re-Enter Password:

Confirms the password entered in the **Password** field.

External JNDI Name:

The JNDI name that is used to bind the queue into the application server name space.

As a convention, use the fully qualified JNDI name, for example, `jms/`*`Name`*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI API by the platform.

Data type String

Connection Type:

Whether this JMS destination is a queue (for point-to-point) or topic (for publication or subscription).

Select one of the following options:
Queue
A JMS queue destination for point-to-point messaging.
Topic A JMS topic destination for publish subscribe messaging.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Generic JMS destination settings for application clients:

Use this panel to view or change the configuration properties of the selected JMS destination for use with the associated JMS provider.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Messaging Providers** > *new JMS Provider instance*. Right-click **Destinations**, and click **New**. The following fields are displayed on the **General** tab.

A JMS destination is used to configure the properties of a JMS destination for the associated generic JMS provider. Connections to the JMS destination are created by the associated JMS connection factory. A JMS destination for use with a generic JMS provider (not the default messaging provider or WebSphere MQ as a JMS provider) has the following properties.

Name:

The name by which the queue is known for administrative purposes within WebSphere Application Server.

Data type String

Description:

A description of the queue, for administrative purposes.

JNDI Name:

The JNDI name of the actual (physical) name of the JMS destination bound into JNDI.

External JNDI Name:

The JNDI name that is used to bind the queue into the application server name space.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Destination Type:

Whether this JMS destination is a queue (for point-to-point) or topic (for publishing or subscribing).

Select one of the following options:
Queue
A JMS queue destination for point-to-point messaging.
Topic A JMS topic destination for pub/sub messaging.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Example: Configuring JMS provider, JMS connection factory and JMS destination settings for application clients:

You can configure JMS Provider, JMS Connection Factory and JMS Destination settings. This topic provides the required fields, special cases, and an example.

The purpose of this article is to help you to configure JMS Provider, JMS Connection Factory and JMS Destination settings.
- Required fields include:
  - JMS Provider Properties page: name, and at least one protocol provider
  - JMS Connection Factory Properties page: name, jndiName, destination type
  - JMS Destination Properties page: name, jndiName, destination type

- Special cases:
  - The destination type must be `QUEUE`, or `TOPIC`.
- Example:

```
<resources.jms:JMSProvider xmi:id="JMSProvider_3" name="genericJMSProvider:name"
description="genericJMSProvider:description"
externalInitialContextFactory="genericJMSProvider:contextFactoryClass"
externalProviderURL="genericJMSProvider:providerUrl">
<classpath>genericJMSProvider:classpath</classpath>
<factories xmi:type="resources.jms:GenericJMSDestination"
xmi:id="GenericJMSDestination_1" name="jmsDestination:name"
jndiName="jmsDestination:jndiName" description="jmsDestination:description"
externalJNDIName="jmsDestination:externalJndiName" type="QUEUE">
<propertySet xmi:id="J2EEResourcePropertySet_15">
<resourceProperties xmi:id="J2EEResourceProperty_17" name="jmsDestination:customName"
value="jmsDestination:customValue"/>
</propertySet>
</factories>
<factories xmi:type="resources.jms:GenericJMSConnectionFactory"
xmi:id="GenericJMSConnectionFactory_1" name="jmsCF:name" jndiName="jmsCF:jndiName"
description="jmsCF:description" userID="jmsCF:user" password="{xor}NTIsHBllMT4yOg=="
externalJNDIName="jmsCF:externalJndiName" type="QUEUE">
<propertySet xmi:id="J2EEResourcePropertySet_16">
<resourceProperties xmi:id="J2EEResourceProperty_18" name="jmsCF:customName"
value="jmsCF:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_17">
<resourceProperties xmi:id="J2EEResourceProperty_19"
name="genericJMSProvider:customName" value="genericJMSProvider:customValue"/>
</propertySet>
</resources.jms:JMSProvider>
```

Configuring new JMS connection factories for application clients:

Use this task to create a new Java Message Service (JMS) connection factory configuration for your application client.

Procedure

1. Click the JMS provider for which you want to create a connection factory in the tree. Complete one of the following actions:
   - Configure a new JMS provider.
   - Click an existing JMS provider.
2. Expand the JMS provider to view its Connection Factories folder.
3. Click the connection factory folder, and complete one of the following actions:
   - Right-click the folder and select**New**.
   - Click **Edit > New** on the menu bar.
4. Configure the JMS connection factory properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Configuring new JMS destinations for application clients:

Use this task to create a new Java Message Service (JMS) destination configuration for your application client.

Procedure

1. Click the JMS provider in the tree for which you want to create a destination. Complete one of the following actions:
   - Configure a new JMS provider.

- Click an existing JMS provider.

2. Expand the JMS provider to view its Destinations folder.
3. Click the provider folder, and complete one of the following actions:
   - Right-click the folder and select **New**.
   - Click **Edit > New** on the menu bar.
4. Configure the JMS destination properties in the displayed fields.
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Configuring new resource environment providers for application clients:

You can create new resource environment provider configurations for your application client using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

During this task, you create new resource environment provider configurations for your application client.

About this task

To configure a new resource environment provider, perform the following steps:

Procedure

1. Start the Application Configuration Resource Tool and open the EAR file for which you want to configure the new Java Message Service (JMS) provider. The EAR file contents display in a tree view.
2. Select from the tree the JAR file in which you want to configure the new JMS provider.
3. Expand the JAR file to view its contents.
4. Click the **Resource Environment Providers** folder. Take one of the following actions:
   - Right-click the provider folder, and click **New**.
   - Click **Edit > New** on the menu bar.
5. Configure the JMS provider properties in the displayed fields.
6. Click **OK** when you finish.
7. Click **File > Save** on the menu bar to save your changes.

Resource environment provider settings for application clients:

Use this page to specify resource environment entry properties.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected Java Archive (JAR) file. Right-click **Resource Environment Providers**, and click **New**. The following fields are displayed on the **General** tab:

Name:

Specifies the administrative name for the resource environment provider.

Description:

Specifies a description of the resource environment provider for your administrative records.

Class Path:

Specifies the path to the JAR file that contains the implementation classes for the resource environment provider.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Configuring new resource environment entries for application clients:

You can create new resource environment entries for your client application using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

During this task, you create new resource environment entries for your client application.

About this task

Procedure

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the EAR file for which you want to configure the new resource environment entry. The EAR file contents are in the displayed tree view.
3. Click the desired resource environment provider, and complete the following action to configure new providers:
   - Configure a new resource environment provider.
4. Expand the resource environment provider to view the Resource Environment Entries folder.
5. Click the resource environment entries folder, and complete one of the following actions:
   - Right-click the folder and select **New**.
   - Click **Edit > New** on the menu bar.
6. Configure the resource environment entry properties in the displayed fields.
7. Click **OK**.
8. Click **File > Save** on the menu bar to save your changes.

Resource environment entry settings for application clients:

Use this page to specify resource environment entry properties.

To view this Application Client Resource Configuration Tool (ACRCT) page, click **File** > **Open**. After you browse for an EAR file, click **Open**. Expand the selected JAR file > **Resource Environment Providers** > *resource environment instance*. Right-click **Resource Environment Entries**, and click **New**. The following fields appear on the **General** tab:

Name:

Specifies the administrative name for the resource environment entry.

Description:

Specifies a description of the URL for your administrative records.

JNDI Name:

Specifies the Java Naming and Directory Interface (JNDI) name for the resource, including any naming subcontexts.

Use this name to link to the binding information of the platform. The binding associates the resources defined in the deployment descriptor of the module to the actual (or physical) resources bound into JNDI by the platform.

Custom Properties:

Specifies name-value pairs for setting additional properties on the object that is created at run time for this resource.

You must enter a name that is a public property on the object and a value that can be converted from a string to the type required by the set method of the property. The acceptable properties and values depend on the object that is created. Refer to the object documentation for a list of valid properties and values.

Example: Configuring Resource Environment settings:

You can configure Resource Environment settings. This topic provides the required fields and an example.

The purpose of this topic is to help you configure Resource Environment settings.

- Required fields:
  - Resource Environment Provider page: **Name**
  - Resource Environment Entry page: **Name, JNDI Name**
- Example:

```
<resources.env:ResourceEnvironmentProvider xmi:id="ResourceEnvironmentProvider_1"
name="resourceEnvProvider:name" description="resourceEnvProvider:description">
<classpath>resourceEnvProvider:classpath</classpath>
<factories xmi:type="resources.env:ResourceEnvEntry" xmi:id="ResourceEnvEntry_1"
name="resourceEnvEntry:name" jndiName="resourceEnvEntry:jndiName"
description="resourceEnvEntry:description">
<propertySet xmi:id="J2EEResourcePropertySet_20">
<resourceProperties xmi:id="J2EEResourceProperty_22"
name="resourceEnvEntry:customName" value="resourceEnvEntry:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_21">
<resourceProperties xmi:id="J2EEResourceProperty_23"
name="resourceEnvProvider:customName" value="resourceEnvProvider:customValue"/>
</propertySet>
</resources.env:ResourceEnvironmentProvider>
```

Example: Configuring resource environment custom settings for application clients:

You can configure resource environment custom settings.

The purpose of this topic is to help you configure resource environment custom settings.

- The custom page applies to every resource type. You can specify as many custom names and values as you need.
- Example:

```
<propertySet xmi:id="J2EEResourcePropertySet_20">
<resourceProperties xmi:id="J2EEResourceProperty_22"
name="resourceEnvEntry:customName" value="resourceEnvEntry:customValue"/>
</propertySet>
```

Running a Java EE client application with launchClient

After deploying a Java EE client application onto a machine with an Application Client installation or in a WebSphere Application Server node, you can start the application by using the launchClient command on that machine.

Before you begin

Before you can use the launchclient command to run a Java EE client application, you must have deployed the application.

This task only applies to Java EE client applications.

About this task

The Java Platform, Enterprise Edition (Java EE) specification requires support for a client container that runs Java applications (known as Java EE client applications) and provides Java EE services to the applications. Java EE services include naming, security, and resource connections.

Procedure

1. Start the Qshell environment.

   On the CL command line, type the command:

   ```
   STRQSH
   ```

2. Enter the following command to launch Java EE application clients:

   ```
   app_client_root/bin/launchClient
   ```

   where *app_client_root* is `/QIBM/ProdData/WebSphere/AppServer/V8/Base` or `/QIBM/ProdData/WebSphere/AppServer/V8/ND`.

3. Pass parameters to the `launchClient` command or to your application client program as well. The `launchClient` command allows you to do both. The `launchClient` command requires that the first parameter is either:
   - An EAR file specifying the application client to launch.
   - A request for `launchClient` usage information.

   The following example illustrates the command line invocation syntax for the launchClient tool:

   ```
   launchClient [-profileName pName | -JVMOptions options | -help | -?] userapp [-CCname=value] [app args]
   ```

   where

   - *userapp* is the path and the name of the EAR file that contains the application client.
   - *-CCname=value* is the client container name-value pair parameter. See the client container parameters section, for supported name-value pair arguments.
   - *app args* are arguments that pass to the application client.
   - *-profileName* defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment or in an Application Clients installation.
   - *-JVMOptions* is a valid Java standard or non-standard option string. Insert quotation marks around the string.
   - *-help, -?* prints the usage information.

   All other parameters intended for the `launchClient` command must begin with the -CC prefix.

   Parameters that are not EAR files, or usage requests, or that do not begin with the -CC prefix, are ignored by the application client run time, and are passed directly to the application client program.

   The `launchClient` command retrieves parameters from three places:
   - The command line
   - A properties file
   - System properties

The parameters are resolved in the order listed above, with command line values having the highest priority and system properties the lowest. Using this prioritization you can set and override default values.

4. Specify the server name.

   By default, the launchClient command uses *your_server_name* for the `BootstrapHost` property value.

   This setting is effective for testing your application client when it is installed on the same computer as the server. However, in other cases override this value with the name of your server. You can override the `BootstrapHost` value by invoking `launchClient` command with the following parameters:

   ```
   launchClient myapp.ear -CCBootstrapHost=abc.midwest.mycompany.com
   ```

   You can also override the default by specifying the value in a properties file and passing the file name to the launchClient shell.

   Security is controlled by the server. You do not need to configure security on the client because the client assumes that security is enabled. If server security is not enabled, then the server ignores the security request, and the application client functions as expected.

Example

You can store launchClient values in a properties file, which is a good method for distributing default values. You can then override one or more values on the command line. The format of the file is one `launchClient -CC` parameter per line without the `-CC` prefix. For example:

```
 verbose=true classpath=/usr/lpp/mydir/util.jar;/usr/lpp/mydir/harness.jar;/usr/lpp
/production/G19/global.jar BootstrapHost=abc.westcoast.mycompany.com tracefile=/usr
/lpp/WebSphere/mylog.txt
```

launchClient tool:

This topic describes the Java Platform, Enterprise Edition (Java EE) command line syntax for the launchClient tool for WebSphere Application Server.

Important: All users who run commands from a specific profile must have authority to modify files that are created by other users that use the same profile. Otherwise, you might see a permission denied error in the log files. To avoid this issue, consider one of the following policies:

- Use specific profiles for distinct user authorities
- Always use the same user for all of the commands that are run in a given profile
- Ensure that all users of a specific profile belong to the same group. In addition, ensure that each user of a group has the read and write authority to the files that are created by other members in the same profile.

The following example illustrates the command line invocation syntax for the launchClient tool:

`launchClient [-profileName pName | -JVMOptions options | -help | -?] userapp [-CCname=value] [app args]`

where

- *userapp* is the path and the name of the EAR file that contains the application client.
- *-CCname=value* is the client container name-value pair parameter. See the client container parameters section, for supported name-value pair arguments.
- *app args* are arguments that pass to the application client.
- *-profileName* defines the profile of the Application Server process in a multi-profile installation. The -profileName option is not required for running in a single profile environment or in an Application Clients installation.
- *-JVMOptions* is a valid Java standard or nonstandard option string, except `-cp` or `-classpath`. Insert quotation marks around the string.
- *-help, -?* prints the usage information.

The first parameter must be -help, -? or contain no parameter at all. The -profileName pName and -JVMOptions options are optional parameters. If used, they must appear before the *<userapp>* parameter. All other parameters are optional and can appear in any order after the *userapp* parameter. The Java EE Application client run time ignores any optional parameters that do not begin with a -CC prefix and passes those parameters to the application client.

Client container parameters

Supported arguments include:

-CCadminConnectorHost
Specifies the host name of the server from which configuration information is retrieved.

The default is the value of the -CCBootstrapHost parameter or the value, your.server.name, if the -CCBootstrapHost parameter is not specified.

-CCadminConnectorPort
Indicates the port number for the administrative client function to use. The default value is 8880 for SOAP connections and 2809 for Remote Method Invocation (RMI) connections.

-CCadminConnectorType
Specifies how the administrative client connects to the server. Specify RMI to use the RMI connection type, or specify SOAP to use the SOAP connection type. The default value is SOAP.

-CCadminConnectorUser
Administrative clients use this user name when a server requires authentication. If the connection type is SOAP, and security is enabled on the server, this parameter is required.

-CCadminConnectorPassword
The password for the user name that the -CCadminConnectorUser parameter specifies.

-CCaltDD
The name of an alternate deployment descriptor file. This parameter is used with the -CCjar parameter to specify the deployment descriptor to use. Use this argument when a client JAR file is configured with more than one deployment descriptor. Set the value to null to use the client JAR file standard deployment descriptor.

-CCBootstrapHost
The name of the host server you want to connect to initially. The format is:
your_server_of_choice.com

-CCBootstrapPort
The server port number. If you do not specify this argument, the WebSphere Application Server default value is used.

-CCclassLoaderMode
Specifies the class loader mode. If PARENT_LAST is specified, the class loader loads classes from the local class path before delegating the class loading to its parent. The classes loaded for the following are affected:

- Classes defined for the Java EE application client
- Resources defined in the Java EE application
- Classes specified on the manifest of the Java EE client JAR file
- Classes specified using the -CCclasspath option

If PARENT_LAST is not specified, then the default mode, PARENT_FIRST, causes the class loader to delegate the loading of classes to its parent class loader before attempting to load the class from its local class path.

-CCclasspath
A class path value. When you launch an application, the system class path is used. If you want to

access classes that are not in the EAR file or part of the system class paths, specify the appropriate class path here. Multiple paths can be concatenated.

-CCD
Use this option to have the WebSphere Application Server set the specified system property during initialization. Do not use the equals (=) character after the -CCD. For example: -CCDcom.ibm.test.property=testvalue. You can specify multiple -CCD parameters. The general format of this parameter is -CCD<property key>=<property value>. For example, -CCDI18NService.enable=true.

-CCdumpJavaNameSpace
Controls generation of a dump of the java: name space for the application that is launched, which can be used for debugging purposes. A value of **true** generates a dump in short format, and includes the name and object type for each binding. A value of **long** generates a dump in long format, and includes additional information for each binding over short format, such as the local object type and string representation of the local object. The default value is **false**, and does not generate a dump.

-CCexitVM
Use this option to have the WebSphere Application Server call the System.exit() method after the client application completes. The default is false.

-CCinitonly
Use this option to initialize application client run time for ActiveX application clients without launching the client application. The default is false.

-CCjar
The name of the client Java Archive (JAR) file that resides within the EAR file for the application you wish to launch. Use this argument when you have multiple client JAR files in the EAR file.

-CCpropfile
Indicates the name of a properties file that contains launchClient properties. Specify the properties without the -CC prefix in the file, with the exception of the securityManager, securityMgrClass and securityMgrPolicy properties. See the following example: verbose=true.

-CCproviderURL
Provides bootstrap server information that the initial context factory can use to obtain an initial context. WebSphere Application Server initial context factory can use either a Common Object Request Broker Architecture (CORBA) object URL or an Internet Inter-ORB Protocol (IIOP) URL. CORBA object URLs are more flexible than IIOP URLs and are the recommended URL format to use. This value can contain more than one bootstrap server address. This feature can be used when attempting to obtain an initial context from a server cluster. You can specify bootstrap server addresses, for all servers in the cluster, in the URL. The operation will succeed if at least one of the servers is running, eliminating a single point of failure. The address list does not process in a particular order. For naming operations, this value overrides the -CCBootstrapHost and -CCBootstrapPort parameters. A CORBA object URL specifying multiple systems is illustrated in the following example:

```
-CCproviderURL=corbaloc:iiop:myserver.mycompany.com:9810,:mybackupserver.mycompany.com:2809
```

This value is mapped to the java.naming.provider.url system property.

-CCsecurityManager
Enables and runs the WebSphere Application Server with a security manager. The default is disable.

-CCsecurityMgrClass
Indicates the fully qualified name of a class that implements a security manager. Only use this argument if the -CCsecurityManager parameter is set to enable. The default is java.lang.SecurityManager.

-CCsecurityMgrPolicy
Indicates the name of a security manager policy file. Only use this argument if the -CCsecurityManager parameter is set to enable. When you enable this parameter, the java.security.policy system property is set. The default is *app_server_root*/properties/client.policy.

-CCsoapConnectorPort
The Simple Object Access Protocol (SOAP) connector port. If you do not specify this argument, the WebSphere Application Server default value is used.

-CCtrace
Use this option to obtain debug trace information. You might need this information when reporting a problem to IBM customer support. The default is `false`. For more information, read the Enabling trace topic.

-CCtracefile
Indicates the name of the file to which trace information is written. The default is to write output to the console.

-CCtraceMode
Specifies the trace format to use for tracing. If the valid value, `basic`, is not specified the default is advanced. Basic tracing format is a more compact form of tracing.

For more information on basic and advanced trace formatting, refer to the Interpreting trace output topic.

-CCverbose
This option displays additional information messages. The default is `false`.

If you are using an EJB client application with security enabled, edit the `sas.client.props` file, which is located in the *profile_root*`/properties` directory. Within the file, change the `com.ibm.CORBA.loginSource` value to *none*.

For more information on the `sas.client.props` utility, refer to the Manually encoding passwords in properties files and the PropFilePasswordEncoder command reference topics.

RMI connection with security. Used with the EJB and administrative client application.

Using Jacl:

```
wsadmin -conntype RMI -port  rmiportnumber -user userid
-password password
```

Using Jython:

```
wsadmin -lang jython -conntype RMI -port  rmiportnumber -user userid
-password password
```

rmiportnumber for your connection displays in the administrative console as BOOTSTRAP_ADDRESS.

Attention: On the AIX®, HP-UX, Linux, IBM i, Solaris, and z/OS operating systems, the use of -password option may result in security exposure as the password information becomes visible to the system status program, such as ps command, which can be invoked by other users to display all of the running processes. Do not use this option if security exposure is a concern. Instead, specify user and password information in the `soap.client.props` file for SOAP connector or `sas.client.props` file for RMI connector. The `soap.client.props` and `sas.client.props` files are located in the properties directory of your WebSphere Application Server profile.

If Kerberos (KRB5) is enabled for administrative authentication, the authentication target supports BasicAuth and KRB5. To use KRB5, update the `sas.client.props`, `soap.client.props`, and `ipc.client.props` files, according to the connector type.

Attention: When using Kerberos authentication, the user password does not flow across the wire. A one-way hash of password is used to identify the client.

The following examples demonstrate correct syntax.

```
/QIBM/ProdData/WebSphere/AppServer/V61/Base/bin/launchClient /home/earfiles/myapp.ear
   -profileName myprofile -CCBootstrapHost=myWASServer -CCverbose=true app_parm1 app_parm2
```

Specifying the directory for an expanded EAR file:

You can archive the `Manifest.mf` client Java Archive (JAR) files instead of automatically cleaning them up after the application exits.

Before you begin

Each time the launchClient tool is called, it extracts the Enterprise Archive (EAR) file to a random directory name in the temporary directory on your hard drive. Then the tool sets up the thread ClassLoader to use the extracted EAR file directory and JAR files included in the `Manifest.mf` client Java Archive (JAR) file. In a normal J2EE Java client, these files are automatically cleaned up after the application exits. This cleanup occurs when the client container shutdown hook is called. To avoid extracting the EAR file (and removing the temporary directory) each time the launchClient tool is called, complete the following steps:

Procedure

1. Specify a directory to extract the EAR file by setting the `com.ibm.websphere.client.applicationclient.archivedir` Java system property. If the directory does not exist or is empty, the EAR file is extracted normally. If the EAR file was previously extracted, the launchClient tool reuses the directory.
2. Delete the directory before running the launchClient tool again, if you need to update your EAR file. When you call the `launchClient` command, it extracts the new EAR file to the directory. If you do not delete the directory or change the system property value to point to a different directory, the launchClient tool reuses the currently extracted EAR file and does not use your changed EAR file. When specifying the `com.ibm.websphere.client.applicationclient.archivedir` property, make sure that the directory you specify is unique for each EAR file you use. For example, do not point the `MyEar1.ear` and the `MyEar2.ear` files to the same directory.

Downloading and running a Java EE client application using Java Web Start

Learn about the Java Web Start technology that is provided by the Java Standard Edition runtime environment to deploy Java Enterprise Edition application clients, including Thin application clients, on the remote client machine with a single click from a web browser on the client machine.

Before you begin

The supported client platforms for deploying application clients using the Java Web Start are the same as the IBM Application Client for WebSphere Application Server supported platforms, except Linux on Power® and OS/400® operating systems.

Before you begin this task, see the following topics to understand Java Web Start technology and its components:

- “Java Web Start architecture for deploying application clients” on page 143
- “Client application Java Network Launcher Protocol deployment descriptor file” on page 144
- “ClientLauncher class” on page 147

Note: The Sun Java Web Start, which is available from Sun Microsystems, is not compatible with the IBM Runtime Environment, Java 2 Technology Edition, which is provided by WebSphere Application Server and the IBM Application Client. The IBM Runtime Environment contains some additional functionality that is not supported in the Sun Java Web Start. Also, the IBM Runtime Environment uses a different packaging structure than the Sun Java Web Start. Use the IBM Runtime Environment.

About this task

To deploy application clients using Java Web Start, the client machine must have at least a Java SE runtime environment installed. The Java SE runtime environment includes the Java Web Start, which

implements the JSR 56: Java Network Launching Protocol and API. The application clients Enterprise Archive (EAR) file is a Java archive (JAR) resource in a JNLP descriptor file that resides on a central server. The JNLP descriptor file also specifies the runtime environment requirement for running the application.

WebSphere Application Server provides a launcher class to launch the Java EE application client in the application client container inside of Java Web Start. The client machine might not have the IBM Application Client for WebSphere Application Server installed. If this is the case, create and install an application client container and runtime package as a runtime environment through Java Web Start. The JNLP descriptor file specifies this runtime environment as the required runtime environment for running the Java EE application client.

WebSphere Application Server also provides command-line utility programs to create this application client container and runtime package from an existing IBM Application Client for WebSphere Application Server installation, as well as an installer class to install this package as a runtime environment for the application client container and also the Java Runtime Environment (JRE) in the IBM Application Client for WebSphere Application Server installation. To run the Java EE application client, the EAR file is deployed as a JAR resource that is described in the JNLP descriptor file.

Procedure

1. Identify the client machine operating system, and install the corresponding IBM Application Client for WebSphere Application Server on a development machine. For example, if the Java EE application clients are targeted to run on Windows operating systems, install the IBM Application Client for WebSphere Application Server for Windows.
2. Run the utility programs to create the application client container and runtime package.
   a. Use the “buildClientRuntime tool” on page 152 utility to create the package.
   b. Use the “buildClientLibJars tool” on page 144 utility to create the JAR files containing the launcher and the installer class. This utility also zips up the properties files in the <app_client_root>/properties directory.
3. Create the runtime installer JNLP descriptor file. The JNLP response must be included in the JNLP version ID to indicate the current runtime version in the response header, for example, `x-java-jnlp-version-id=1.6.0`. Using a servlet of a JavaServer Pages (JSP) file to provide a dynamic JNLP response.
4. Create the Java EE application client launch JNLP descriptor file.
5. Package the application client container runtime environments and the Java EE application in an Enterprise Archive (EAR) file. Depending on your preferred deployment strategy, the files can be in two separate Web modules, or combined into one.
6. All JAR resources must be Java signed, including the Java EE application client EAR file.
7. Deploy the Enterprise Archive file on an application server, and start the application. The Java EE application client is ready to be deployed.

Example

A Java Web Start deployment Sample is included in the client samples. This Sample demonstrates the steps to deploy a Java EE application client with an automated ANT script. The Sample has a servlet to generate the runtime installer JNLP response with JNLP version ID, for example, `x-java-jnlp-version-id`.

Important: When the application client initially launches using Java Web Start from Sun Microsystems Java SE Runtime Environment 6.0, it installs the Application Client runtime, which includes the IBM JRE. An null pointer exception (NPE) is thrown from the `com.sun.deploy.services.WPlatformService.getSecureRandom()` method. This is a known bug in Sun Java SE 6 (http://bugs.sun.com/bugdatabase/view_bug.do?bug_id=6505528). If you experience this exception, relaunch the application. The NPE only occurs on the first launch of the application client.

Java Web Start architecture for deploying application clients:

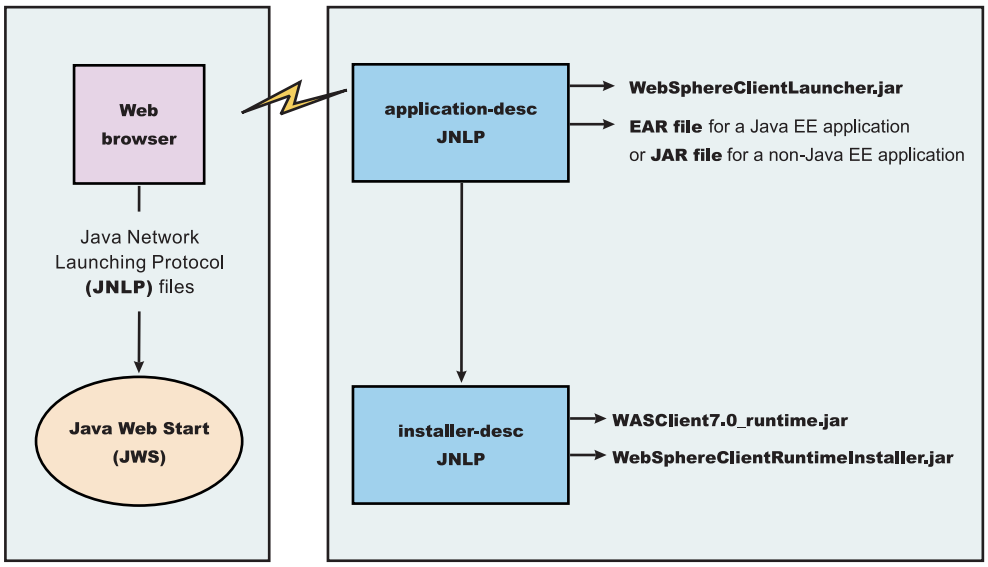
Java Web Start is an application-deployment technology that includes the portability of applets, the maintainability of servlets and JavaServer Pages (JSP) file technology, and the simplicity of mark-up languages such as XML and HTML. It is a Java application that allows full-featured Java EE client applications to be launched, deployed and updated from a standard Web server. The Java Web Start client is used with platforms that support a web browser.

Java Web Start is not supported.

Upon launching Java Web Start for the first time, you might download new client applications from the Web. Each time you launch JWS thereafter, you can initiate applications either through a link on a web page or (in Windows) from desktop icons or the Start menu. You can deploy applications quickly using Java Web Start, cache applications on the client machine, and launch applications remotely offline. Additionally, because Java Web Start is built from the Java Platform, Enterprise Edition (Java EE) infrastructure, the technology inherits the complete security architecture of the Java EE platform.

The technology underlying Java Web Start is the Java Network Launching Protocol & API (JNLP). Java Web Start is a JNLP client and it reads and parses a JNLP descriptor file (JNLP file). Based on the JNLP descriptor, it downloads appropriate pieces of a client application and any of its dependencies. If any of the pieces of the application are already cached on the client machine, then those components are not downloaded again, unless they have been updated on the server machine. After you download and cache the client application, JWS launches it natively on the client machine.

The following diagram shows an overview of launching a client application, include the Application Client for WebSphere Application Server as a dependent resource, using Java Web Start.



The web browser running on a client machine connects to a web application located on a server machine. The client application JNLP descriptor file is downloaded and processed by Java Web Start on the client machine.

In this diagram, there are two JNLP descriptor files:

- Client application JNLP descriptor (application-desc in the diagram)
- Application Clients run-time installer JNLP descriptor (installer-desc in the diagram)

Each of these JNLP descriptor files, the client application (JAR or EAR) and the dependent resource JAR files are packaged as web applications in an EAR file. This EAR file is deployed to an Application server.

The client machine with JWS installed uses a web browser to connect to the URL of the client application JNLP descriptor file to download and run the client application.

Using Java Web Start from Java SE Runtime Environment 6.0 or later is highly recommended. All the platforms supported by the application client for WebSphere Application Server are supported with the exception Linux on Power and OS/400 platforms.

You can use the following:

- Java Web Start on the Java Standard Edition Developer Kits that IBM provides, packaged in Application Client for WebSphere Application Server
- Java Web Start on Sun Microsystems Java SE 6 Development Kit or Java SE Runtime Environment 6.0, which you can download from the Sun Microsystems website for Windows, Linux and Solaris operating systems
- Java Web Start on HP-UX JDK or JRE for Java Platform, Standard Edition, Version 6, which you can download from the HP website

buildClientLibJars tool:

For a Java Platform, Enterprise Edition (Java EE) application client application and or Thin application client application to be launched using Java Web Start (JWS), the properties files bundled in Application Client for WebSphere Application Server must be installed in the Java Web Start. Use this tool to create those property JAR files. The Java Web Start client is used with platforms that support a web browser.

Java Web Start is not supported on WebSphere Application Server for IBM i.

The buildClientLibJars tool copies the JAR files from the Application Client for WebSphere Application Server installation and creates a `properties.jar` file, which contains the properties files from the Application Clients installation properties directory to a specified location. When this property is created, the tool uses the value of `keystore`, `storepass`, `alias` and `storetype` to sign all of the JAR files in the specified location.

```
Windows usage: buildClientLibJars.bat  [-help] [-verbose] destdir keystore storepass alias storetype

Unix usage:    buildClientLibJars.sh  [-help] [-verbose] destdir keystore storepass alias storetype
```

where:

- `-help` will display the message
- `-verbose` will turn on verbose message
- `destdir` will output the destination directory name
- `keystore` is the key store file
- `storepass` is the key store password
- `alias` key is the alias name
- `storetype` is the key store type

Client application Java Network Launcher Protocol deployment descriptor file:

The deployment descriptor file is the main Java Network Launcher Protocol (JNLP) descriptor file for the client application.

Location

The client application has an Application Clients runtime dependency that provides the following:

- Java SE Runtime Environment from IBM
- Application Clients run-time properties

- SSL KeyStore and TrustStore file
- Application Clients run-time library JAR files (optional for Thin Application client applications)

If the Application Clients run-time dependency is not met, it is downloaded and installed in Java Web Start (JWS), as described by the Application Clients run-time installer JNLP descriptor file. For example:

```
<j2se version="1.6" href="http://your_server.com/jws/wasappclient/download.jnlp"/>
```

Usage notes

The client application must also include the `WebSphereClientLauncher.jar` file, which contains the launcher class, com.ibm.websphere.client.launcher.ClientLauncher, that completes one of the following actions:

- If it is a Java Platform, Enterprise Edition (Java EE) Application client application (that is the resources for the application contain an EAR file with a client application), the EAR file must be specified as a JAR resource so that it can be downloaded to JWS and specified in the system property, `com.ibm.websphere.client.launcher.ear`. See “JNLP descriptor file for a Java EE Application client application” on page 146 for an example.
- If it is a Thin Application client application, the Thin Application client application JAR file must be specified as a JAR resource so that it can be downloaded to JWS and the name of the class containing main method entry point is specified in the system property, `com.ibm.websphere.launcher.main`. See “JNLP descriptor file for a Thin Application client application” on page 146 for an example.

The JNLP specification requires all the resource (JAR or EAR) files used in a JNLP file to be signed.

You can specify the –CC arguments defined in the launchClient tool for a J2EE Application client application in application arguments section of the JNLP descriptor files. However, only –CCD is supported for a Thin Application client application to define system properties and the JNLP <property> tag can also be used to define system properties. See the following example for details:

```
<property name="java.naming.provider.url" value="corbaloc:iiop:myserver.com:9089"/>
```

For a J2EE Application client application, specify the following application arguments as defined in the JNLP.

1. Specify your target server provider URL, as shown in the following example:

   ```
   <argument> >-CCDjava.naming.provider.url =corbaloc:iiop:myserver.mydomain.com:9080 </argument>
   ```

2. Specify the SSL Key File and SSL Trust File location. These files are expected to be available in the client machine. To use the ones in the Application Clients run-time dependency installed in JWS cache, specify these application arguments:

   ```
   <argument> -CCDcom.ibm.ssl.keyStore=${WAS_ROOT}/etc/key.p12 </argument>
   <argument> -CCDcom.ibm.ssl.trustStore=${WAS_ROOT}/etc/trust.p12 </argument>
   ```

3. Specify the initial naming context factor, as shown in the following example:

   ```
   <argument>-CCDjava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory </argument>
   ```

   For a Thin Application client application, you also need to specify the actual location of the `sas.client.props` and `ssl.client.props` files located in the Application Clients runtime dependency that is installed in the JWS cache.

   ```
   <argument>-CCDcom.ibm.CORBA.ConfigURL=file:${WAS_ROOT}/properties/sas.client.props </argument>
   <argument>-CCDcom.ibm.SSL.ConfigURL=file:${WAS_ROOT}/properties/ssl.client.props </argument>
   ```

   If any of the default settings in the `sas.client.props` and `sas.client.props` file need modifying, use the –CCD to change the settings through the system properties, as shown in the following example:

   ```
   <argument>-CCDjavacom.ibm.CORBA.securityEnabled=false </argument>
   ```

   Important: The ${WAS_ROOT} token used in the JNLP file is replaced by the launcher class, com.ibm.websphere.client.launcher.ClientLauncher, to the actual location of the Application Clients run-time dependency installation in the JWS cache. If you are using JSP to dynamically create this JNLP description file, you must escape this token because it has a different meaning in JSP 2.0. See the following example for details:

```
<argument>-CCDcom.ibm.ssl.keyStore=\${WAS_ROOT}/etc/key.p12 </argument>
<argument>-CCDcom.ibm.ssl.trustStore=\${WAS_ROOT}/etc/trust.p12 </argument>
```

JNLP descriptor file for a Java EE Application client application:

The deployment descriptor file is the main Java Network Launcher Protocol (JNLP) descriptor file for the client application.

Here is an example of the client application JNLP descriptor file for a Java EE Application client application:

```
<?xml version="1.0" encoding="utf-8"?>
<!--
This sample program is provided AS IS and may be used, executed, copied and modified

JNLP descriptor file for a Thin Application client application:

The deployment descriptor file is the main Java Network Launcher Protocol (JNLP) descriptor file for the client application. If it is a Thin Application client application, then the launcher class uses the current JVM from the Application Clients run-time dependency and invokes the Thin Application client application main method.

Here is an example of the JNLP descriptor file for a Thin Application client application.

```
 This sample program is provided AS IS and may be used, executed, copied and modified

ClientLauncher class:

The class, com.ibm.websphere.client.installer.ClientLauncher, contains a main() method that is called by Java Web Start (JWS) to launch the client application. The Java Web Start client is used with platforms that support a web browser.

Java Web Start is not supported.

This client is packaged in the `WebSphereClientLauncher.jar` file that is located in the Application Client for WebSphere Application Server installation under the <*app_client_root*>/ lib/webstart directory.

The launcher class requires that the following properties are defined. These properties are not defined in a separate properties file. Instead, the properties are defined as part of the Java Network Launching Protocol (JNLP) files.

com.ibm.websphere.client.launcher.main
If the client application is a Thin Application client, then this property should be specified. It specifies the class where the main entry point of the client application resides.

com.ibm.websphere.client.launcher.ear
If the client application is a Java Platform, Enterprise Edition (Java EE) Application client, then this property should be specified. It specifies the name of the EAR file to be executed. This property takes precedence over com.ibm.websphere.client.launcher.main. However, only one of the two properties should be specified.

Application client launcher for Java Web Start:

The application client launcher for Java Web Start is a Java class, com.ibm.websphere.client.installer.ClientLauncher, which has a main() method that Java Web Start calls to start the application client container and to invoke the application client's main() method. It provides similar functions as the **lauchClient** command line tool to start application clients from the command line.

The com.ibm.websphere.client.launcher.ClientLauncher class is packaged in the WebSphereClientLauncher.jar file under the <app_client_root>/lib/webstart directory.

The launcher tool requires that the following properties are defined.

com.ibm.websphere.client.launcher.main
If the client that is to be run is a thin client, then this property should be specified. It specifies the class where the main entry point of the application resides. It is the main class name for a Thin application client. If it is set, the launcher will not start the client container, it will rather invoke the main method for the application directly. However, if `com.ibm.websphere.client.launcher.ear` is also set, it will be ignored.

com.ibm.websphere.client.launcher.ear
If the client that is to run is the Java Platform, Enterprise Edition (Java EE) client, then this property should be specified. It specifies the name of the ear file to be executed. This property takes precedence over `com.ibm.websphere.client.launcher.main` although only one of the two properties should be specified.

These properties are not defined in a separate properties file. Instead, they are defined as part of the Java Network Launching Protocol files.

When `com.ibm.websphere.client.launcher.ear` is set, the application client launcher for JWS supports almost all of the –CC arguments as the **lauchClient** command line tool supports. However, if only `com.ibm.websphere.client.launcher.main` is set, the launcher will only support the –CCD argument. The following table shows the comparison of the supported –CC arguments for the **launchClient** command line tool and the application client launcher for JWS:

Table 14. Comparison of the supported –CC arguments for the **launchClient** *command line tool and the application client launcher for JWS. Comparison of the supported –CC arguments*

-CC argument	launchClient	Application client launcher for JWS
-CCverbose	Yes	Yes
-CCjar	Yes	Yes
-CCclasspath	Yes	N/A
-CCadminConnectorHost	Yes	Yes
-CCadminConnectorPort	Yes	Yes
-CCadminConnectorType	Yes	Yes
-CCadminConnectorUser	Yes	Yes
-CCaltDD	Yes	Yes
-CCBootstrapHost	Yes	Yes
-CCBootstrapPort	Yes	Yes
-CCproviderURL	Yes	Yes
-CCinitonly	Yes	N/A
-CCtrace	Yes	Yes
-CCtracefile	Yes	Yes
-CCsecurityManager	Yes	N/A
-CCsecurityMgrClass	Yes	N/A
-CCsecurityMgrPolicy	Yes	N/A
-CCD	Yes	Yes
-CCexitVM	Yes	Yes
-CCdumpJavaNameSpace	Yes	Yes
-CCsoapConnectorPort	Yes	Yes
-CCtraceMode	Yes	Yes
-CCclassLoaderMode	Yes	Yes

Macro expansion is supported for the –CCD argument by the application client launcher for JWS. The launcher will automatically substitute certain macro keys (enclosed with ${...}) with the calculated value at runtime. For example, if a macro key is used in the –CCD argument in the application client JNLP manifest file,

```
<argument>-CCDcom.ibm.ssl.keyStore= ${WAS_ROOT}/etc/key.p12</argument>
```

it will be expanded to the JWS cache installation root location and the argument will become:

```
-CCDcom.ibm.ssl.keyStore=/home/tiu/.java/deployment/cache/javaws/ext/E1134532441112/etc/key12.p12
```

The following table shows the three macro keys that are currently supported and will be substituted by the launcher:

Table 15. Currently supported macro keys. Supported macro keys

Macro key	Value
${WAS_ROOT}	Installation root location within the JWS cache that is used by the application client container and runtime installer for JWS.
${JAVA_HOME}	Location of Java home. The return value of System.getProperty(“java.home”).

Table 15. Currently supported macro keys (continued). Supported macro keys

Macro key	Value
${USER_HOME}	Location of user home. The return value of System.getProperty("user.home").

Preparing the application client run time dependency component for Java Web Start:

To launch a Java Platform, Enterprise Edition (Java EE) application client application, a Thin application client application, or both using Java Web Start (JWS), a Java Runtime Environment implementation Java archive (JAR) that IBM provides, the library JAR files and properties files bundled in Application Client for WebSphere Application Server must be installed in the JWS. Learn the steps to build the application client run time dependency component from an application client installation. It is packaged as a web application archive (WAR) file that can be installed in an application Server.

Before you begin

Install the Application Client for WebSphere Application Server for the operating system to which the client application deploys. If there is a requirement to deploy the client application to multiple operating systems, the application client run time dependency component must be built separately for each operating system that client application supports.

Procedure

1. Install the Application Client for WebSphere Application Server for the client application supported operating systems.
2. Change the directory to the installation bin directory.
3. Run the "buildClientRuntime tool" on page 152 to generate the application client run time JAR file, which contains the Java Standard Edition Runtime Environment, the run time library JAR files, properties files, and the SSL KeyStore and TrustStore files from the application client installation.
4. Run the buildClientLibJars tools to package up the properties files in the properties directory of the application client installation into a properties.jar file in the specified location. The buildClientLibJars tools will also copy the `WebSphereClientLauncher.jar` file and `WebSphereClientRuntimeInstaller.jar` file from the application client installation to the specified location. All jar files in the specified location will be signed by the provided certificate.

   For example, if you are using Version 7.0 and using the test certificate that is included in the application client installation:

   ```
   buildClientLibJars C:\Temp\webstart ..\etc\DummyClientKeyFilejar WebAS "websphere dummy client" JKS
   ```
5. Create a JavaServer Pages (JSP) file or use a servlet to generate the application client run time installer Java Network Launching Protocol (JNLP) descriptor to respond to Java Web Start request. See the Java Web Start deployment sample in the application client installation.
6. Package the two signed JAR files, `WASClient7.0_windows.jar` and `WebSphereClientRuntimeInstaller.jar`, and the JSP file or servlet for generating the Application Client run time installer JNLP descriptor into a web application archive (WAR) file. This WAR file is packaged into an EAR file that can be deployed to an application server. See the Java Web Start deployment sample in the application client installation.

Results

Your web application is ready to serve the application client run time and the JRE environment.

Example

```
<!-- This sample program applies to WebSphere Application Server, Version 6.1.
It is provided AS IS and may be used, executed, copied and modified
without royalty payment by customer (a) for its own instruction and study, (b) in order
```

```
to develop applications designed to run with an IBM WebSphere product, either for customer's
own internal use or for redistribution by customer, as part of such an application, in
customer's own products.

```

1. Specifies that the file is a JNLP mime type so that the browser can process the JNLP file.
2. Specifies the exact version of this Application Client run time dependency component in the response by setting the HTTP header field: `x-java-jnlp-version-id`.
3. Specifies the required JRE version to run the installer program.
4. Specifies the installer `WebSphereClientRuntimeInstaller.jar` file, which contains the ClientRuntimeInstaller class.
5. Specifies a system property that defines the version of Application Client run time dependency component. This version is registered to the JNLP client.
6. Specifies resources for a particular platform. Each supported client application platform needs its own separate JAR file.
7. Specifies the Application Client run time dependency component JAR file.
8. Specifies the program to call that starts a JVM for the client application.

buildClientRuntime tool:

For a Java Platform, Enterprise Edition (Java EE) application client application and or Thin application client application to be launched using Java Web Start (JWS), the library JAR files bundled in Application Client for WebSphere Application Server must be installed in the Java Web Start. Use this tool to build those JAR files. The Java Web Start client is used with platforms that support a web browser.

The Java Web Start client is not supported on WebSphere Application Server for OS/400.

The buildClientRuntime tool builds the required components from the WebSphere Application Server clients installation into the JAR file specified on the command. This JAR file contains:

- License files
- Java SE Runtime Environment 6 (JRE 6) that IBM provides
- Application Clients runtime properties and configuration
- SSL KeyStore and TrustStore files
- Runtime library JAR files

In the case of building an Application Clients runtime JAR file only for serving Thin Application client applications and not for Java EE Application client applications, the runtime library JAR files and the Application Clients runtime properties files are not included, except the configuration files,

sas.client.props, ssl.client.props and soap.client.props, located in the WAS_ROOT/properties directory. The Java Web Start client is used with platforms that support a web browser.

The command-line invocation syntax for the buildClientRuntime tool is shown in the following example:

```
Windows Usage:    buildClientRuntime.bat  [-help] [-verbose] outfile keystore storepass alias storetype

Unix Usage:         buildClientRuntime.sh    [-help] [-verbose] outfile keystore storepass alias storetype
```

where:

- -help will display the message
- -verbose will turn on verbose message
- outfile is the output file name
- keystore is the key store file
- storepass is the key store password
- alias is the key alias name
- storetype is the key store type

ClientRuntimeInstaller class:

This section provides information on the ClientRuntimeInstaller class.

This class, com.ibm.websphere.client.installer.ClientRuntimeInstaller, contains a main() method that Java Web Start (JWS) calls to install the Application Client for WebSphere Application Server run-time dependency component in JWS cache. It is packaged in WebSphereClientRuntimeInstaller.jar file located in the Application Client for WebSphere Application Server installation in the *<app_server_root>*/JWS directory.

Specify the WebSphereClientRuntimeInstaller.jar file and the Application Client run-time dependency component JAR file as JAR resources in the Application Client run-time installer Java Network Launcher Protocol (JNLP) descriptor file. See the following example for details:

```
<jar href="Launcher/WebSphereClientRuntimeInstall.jar" main="true"/>
<jar href="Launcher/WASClient6.1_windows.jarRuntimeInstall.jar" main="true"/>
```

The ClientRuntimeInstaller class main method requires the following properties to be set in the JNLP file:

com.ibm.websphere.client.jre.version
: Specifies a Java Runtime Environment (JRE) version name that is to be used when referring to the Application Client run-time dependency component.

com.ibm.websphere.client.jre.launch.java
: Specifies the relative location of the javaw.exe program in the Application Client run-time dependency component JAR file.

The previously mentioned properties, JRE version name and the location of the javaw.exe program are registered to the Java Web Start Application Manager, as shown in the following example:

```
<property name="com.ibm.websphere.client.jre.version" value="WASclient6.1"/>
<property name="com.ibm.websphere.client.jre.launch.java" value="java\jre\bin\javaw.exe"/>
```

Using the Java Web Start sample:

The EAR file, WasAppClientRuntime.ear, is provided in the *app_client_root*/samples/bin/WasAppClientRuntime directory of the Client Application for WebSphere Application Server installation. This EAR file provides a sample Application Clients run-time installer JNLP descriptor file and a sample Application Clients run-time library component JNLP descriptor file. Follow the steps in this task to build the Application Clients run-time dependency component and the Application Clients run-time library

component. Add these components to the WebSphereClientRuntime.ear file, and then install the EAR file in an Application Server to be used by the client application.

About this task

There is a new Java Web Start sample available in the client sample gallery for WebSphere Application Server V7.0. Refer to the client sample gallery in the Application Client for WebSphere Application Server product. The name of the new sample is "Java Web Start Deployment Sample".

Installing Java Web Start:

Learn about the steps that are necessary to install Java Web Start (JWS).. Java Web Start technology is provided by the Java SE runtime environment to deploy Java EE application clients (including Thin application clients) on the remote client machine with a single click from a web browser on the client machine.

Before you begin

Before you begin this task, see the “Preparing the application client run time dependency component for Java Web Start” on page 150 topic to understand Java Web Start (JWS) technology and components.

Note: The Sun Java Web Start, which is available from Sun Microsystems, is not compatible with the IBM Runtime Environment, Java 2 Technology Edition, which is provided by WebSphere Application Server and the IBM Application Client. The IBM Runtime Environment contains some additional functionality that is not supported in the Sun Java Web Start. Also, the IBM Runtime Environment uses a different packaging structure than the Sun Java Web Start. Use the IBM Runtime Environment.

About this task

Complete the following steps to install JWS:

Procedure

1. Install IBM Application Client for WebSphere Application Server.
2. Change your directory to the javaws path.
   - *client_install_root*\java\jre\lib\javaws
3. Run the update settings script from the path mentioned in the previous step.
   - Run the updateSetting.sh script
4. Change your path to the JWS installed path. For example, enter:
   - *client_install_root*\java\jre\javaws
5. Run javaws from the path mentioned in the previous step.
   - Run ./javaws command.

Using a static JNLP file with Java Web Start for Application clients:

Do not use JSP to dynamically generate a JNLP file, otherwise the JNLP jsp page cannot be opened in some IE browsers.

About this task

To use a static JNLP file, you will need to add the following mime type mapping in the web.xml file:

```
<?xml version="1.0" encoding="UTF-8"?>
<web-app id="WebApp_ID" version="2.4" xmlns="http://java.sun.com/xml/ns/j2ee"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
```

```
xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee
http://java.sun.com/xml/ns/j2ee/web-app_2_4.xsd">
       <display-name>
       WAS Client runtime for Java Web Start</display-name>
       <welcome-file-list>
              <welcome-file>index.html</welcome-file>
              <welcome-file>index.htm</welcome-file>
              <welcome-file>index.jsp</welcome-file>
              <welcome-file>default.html</welcome-file>
              <welcome-file>default.htm</welcome-file>
              <welcome-file>default.jsp</welcome-file>
       </welcome-file-list>
       <mime-mapping>
       <extension>jnlp</extension>
       <mime-type>application/x-java-jnlp-file</mime-type>
       </mime-mapping>
</web-app>
```

Running the IBM Thin Client for Enterprise JavaBeans (EJB)

An EJB Client is a Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) Java Platform, Standard Edition (Java SE) application that accesses remote Enterprise Java Beans from a server through Java Naming and Directory Interface (JNDI) look up. IBM Thin Client for EJB offers a smaller footprint and is easy to deploy to a Java SE environment and an Eclipse Rich Client Platform (RCP) environment. You can bundle the IBM Thin Client for EJB library using the WebSphere Application Server installation or the Application Client for WebSphere Application Server installation with your application. The IBM Thin Client for EJB also extends the choice of Java SE runtime. It can be run in the Java Runtime Environment (JRE) that is packaged with the WebSphere Application Server product, the Sun Microsystems JRE that is downloaded from the Sun Microsystems website, or the JRE that is downloaded from the HP website.

Before you begin

The IBM ORB implementation library is required if the IBM Thin Client for EJB is running with a non-IBM product JRE on a non-IBM product platform. For example, running the IBM Thin Client for EJB with Sun Microsystems JRE on Windows, Linux, or Solaris, and with the HP JRE on HP-UX. The IBM-provided Solaris hybrid and HP hybrid JRE are not considered non-IBM product JRE environments.

The IBM Thin Client for EJB can access version 2.x and version 3.x EJB on the WebSphere Application Server using the JNDI lookup, but it cannot access version 3.x EJB through resource injection. Resource injection is supported if the client application is a Java Platform, Enterprise Edition (Java EE) Application Client running within the Java Platform, Enterprise Edition (Java EE) Application Client Container.

Before you set up an EJB Thin Client environment, obtain the Java archive (JAR) file for the EJB Thin Client for WebSphere Application Server. To obtain the EJB Thin Client for WebSphere Application Server, install WebSphere Application Server or Application Client. The EJB Thin Client for WebSphere Application Server file, `com.ibm.ws.ejb.thinclient_8.0.0.jar`, is located in the *app_server_root*`\runtimes` directory.

Copy the Java archive (JAR) file for the IBM Thin Client for EJB with WebSphere Application Server product, `com.ibm.ws.ejb.thinclient_8.0.0.jar` and the `endorsed_apis_8.0.0.jar` files, to other machines to create a lightweight client environment that enables communications with the products. Copies of the IBM Thin Client for EJB are subject to the same terms and conditions of the license agreement for the WebSphere product where you obtained the Thin Client for EJB. Refer to the license agreements for correct usage and other limitations.

Copy the *app_server_root*`\runtimes\endorsed\endorsed_apis_8.0.0.jar` file into the default directory, `JAVA_JRE\lib\endorsed`. Alternatively, you can use the java.endorsed.dirs property to specify a directory of your choice. If you choose to use an alternative directory, it is a best practice to only include the endorsed_apis JAR file.

The IBM Thin Client for EJB with WebSphere Application Server runs on distributed operating systems with JDK support, including both Version 5 and Version 6. When using the IBM Thin Client for EJB as a standalone Java SE application with a non-IBM product JRE, you must override the default ORB implementation for the JRE through one of following methods:

- Include the com.ibm.ws.orb_8.0.0.jar file in the Java system classpath.
- Override the default ORB implementation in the JRE, using Java Endorsed Standards Override Mechanism.
- Set the java.endorsed.dirs path to a directory that contains the com.ibm.ws.orb_8.0.0.jar file.

When running the IBM Thin Client for EJB as an Eclipse RCP application, it is recommended to use method two, to override the default JRE ORB implementation.

Important: The Pluggable Application Client is deprecated. It is replaced by the IBM Thin Client for EJB.

Attention: When running the IBM Thin Client for EJB, and the `-Djava.util.logging.manager=com.ibm.ws.bootstrap.WsLogManager` command line option is used, a ClassDefNotFoundError error is thrown. The use of WsLogManager is not supported in the IBM Thin Client for EJB, but you can use another Java logging manager.

About this task

Run the IBM Thin Client for EJB, by completing the following steps.

Procedure

1. Invoke the client application. Run the following Java command:

   Add the following system properties to the Java command if you want authentication and SSL enabled:
2. Provide IIOP authentication configuration and Client SSL Configuration. Add the following system properties to the Java command:

   ```
   -Dcom.ibm.SSL.ConfigURL=file:///home/user1/ssl.client.props
   -Dcom.ibm.CORBA.ConfigURL=file:///home/user1/sas.client.props
   ```

   You can obtain the `ssl.client.props` file and `sas.client.props` file from the WebSphere Application Server installation and modify the file to suit your environment. You must, at a minimum, update the location of the key files in the `ssl.client.props` file to the match location of your target environment. For example,

   ```
   -Dcom.ibm.ssl.keyStore=/home/user1/etc/key.p12
   -Dcom.ibm.ssl.trustStore=/home/user1/etc/trust.p12
   ```

   Recommended SSL configuration settings when running the application with a non-IBM product JRE:

   ```
   com.ibm.ssl.protocol=SSL
   com.ibm.ssl.trustManager=SunX509
   com.ibm.ssl.keyManager=SunX509
   com.ibm.ssl.contextProvider=SunJSSE

   com.ibm.ssl.keyStoreType=JKS
   com.ibm.ssl.keyStoreProvider=SUN
   com.ibm.ssl.keyStore=/home/user1/etc/key.jks

   com.ibm.ssl.trustStoreType=JKS
   com.ibm.ssl.trustStoreProvider=SUN
   com.ibm.ssl.trustStore=/home/user1/etc/trust.jks
   ```

   The key store file and trust store file must be created using the Java keytool utility before the application runs. The automatic key file generation is not supported with a non-IBM product JRE.

   You must override the default ORB implementation of the non-IBM product JRE with the `com.ibm.ws.orb_8.0.0.jar` file, or add it to the classpath.
3. Run your client application:
   - Enter the following command if you have copied the endorsed_apis_8.0.0.jar file into the `JAVA_JRE\lib\endorsed` default directory; for example:

```
$JAVA_HOME/bin/java -Dcom.ibm.SSL.ConfigURL=file:///home/sample/ssl.client.props <your_client_application>
```

- Enter the following command if you have copied the endorsed_apis_8.0.0.jar file into a directory other than the default JAVA_JRE\lib\endorsed directory; for example:

```
$JAVA_HOME/bin/java
-Djava.endorsed.dirs=<directory_that_includes_endorsed_apis_8.0.0.jar>
-Dcom.ibm.SSL.ConfigURL=file:///home/sample/ssl.client.props <your_client_application>
```

What to do next

Enable trace for the IBM Thin Client for EJB by adding the following to the Java command.

```
-Dcom.ibm.ejs.ras.lite.traceSpecification=*=all
```

Running Java thin client applications

You can run Java thin client applications on machines installed with either a WebSphere Application Client installation or a WebSphere Application Server installation.

About this task

Important: Java thin clients are not packaged with JDBC provider classes. For example, the WebSphere Application Server Version 7.0 Java thin client is not packaged with Apache Derby 10.2 classes. Likewise, the version 6.1 Java thin client is not packaged with Cloudscape Version 5.1, Cloudscape Version 10.0, or Cloudscape version 10.1 classes. Therefore, to utilize the JDBC provider classes (such as Apache Derby, Oracle, DB2, Informix®, or Sybase) on a Java thin client, you must:

1. Add the classes to your Java thin client application environment.
2. Make the classes visible to the Java thin client application. To do this, add the path to the classes in the client classpath within the script that launched the client program.

Otherwise, any attempt to load a database class (such as through the JNDI lookup of a datasource) results in a ClassNotFoundException.

The Java invocation to run a Java thin client application varies between a client and a server. If your Java thin client application needs to run on both a client installation and a server installation, follow the steps in the Running a Java thin client application on a server machine topic.

Procedure

- “Running a Java thin client application on a client machine” on page 159
- “Running a Java thin client application on a server machine” on page 159

Example

Your Java thin application client no longer needs additional code to set security providers if you have enabled security for your WebSphere Application Server instance. This code found in IBM i Java thin or pluggable application clients should be removed to prevent migration and compatibility problems. The java.security file from your WebSphere instance in the properties directory is now used to configure the security providers.

- Running the thin or pluggable application client with security enabled

Running the thin or pluggable application client with security enabled. The following code examples illustrates how security providers were set programmatically in the main() method and occurred prior to any code that accessed enterprise beans:

```
import java.security.*;
  ...
  if (System.getProperty("os.name").equals("OS/400")) {

    // Set the default provider list first.
```

```
   Provider jceProv = null;
   Provider jsseProv = null;
   Provider sunProv = null;

   // Allow for when the Provider is not needed, when
   // it is not in the client application's classpath.
   try {
     jceProv = new com.ibm.crypto.provider.IBMJCE();
   }
   catch (Exception ex) {
ex.printStackTrace();
   throw new Exception("Unable to acquire provider.");
}

   try {
     jsseProv = new com.ibm.jsse.JSSEProvider();
   }
   catch (Exception ex) {
ex.printStackTrace();
   throw new Exception("Unable to acquire provider.");
}

   try {
     sunProv = new sun.security.provider.Sun();
   }
   catch (Exception ex) {
ex.printStackTrace();
   throw new Exception("Unable to acquire provider.");
}

   // Enable providers early and ahead of other providers
   // for consistent performance and function.
   if ( (null != sunProv) && (1 != Security.insertProviderAt(sunProv, 1)) ) {
     Security.removeProvider(sunProv.getName());
     Security.insertProviderAt(sunProv, 1);
   }
   if ( (null != jceProv) && (2 != Security.insertProviderAt(jceProv, 2)) ) {
     Security.removeProvider(jceProv.getName());
     Security.insertProviderAt(jceProv, 2);
   }
   if ( (null != jsseProv) && (3 != Security.insertProviderAt(jsseProv, 3)) ) {
     Security.removeProvider(jsseProv.getName());
     Security.insertProviderAt(jsseProv, 3);
   }

   // Adjust default ordering based on admin/startstd properties file.
   // Maximum allowed in property file is 20.
   String provName;
   Class  provClass;
   Object provObj =  null;

   for (int i = 0; i < 21; i++) {
     provName = System.getProperty("os400.security.provider."+ i);

     if (null != provName) {

       try {
         provClass = Class.forName(provName);
         provObj = provClass.newInstance();
       }
       catch (Exception ex) {
         // provider not found
         continue;
       }

       if (i != Security.insertProviderAt((Provider) provObj, i)) {
```

```
          // index 0 adds to end of existing list
          if (i != 0) {
            Security.removeProvider(((Provider) provObj).getName());
            Security.insertProviderAt((Provider) provObj, i);
          }
        }
      } // end if (null != provName)
    } // end for (int i = 0; i < 21; i++)
  } // end if ("os.name").equals("OS/400")
```

For examples of Java thin client applications, refer to the Samples section of the information center.

Running a Java thin client application on a client machine

To run a Java thin client application on a machine with Application Client for WebSphere Application Server installed, use the setup Client command then start the application.

Before you begin

Before performing this task, you must install the Java thin application client from the Application Client for WebSphere Application Server installation.

Procedure

1. Set up the client application environment. Run the setupClient command.

   Use the setupClient script.
   a. Start the Qshell environment. On the CL command line, run the `STRQSH` command.
   b. On the Qshell command line, run the following command using the dot (.) operator:

      `. app_client_root/bin/setupClient [-profileName profileName]`

2. Run a Java command to invoke your client application.

   Run the following command on the Qshell command line:

```
java ${JAVA_FLAGS_EXT} -classpath "$WAS_CLASSPATH:jars_and_classes" -Djava.naming.provider.url=URL class_name app_parm
```

Running a Java thin client application on a server machine

To run a Java thin client application on a machine with WebSphere Application Server installed, use the setupClient command then start the application.

Before you begin

You must install WebSphere Application Server before performing this task.

Procedure

1. Set up the Thin application client environment.

   Use the setupClient script.
   a. Start the Qshell environment. On the CL command line, run the STRQSH command.
   b. On the Qshell command line, run the following command using the dot (.) operator:

      `. app_server_root/bin/setupClient [-profileName profileName]`

2. Run the application client.

   Run the following command on a Qshell command line.

```
java ${JAVA_FLAGS_EXT} -classpath "$WAS_CLASSPATH:jars_and_classes" -Djava.naming.provider.url=URL class_name app_parm
```

   When using the WebSphere Application Server launcher, run the following command on a Qshell command line:

```
java ${JAVA_FLAGS_EXT} -classpath "$WAS_CLASSPATH:jars_and_classes" -Djava.naming.provider.url=URL com.ibm.ws.bootstrap.
```

Managing resources for Java EE client applications

You can manage resources for Java Platform, Enterprise Edition (Java EE) application clients by using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

Before you can manage resources for a Java EE client application, you must have deployed that application.

About this task

After deploying a Java EE client application client, you might want to or need to update the resources that you configured for that client application.

If you want to manage the resources of a Java EE client application deployed on z/OS, you can run the Application Client Resource Configuration Tool (ACRCT) on Windows, according to the following steps, and then reinstall the application on z/OS.

Updating data source and data source provider configurations with the Application Client Resource Configuration Tool

You can update the configuration of an existing data source or data source provider using the Application Client Resource Configuration Tool (ACRCT).

About this task

During this task, you update the configuration of an existing data source or data source provider. Perform this task when your database configuration changes.

Procedure

1. Start the Application Client Resource Configuration Tool (ACRCT), and open the Enterprise Archive (EAR) file containing the data source or data source provider. The EAR file contents display in a tree view.
2. Select Java Archive (JAR) file from the navigation tree containing the data source or data source provider to update.
3. Expand the JAR file to view its contents until you locate the particular data source or data source provider to update. Take one of the following actions:
   - Right-click the data source object and click **Properties**.
   - Click **Edit > Properties** on the menu bar.
4. Update the properties in the displayed fields. For detailed field help, refer to the Data source provider properties topic.
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Updating URLs and URL provider configurations for application clients

You can update URLs and URL provider configurations for application clients using the Application Client Resource Configuration Tool (ACRCT).

Procedure

1. Start the tool and open the Enterprise Archive (EAR) file containing the URL or URL provider. The EAR file contents are displayed in a tree view.
2. Select from the tree the Java Archive (JAR) file containing the URL or URL provider to update.

3. Expand the JAR file to view its contents.
4. Keep expanding the JAR file contents until you locate the particular URL or URL provider to update. Take one of the following actions:
   a. Right-click the URL object and click **Properties**.
   b. Click **Edit** > **Properties** on the menu bar.
5. Update the properties in the displayed fields.
6. Click **OK** when you finish.
7. Click **File > Save** on the menu bar to save your changes.

Updating mail session configurations for application clients

You can update the configuration of an existing JavaMail session using the Application Client Resource Configuration Tool (ACRCT).

About this task

During this task, you update the configuration of an existing JavaMail session. You cannot update the name of the default JavaMail provider, and you cannot delete the default JavaMail provider from the navigation tree.

Procedure

1. Start the tool and open the Enterprise Archive (EAR) file containing the JavaMail session. The EAR file contents are displayed in the navigation tree view.
2. Select the Java Archive (JAR) file containing the JavaMail session to update from the navigation tree.
3. Expand the JAR file to view its contents.
4. Keep expanding the JAR file contents until you locate the particular JavaMail session to update. Take one of the following actions:
   a. Right-click the object and click **Properties**
   b. Click **Edit > Properties** from the menu bar.
5. Update the properties in the displayed fields.
6. Click **OK** when you finish.
7. Select **File > Save** from the menu bar to save your changes.

Updating Java Message Service provider, connection factories, and destination configurations for application clients

You can update the configuration of an existing Java Message Service (JMS) provider, connection factory or destination using the Application Client Resource Configuration Tool (ACRCT).

About this task

During this task, you update the configuration of an existing Java Message Service (JMS) provider, connection factory or destination.

Procedure

1. Start the tool and open the Enterprise Archive (EAR) file containing the Java Message Service (JMS) provider, connection factory, or destination. The EAR file contents display in a tree view.
2. Select the Java Archive (JAR) file containing the JMS provider, connection factory, or destination to update from the navigation tree.
3. Expand the JAR file to view its contents until you locate the particular JMS provider, connection factory, or destination to update. When you find it, do one of the following actions:
   - Right-click the provider, and click **Properties**.

- Click **Edit > Properties** on the menu bar.

4. Update the properties in the displayed fields. For detailed field help, see:
   - JMS provider properties
   - WebSphere Application Server Queue connection factory properties
   - WebSphere Application Server Topic connection factory properties
   - WebSphere Application Server Queue destination properties
   - WebSphere Application Server Topic destination properties
5. Click **OK**.
6. Click **File > Save** to save your changes.

Updating WebSphere MQ as a Java Message Service provider, and its JMS resource configurations, for application clients

You can update an existing configuration of WebSphere MQ as a Java Message Service (JMS) provider, and update the configuration of WebSphere MQ connection factories or WebSphere MQ destinations.

About this task

Use this task to update an existing configuration of WebSphere MQ as a Java Message Service (JMS) provider, and to update the configuration of WebSphere MQ connection factories or WebSphere MQ destinations.

Procedure

1. Start the Application Client Resource Configuration Tool (ACRCT).
2. Open the Enterprise Archive (EAR) file containing the WebSphere MQ JMS provider, WebSphere MQ connection factory, or WebSphere MQ destination. The EAR file contents are displayed in the navigation tree view.
3. Select the Java Archive (JAR) file containing the JMS provider, connection factory, or destination to update.
4. Expand the JAR file to view its contents until you locate the particular JMS provider, connection factory, or destination that you want to update. Complete one of the following actions:
   - Right-click the appropriate object and click **Properties**.
   - Click **Edit > Properties** on the menu bar.
5. Update the properties in the displayed fields. For detailed field help, see:
   - JMS provider properties
   - MQ Queue connection factory properties
   - MQ Topic connection factory properties
   - MQ Queue destination properties
   - MQ Topic destination properties
6. Click **OK**.
7. Click **File > Save** to save your changes.

Updating resource environment entry and resource environment provider configurations for application clients

You can update the configuration of an existing resource environment entry or resource environment provider using the Application Client Resource Configuration Tool (ACRCT).

About this task

During this task, you update the configuration of an existing resource environment entry or resource environment provider.

Procedure

1. Start the tool and open the Enterprise Archive (EAR) file containing the resource environment entry or resource environment provider. The EAR file contents display in a navigation tree view.
2. Select from the tree the Java Archive (JAR) file containing the resource environment entry or resource environment provider to update.
3. Expand the JAR file to view its contents until you locate the resource environment entry or resource environment provider to update. Take one of the following actions:
   - Right-click the resource environment object, and click **Properties**.
   - Click **Edit > Properties** on the menu bar.
4. Update the properties in the displayed fields. For detailed field help, see:
   - Resource environment provider properties
   - Resource environment entry properties
5. Click **OK** when you finish.
6. Click **File > Save** on the menu bar to save your changes.

Example

- Configuring resource environment custom settings for application clients
- Configuring Resource Environment settings

Configuring resource environment custom settings for application clients: This code example illustrates how the custom page applies to every resource type. You can specify as many custom names and values as you need:

```
<propertySet xmi:id="J2EEResourcePropertySet_20">
<resourceProperties xmi:id="J2EEResourceProperty_22"
name="resourceEnvEntry:customName" value="resourceEnvEntry:customValue"/>
</propertySet>
```

Configuring Resource Environment settings: This code example illustrates how to configure Resource Environment settings:

```
<resources.env:ResourceEnvironmentProvider xmi:id="ResourceEnvironmentProvider_1"
name="resourceEnvProvider:name" description="resourceEnvProvider:description">
<classpath>resourceEnvProvider:classpath</classpath>
<factories xmi:type="resources.env:ResourceEnvEntry" xmi:id="ResourceEnvEntry_1"
name="resourceEnvEntry:name" jndiName="resourceEnvEntry:jndiName"
description="resourceEnvEntry:description">
<propertySet xmi:id="J2EEResourcePropertySet_20">
<resourceProperties xmi:id="J2EEResourceProperty_22"
name="resourceEnvEntry:customName" value="resourceEnvEntry:customValue"/>
</propertySet>
</factories>
<propertySet xmi:id="J2EEResourcePropertySet_21">
<resourceProperties xmi:id="J2EEResourceProperty_23"
name="resourceEnvProvider:customName" value="resourceEnvProvider:customValue"/>
</propertySet>
</resources.env:ResourceEnvironmentProvider>
```

- Required fields:
  - Resource Environment Provider page: Name
  - Resource Environment Entry page: Name, JNDI Name

Removing application client resources

You can remove Java Platform, Enterprise Edition (Java EE) application client resources using the Application Client Resource Configuration Tool (ACRCT).

Before you begin

The option to delete an item does not offer a confirmation dialog. As a safeguard, consider saving your work right before you begin this task. If you change your mind after removing an item, you can close the EAR file without saving your changes, canceling your deletion. Remember to close the EAR file immediately after the deletion, or you also lose any unsaved work that you performed since the deletion.

This task only applies to Java EE application clients.

Procedure

1. Start the Application Client Resource Configuration Tool (ACRCT) and open the Enterprise Archive (EAR) file from which you want to remove an object. The EAR file contents display in the navigation tree view. If you already have an EAR file open and have made some changes, click **File > Save** to save your work before preceding to delete an object.
2. Locate the object that you want to remove in the tree.
3. Right-click the object, and click **Delete**.
4. Click **File > Save**.

clientUpgrade script

The clientUpgrade script migrates application client modules and their resources in an enterprise archive (EAR) file so that these application clients can run in WebSphere Application Server Version 8. The script converts an EAR file that you want to migrate and then overwrites the original EAR file with the converted EAR file.

The following title provides information about the clientUpgrade script.

Attention: This command was deprecated in Version 6.1.

Type	Description
Product	The clientUpgrade script is available in the WebSphere Application Server (WebSphere Application Server, Express and WebSphere Application Server (base)) product only.
Authority	To run this script, your user profile must have *ALLOBJ authority.

Syntax	The syntax of the clientUpgrade script is:
	`clientUpgrade` *`EAR_file`* `[ -clientJAR` *`client_JAR_file`* `]`
	`[ -logFileLocation` *`logFileLocation`* `]`
	`[ -traceString` *`trace_spec`* `[ -traceFile` *`file_name`* `] ]`

Parameters	The parameters of the clientUpgrade script are: • *EAR_file* -- This is a required parameter. The value EAR_file specifies the fully-qualified path of the EAR file that contains the application client modules that you want to migrate. • -clientJAR -- This is an optional parameter. The value client_JAR_file specifies a JAR file that you want to migrate. The script overwrites the original EAR file with a new EAR file that contains only the specified JAR files. If you do not specify this parameter, the clientUpgrade script migrates all client JAR files in the EAR file. • -logFileLocation -- Use this optional parameter to specify an alternate location to store the log output. • -traceString -- This is an optional parameter. The value trace_spec specifies the trace information that you want to collect. To gather all trace information, specify "*=all=enabled" (including the double quotation marks (")). By default, the script does not gather trace information. If you specify this parameter, you must also specify the -traceFile parameter. • -traceFile -- This is an optional parameter. The value file_name The value file_name specifies the name of the output file for trace information. If you specify the -traceString parameter but do not specify the -traceFile parameter, the script does not generate a trace file.

Type	Description
Logging	The clientUpgrade script displays status while it runs. It also saves more extensive logging information to the `clientupgrade.log` file. This file is located in the `/QIBM/UserData/WebSphere/AppServer/V8/edition/profiles/default/logs` directory (for a default installation using the default profile) or in the location specified by the -logFileLocation parameter.

These examples demonstrate correct syntax. In this example, the `My51Application.ear` file is migrated from WebSphere Application Server Version 5.1, The script overwrites the original EAR file with a new file that you can deploy in your WebSphere Application Server Version 8 profile.

```
clientUpgrade /My51Application/My51Application.ear
```

In this example, only the `myJarFile.jar` client JAR file is migrated. The script overwrites `My51Application.ear` with an EAR file that contains `myJarFile.jar`. You can deploy the new EAR file in your WebSphere Application Server profile.

```
clientUpgrade /My51Application/My51Application.ear -clientJAR myJarFile.jar
```

Chapter 6. Administering Communications Enabled Applications

Communications Enabled Applications (CEA) is a functionality that provides the ability to add dynamic web communications to any application or business process. The product provides a suite of integrated telephony and collaborative web services that extends the interactivity of enterprise and web commerce applications. With the CEA capability, enterprise solution architects and developers can use a single core application to enable multiple modes of communication. Enterprise developers do not need to have extensive knowledge of telephony or Session Initiation Protocol (SIP) to implement CEA. The CEA capability delivers call control, notifications, and interactivity and provides the platform for more complex communications.

Administering communications enabled applications

Configuring services for communications enabled applications

CEA settings

Use this page to configure the Representational State Transfer (REST) interface and the computer-telephony integration (CTI) gateway to enable Communications Enabled Applications (CEA). A CTI application manages the event flow that is generated by the telephony switch, IP PBX, during the life cycle of a call.

- To view this administrative console page in a single-server environment, click **Servers > Server Types > WebSphere application servers > *server_name* > Communications Enabled Applications (CEA)**.
- To view this administrative console page in a clustered environment, click **Servers > Clusters > WebSphere application server clusters > *server_cluster* > Communications Enabled Applications (CEA)**.

  Because servers in a cluster are clones of each other, you only need to make configuration changes from the main cluster panel for the cluster, not for each individual server in the cluster.

  The CEA system application uses a SIP session for state replication and therefore relies on replication domains and clustering to provide failover support, similar to any other SIP application. See the topic Replicating SIP sessions for more information.

Enable communications service:

Specifies to enable or disable the communications service for this server or cluster. Disabling the field prevents the service from starting and saves system resources.

Context root:

Specifies the context root of the REST interface. Use this field to assign a different context root to the REST interface.

The context root is combined with the defined servlet mapping for the REST interface to compose the full URL that users type to make a REST request. For example, if the context root is `/gettingstarted` and the servlet mapping is `CommServlet/call`, then the URL is `http://host:port/gettingstarted/CommServlet/call`.

Virtual host:

Specifies the name of the virtual host to which the REST interface is currently mapped.

Expanding the menu list displays a list of the defined virtual hosts. To change a mapping, select a different virtual host from the list.

Maximum hold time:

Specifies the time in seconds in which a GET /event call to the REST interface waits for new or changed data or status before timing out.

Data Type	Integer
Default	30

Use SIP CTI (ECMA TR/87) gateway for telephony access:

Select this option to use the SIP CTI gateway for telephony access.

Host name or IP address:

Specifies the address or fully qualified domain name, FQDM, of the CTI gateway to be connected to by the CEA service.

Data Type	string
Default	localhost

Port:

Specifies the port of the CTI gateway to be connected to by the CEA service.

Data Type	integer
Default	5060

Protocol:

Specifies the protocol to be used when connecting to the CTI, TR/87, gateway. The default value is TCP.

Extract user name from request:

When enabled, an attempt is made to extract the user name from the HTTP request. If the name cannot be extracted, the Superuser name is used. This name is used when opening a new TR/87 session to the CTI gateway.

Attention: After you enable the **Extract user name from request** option, an attempt is made to extract the user name from the HTTP request. However, the user name has a null value even for authenticated users. The CEA Rest Service Servlet is an unprotected URI. Thus, you also must enable the **Use available authentication data when an unprotected URI is accessed** option. Use the administrative console to enable the **Use available authentication data when an unprotected URI is accessed** option under **Security > Global security > Web and SIP security > General settings**. After you enable this option, the user name is available to the CEA Rest Service Servlet during the request.

Superuser name:

Specifies the name that is used when opening a new TR/87 session to the configured CTI gateway. This requires that the CTI gateway be configured with a superuser account that is used to create phone calls on behalf of all end users.

Data Type	string
Default	ceauser

Attention: You can specify a **Superuser name** on the CEA settings panel. The superuser corresponds to a user, who is configured on the PBX, and has the ability to control any phone that is configured on the PBX. Also, the superuser has the ability to control multiple phones concurrently. This functionality, however, is not supported on every PBX. The Cisco PBX requires that you set a user name for each phone that you want to control. The **Superuser name** field on the CEA settings panel can only pass a single user name; therefore, it can only control a single device. To control multiple phones concurrently using the Cisco PBX, you must derive the user name from the user credentials for this PBX. To accomplish this task, ensure that the **Extract user name from request** check box is selected on the CEA settings panel.

Use a third-party Web services provider for telephony access:

Select this option to specify a third-party Web services provider for telephony access. Instead of using SIP CTI, this approach uses a third-party service that has implemented specific Web services to utilize a different method to connect to the telephony infrastructure.

Third-party Web services provider's WSDL:

The URL path pointing to a third-party Web services provider's WSDL. If a value is specified, the SIP CTI gateway is not used.

CEA custom properties

This topic discusses the CEA custom properties that you can set on the administrative console.

To view the administrative console page associated with this topic, click **Servers > Clusters > WebSphere application server clusters > *server_cluster* > Communications Enabled Applications (CEA) > Custom properties**.

Specify a property and its value as a name-value pair on the Custom properties page. You can use the custom properties page to define the following CEA custom properties:

- “SIP_RFC3263_auto_resolve”
- “sipOverTlsPbxOverride”

SIP_RFC3263_auto_resolve:

Disables the automatic DNS resolve for SIP messages. If this property is set to `false` for a SIP container, DNS resolve is only triggered by application APIs.

Data type	Boolean
Default	True

sipOverTlsPbxOverride:

Changes proxy behavior to send "sip:" formatted messages over a TLS connection instead of the default "sips:" message format.

Data type	String
Default	True

Configuring communications enabled applications in a cluster

You can configure multiple application servers to use the Communications Enabled Applications (CEA) capability in a cluster environment to balance workload demands.

About this task

To scale to two or more application servers running CEA, you must create a cluster that includes each application server. Clusters are groups of servers that are managed together and participate in workload management. You must use proxy servers to distribute the requests to the CEA application servers, but not IBM HTTP Servers. CEA is implemented as a converged application that combines both HTTP and session initiation protocol (SIP) protocols. However, IBM HTTP Server is limited to handling the HTTP protocol. The proxy server is a converged proxy so it handles both HTTP and SIP protocols.

Procedure

1. Identify the application servers or nodes that are running CEA that you want to manage as a cluster.
2. Create the cluster using the administrative console. For details on creating the cluster, read about creating a cluster using basic cluster settings.
3. Install a SIP proxy server. The SIP proxy server routes HTTP and SIP requests to the back-end application servers. This proxy server provides high performance SIP proxy capabilities that you can use at the edge of the network to route, load balance, and improve response times for SIP dialogs to backend SIP resources. For details on installing a SIP proxy server, read about installing a SIP proxy server.
4. Configure the SIP converged proxy server. Select the default cluster to specify where you want the SIP proxy to route requests. After you choose a default cluster, your SIP proxy server is functional.

Results

You have successfully configured a cluster environment for CEA applications.

Chapter 7. Administering Data access resources

This page provides a starting point for finding information about data access. Various enterprise information systems (EIS) use different methods for storing data. These backend data stores might be relational databases, procedural transaction programs, or object-oriented databases.

The flexible IBM WebSphere Application Server provides several options for accessing an information system backend data store:

- Programming directly to the database through the JDBC 4.0 API, JDBC 3.0 API, or JDBC 2.0 optional package API.
- Programming to the procedural backend transaction through various J2EE Connector Architecture (JCA) 1.0 or 1.5 compliant connectors.
- Programming in the bean-managed persistence (BMP) bean or servlets indirectly accessing the backend store through either the JDBC API or JCA-compliant connectors.
- Using container-managed persistence (CMP) beans.
- Using the IBM data access beans, which also use the JDBC API, but give you a rich set of features and function that hide much of the complexity associated with accessing relational databases.

Service Data Objects (SDO) simplify the programmer experience with a universal abstraction for messages and data, whether the programmer thinks of data in terms of XML documents or Java objects. For programmers, SDOs eliminate the complexity of the underlying data access technology such as, JDBC, RMI/IIOP, JAX-RPC, and JMS, and message transport technology such as, java.io.Serializable, DOM Objects, SOAP, and JMS.

Deploying data access applications

Deploying a data access application includes more than installing your web application archive (WAR) or enterprise archive (EAR) file onto a server. Deployment can include tasks for configuring your application to use the data access resources of the server and overall runtime environment.

Before you begin

You can deploy only application code that is assembled into the appropriate modules. See the topic, Assembling data access applications for guidelines, for this process.

About this task

Perform the following steps if your application requires access to a relational database (RDB). When your application requires access to a different type of enterprise information system (EIS), such as an object-oriented database or the Customer Information Control System (CICS®), consult the topics, Relational resource adapters and JCA, and Accessing data using Java EE Connector Architecture connectors.

Procedure

1. If your RDB configuration does not exist, do the following steps:
   a. Create a database to hold the data.
   b. Create tables required by your application.
      If your application uses container managed persistence (CMP) entity beans to access the data You can create the tables using the data definition language (DDL) generated from the enterprise bean configuration. For more information, see the topic, Recreating database tables from the exported table data definition language.

If your application uses bean managed persistence (BMP) entity beans, or *does not* **use entity beans**

You must use your database server interfaces to create the tables.

The Enterprise JavaBeans (EJB) to RDB Mapping wizard of an assembly tool is also used to create your database tables for either type of entity bean. Select the top-down mapping option in the wizard. However, this option does not give you direct control in naming the RDB elements or choosing column types. Additionally, because the top-down process is automatic, it might not provide mappings to reflect the precise relationships that you intend.

If you use Rational Application Developer, consult the information center about the mapping wizard. To learn about all of your assembly tool options, see the assembly tools topic in this information center.

c. Check the data source minimum required settings by vendor to see any database vendor requirements for connecting to an application server. See the topic, Data source minimum required settings, by vendor, for instructions.

2. Optional: Map your entity beans to the database tables through the meet-in-the-middle mapping option of an assembly tool. Complete this step only if you did not create your database schema through the top-down mapping option, did not generate your mapping relationships through bottom-up mapping, or did not generate mappings during the application assembly process. For information about the top-down mapping option see the information center for Rational Application Developer.
3. Install your application onto the application server. See the topic, Installing enterprise application files. When you install the application, you can alter data access settings that were made during application assembly, or, if they were omitted from the assembly process, set them for the first time. These settings include resource bindings and resource authentication aliases, which are addressed in the following substeps:
   a. Bind application resource references to the data sources, or other resource objects, that provide database connectivity. For details on the concept of binding, see the topic, Data source lookups for enterprise beans and web modules.

      Tip: After deployment, you can use the WebSphere Application Server administrative console to alter resource bindings. Click **Applications** > **Application Types** > **Webphere enterprise applications** > ***application_name***, and select the link to the appropriate mapping page. For example, if you want to alter the binding of an EJB module resource, you might click **Map data sources for all 2.x CMP beans**. For a web module resource, click **Resource references**.

   b. Define authentication alias data for resources that must be authenticated with the backend through *container-managed* authorization. In this security configuration, WebSphere Application Server performs EIS signon for data source or connection factory connections. Consult the topic, J2EE connector security for detailed reference on resource authentication.
4. Start the deployed application files using the administrative console, the wsadmin scripting tool startApplication command, or your own Java program.
5. Save the changes to your administrative configuration.
6. Test the application. For example, point a web browser at the URL for a deployed application and examine the performance of the application.

Results

When you deploy an application that uses a DB2 UDB for IBM i back-end database, you might find the following exception in the SystemOut.log file:

```
PMGR6022E: Error using adapter to create or execute an Interaction
```

This type of error indicates that you deployed an application with container-managed persistence (CMP) enterprise beans that were originally configured to access a DB2 database on Windows, Linux, or a supported UNIX system. Using the administrative console, uninstall the affected CMP applications, then

reinstall the applications with the new database setting. Remember to select **Deploy enterprise beans**; on the **EJB deploy** panel, select the appropriate version of your DB2 UDB for IBM i database.

Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

What to do next

If the application does not perform as wanted, update the application, then save and test it again.

Available resources

Use this page to select configured resources that you want to bind to the resource references of the enterprise beans or web modules in your application.

To view this administrative console page:

1. Click **Applications** > **Application Types** > **Websphere enterprise applications** > ***application_name***.
2. Click the link for any of these resource configuration pages:
   - **Resource references**
   - **Map data sources for all 2.x CMP beans**
   - **Provide default data source mapping for modules containing 2.x entity beans**
3. Locate the table row of the EJB or web module that you want to map to a different resource.
4. Within the row, locate the JNDI name of the resource that is currently bound to the EJB or web module.
5. Click **Browse**.

   You now see **Available resources**.

Each table row corresponds to a resource that you can bind to your enterprise bean or web module.

Select

Select the resource that you want to bind to the resource reference of your module.

JNDI name

The Java Naming and Directory Interface (JNDI) name of the resource that you want to bind to the resource reference of your module.

Data type String

Scope

The scope of the resource. Note that this administrative console page displays only resources that are configured for a scope at which your application operates.

Description

The text description of the resource.

Map data sources for all 1.x CMP beans

Use this page to designate how the container-managed persistence (CMP) 1.x beans of an application map to data sources that are available to the application.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Map data sources for all 1.x CMP beans**.

Guidelines for using this administrative console page:

- The table depicts the 1.x CMP bean contents of your application.
- Each table row corresponds to a CMP bean within a specific EJB module. A row shows the JNDI name of the data source mapping target of the bean *only* if you bound them together during application assembly or installation. For every data source that is displayed, you see the corresponding security configuration.
- To set your mappings:
  1. Select a row. Be aware that if you check multiple rows on this page, the data source mapping target that you select in step 2 applies to all of those CMP beans.
  2. Click **Browse** to select a data source from the new page that is displayed, the Available Resources page. The Available Resources page shows all data sources that are available mapping targets for your CMP beans.
  3. Click **Apply**. The console displays the 1.x CMP bean data sources page again. In the rows that you previously selected, you now see the JNDI name of the new resource mapping target.
  4. *Before* you click **OK** to save your new configuration, set the security parameters for the data source. Use the following steps.
- To specify data source security settings:
  1. Select one or more rows in the table.
  2. Type in a user name and password that comprise the authentication alias for signing on to the data source. If these entries are not listed in the application Java Platform, Enterprise Edition (Java EE) Connector (J2C) authentication data list, you must input them into the list after saving your settings on this page. Read the information center topic on managing Java EE Connector Architecture authentication data entries for more information.
  3. Click **Apply** that immediately follows the user name and password input fields.
- Repeat all of the previous steps as necessary.
- Click **OK** to save your settings.

Select
Select the check boxes of the rows that you want to edit.

EJB
The name of an enterprise bean in the application.

EJB Module
The name of the module that contains the enterprise bean.

URI
Specifies location of the module relative to the root of the application EAR file.

JNDI name
The Java Naming and Directory Interface (JNDI) name of the data source that is configured for the enterprise bean.

Data type String

User name
The user name and password that comprise the authentication alias for securing the data source.

Map default data sources for modules containing 1.x entity beans

Use this page to set the default data source mapping for EJB modules that contain 1.x container-managed persistence (CMP) beans. Unless you configure individual data sources for your 1.x CMP beans, this default mapping applies to all beans within the module.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Map default data sources for modules containing 1.x entity beans**.

Guidelines for using this administrative console page:

- The page displays a table that depicts the EJB modules in your application that contain 1.x CMP beans.
- Each table row corresponds to a module. A row shows the JNDI name of the data source mapping target of the EJB module *only* if you bound them together during application assembly. For every data source that is displayed, you see the corresponding security configuration.
- To set your default data source mappings:
  1. Select a row. Be aware that if you check multiple rows on this page, the data source mapping target that you select in step 2 applies to all of those EJB modules.
  2. Click **Browse** to select a data source from the new page that is displayed, the Available Resources page. The Available Resources page shows all data sources that are available mapping targets for your EJB modules.
  3. Click **Apply**. The console displays the 1.x entity bean data sources page again. In the rows that you previously selected, you now see the JNDI name of the new resource mapping target.
  4. *Before* you click **OK** to save your new configuration, set the security parameters for the data source. Use the following steps.
- To specify security settings for the default data source:
  1. Select a row. Be aware that if you check multiple rows on this page, the security settings that you select later apply to all of those data sources.
  2. Type in a user name and password that comprise the authentication alias for signing on to the data source. If these entries are not listed in the application Java Platform, Enterprise Edition (Java EE) Connector (J2C) authentication data list, you must input them into the list after saving your settings on this page. Read the information center topic on managing Java EE Connector Architecture authentication data entries for more information.
  3. Click **Apply** that immediately follows the user name and password input fields.
- Repeat all of the previous steps as necessary.
- Click **OK** to save your work.

Select

Select the check boxes of the rows that you want to edit.

EJB Module

The name of the module that contains the 1.x enterprise beans.

URI

Specifies location of the module relative to the root of the application EAR file.

JNDI name

The Java Naming and Directory Interface (JNDI) name of the default data source for the EJB module.

Data type String

User name

The user name and password that comprise the authentication alias for securing the data source.

Map data sources for all 2.x CMP beans settings

Use this page to map container-managed persistence (CMP) 2.x beans of an application to data sources that are available to the application.

To view this administrative console page, click **Applications** > **Application Types** > **Websphere enterprise applications** > ***application_name*** > **Map data sources for all 2.x CMP beans**.

Each table row corresponds to a CMP bean within a specific EJB module. A row shows the JNDI name of the data source mapping target of the bean only if you bound them together during application assembly. For every data source that is displayed, you see the corresponding security configuration.

Set Multiple JNDI names

Specify the Java Naming and Directory Interface (JNDI) name for multiple EJB modules. Select one or more EJB modules from the table, and select a JNDI name from this list to configure the EJB modules with that JNDI name.

Data type Drop-down list

Set Authorization Type

Specify the authorization type for securing the data source. Select one or more EJB modules from the table to set the authorization type.

Select either **Container** or **Application** from the displayed list. Container-managed authorization indicates that WebSphere Application Server performs signon to the data source. Application-managed authorization indicates that the enterprise bean code performs signon.

Modify Resource Authentication Method

Specify the authorization type and the authentication method for securing the data source. Select one or more EJB modules from the table to modify the resource authentication method.

You can choose between the following authentication methods:

- **None**:
  1. Determine which data source configurations to designate with no authentication method.
  2. Select the appropriate table rows.
  3. Select **None** from the list of authentication method options that precede the table.
  4. Click **Apply**.
- **Use default method (many-to-one mapping)**:
  1. Determine which data source configurations to designate with the WebSphere Application Server DefaultPrincipalMapping login configuration. Apply this option to each data source individually if you want to designate different authentication data aliases. See the information center topic on J2EE Connector security for more information on the default mapping configuration.
  2. Select the appropriate table rows.
  3. Select **Use default method (many-to-one mapping)** from the list of authentication method options that precede the table.
  4. Select an authentication data entry or alias from the list.
  5. Click **Apply**.
- **Use Kerberos authentication**: Specifies to use the Kerberos authentication method.
  1. Ensure that you have configured the Kerberos authentication mechanism in the application server.
  2. Select the appropriate table row.
  3. Select **Use Kerberos authentication** from the list of authentication method options that precede the table.

4. Select an application login configuration from the list.
5. Click **Apply**.
6. To edit the properties of the custom login configuration, click **Mapping Properties** in the table cell.

The application server will attempt to verify that you are connecting to the correct type of database when you select this option.

- **Use trusted connections (one-to-one mapping)**:
  1. Determine which data source configurations to designate with a custom Java Authentication and Authorization Service (JAAS) login configuration. See the information center topic on J2EE Connector security for more information on custom JAAS login configurations.
  2. Select the appropriate table row.
  3. Ensure that the database to which the modules will connect is configured for trusted connections.
  4. Select **Use trusted connections (one-to-one mapping)** from the list of authentication method options that precede the table.
  5. Select an application login configuration from the list.
  6. Click **Apply**.

  The application server will attempt to verify that you are connecting to the correct type of database when you select this option.
- **Custom login configuration**:
  1. Determine which data source configurations to designate with a custom Java Authentication and Authorization Service (JAAS) login configuration. See the information center topic on J2EE Connector security for more information on custom JAAS login configurations.
  2. Select the appropriate table row.
  3. Select **Use custom login configuration** from the list of authentication method options that precede the table.
  4. Select an application login configuration from the list.
  5. Click **Apply**.
  6. To edit the properties of the custom login configuration, click **Mapping Properties** in the table cell.

Select
Select the check boxes of the rows that you want to edit.

EJB
The name of an enterprise bean in the application.

EJB Module
The name of the module that contains the enterprise bean.

URI
Specifies location of the module relative to the root of the application EAR file.

Target resource JNDI name
Specifies the resource to which the CMP bean is bound.

Resource authorization
Specifies the current setting for the resource authorization type.

Modify this setting with **Set authorization type**.

Map data sources for all 2.x CMP beans

Use this page to set the default data source mapping for EJB modules that contain 2.x container-managed persistence (CMP) beans. Unless you configure individual data sources for your 2.x CMP beans, this default mapping applies to all beans within the module.

To view this administrative console panel, click **Applications** > **Application Types** > **Websphere enterprise applications** > ***application_name*** > **Map data sources for all 2.x CMP beans** .

This panel displays a table that depicts the EJB modules in your application that contain 2.x CMP beans. Each table row corresponds to a module. A row shows the JNDI name of the data source mapping target of the EJB module only if you bound them together during application assembly. For every data source that is displayed, you see the corresponding security configuration.

Set Multiple JNDI Names

Specifies the JNDI name to bind to one or more modules. Select one or more modules, click **Set Multiple JNDI Names**, and select the JNDI name for the resource to which you would like to bind the module.

Set Authorization Type

Specifies the authorization type that you to use for the modules. Select one or more modules, click **Set Authorization Type**, and select the authorization type.

You can choose:

- Per application - indicates that the enterprise bean code performs signon.
- Container - indicates that the application server performs signon to the data source.

Modify Resource Authentication Method

Specifies the resource authentication method for the modules that you have configured with container-managed authorization. Select one or more modules, click **Modify Resource Authentication Method**, and select the authentication method.

You can choose between the following authentication methods:

- **None**:
  1. Determine which data source configurations to designate with no authentication method.
  2. Select the appropriate table rows.
  3. Select **None** from the list of authentication method options that precede the table.
  4. Click **Apply**.
- **Use default method (many-to-one mapping)**:
  1. Determine which data source configurations to designate with the WebSphere Application Server DefaultPrincipalMapping login configuration. Apply this option to each data source individually if you want to designate different authentication data aliases. See the information center topic on J2EE Connector security for more information on the default mapping configuration.
  2. Select the appropriate table rows.
  3. Select **Use default method (many-to-one mapping)** from the list of authentication method options that precede the table.
  4. Select an authentication data entry or alias from the list.
  5. Click **Apply**.
- **Use Kerberos authentication**: Specifies to use the Kerberos authentication method.
  1. Ensure that you have configured the Kerberos authentication mechanism in the application server.
  2. Select the appropriate table row.
  3. Select **Use Kerberos authentication** from the list of authentication method options that precede the table.

4. Select an application login configuration from the list.
5. Click **Apply**.
6. To edit the properties of the custom login configuration, click **Mapping Properties** in the table cell.

The application server will attempt to verify that you are connecting to the correct type of database when you select this option.

- **Use trusted connections (one-to-one mapping)**:
  1. Determine which data source configurations to designate with a custom Java Authentication and Authorization Service (JAAS) login configuration. See the information center topic on J2EE Connector security for more information on custom JAAS login configurations.
  2. Select the appropriate table row.
  3. Ensure that the database to which the modules will connect is configured for trusted connections.
  4. Select **Use trusted connections (one-to-one mapping)** from the list of authentication method options that precede the table.
  5. Select an application login configuration from the list.
  6. Click **Apply**.

  The application server will attempt to verify that you are connecting to the correct type of database when you select this option.
- **Custom login configuration**:
  1. Determine which data source configurations to designate with a custom Java Authentication and Authorization Service (JAAS) login configuration. See the information center topic on J2EE Connector security for more information on custom JAAS login configurations.
  2. Select the appropriate table row.
  3. Select **Use custom login configuration** from the list of authentication method options that precede the table.
  4. Select an application login configuration from the list.
  5. Click **Apply**.
  6. To edit the properties of the custom login configuration, click **Mapping Properties** in the table cell.

Select
Select the check boxes of the rows you want to edit.

EJB Module
Specifies the name of the module that contains the 2.x enterprise beans.

URI
Specifies location of the module relative to the root of the application EAR file.

JNDI name
Specifies the Java Naming and Directory Interface (JNDI) name of the default data source for the EJB module.

Data type String

Resource authorization
Specifies the authorization type and the authentication method for securing the data source.

Extended Datasource Properties
When selected, you will be directed to a panel on which you can specify extended properties that the module can use for the DB2 data source.

The application server will attempt to verify that you are connecting to the correct type of database when you select this option.

Installing a resource adapter archive

The application server uses the classes and other code that comprise a resource adapter archive (RAR) to support the resource adapters that you configure.

Before you begin

A RAR file, which is often called a Java EE Connector Architecture (JCA) connector, must comply with the JCA Specification. You can meet these requirements by using a supported assembly tool to assemble a collection of Java archive (JAR) files, other runnable components, and utility classes into a deployable resource adapter archive (RAR). You can then install the RAR file in the application server.

About this task

A resource adapter archive provides the classes and other code to support a resource adapter for access to a specific EIS, such as the Customer Information Control System (CICS). Therefore, you can only configure resource adapters for an EIS after you install the appropriate RAR file.

Important: When you use the **Install RAR** dialog to install a RAR file, the scope you define on the Resource Adapters page has no effect on where the RAR file is installed. You can install RAR files only at the node level, which you specify on the Install RAR page. To set the scope of an RAR file to a specific cluster, or server, after you install the RAR file at each node level, create a copy of the RAR file with the appropriate cluster or server scope.

Procedure

1. Navigate to the **Resource adapter** panel. Click **Resources** > **Resource Adapters** > **Resource adapters**.
2. Install a new resource adapter archive.
   a. Click **Install RAR**. A dialog opens for installing a RAR file and configuring the associated resource adapter. Only click **New** if you want to configure a new resource adapter for a previously installed RAR file.
   b. Browse to find the appropriate RAR file.
      - If your RAR file is located on your local workstation, select **Local path**, and browse to find the file.
      - If your RAR file is located on your server, select **Remote file system**, and specify the fully qualified path to the file.
   c. Click **Next**.
3. Configure the resource adapter name and any other properties needed under *General Properties*. For more details on the settings that you can configure, such as the J2C connection factories, see the topics Installing resource adapters within applications and Configuring resource adapters.
4. Click **OK**.
5. Optional: Create a copy of the RAR file with a different scope level. After you install the RAR file at each node level, you can create another copy of the file that has a specific server or cluster as the scope for that file.

   Note:

   - If you do not create a copy of your RAR at the cluster scope, then you must create identical factories (connection factories, admin object, and activation specifications) at the node level for each of your nodes in the cluster. By creating the copy of your RAR, you provide a

placeholder for your factories and circumvent the need to create identical factories at the node level for each of your nodes in the cluster.

- You must still install the RAR binaries (files, such as jars and xml deployment files) on each node for the RAR to operate successfully.

a. Click **Resources**.
b. Click **Resource Adapters**.
c. Select the scope level and then click **NEW**.
d. Choose the RAR file from the installed archive path.
e. Click **OK**.

Results

You have installed a resource adapter archive that provide access to the EIS when it is properly configured. If you must configure more settings, or change some settings that were configured during the installation process, refer to the topic on configuring a resource adapter in the administrative console for more information.

Installing resource adapters embedded within applications

Install resource adapters in your applications so they can access outside data sources.

Before you begin

The JCA Version 1.6 specification adds support for Java annotations in RAR modules. For more information on annotation support see the topic, JCA 1.6 support for annotations in RAR modules.

About this task

Procedure

1. Assemble an application with RAR modules in it. See the topic Assembling applications for more information.
2. Install the application. Follow the steps in the topic Installing a new application.

   In the **Map modules to servers** step, specify target servers or clusters for each RAR file. Be sure to map all other modules that use the resource adapters defined in the RAR modules to the same targets. Also, specify the web servers as targets that serve as routers for requests to this application. The plug-in configuration file (`plugin-cfg.xml`) for each web server is generated based on the applications that are routed through it.

   In the **Metadata for modules** step of installing an application, you can set or unset the metadata-complete flag as discussed in the topic, JCA 1.6 support for annotations in RAR modules.

   Note: When installing a RAR file on a server, the application server looks for the manifest (MANIFEST.MF) for the connector module. The application server first looks for the RAR file's `connectorModule.jar` file and loads the manifest from the `connectorModule.jar` file. If the class path entry is in the manifest from the `connectorModule.jar`file, the RAR uses that class path.

   To ensure that the installed connector module finds the classes and resources that it needs, check the Class path setting for the RAR using the administrative console. For more information on how to check this setting, see the topics Resource adapter settings and WebSphere relational resource adapter settings.
3. Click **Finish** > **Save** to save the changes.
4. Create connection factories for the newly installed application.

   See the topic, Configuring connection factories for resource adapters within applications to view the steps to complete this step.

Results

Note: A given native library can only be loaded one time for each instance of the Java virtual machine (JVM). Because each application has its own class loader, separate applications with embedded RAR files cannot both use the same native library. The second application receives an exception when it tries to load the library.

If any application deployed on the application server uses an embedded RAR file that includes native path elements, then you must always ensure that you shut down the application server cleanly, with no outstanding transactions. If the application server does not shut down cleanly it performs *recovery* upon server restart and loads any required RAR files and native libraries. On completion of recovery, do not attempt any application-related work. Shut down the server and restart it. No further recovery is attempted by the application server on this restart, and normal application processing can proceed.

Install RAR

Use this page to install a resource archive (RAR) file in one of two ways. You can either upload a RAR file from the local file system, or specify an existing RAR file on a server. The RAR file must be installed at the node level, and you can select the node on this page.

To view this page in the administrative console click **Resources** > **Resource Adapters** > **Resource Adapters** > **Install RAR**.

For information about installing a resource adapter, see the topic, Installing a resource adapter archive (RAR) file.

Scope

Specifies the scope of the resource adapter. Only applications that are installed within this scope can use this adapter.

Local file system

Specifies the path of a RAR that resides on the same server as the console.

Data type String

Remote file system

Specifies the path of a RAR that resides on one of the nodes of the cell.

Data type String

Deploying SQLJ applications

Use Structured Query Language in Java (SQLJ) to develop data access applications that connect to DB2 databases. SQLJ is a set of programming extensions that enable you to use the Java programming language to embed statements that provide SQL (Structured Query Language) database requests.

About this task

The advantages of developing applications with SQLJ include improved performance and a shorter, more efficient development cycle. You can achieve the following with SQL:

- Improve performance by using static SQL statements.
- Reduce the development cycle:
  - Write less code with the simpler SQLJ syntax, which reduces the number of lines of code that is required to execute statements, set parameters, and retrieve parameters.

– Detect programming errors earlier in the development phase with the online check function, which performs data type validation and schema validation. See the DB2 documentation for a complete list of customization options.

Consider using SQLJ in situations where dynamic SQL is not needed, and where applications use DB2 as the database server.

The application server includes enhanced SQLJ support for applications that use container-managed persistence (CMP). The enhanced support includes the following items: include:

- Deploying CMP beans during the application installation in the application server.
- Customizing and binding SQLJ profiles with the administrative console or scripting.
- Customizing and binding SQLJ applications again without needing to reinstall the application.

These enhancements reduce the complexity of installing, deploying, and customizing SQLJ applications for both container-managed and bean-managed persistence.

Procedure

1. Acquire the required drivers to deploy an SQLJ application in the application server. You need the following files, depending on the JDBC provider that you use:

JDBC provider type	Required files
DB2 Using IBM JCC Driver This driver is also known as: • IBM Data Server Driver for JDBC and SQLJ • IBM DB2 Driver for JDBC and SQLJ • IBM DB2 Universal JDBC Driver.	db2jcc.jar or db2jcc4.jar
DB2 Universal JDBC driver (deprecated)	db2jcc.jar

2. Deploy the SQLJ application.
   - Deploy applications that use container-managed persistence (CMP):
     – “Deploying SQLJ applications that use container-managed persistence (CMP)” on page 184 with the DB2 Using IBM JCC Driver.
     – “Deploying SQLJ applications that use container-managed persistence (CMP) with the ejbdeploy tool” on page 185.
   - “Deploying SQLJ applications that use bean-managed persistence, servlets, or sessions beans” on page 186.
   - “Using embedded SQLJ with the DB2 for z/OS Legacy driver” on page 196 (deprecated).
3. Customize and bind the SQLJ profiles. Before the application server can use an SQLJ application, the SQLJ statements must be processed for the database server. By default, four DB2 packages are created in the database; one package is created for each isolation level. The customization process augments the profiles with information that is specific to the database. If you do not customize the SQLJ profiles, the SQLJ application uses dynamic SQL like a JDBC application.
   - “Customizing and binding profiles for Structured Query Language in Java (SQLJ) applications” on page 188.
   - Customize and bind SQLJ profiles with the wsadmin scripting tool. See the topic, Customizing and binding SQLJ profiles with the wsadmin tool.
   - “Customizing and binding SQLJ profiles with the db2sqljcustomize tool” on page 190.

Deploying SQLJ applications that use container-managed persistence (CMP)

Embed Structured Query Language in Java (SQLJ) statements in your applications to maximize the efficiency of transactions with your databases. Before your applications can take advantage of SQLJ, you must deploy the application and customize the SQLJ profiles that are created. The application server provides functionality to use SQLJ as the persistence mechanism for enterprise beans that use container-managed persistence. Deploy the CMP beans in the application server to enable SQLJ support.

Before you begin

You need an application that uses SQLJ and container-managed persistence. Develop this application in Rational Application Developer or another development tool.

About this task

Deploy SQLJ applications in the application server to simplify the process of SQLJ translation and bean deployment. The application server includes these new features for SQLJ support:

- Deploying CMP beans during the application installation in the application server.
- Customizing and binding SQLJ profiles with the administrative console or scripting.
- Customizing and binding SQLJ applications again without needing to reinstall the application.

You can also deploy the SQLJ application using the ejbdeploytool. Read the topic on deploying SQLJ applications that use container-managed persistence (CMP) with the ejbdeploy tool for more information.

Procedure

1. Create a top-down mapping to a DB2 database.
2. From your DB2 installation, copy the `sqlj.zip` file to a directory on your workstation.
3. Deploy the EAR file in the administrative console.
   a. Click **Applications** > **Install New application**.
   b. Select **Local file system** or **Remote file system**, and browse to the EAR file.
   c. Select **Detailed - Show all installation options and parameters**. Click **Next**.
   d. In **Step 1: Select installation options**, select **Deploy enterprise beans**. Configure any other options, and click **Next**.
   e. In **Step 3: Provide options to perform the EJB deploy**, select **SQLJ** for **Deploy EJB option - Database access type**.
   f. Enter the location of the `sqlj.zip` file in the **SQLj class path** field.
   g. Complete the installation process for the application.

What to do next

After the enterprise application is deployed, customize the SQLJ profiles using the administrative console, scripting, or the db2sqljcustomize tool:

- For administrative console support, read the topic on customizing and binding profiles for Structured Query Language in Java (SQLJ) applications.
- For scripting support, read the topic on the application management command group for the AdminTask object.
- For use of the db2sqljcustomize tool, read the topic on customizing and binding SQLJ profiles with the db2sqljcustomize tool.

Deploying SQLJ applications that use container-managed persistence (CMP) with the ejbdeploy tool

Embed Structured Query Language in Java (SQLJ) statements in your applications to maximize the efficiency of transactions with your databases. Before your applications can take advantage of SQLJ, you must deploy the application and customize the SQLJ profiles that are created. The application server provides functionality to use SQLJ as the persistence mechanism for enterprise beans that use container-managed persistence. Use the ejbdeploy tool to deploy the application.

About this task

You can deploy SQLJ applications with the ejbdeploy tool to deploy the enterprise application in a stand-alone environment.

Alternatively, the application server includes enhanced SQLJ support for applications that use container-managed persistence (CMP). The new features include:

- Deploying CMP beans during the application installation in the application server.
- Customizing and binding SQLJ profiles with the administrative console or scripting.
- Customizing and binding SQLJ applications again without needing to reinstall the application.

These enhancements reduce the complexity of installing, deploying, and customizing SQLJ applications for both container-managed and bean-managed persistence.Read the topic on deploying SQLJ applications that use container-managed persistence (CMP) for more information.

Procedure

1. Create a top-down mapping to a DB2 database.
2. From your DB2 installation, copy the `sqlj.zip` file to a directory on your workstation.
3. Modify the Java build path of your enterprise bean JAR project to include the `sqlj.zip` file.
4. Use Rational Application Developer or the DB2 SQLJ translator to automatically translate SQLJ.
   - Use Rational Application Developer:
     a. From the Project Navigator, click ***EJB_JAR_PROJECT_NAME*** > ***SOURCE_FOLDER*** > **META-INF** > **backends** > ***database_version***.
     b. Open Map.mapxmi in the Mapping editor.
     c. On the **Overview** panel, highlight the name of your JAR project in the Enterprise Beans column. You must highlight the name of the JAR project, not the name of one of the enterprise beans that is listed.
     d. On the **Properties** panel, expand **SQLJ**.
     e. Set **Is using SQLJ?** to `True`.
     f. Set **Translator Module** to the fully qualified path of the sqlj.zip file on your workstation.
     g. Save the Map.mapxmi file.
     h. Export the enterprise archive (EAR) file.
   - Use the DB2 SQLJ translator. This tool creates a .java version of your .sqlj file and a serialized profile, with a .ser extension, that is used later in processing. Refer to the DB2 documentation for more information on the SQLJ translator tool.
5. Deploy the EAR file with the ejbdeploy tool.
   a. Verify that the app_server_root/bin directory is in your class path.
   b. Run the ejbdeploy command utility with the `-sqlj` option. The ejbdeploy command will generate an EAR file with the name you specify and an Ant script with the name *application_name*.ear.xml.
      For example: :

```
ejbdeploy d:\application_name.ear
          working d:\deployed_application_name.ear
          -sqlj
          -dbvendor DB2UDB_V81
          -cp "C:\PROGRA~1\IBM\SQLLIB\java\sqlj.zip"
```

Note: Supply the location of the SQLJ translator sqlj.zip file with -cp, which is the class path option The ejbdeploy command does not access `sqlj.zip` from your system class path.

6. Choose the option for customization.
   - Use the application server's SQLJ support. Install the deployed application to customize the SQLJ profiles with the application server or scripting.
     a. Install the enterprise application in the application server.

        Note: Do not select **Deploy enterprise beans** during the application installation process in the administrative console. If you redeploy the enterprise beans from the administrative console, you will lose the customization changes that you have made.

     b. Customize the SQLJ profiles.
        – For administrative console support, read the topic on customizing and binding profiles for Structured Query Language in Java (SQLJ) applications.
        – For scripting support, read the topic on the application management command group for the AdminTask object.
   - Customize and bind the SQLJ profiles with the db2sqljcustomize tool. Read the topic on customizing and binding SQLJ profiles with the db2sqljcustomize tool.

Deploying SQLJ applications that use bean-managed persistence, servlets, or sessions beans

You can embed Structured Query Language in Java (SQLJ) statements in your applications to maximize the efficiency of transactions with your databases. Before your applications can take advantage of SQLJ, deploy the application and customize the created SQLJ profiles. You can use Rational Application Developer or the DB2 SQLJ translator to translate the application before deploying it on the application server.

Before you begin

Create an SQLJ application using Rational Application Developer or another development tool.

About this task

To deploy SQLJ applications that do not use container-managed persistence, translate the SQLJ application first to configure it for the application server environment. After translation, customize the SQLJ profiles in the application server, with scripting, or with the db2sqljcustomizer tool.

SQLJ support for applications that use bean-managed persistence include these features:

- Customizing and binding SQLJ profiles with the administrative console or scripting.
- Customizing and binding SQLJ applications again without reinstalling the application.

Procedure

1. Optional: Create a backup copy of your .java file. For example if your file is called `MyServlet.java`, copy `MyServlet.java` to `MyServlet.java.bkup`.
2. Optional: Rename your .java file to a file name with an `.sqlj` extension. For example, if your application is a servlet named `MyServlet.java`, rename `MyServlet.java` to `MyServlet.sqlj`

3. Optional: Edit the SQLJ file to convert the JDBC syntax to SQLJ syntax. When using SQLJ, if you want connection management for the application server to function properly, specify correct connection contexts.

   For example, convert the following JDBC operation:

   ```
   Connection con = dataSource.getConnection();
   Statement stmt = con.createStatement();
   stmt.execute("INSERT INTO users VALUES (1, 'user1')");
   con.commit();
   ```

   to the following SQLJ:

   ```
   // At the top of the file and just below the import statements, define Connection_Context
   #sql context Connection_context;
   .
   .
   Connection con = dataSource.getConnection();
   .
   .
   Connection_context ctx1 = new Connection_context(con);
   .
   .
   #sql [ctx1] {INSERT INTO users VALUES (1, 'user1')};
   .
   .
   con.commit(); ctx1.close();
   ```

   When you run the SQLJ translator, the `.java` file that is created has the same name as your old `.java` file. This provides you with a seamless transition to the SQLJ technology.
4. From your DB2 installation, copy the `sqlj.zip` file to a directory on your workstation. Modify the Java build path of your enterprise bean Java archive (JAR) file project to include the `sqlj.zip` file.
5. Use Rational Application Developer or the DB2 SQLJ translator to automatically translate SQLJ.
   - Use Rational Application Developer:
     a. In the Project Navigator, right-click your JAR project, and select **Add SQLJ Support...**.
     b. Select the check boxes for the applications for which you want SQLJ support.
     c. In the **SQLJ JAR file** field, type the fully qualified path to the `sqlj.zip` file that you previously copied to your workstation.
     d. Click **Finish**.
     e. Export the enterprise archive (EAR) file.
   - Use the DB2 SQLJ translator. This tool creates a `.java` version of the `.sqlj` file and a serialized profile, with an `.ser` extension, that is used later in processing. Refer to the DB2 documentation for more information about the SQLJ translator tool.
6. Package your JAR file for the enterprise application.
7. Install the application onto the application server, or customize the profiles with the db2sqljcustomize tool.
   - Customize the profiles with the application server.
     a. Package the JAR file for your enterprise beans, servlets, and any `.ser` files into an enterprise archive.
     b. Install the application in the application server, and customize SQLJ profiles with the administrative console or the wsadmin tool.

        Note: Do not select **Deploy enterprise beans** during the application installation process in the administrative console. If you redeploy the enterprise beans from the administrative console, you lose the customization changes that you have made.

        The application server provides enhanced support for SQLJ applications. Install the SQLJ application in the application server, and you can customize and bind SQLJ profiles through the administrative console or scripting:

  - To customize the SQLJ profiles with the administrative console, read the topic about customizing and binding profiles for Structured Query Language in Java (SQLJ) applications.
  - To customize SQLJ profiles with scripting, read the topic about the application management command group for the AdminTask object.
- To use the db2sqljcustomize tool, read the topic about customizing and binding SQLJ profiles with the db2sqljcustomize tool for more information.

Customizing and binding profiles for Structured Query Language in Java (SQLJ) applications

Simplify the process of customizing and binding SQLJ profiles for your applications by performing these functions in the administrative console or with scripting. SQLJ profiles must be customized and bound before the enterprise application can use the application's embedded SQL.

Before you begin

You must have an SQLJ application that has already been deployed and installed in the application server.

For SQLJ applications that use container-managed persistence, you can deploy the application in two ways:

- Deploy the SQLJ application in the application server. See the topic on deploying SQLJ applications that use container-managed persistence (CMP) for more information.
- Deploy SQLJ applications with the ejbdeploy tool. See the topic on deploying SQLJ applications that use container-managed persistence (CMP) with the ejbdeploy tool.

For SQLJ application that use bean-managed persistence, see the topic on deploying SQLJ applications that use bean-managed persistence, servlets, or session beans.

About this task

To take advantage of SQLJ applications in the application server, you need to customizing the SQLJ profiles that contain the embedded SQL statements. By default, four DB2 packages are created in the database; one for each isolation level. The customization process augments the profiles with information that is specific to the DB2 database. The database uses this information at run time.

In addition to profile customization, you need to bind the customized profiles to the DB2 database. Profile binding should only take place after the SQLJ profiles are customized.

You can also customize and bind profiles with scripting or the db2sqljcustomize tool:

- For scripting support, read the topic on the application management command group for the AdminTask object.
- For information on the db2sqljcustomize tool, read the topic on customizing and binding SQLJ profiles with the db2sqljcustomize tool for more information. If you customize profiles with the db2sqljcustomize tool, you will need to reinstall the application.

Procedure

1. Make sure the necessary database tables exist, as described in the topic on deploying data access applications.
2. Navigate to the SQLJ application that is installed in the application server. Click **Applications** > **Websphere enterprise applications** > ***app_name***.

   Note: Do not run multiple sessions of the administrative console to customize and bind profiles that are in the same EAR file.

3. Navigate to the SQLJ profiles section. Click **SQLj profiles**. When you click this link, the application server expands the EAR file for the application into a temporary directory; there might be a delay before the panel for SQLJ profiles is displayed.
4. Select **Customize and bind profiles** or **Bind packages**. Choose your option based on the profiles with which you are working:
   - If your profiles have not been customized, or you want to customize the profiles again, choose **Customize and bind profiles**.
   - If the profiles are already customized, choose **Bind packages**.
5. Choose to select profiles or a profile group to customize and bind.
   - Select profiles from the list that is provided.
     a. Select the profiles from the list and click **Add**. The list displays the SQLJ profiles that are present in the enterprise application.

        Note:
        – Select more than one profile by holding CTRL.
        – Select a contiguous list of profiles by selecting the first profile name, holding SHIFT, and selecting the last profile. You will select the first profile, last profile, and any profiles in the middle.

     b. Select **Customize/bind the selected SQLj profiles as a group** This option specifies that the application server will create a .grp file that contains the SQLj profiles that are processed. You can use the .grp file for other binding operations in the future. After you have completed this panel and click **OK**, you will be given an option to download the .grp file.
   - Select **Use a profile group file to specify profiles to customize/bind**. Select this to specify a profile group to process. Click **Browse...** to locate the file on the system.
6. Complete the necessary information to connect to the database. You need to complete the following fields:

   Database URL
   Specifies the URL of the database to which the profile/s will be bound. The typical syntax is:
   `jdbc:db2://<host name="">:<port>/<database name="">.</database></port></host> or`

   or
   `fully_qualified_host_name``:`*`port`*

   User Specifies the user ID for the database administrator on the server where the database is located.

   Password
   Specifies the password for the database administrator on the server where the database is located.

   Additional options
   Specifies additional options to use during the customization and bind processes. See the DB2 documentation for a complete list of customization options.

   Class path
   Specifies the class path where sqlj.zip, and db2jcc.jar or db2jcc4.jar are located.
7. Click **OK**.

   Note: If you are processing a large enterprise application, or you are processing many SQLJ profiles, the process might take longer than the default timeout for the administrative console. The default connection timeout for the application server's administrative console is set to 30 minutes. If the default timeout is reached and you lose the connection to the server, you can check the system output log for the final results of the customization and bind process.

To prevent this disconnection, configure the console session timeout to a longer period of time. After a successful customization and binding process, check the system output log for the total processing time. Use that time period as a basis for the new timeout value. For information about how to configure the console timeout, see the topic on changing the console session expiration.

Results

After the application server finishes processing the SQLJ profiles, you will see the results from the customization and binding. The results panel displays messages from the database server, as well as summary results from the application server.

If the operation completed successfully, the following message will be printed to the system log:

```
ADMA0507I=ADMA0507I: The SQLJ operation on application {0} completed successfully.  Exit code: {1}
ADMA0507I.explanation=This informational message indicates the program status.
ADMA0507I.useraction=No user action is required.
```

If the operation did not complete successfully, the following message will be printed to the system out log:

```
ADMA0506I=ADMA0506I: The SQLJ operation on application {0} did not complete successfully.  Exit code: {1}
ADMA0506I.explanation=The SQLJ operation encountered a problem.  This informational message indicates
the program status. Prior messages in the command output give details of the problem.
ADMA0506I.useraction=Check the command output for the cause of the problem.
```

Customizing and binding SQLJ profiles with the db2sqljcustomize tool

Customize and bind SQLJ profiles with the db2sqljcustomize tool before you install the SQLJ application in the application server.

Before you begin

To perform this task, you must have SQLJ application that has been deployed, but the application should not be installed in the application server. If the application is already installed in the application server, you will need to reinstall the application after you customize the profiles. You also need serialized profiles for the SQLJ application.

For SQLJ applications that use container-managed persistence, you can deploy the application in two ways:

- Deploy the SQLJ application in the application server. See the topic on deploying SQLJ applications that use container-managed persistence (CMP) for more information.
- Deploy SQLJ applications with the ejbdeploy tool. See the topic on deploying SQLJ applications that use container-managed persistence (CMP) with the ejbdeploy tool.

For SQLJ application that use bean-managed persistence, see the topic on deploying SQLJ applications that use bean-managed persistence, servlets, or sessions beans.

About this task

To take advantage of SQLJ applications in the application server, you need to customize the SQLJ profiles. The customization process augments the profiles with information that is specific to the DB2 database. The database uses this information at run time. By default, four DB2 packages are created in the database; one package is created for each isolation level.

The application server supports customizing and binding the SQLJ profiles in the administrative console or with scripting:

- For administrative console support, read the topic on customizing and binding profiles for Structured Query Language in Java (SQLJ) applications.

- For scripting support, see the topic on the application management command group for the AdminTask object.

Procedure

1. Make sure the necessary database tables exist, as described in the topic on deploying data access applications.
2. Transfer the serialized profiles to the environment on which you installed your application. Alternatively, use the Java `jar` command to extract the serialized profiles from the JAR file in your installed EAR directory.
3. Add the location for the SQLJ profiles and the application's JAR file to your environment's class path.
4. Make sure the necessary database tables exist, as described in the topic on deploying data access applications.
5. Optional: If your application is not running in a clustered environment, you can use the Ant script to make customization easier. If you run a batch SQLJ customization against an EAR file with the ejbdeploy tool, the tool produces an Ant script that is named *application_name*.ear.xml. You can use this script file to run the DB2 customizer program against the serialized profiles in all of the enterprise bean JAR files for the associated EAR file. The script updates each enterprise bean's JAR file with a serialized profile and replaces the JAR files in the existing EAR file with the modified versions.
   a. Change the values of the database URL, and the database user and password properties in ejbdeploy.sqlj.properties. This file is a common file to all Ant scripts that are generated by the ejbdeploy command. The ejbdeploy.sqlj.properties script defines the global properties for:
      - Database URL - db.url
      - User - db.user
      - Password - db.password

      The Ant script uses the URL, user, and password properties in the serialized profile to customize the profile. By default, the properties for the serialized profile are created from the global properties.
   b. Run the Ant script, specifying the `properties` target. For example:

      ```
      ws_ant -buildfile application_name.ear.xml properties
      ```

      This script creates the properties file, *application_name*.ear.properties. The *application_name*.ear.properties file contains properties that specify the default names for the packages corresponding to each serialized profile in the EAR file. This is a sample properties file:

      ```
      url.MyEJB1.jar.DB2UDBNT_V8_1=jdbc:db2://localhost:50000/MyDB1
      user.MyEJB1.jar.DB2UDBNT_V8_1=dbuser
      password.MyEJB1.jar.DB2UDBNT_V8_1=dbpassword
      pkg.MyEJB1.jar.DB2UDBNT_V8_1=TEST
      url.MyEJB2.jar.DB2UDBNT_V8_1=jdbc:db2://localhost:50000/MyDB2
      user.MyEJB2.jar.DB2UDBNT_V8_1=dbuser
      password.MyEJB2.jar.DB2UDBNT_V8_1=dbpassword
      pkg.MyEJB2.jar.DB2UDBNT_V8_1=WORK
      ```
   c. Use the DB2 Control Center to identify the packages that are installed in the database. The DB2 SQLJ customizer requires a type 4 database URL in the form of:

      ```
      jdbc:db2://host-name:port/database-name
      ```

      It also requires a user and password. The value of the port is 50000, unless you change it when you install DB2.
   d. Change the names that are used by the script file to ensure that the names for each customization profile do not conflict with existing package names that are in the database. Ant scripts that are generated for different EAR files use the same package names by default, and the script will overwrite existing packages unless you change the names. Overwritten packages can cause errors at run time.

DB2 uses the first seven characters of the package name. The DB2 customizer uses this name to create four packages in the database. For example, if you specify the name TEST, the DB2 customizer will create packages called TEST1, TEST2, TEST3, and TEST4.

e. Run the Ant script. The Ant script updates the original EAR file with the modified serialized profiles.

Note: Verify that you have db2jcc.jar in the class path. This file should have been added to the class path environment variable when DB2 V8 FixPak1 was installed.

A sample Ant command looks like this:

```
ws_ant -Dwork.dir=tmp
       -Dscript.property.file=other.properties
       -buildfile application_name.ear.xml
```

where:

- `-buildfile` specifies the XML file to create.
- `-Dscript.property.file` specifies a different properties file. This parameter is optional. If you want your Ant script to use a another file instead of *application_name*.ear.properties, specify the Dscript.property.file property when you run the script.
- `-Dwork.dir` specifies a temporary working directory for the script. The script will create and delete files and subdirectories in this directory. If the working directory contains existing files and directories with the same name as the files and directories used by the script, the script will erase or overwrite the files and directories. This script creates and uses a directory called `tmp` as its working directory.

f. Proceed to installing the application in the application server..

6. Run the db2sqljcustomize tool to customize the SQLJ profiles that correspond to each enterprise bean's JAR file. When you generate your deployment code, serialized profiles (files with a .ser extension) that are specific to your application are created. These profiles exist in the same directory as your SQLJ files, and the files must be customized to the environment before they can be used. When you run the DB2 SQLJ customizer against the serialized profiles, you create static SQL in the database that DB2 will use at run time. The customization phase creates four database packages that contain static SQL, one for each isolation level.

a. Optional: Consider using the SQLJ customizer tool to enable context caching for your application's data source connections. DB2 V8.1 fix pack 6 provides the new caching option with the db2sqljcustomize tool called db2optimize. You can run this option if your application uses the explicit connection context instead of the default context.

Note:

- SQLJ context caching support requires the DB2 with IBM JCC driver or Version 2.2 or later of the DB2 Universal JDBC Driver with APAR PQ87786 applied.
- If you want to enable context caching for an application or BMP bean that caches connections across transaction boundaries, you cannot use shareable connections. Use the get/use/close pattern of connection usage when you invoke the db2optimize option, or an object closed exception occurs. The following code gives an example of incorrect connection usage for context caching:

```
utx.begin();
     cons =ds.getConnection(
     request.getParameter("db.user"),
     request.getParameter("db.password"));
         cmctx1 = new CM_context(cons);
         #sql [cmctx1] {DELETE FROM cmtest WHERE id=1};
 utx.commit();
       //The next statement verifies the result:
         #sql [cmctx1] cursor1 = {SELECT id, name FROM cmtest WHERE id=1};
```

In this case, the `Select` statement elicits an object closed exception. To prevent the exception from occurring, close the connection before committing the transaction. Then get a new connection and a new context before running the `Select` statement.

The following example code demonstrates proper syntax for running the option on the serialized profile:

```
sqlj -db2optimize SQLJTransactionTest.sqlj
db2sqljcustomize -url jdbc:db2://localhost:50000/dbname -user USER_NAME -password PASSWORD
SQLJTransactionTest_SJProfile0.ser
```

b. Run the db2sqljcustomize tool to customize the SQLJ profiles. After you successfully run the db2sqljcustomize command, customized profiles exist in the directory from which you issued the command. If you run the db2sqljcustomize command from the directory that contains the serialized profiles that were not customized, the customized versions will overwrite previous versions that have the same file names.

   The recommended syntax for running the db2sqljcustomize command is:

   ```
   db2sqljcustomize -url JDBC_URL -user USER_NAME  -password PASSWORD
   [-rootpkgname PACKAGE_NAME] SERIALIZED_PROFILE1 SERIALIZED_PROFILE2 ...
   ```

   where:

   - *JDBC_URL* is the JDBC URL that is used to access the DB2 system where your tables reside.
   - *USER_NAME* is a valid user name for the DB2 system where your tables reside.
   - *PASSWORD* is the password for the specified user name.
   - *PACKAGE_NAME* is a valid partitioned data set (PDS) member name, up to seven characters long. Each of the four packages that are created by the profile customizer begin with this name and are appended with a number from 1 to 4. If you customize only one serialized profile, this value defaults to a shortened version of the serialized profile name and the -rootpkgname parameter is not required. If you customize more than one serialized profile with the same command, there is no default value and the -rootpkgname parameter is required.
   - *SERIALIZED_PROFILE#* is the name of the serialized profile that you are customizing.
     – To customize more than one serialized profile with the same command, list multiple files, separated by spaces.
     – Alternatively, you can specify the `-rootpkgname` parameter to customize more than one serialized profile with the same command.

   Note: The following options provide more control over the customization process:

   - `-automaticbind yes` specifies to run the DB2 SQLJ customizer against the serialized profiles to create static SQL in the database that the database will use at run time. The customization phase creates four database packages that contain static SQL, one for each isolation level.
   - `-onlinecheck NO and -bindoptions "VALIDATE RUN"` specifies settings to bypass errors during a profile customization and ensure a successful customization.

7. Update the JAR file for the enterprise beans with the serialized profiles.
8. Use the `jar` command to replace the serialized profiles in your JAR file with the customized profiles.

   Note: The customized files must be placed in a location that is part of the application class path, and they must exist ahead of the serialized profiles that are not customized in your JAR file. If you decide to replace the serialized profiles in your JAR file, maintain the directory structure in which the profiles exist.
9. Package the JAR file for the enterprise bean, servlets, and serialized profiles into an enterprise archive (EAR) file.
10. Install the application in the application server.

Note: Do not select **Deploy enterprise beans** during the application installation process in the administrative console. If you redeploy the enterprise beans from the administrative console, you will lose the customization changes that you have made.

SQLJ profiles and pureQuery bind files settings

Use this panel to do customization and binding for the Structured Query Language in Java (SQLJ) profiles for DB2 that are included in this application. You can also use this panel to do binding for pureQuery bind files in the application. You can view SQLJ profiles for other database types, but you cannot change these profiles. PureQuery bind files are only valid for DB2. Use SQLJ or pureQuery to develop data access applications that connect to DB2 databases. SQLJ is a set of programming extensions that enable a programmer to use the Java programming language to embed statements that provide SQL database requests. PureQuery provides an alternate set of APIs that can be used instead of JDBC to access the DB2 database.

To view this administrative console page, click **Applications** > **Websphere enterprise applications** > ***app_name*** > **SQLJ profiles and pureQuery bind files**.

Advantages of developing applications with SQLJ include improved performance and a shorter, more efficient development cycle. With SQLJ, you can:

- Improve performance by using static SQL statements.
- Reduce the development cycle by:
  - Writing less code with the simpler SQLJ syntax, which reduces the amount of code that is required to execute statements, and set and retrieve parameters.
  - Detecting programming errors earlier in the development phase with the online check function, which performs data type and schema validation. Activate this function by running it as an option with the **db2sqljcustomize** command. See the DB2 documentation for a complete description of the SQLJ customize command.

DB2 pureQuery run time is an alternative set of APIs to JDBC or SQLJ. Advantages of developing applications with pureQuery include allowing SQL execution to be either dynamic or static. In addition to improved performance by using static SQL statements, pureQuery has better problem determination and diagnosis because it allows for errors at the DB2 server to be related back to application artifacts rather than to SQL that was generated by an application generator.

Customize and bind profiles:

Specifies that the application server processes the SQLJ profiles that you select from this application.

Note: This selection does not apply to pureQuery. If selected, this option is ignored when processing pureQuery bind files.

By default, one DB2 package is created in the database for each isolation level. The customization process augments the profile or profiles with information that is specific for the DB2 database for use at run time. Typically, the customization process should run after the SQLJ application has been translated and before the application is started. If you do not run the customization step, the SQLJ application uses dynamic SQL like a JDBC application.

Binding DB2 SQLJ profiles involves the process of binding the customized SQLJ profiles to the DB2 database.

Bind packages:

Specifies that the application server binds the SQLJ profiles that you select to the DB2 database server.

Note: This selection does not apply to pureQuery. If selected, this option is ignored when processing pureQuery bind files.

Bind packages from the SQLJ application that have already been customized.

Select and order the profiles to customize/bind:

Specifies the profiles to process from the list that is provided.

- Select a profile or group of profiles from the **Available profiles**, and click **Add** to add the profile that is selected to **Selected Profiles**.
- Select a profile or group of profiles from the **Selected Profiles**, and click **Remove** to add the profile that is selected to **Available profiles**.

When SQLJ or pureQuery profiles have been added to **Selected Profiles**, select profiles from that list and use **Move Up** or **Move Down** to change the order in which the profiles are processed.

Customize/bind the selected SQLJ profiles as a group:

Specifies that the application server creates a .grp file that contains the SQLJ profiles that you selected.

Note: This selection does not apply to pureQuery. If selected, this option is ignored when processing pureQuery bind files.

When you click **OK**, there is an option on the next panel to download the .grp file.

Use a profile group file to specify profiles to customize/bind:

Specifies a profile group file from the local file system to customize or bind.

Database URL:

Specifies the URL of the database to which the profile or profiles are bound.

The typical syntax is:

```
jdbc:db2://host_name:port_name/database_name
```

User:

Specifies the user ID for the database administrator on the server where the database is located.

Password:

Specifies the password for the database administrator on the server where the database is located.

Additional options:

Specifies additional options to use during the customization and bind processes.

Options for pureQuery binding uses the following syntax:

```
-bindoptions "BLOCKING NO"
```

For more information about pureQuery bind options, refer to the DB2 pureQuery Bind Utility topic.

Class path:

Specifies the class path where the sqlj.zip, and db2jcc.jar or db2jcc4.jar files for SQLJ are located. Specifies the class path where the pdq.jar, pdqmgt.jar, db2jcc.jar, db2jcc_license_cisuz.jar files for pureQuery are located.

Download SQLJ profile group

Use this panel to download the group file for the Structured Query Language in Java (SQLJ) profiles that are bound together as a single package on the DB2 database server. You can use the file when performing future customization or binding work on the application. Click the link that is provided to download the profile group to your local file system. The group file has a filename extension of .grp and a HTTP Content-Type of text/plain.. Your web browser settings might cause the browser to display the file contents rather than prompting you for a download destination. If this happens, you can manually copy and paste the contents into your own .grp file.

Note: This topic does not apply to IBM Optim™ PureQuery Runtime. IBM Optim PureQuery Runtime does not support binding pureQuery bind files as a group.

Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***app_name*** > **SQLJ profiles and pureQuery bind files**. When you are selecting the profiles to customize and bind, select **Customize/bind the selected SQLJ profiles as a group** to view this console panel.

Review results

Use this panel to review the results from the customization and binding process for the Structured Query Language in Java (SQLJ) profiles or pureQuery bind files. Use SQLJ or IBM Optim PureQuery Runtime to develop data access applications that connect to DB2 databases. SQLJ is a set of programming extensions that enable a programmer to use the Java programming language to embed statements that provide SQL (Structured Query Language) database requests. IBM Optim PureQuery Runtime provides an alternate set of APIs that can be used instead of JDBC to access the DB2 database.

Click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **SQLj profiles and pureQuery bind**. Select profiles to customize and bind, complete the necessary fields, and click **OK** to view this console panel.

Review results:

Displays the results of the customization and bind process. The field shows information that is received from the database and summary statements from the application server.

Using embedded SQLJ with the DB2 for z/OS Legacy driver

Structured Query Language in Java (SQLJ) is a set of programming extensions that enable a programmer, using the Java programming language, to embed statements that provide Structured Query Language (SQL) database requests. You can use the DB2 for z/OS Legacy driver with your data access applications.

About this task

Notes:

1. To use SQLJ with WebSphere Application Server for z/OS and the DB2 for z/OS Legacy Driver, install DB2 APAR PQ76442.
2. Container Managed Persistence (CMP) beans generated using SQLJ are not supported by the DB2 for z/OS Legacy Driver. Use the DB2 Universal Driver for CMPs that are generated using SQLJ.

Following are the steps required to develop applications with SQLJ that run on WebSphere Application Server for z/OS v6.0 using the DB2 for z/OS Legacy driver.

Procedure

1. Design your application in Rational Application Developer according to your requirements, using SQLJ when necessary. For example, if you develop a bean called Test that uses BMP, code TestBean.sqlj (instead of TestBean.java).

a. From your DB2 for z/OS installation, copy the `db2sqljclasses.zip` file to a directory on your workstation, then modify the Java Build Path of your EJB Java archive (JAR) project to include the `db2sqljclasses.zip` file.

b. Translate your SQLJ code according to the following steps:

   1) Locate your SQLJ file, then use ASCII mode transfer to FTP it to an HFS in your z/OS environment.

   2) Use the sqlj command to translate your SQLJ code into Java code. Two files are produced, one with a `.java` extension and the other with an `.ser` extension.

      ```
      sqlj -compile=false SQLJ_FILE_NAME
      ```

   3) Use ASCII mode transfer for the `.java` file and BINARY mode transfer for the `.ser` file to move these files back to the directory on your workstation where the SQLJ file resides.

   4) Refresh the project.

c. Generate deployment code for your application.

d. Export your EAR file.

2. Install your application

   a. Create a data source with the DB2 for zOS Local JDBC Provider (RRS). When you define your JDBC Provider and data source, the default values are sufficient for providing SQLJ support.

   b. Install your application into WebSphere Application Server.

      Use the data source you created in Step 1 to resolve your resource references.

3. Customize your serialized profiles When you generate your deployment code, serialized profiles, or files with an `.ser` extension, that are specific to your application, are created. These profiles must be customized in a z/OS environment before they can be used.

   a. Use binary transfer to transfer the serialized profiles to the z/OS environment on which you installed your application. Alternatively, use the Java jar command to extract the serialized profiles from the EJB JAR file in your installed EAR directory.

   b. Use the db2profc command to customize your serialized profiles. You can get information about the various options associated with this command from the DB2 documentation; however, here are the minimum requirements to customize your profile:

      ```
      db2profc -pgmname=PROGRAM_NAME PROFILE_NAME
      ```

      - Where:
        - *PROGRAM_NAME* must be a valid MVS™ PDS member name, and can be up to seven characters.
        - *PROFILE_NAME* is the name of the serialized profile that you want to customize. You must run db2profc one time for each profile.
      - The profile customizer creates four DBRM data sets in the PDS *USERNAME*.DBRMLIB.DATA. The member names of the DBRMs begin with what you specified as *PROGRAM_NAME*.
      - Ensure that your CLASSPATH environment variable includes:
        - The location of the serialized profile
        - The EJB JAR file in your installed EAR directory
      - Allocate a PDS to contain the DBRMs that are created. Name this PDS *USERNAME*.DBRMLIB.DATA, where *USERNAME* is the user who implements the db2profc command.

        The following fields are an example:

        ```
        Space units=TRACK
        Primary quantity=15
        Secondary quantity=5
        Directory blocks=10
        Record format=FB
        Record length=80
        Block size=27920
        Data set name type=PDS
        ```

c. Place the existing serialized profiles, which are now customized, into a location that is part of the application classpath and that is ahead of the serialized profiles that exist in your EJB JAR file.

   The output of the DB2 profile customizer and the input file have the same name. Move the output file ahead of the original serialized profile in the classpath. Alternatively, you can move the customized profile into the EJB JAR file, replacing the original. It is recommended that you replace the original file.

   IMPORTANT: If you run the db2profc command from the directory where the serialized profile exists, the profile customizer overwrites the serialized profile. Because you need only the customized version after the profile customizer has run, this is not a problem.

d. Bind your DBRMs into a package.

   Note: You must create your database tables before binding your DBRMs. If you do not, the bind job fails.

   The db2profc customization command creates a series of DBRMs that must be bound into packages. For each customized profile, four DBRMs are created.

   These DBRMs:

   - Are located in *USERNAME*.DBRMLIB.DATA
   - All have names that begin with what you specified as *PROGRAM_NAME*
   - Are numbered from 1-through-4

     For example, if you log in as IBMUSER, and you specify -pgmname=TESTBMP, then run the db2profc command, the four data sets, TESTBMP1, TESTBMP2, TESTBMP3, AND TESTBMP4 are created and placed in the PDS IBMUSER.DBRMLIB.DATA.

     These data sets must be bound into packages with isolation of UR, CS, RS, and RR. You must run a bind for each serialized profile that you customize.

e. After you bind all of the DBRMs into packages, bind the packages into a plan. Name the plan whatever you like.

   IMPORTANT: You must also include the JDBC packages in the package list (PKLIST) of your new plan. The default names for the JDBC packages to include are DSNJDBC.DSNJDBC1, ..., DSNJDBC.DSNJDBC4. If your installation did not use the default names for the JDBC packages, contact your DB2 administrator to determine the names of the JDBC packages that you need to include.

   Following is a sample job used to bind a new plan.

   - One serialized profile was created while logged on as IBMUSER.
   - **-pgmname=TESTBMP** was specified to run db2profc.
   - The new plan is named SQLJPLAN.

```
//BBOOLS  JOB (516B,1025),'IBMUSER',MSGCLASS=H,CLASS=A,PRTY=14,
//         NOTIFY=&SYSUID,TIME=1440,USER=IBMUSER,PASSWORD=IBMUSER,
//         MSGLEVEL=(1,1)
//*********************************************************************
//BINDOLS  EXEC PGM=IKJEFT01,DYNAMNBR=20
//DBRMLIB  DD  DSN=IBMUSER.DBRMLIB.DATA,DISP=SHR
//*        DD  DSN=MVSDSOM.DB2710.SDSNDBRM,DISP=SHR
//SYSTSPRT DD  SYSOUT=*
//SYSPRINT DD  SYSOUT=*
//SYSUDUMP DD  SYSOUT=*
//SYSTSIN  DD  *

 DSN SYSTEM(DB2)

 BIND -
     PACKAGE(TESTBMP) -
     QUALIFIER(IBMUSER) -
     MEMBER(TESTBMP1) -
     VALIDATE(BIND) -
     ISOLATION(UR) -
```

```
    SQLERROR(NOPACKAGE) -

BIND -
    PACKAGE(TESTBMP) -
    QUALIFIER(IBMUSER) -
    MEMBER(TESTBMP2) -
    VALIDATE(BIND) -
    ISOLATION(CS) -
    SQLERROR(NOPACKAGE) -

BIND -
    PACKAGE(TESTBMP) -
    QUALIFIER(IBMUSER) -
    MEMBER(TESTBMP3) -
    VALIDATE(BIND) -
    ISOLATION(RS) -
    SQLERROR(NOPACKAGE) -

BIND -
    PACKAGE(TESTBMP) -
    QUALIFIER(IBMUSER) -
    MEMBER(TESTBMP4) -
    VALIDATE(BIND) -
    ISOLATION(RR) -
    SQLERROR(NOPACKAGE) -

BIND PLAN(SQLJPLAN)                -
 QUALIFIER(IBMUSER)                -
 PKLIST(TESTBMP.*                  -
        DSNJDBC.*                ) -
 ACTION(REPLACE) RETAIN            -
 VALIDATE(BIND)

END
/*
```

f. Grant the appropriate authority to your new plan. Use an interface to DB2, such as SPUFI, to grant the authority. Issue this command:

```
GRANT EXECUTE ON PLAN PLANNAME TO APPSERVERID
```

Where:

- *PLANNAME* is the name of the plan that you bound.
- *APPSERVERID* is the ID under which WebSphere Application Server runs; for example, CBSYMSR1.

4. Configure your data source to use your new plan
   a. From the WebSphere Application Server for z/OS Administrative Console, navigate to your Data Source and select Custom Properties.
   b. Select the Custom Property **planName**.
   c. Update the value of **planName** with what you named your plan when it was bound.
   d. Set **enableSQLJ** to **true**.
5. Stop and restart your server.
6. Run your application.

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This topic describes the conventions in use for WebSphere Application Server.

Default product locations - IBM i

These file paths are default locations. You can install the product and other components in any directory where you have write access. You can create profiles in any valid directory where you have write access. Multiple installations of WebSphere Application Server products or components require multiple locations.

app_client_root
The default installation root directory for the Application Client for IBM WebSphere Application Server is the `/QIBM/ProdData/WebSphere/AppClient/V8/client` directory.

app_client_user_data_root
The default Application Client for IBM WebSphere Application Server user data root is the `/QIBM/UserData/WebSphere/AppClient/V8/client` directory.

app_client_profile_root
The default Application Client for IBM WebSphere Application Server profile root is the `/QIBM/UserData/WebSphere/AppClient/V8/client/profiles/`*`profile_name`* directory.

app_server_root
The default installation root directory for WebSphere Application Server - Express is the `/QIBM/ProdData/WebSphere/AppServer/V8/Express` directory.

java_home

Table 16. Root directories for supported Java Virtual Machines.

This table shows the root directories for all supported Java Virtual Machines (JVMs).

JVM	Directory
32–bit IBM Technology for Java	`/QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit`
64–bit IBM Technology for Java	`/QOpenSys/QIBM/ProdData/JavaVM/jdk60/64bit`

plugins_profile_root
The default Web Server Plug-ins profile root is the `/QIBM/UserData/WebSphere/Plugins/V8/webserver/profiles/`*profile_name* directory.

plugins_root
The default installation root directory for Web Server Plug-ins is the `/QIBM/ProdData/WebSphere/Plugins/V8/webserver` directory.

plugins_user_data_root
The default Web Server Plug-ins user data root is the `/QIBM/UserData/WebSphere/Plugins/V8/webserver` directory.

product_library
product_lib
This is the product library for the installed product. The product library for each Version 8.0 installation on the system contains the program and service program objects (similar to `.exe`, `.dll`, `.so` objects) for the installed product. The product library name is `QWAS8`*`x`* (where *x* is A, B, C, and so on). The product library for the first WebSphere Application Server Version 8.0 product installed on the system is `QWAS8A`. The *`app_server_root`*`/properties/product.properties` file contains the value for the product library of the installation, `was.install.library`, and is located under the *`app_server_root`* directory.

profile_root
The default directory for a profile named *profile_name* for WebSphere Application Server - Express is the `/QIBM/UserData/WebSphere/AppServer/V8/Express/profiles/`*`profile_name`* directory.

shared_product_library
The shared product library, which contains all of the objects shared by all installations on the system, is `QWAS8`. This library contains objects such as the product definition, the subsystem description, the job description, and the job queue.

user_data_root
The default user data directory for WebSphere Application Server - Express is the `/QIBM/UserData/WebSphere/AppServer/V8/Express` directory.

The `profiles` and `profileRegistry` subdirectories are created under this directory when you install the product.

web_server_root
The default web server path is /www/*web_server_name*.

Administering data access applications

These administrative tasks consist primarily of configuring the objects, or resources, through which applications connect with a backend, and tuning those resources to handle the volume of connection requests.

Procedure

1. If your application contains web modules or EJB modules that require access to a backend, configure resources according to your type of enterprise information system (EIS):
   - For a relational database, follow the steps outlined in the topic, Configuring a JDBC provider and data source. If you are using a DB2 database, the topic, Configuring an application to use pureQuery is another option. IBM Optim PureQuery Runtime provides an alternative to JDBC as a way to access the DB2 database.
   - For a non-relational database, or another type of EIS such as the Customer Information Control System (CICS), you must configure a resource adapter and connection factories. The topic, Accessing data using Java EE Connector Architecture connectors, provides information on setting up these objects.

   Note: When you specify the Java Naming and Directory Interface (JNDI) name for resources, adhere to the following requirements:
   - Do not assign duplicate JNDI names across different resource types (such as data sources versus J2C connection factories or JMS connection factories).
   - Do not assign duplicate JNDI names for multiple resources of the same type in the same scope.
2. Configure an authentication alias for the new web module resource or EJB module resource only if the application code, rather than WebSphere Application Server, authenticates connections with the backend. This security configuration is called component-managed authorization, and is indicated in the application deployment descriptor as `res-auth = Application`.

   Container-managed authorization, which is designated as `res-auth = Container`, indicates that Application Server performs signon for backend connections. The container-managed authentication alias must be specified on the application resource reference. This task can be done during application assembly or deployment, along with mapping the resource reference to a data source or connection factory resource. After application deployment, however, you can alter the container-managed authentication alias using the administrative console. Click **Applications** > **Websphere enterprise applications** > ***application_name***, and select the link to the appropriate mapping page. For example, if you want to alter the alias of an EJB module resource, you might click **Map data sources for all 2.x CMP beans**. For a web module resource, click **Resource References**.

   Read the J2EE connector security topic for detailed reference on resource authentication.
3. If your application contains a client module that requires data access, see the topic, Configuring data access for application clients. In this single configuration process, you can define authentication data for either component-managed or container-managed signon.
4. Specify connection pool settings.

5. Test a connection to the new data source. See the article, Test connection service, for information on the available methods for testing connections. This article also addresses important data source settings that can affect the accuracy of your test connection results.
6. Set the JDBC trace service. The JDBC trace log information augments the JVM log data for data source failures.

   To activate the trace using the administrative console, read the topic, Enabling trace at server startup.. Specify **WAS.database** as the trace group and select **com.ibm.ws.db2.logwriter** as the trace string.
7. Gather connection pool statistics by activating the JDBC connection pool counters or the J2C connection pool counters. Alternatively, you can use Performance Monitoring Infrastructure (PMI) method calls to gather connection statistics; see the topic, Connection and connection pool statistics.
8. Tune your database to accommodate the connection volume. If you use DB2 UDB for iSeries®, see the topic, DB2 Universal Database performance tips, as a starting point reference.

Configuring Java EE Connector connection factories in the administrative console

To access an enterprise information system (EIS), configure connection factories, which instantiate resource adapter classes for establishing and maintaining resource connections.

About this task

An application component uses a connection factory to access a connection instance, which the component then uses to connect to the underlying enterprise information system (EIS). Examples of connections include database connections, Java Message Service connections, and SAP R/3 connections.

Procedure

1. Click **Resources** > **Resource Adapters** > **Resource adapters**.
2. In the **Resource adapters** panel, select the resource adapter that you want to configure.
3. From the **Additional Properties** heading, click **J2C connection factories**.
   a. Click **New**.
   b. Specify any properties for the connection factory in the **General Properties** panel.
   c. Select the authentication preference.
   d. Select the aliases for **Component-managed authentication**, **Container-managed authentication**, or both. Some choices for the mapping-configuration alias do not use a container-managed authentication alias, so you will not be able to select a container-managed alias if one of those mapping-configuration aliases is selected.

      If you have defined security domains in the application server, you can click **Browse...** to select an authentication alias for the resource that you are configuring. Security domains allow you to isolate authentication aliases between servers. The tree view is useful in determining the security domain to which an alias belongs, and the tree view can help you determine the servers that will be able to access each authentication alias. The tree view is tailored for each resource, so domains and aliases are hidden when you cannot use them.

      Note: If the resource adapter supports XA, an option for **Authentication alias for XA recovery** will be available.

      If there are no aliases that are available, or you want to define a different alias:
      1) Click **Apply** to save the current settings.
      2) Click **JAAS - J2C authentication data** from the **Related Items** heading.
      3) Click **New**.
      4) Define the properties for the alias in **General Properties**.
      5) Click **OK**.
   e. Click **OK**.

4. Click the name of the J2C connection factory that you created.
5. From the **Additional Properties** heading, click **Connection pool properties**.
   a. Change any values by clicking the property name. For more information on the settings for connection pools, read the topic Tuning connection pools, or the topic, Connection pool settings.
   a. Click **OK**.
6. Click **Custom properties** from the **Additional Properties** heading.
   a. Click any property name to change its value. If the **UserName** and **Password** properties are defined, they will be overridden by the component-managed authentication alias that you specified in the previous step.
   b. Click **Save**.
7. Restart the application server for the changes to take effect.

Configuring connection factories for resource adapters within applications

To access an enterprise information system (EIS), configure connection factories, which instantiate resource adapter classes for establishing and maintaining resource connections.

About this task

An application component uses a *connection factory* to access a connection instance, which the component then uses to connect to the underlying enterprise information system (EIS). Examples of connections include database connections, Java Message Service connections, and SAP R/3 connections.

Procedure

1. Optional: Install the application if it is not already installed on the application server.
   a. Click **Applications** > **Install New Application**.
   b. Browse to find the appropriate EAR file, which contains an RAR file.
   c. Click **Next**.
   d. Select **Resource ref mapping to a J2C Connection Factory**, then click **Next**.
   e. In **Step 2: Map module to servers**, select the resource adapters with which to associate your application and click **Next**.
   f. Complete the installation process for the application. For more information on installing applications, refer to the topic, Installing enterprise application files with the console.
2. Select the application that you want to configure.
3. Click **Modules** > **Manage Modules**.
4. Select the name of the RAR file in the **Manage Modules** panel.
5. Click **Resource Adapter** under the **Additional Properties** heading.
6. Under the **Additional Properties** heading, click **J2C connection factories**.
   a. Click **New**.
   b. Specify any properties for the connection factory in the **General Properties** panel.
   c. Select the authentication preference.
   d. Select an alias for **Component-managed authentication** if any application components with *Application* or *Per connection factory* authentication specified in the resource reference are going to be getting connections from this connection factory using the empty-argument getConnection() method. For resources that support XA, you can specify an Authentication alias for XA recovery. If there are no aliases that are available, or you want to define a different alias:
      1) Click **Apply** to save the current settings.
      2) Click **JAAS - J2C authentication data** under the **Related Items** heading.
      3) Click **New**.
      4) Define the properties for the alias in **General Properties**.

5) Click **OK**.

e. Click **OK**.

7. Click the name of the J2C connection factory that you created.
8. Under the **Additional Properties** heading, click **Connection pool properties**.
   a. Change any values by clicking on the property name. For more information on the settings for connection pools, refer to the topic, Tuning connection pools, or the topic, Connection pool settings.
   a. Click **OK**.
9. Click **Custom properties** under the **Additional Properties** heading.
   a. Click any property name to change its value. If the **UserName** and **Password** properties are defined, they will be overridden by a **component-managed authentication** alias that you might have configured.
   b. Click **Save**.

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This topic describes the conventions in use for WebSphere Application Server.

Default product locations - IBM i

These file paths are default locations. You can install the product and other components in any directory where you have write access. You can create profiles in any valid directory where you have write access. Multiple installations of WebSphere Application Server products or components require multiple locations.

app_client_root
The default installation root directory for the Application Client for IBM WebSphere Application Server is the `/QIBM/ProdData/WebSphere/AppClient/V8/client` directory.

app_client_user_data_root
The default Application Client for IBM WebSphere Application Server user data root is the `/QIBM/UserData/WebSphere/AppClient/V8/client` directory.

app_client_profile_root
The default Application Client for IBM WebSphere Application Server profile root is the `/QIBM/UserData/WebSphere/AppClient/V8/client/profiles/`*`profile_name`* directory.

app_server_root
The default installation root directory for WebSphere Application Server - Express is the `/QIBM/ProdData/WebSphere/AppServer/V8/Express` directory.

java_home

Table 17. Root directories for supported Java Virtual Machines.

This table shows the root directories for all supported Java Virtual Machines (JVMs).

JVM	Directory
32–bit IBM Technology for Java	`/QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit`
64–bit IBM Technology for Java	`/QOpenSys/QIBM/ProdData/JavaVM/jdk60/64bit`

plugins_profile_root
The default Web Server Plug-ins profile root is the `/QIBM/UserData/WebSphere/Plugins/V8/webserver/profiles/`*profile_name* directory.

plugins_root
The default installation root directory for Web Server Plug-ins is the `/QIBM/ProdData/WebSphere/Plugins/V8/webserver` directory.

plugins_user_data_root
The default Web Server Plug-ins user data root is the /QIBM/UserData/WebSphere/Plugins/V8/webserver directory.

product_library
product_lib
This is the product library for the installed product. The product library for each Version 8.0 installation on the system contains the program and service program objects (similar to .exe, .dll, .so objects) for the installed product. The product library name is QWAS8*x* (where *x* is A, B, C, and so on). The product library for the first WebSphere Application Server Version 8.0 product installed on the system is QWAS8A. The *app_server_root*/properties/product.properties file contains the value for the product library of the installation, was.install.library, and is located under the *app_server_root* directory.

profile_root
The default directory for a profile named *profile_name* for WebSphere Application Server - Express is the /QIBM/UserData/WebSphere/AppServer/V8/Express/profiles/*profile_name* directory.

shared_product_library
The shared product library, which contains all of the objects shared by all installations on the system, is QWAS8. This library contains objects such as the product definition, the subsystem description, the job description, and the job queue.

user_data_root
The default user data directory for WebSphere Application Server - Express is the /QIBM/UserData/WebSphere/AppServer/V8/Express directory.

The profiles and profileRegistry subdirectories are created under this directory when you install the product.

web_server_root
The default web server path is /www/*web_server_name*.

Connection pool settings

Use this page to configure connection pool settings.

This administrative console page is common to JDBC data sources and JMS connection factories (unified, queue, or topic connection factories). To view this page, the path depends on the type of resource, but generally you select an instance of the resource type then click **Connection Pool**. For example:

- Click **Resources** > **JDBC** > **Data Sources** > ***data_source*** > **[Additional Properties] Connection pool properties**
- Click **Resources** > **JMS->Queue connection factories->*queue_connection_factory*->[Additional Properties] Connection pool**

Note: Connection pooling is not supported in an application client. The application client calls the database directly and does not go through a data source. If you want to use the getConnection() request from the application client, configure the JDBC provider in the application client deployment descriptors, using Rational Application Developer or an assembly tool. The connection is established between application client and the database. Application clients do not have a connection pool, but you can configure JDBC provider settings in the client deployment descriptors.

Connection timeout:

Specifies the interval, in seconds, after which a connection request times out and a ConnectionWaitTimeoutException is thrown.

This value indicates the number of seconds that a connection request waits when there are no connections available in the free pool and no new connections can be created. This usually occurs because the maximum value of connections in the particular connection pool has been reached.

For example, if Connection timeout is set to 300, and the maximum number of connections are all in use, the pool manager waits for 300 seconds for a physical connection to become available. If a physical connection is not available within this time, the pool manager initiates a `ConnectionWaitTimeout` exception. In most cases, you should not retry the getConnection() method; if a longer wait time is required you should increase the Connection timeout setting value. If a `ConnectionWaitTimeout` exception is caught by the application, review the expected connection pool usage of the application and tune the connection pool and database accordingly.

If the Connection timeout is set to 0, the pool manager waits as long as necessary until a connection becomes available. This happens when the application completes a transaction and returns a connection to the pool, or when the number of connections falls below the value of Maximum Connections, and a new physical connection is created.

If Maximum Connections is set to 0, an infinite number of physical connections are enabled, and the Connection timeout value is ignored.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Maximum connections:

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. When this number is reached, no new physical connections are created. The requester waits until a physical connection that is currently in use returns to the pool, or until a ConnectionWaitTimeoutException error displays. For example, if the Max Connections value is set to `5`, and there are 5 physical connections in use, the pool manager waits for the amount of time specified in Connection timeout for a physical connection to become free.

Knowing the number of connection pools that can potentially request connections from the backend, such as a DB2 database or a CICS server, helps you determine a value for the Maximum Connections property.

For multiple stand-alone application servers that use the same data source configuration, or J2C connection factory configuration, a separate physical connection pool exists for each server. If you clone these same application servers, WebSphere Application Server (base) implements a separate connection pool for each clone.

All of these connection pools correspond to the same data source or connection factory configuration. Therefore all of these connection pools can potentially request connections from the same backend resource, at the same time. The single Maximum Connections value that you set on this console panel applies to every one of these connection pools. Consequently, setting a high Maximum Connections value can result in a load of connection requests that overwhelms your backend resource.

Data type	Integer
Default	10
Range	0 to maximum integer If Max Connections is set to 0, the Connection timeout value is ignored.

Tip: For better performance, set the value for the connection pool lower than the value for the maximum thread pool connections of the web container. To configure this setting click **Servers** > **Server types**

> **WebSphere application servers** > ***server*** > **Thread Pools**, and modify the web container property. Lower settings, such as 10-30 connections, perform better than higher settings, such as 100.

You can use the Tivoli® Performance Viewer to find the optimal number of connections in a pool. If the number of concurrent waiters is greater than 0, but the processor load is not close to 100%, consider increasing the connection pool size. If the Percent Used value is consistently low under normal workload, consider decreasing the number of connections in the pool.

Minimum connections:

Specifies the minimum number of physical connections to maintain.

If the size of the connection pool is at or below the minimum connection pool size, the Unused timeout thread does not discard physical connections. However, the pool does not create connections solely to ensure that the minimum connection pool size is maintained. Also, if you set a value for Aged timeout, connections with an expired age are discarded, regardless of the minimum pool size setting.

For example, if the Minimum Connections value is set to 3, and one physical connection is created, the Unused timeout thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the Minimum Connections setting.

Data type	Integer
Default	1
Range	0 to max int

Reap time:

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if Reap Time is set to 60, the pool maintenance thread runs every 60 seconds. The Reap Time interval affects the accuracy of the Unused timeout and Aged timeout settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the Reap Time value less than the values of Unused timeout and Aged timeout. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value specified in Unused timeout, until it reaches the number of connections specified in Minimum Connections. The pool maintenance thread also discards any connections that remain active longer than the time value specified in Aged timeout.

The Reap Time interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread, set Reap Time to `0`, or set both Unused timeout and Aged timeout to `0`. The recommended way to disable the pool maintenance thread is to set Reap Time to `0`, and Unused timeout and Aged timeout are ignored. However, if Unused timeout and Aged timeout are set to `0`, the pool maintenance thread runs, but only physical connections that timeout, because of non-zero timeout values, are discarded.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Unused timeout:

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the Unused timeout value higher than the Reap timeout value for optimal performance. Unused physical connections are only discarded if the current number of connections exceeds the Minimum Connections setting. For example, if the unused timeout value is set to `120`, and the pool maintenance thread is enabled (Reap Time is not `0`), any physical connection that remains unused for 2 minutes is discarded.

The accuracy and performance of this timeout are affected by the Reap Time value. See “Reap time” on page 207 for more information.

Data type	Integer
Units	Seconds
Default	1800
Range	0 to max int

Aged timeout:

Specifies the interval in seconds before a physical connection is discarded.

Setting Aged timeout to 0 supports active physical connections remaining in the pool indefinitely. Set the Aged timeout value higher than the Reap timeout value for optimal performance.

For example, if the Aged timeout value is set to `1200`, and the Reap Time value is not `0`, any physical connection that remains in existence for 1200 seconds (20 minutes) is discarded from the pool. The only exception is if the connection is involved in a transaction when the aged timeout is reached, the application server will not discard the connection until after the transaction is completed and the connection is closed.

The accuracy and performance of this timeout are affected by the Reap Time value. See “Reap time” on page 207 for more information.

Data type	Integer
Units	Seconds
Default	0
Range	0 to max int

Purge policy:

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**.

Data type	String

Defaults

- EntirePool for J2C connection factories and JMS-related connection factories
- EntirePool for WebSphere Version 4.0 data sources
- EntirePool for current version data sources that you create through the administrative console
- EntirePool for current version data sources that you script through wsadmin AdminConfig commands, starting JDBC templates that are built into WebSphere Application Server. For information about the command createUsingTemplate, see the topic, Commands for the AdminConfig object.
- FailingConnectionOnly for data sources that you script in wsadmin tool without starting JDBC templates

:

Range

EntirePool
All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and issues a stale connection Exception during the next operation on that connection. Subsequent getConnection() requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this closure is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice.

FailingConnectionOnly
Only the connection that caused the stale connection exception is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a possibility that the next getConnection() request from the application can return a connection from the pool that is also stale. The result is more stale connection exceptions.

The connection pretest function attempts to insulate an application from pooled connections that are not valid. When a backend resource, such as a database, goes down, pooled connections that are not valid might exist in the free pool. This is especially true when the purge policy is failingConnectionOnly; in this case, the failing connection is removed from the pool. Depending on the failure, the remaining connections in the pool might not be valid.

Connection pool advanced settings

Use this page to specify connection pooling related settings.

This administrative console page is common to a range of resource types: for example, JDBC data sources and JMS queue connection factories. To view this page, the path depends on the type of

resource, but generally you select an instance of the resource provider, then an instance of the resource type, then click **Connection pool properties** > **Advanced connection pool properties**.

For example, click:

- **Resources** > **JDBC** > **JDBC providers** > ***JDBC_provider*** > **Data sources** > ***data_source*** > **Connection pool properties** > **Advanced connection pool properties**
- **Resources** > **JMS** > **JMS provider** > **Default messaging** > **Queue connection factory** > ***JMS_queue_connection_factory*** > **Connection pool properties** > **Advanced connection pool properties**.

The Connection Pool Partition Support creates buckets and hashes on the buckets for optimizing the connection pool for getConnection method requests. The number of shared partitions, the number of free pool partitions, and the free pool distribution table size are properties that are related to reducing the time a thread must wait for a synchronization lock. On systems with a single processor, these values do not make a difference. On systems with multiple processors, these settings can reduce the performance cost that is associated with managing multiple threads.

When the default values are used, which means that the partitions are set to 0, the connection pool automatically selects the best values. The ability to change the default values is primarily provided for connection pools that exceed 500 maximum connections. When the connection pool exceeds 500 maximum connections, the formula that is used for auto-tuning the connection pool might create large objects whose size you might want to reduce. Performance might be reduced by reducing the partition size. However, that impact is normal when you weigh memory versus performance.

Number of shared partitions:

Specifies the number of partitions that are created in each of the shared pools.

Partition support is always enabled. The default values of 0 should be used to enable the connection pool to pick the best values for performance. In some cases where large multiprocessor systems are used, adjusting the partition support properties might help performance.

Data type	integer
Default value	0
Range	0 to max int

Number of free pool partitions:

Specifies the number of partitions that are created in each of the free pools.

Data type	integer
Default value	0
Range	0 to max int

Free pool distribution table size:

Determines the distribution of Subject and CRI hash values in the table that indexes connection usage data.

These hash values are used to match connection request credentials with the connections. A free pool distribution table size larger than 1 can yield more efficient distribution of hash values, to help minimize search collisions within the table. Fewer collisions can result in faster retrieval of a connection that matches a request. Use a larger value for free pool distribution table size if your resource receives many incoming requests with varying credentials. Smaller values (1) should be used if the same credentials apply to all incoming requests for the resource. The value of 0 means random distribution.

Data type	integer
Default value	0
Range	0 to max int

Surge threshold:

Specifies the number of connections created before surge protection is activated.

Surge protection is designed to prevent overloading of a data source when too many connections are created at the same time. Surge protection is controlled by two properties, *surge threshold* and *surge creation interval*.

The surge threshold property specifies the number of connections created before surge protection is activated. After you reach the specified number of connections, you enter *surge mode*.

The surge creation interval property specifies the amount of time, in seconds, between the creation of connections when in surge mode.

For example, assume the follow settings:
- maxConnections = 50
- surgeThreshold = 10
- surgeCreationInterval = 30 seconds

If the connection pool receives 15 connection requests, 10 connections are created at about the same time. The 11th connection is created 30 seconds after the first 10 connections. The 12th connection is created 30 seconds after the 11th connection. Connections continue to be created every 30 seconds until there are no more new connections needed or you reach the maxConnections value.

Surge connection support starts if the surge threshold is > -1 and the surge creation interval is > 0. The surge threshold property has a default value of -1, which indicates that it is turned off.

Data type	integer
Default value	-1
Range	-1 to max int

Surge creation interval:

Specifies the amount of time between connection creates when you are in surge protection mode.

When the number of connections specified for the surge threshold property is reached, the surge creation interval property dictates how much time each new connection request must wait before fulfillment.

Restriction: Surge protection does not work for a connection pool that is managed through an activation specification that coordinates with a JMS queue connection factory and default messaging provider. To control incoming connections for JMS calls such as **onMessage**, see the help topic for the administrative console page **JMS** > **Activation specification** > *activation_specification_name*.

Data type	integer
Default value	0
Range	0 to max int

Stuck timer interval:

A *stuck* connection is an active connection that is not responding or returning to the connection pool. If the pool is stuck (you have reached the stuck threshold), a resource exception is given to all new connection requests until the pool is unstuck. The stuck timer interval property is the interval for the timer, for example, how often the connection pool checks for stuck connections. The default value is 0 seconds.

If an attempt to change the stuck time, stuck timer interval, or stuck threshold properties using the wsadmin scripting tool fails, an `IllegalState` exception occurs. The pool cannot have any active requests or active connections during this request. For the stuck connection support to start, the stuck time and the stuck threshold property values must be greater than 0 and maximum connections must be greater than 0.

Also, the stuck timer interval, if it is set, must be less than the stuck time value. In fact, it is suggested that the stuck timer interval be one-quarter to one-sixth the value of stuck time so that the connection pool checks for stuck connections 4 - 6 times before a connection is declared stuck. This interval check reduces the likelihood of false positives.

Data type	integer
Default value	0
Range	0 to max int

Stuck time:

A *stuck* connection is an active connection that is not responding or returning to the connection pool. If the pool is stuck (you have reached the stuck threshold), a resource exception is given to all new connection requests until the pool is unstuck. The stuck time property is the interval, in seconds, allowed for a single active connection to be in use to the backend resource before it is considered to be stuck.

Data type	integer
Default value	0
Range	0 to max int

Stuck threshold:

A *stuck* connection is an active connection that is not responding or returning to the connection pool. If the pool is stuck (you have reached the stuck threshold), a resource exception is given to all new connection requests until the pool is unstuck. An application can explicitly catch this exception and continue processing. The pool continues to periodically check for stuck connections when the number of stuck connections is past the threshold. If the number of stuck connections drops below the stuck threshold, the pool detects this during its periodic checks and enables the pool to begin servicing requests again. The stuck threshold is the number of connections that must be considered stuck for the pool to be in stuck mode.

Data type	integer
Default value	0
Range	0 to max int

Connection pool (Version 4) settings

Use this page to create a connection pool for a Version 4.0 data source.

You can access this administrative console page in one of two ways:

- **Resources** > **JDBC** > **JDBC Providers** > *JDBC_provider* > **Data sources (WebSphere Application Server V4)** > *data_source* > **Connection pool properties (version 4)**
- **Resources** > **JDBC** > **Data sources (WebSphere Application Server V4)** > *data_source* > **Connection pool properties (version 4)**

Scope: Resources such as JDBC providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource's properties only apply at an individual server level. For example, if you define the scope of a data source at the cell level, all users in that cell can look up and use that data source, which is unique within that cell. However, resource property settings are local to each server in the cell. For example, if you define *max connections* to 10, then each server in that cell can have 10 connections.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

For general information, see *Administrative console scope settings* in the Related Reference section.

Data type String

Minimum pool size:

Specifies the minimum number of connections to maintain in the pool.

The minimum pool size can affect the performance of an application. Smaller pools require less overhead when the demand is low because fewer connections are held open to the database. When the demand is high, the first applications experience a slow response because new connections are created if all others in the pool are in use.

Data type Integer
Default 1
Range Any non-negative integer.

Maximum pool size:

Specifies the maximum number of connections to maintain in the pool.

If the maximum number of connections is reached and all connections are in use, additional requests for a connection wait up to the number of seconds specified as the connection timeout. The maximum pool size can affect the performance of an application. Larger pools require more overhead when demand is high because there are more connections open to the database at peak demand. These connections persist until idled out of the pool. If the maximum value is smaller, longer wait times or possible connection timeout errors during peak times can occur. Ensure that the database can support the maximum number of connections in the application server, in addition to any load that it has outside of the application server.

Data type Integer
Default 10
Range Any positive integer

Connection timeout:

Specifies the maximum number of seconds an application waits for a connection from the pool before timing out and triggering a `ConnectionWaitTimeout` exception. WebSphere Application Server acts on this value only if you set the maximum pool size property, in which case the number of maximum connections serves as a trigger for enforcing the wait timeout property.

Data type Integer

Units	Seconds
Default	180
Range	Any non-negative integer

Setting this value to 0 disables the connection timeout.

If you accept the default value, Application Server issues the ResourceAllocation exception immediately after the pool manager indicates that the maximum number of connections are in use. If you disable connection timeout, Application Server does not issue an exception. Instead, the pool manager queues subsequent connection requests until it can allocate a connection.

Idle timeout:

Specifies the maximum number of seconds that an idle (unallocated) connection can remain in the pool before being removed to free resources.

Connections need to idle out of the pool because keeping connections open to the database can cause database memory problems. However, not all connections are idled out of the pool, even if they are older than the Idle Timeout setting. A connection is not idled if removing the connection would cause the pool to shrink below its minimum size. Setting this value to 0 disables the idle timeout.

Data type	Integer
Units	Seconds
Default	1800
Range	Any non-negative integer

Orphan timeout:

Specifies the maximum number of seconds that an application can hold a connection without using it before the connection returns to the pool

If there is no activity on an allocated connection for longer than the Orphan Timeout setting, the connection is marked for orphaning. After another Orphan Timeout number of seconds, if the connection still has no activity, the connection returns to the pool. If the application tries to use the connection again, it is issued a stale connection exception. Connections that are enlisted in a transaction are not orphaned. Setting this value to 0 disables the orphan timeout.

Data type	Integer
Units	Seconds
Default	1800
Range	Any non-negative integer

Statement cache size:

Specifies the number of cached prepared statements to keep per connection.

The largest value you would need to set your cache size to if you do not want any cache discards is determined as follows: for each application that uses this data source on a particular server, add up the number of unique prepared statements (as determined by the *sql* string, concurrency, and the scroll type). This is the maximum number of possible prepared statements that can be cached on a given connection over the life of the server. Setting the cache size to this value means you never have cache discards. This provides better performance. However, because of potential resource limitations, this might not always be possible.

Data type	Integer
Default	10
Range	Any non-negative integer

Disable auto connection cleanup:

Specifies whether the connection pooling software automatically closes connections from the data source at the end of a transaction. Set this property if you want to maintain and reuse the same connection across multiple transactions.

The default is *false*, which indicates that when a transaction completes, the application server closes the connection and returns it to the pool. Any use of the connection after the transaction has ended results in a stale connection exception, because the connection is closed and has returned to the pool. This mechanism ensures that connections are not held indefinitely by the application. If the value is set to true, the connection is not returned to the pool at the end of a transaction. In this case, the application must return the connection to the pool by calling the close() method. If the application does not close the connection, the pool can run out of connections for other applications to use.

Data type	Boolean (check box)
Default	False (clear)

J2C Connection Factories collection

Use this page to view Java 2 Connector (J2C) connection factories, which represent sets of connection configuration values.

Application components such as enterprise beans have resource reference descriptors that refer to the connection factory, not the resource adapter. The connection factory is really a configuration properties list holder. In addition to the arbitrary set of configuration properties defined by the vendor of the resource adapter, there are several standard configuration properties that apply to the connection factory. These standard properties are used by the Java 2 Connectors connection pool manager in the application server run time and are not known by the vendor-supplied resource adapter code.

You can access this administrative console page in one of two ways:

- **Resources** > **Resource Adapters** > **J2C connection factories**
- **Resources** > **Resource Adapters** > **Resource adapters** > ***resource_adapter*** > **J2C connection factories**

Name:

Specifies the display name of a connection factory.

Data type	String

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name of this connection factory.

Data type	String

Scope:

Specifies the scope of the connection factory. Only applications that are installed within this scope can use this connection factory.

Provider:

Specifies the resource adapter that WebSphere Application Server uses for this connection factory.

Description:

Specifies a text description of this connection factory.

Data type String

Connection factory interface:

Specifies the fully qualified name of the interface that provides the implementation class for the connection factory.

Category:

Specifies a string that you can use to classify or group this connection factory.

Data type String

J2C connection factories settings:

Use this panel to specify settings for a connection factory.

You can access this administrative console page in one of two ways:

- **Resources** > **Resource Adapters** > **J2C connection factories** > ***J2C_connection_factory***
- **Resources** > **Resource Adapters** > **Resource adapters** > ***resource_adapter*** > **J2C connection factories** > ***J2C_connection_factory***

Scope:

Specifies the scope of the resource adapter that connects applications to an enterprise information system (EIS) through this connection factory. Only applications that are installed within this scope can use this connection factory.

Provider:

Specifies the resource adapter that WebSphere Application Server uses for this connection factory.

Provider can be set only when you create a new connection factory. The list shows all of the existing resource adapters that are defined at the relevant scope. Select one from the list if you want to use an existing resource adapter as Provider.

Create new provider:

Provides the option of configuring a new resource adapter for the new connection factory.

Create New Provider is displayed only when you create, rather than edit, a connection factory.

Clicking **Create New Provider** triggers the console to display the resource adapter configuration page, where you create a new adapter. After you click **OK** to save your settings, you see the connection factory collection page. Click **New** to define a new connection factory for use with the new resource adapter; the console now displays a configuration page that lists the resource adapter as the new connection factory Provider.

Name:

Specifies the name of this connection factory.

This is a required property.

Data type String

JNDI name:

Specifies the JNDI name of this connection factory.

For example, the name could be *eis/myECIConnection*.

After you set this value, save it and restart the server. You can see this string when you run the *dumpNameSpace* tool. This is a required property. If you do not specify a JNDI name, it is completed by default using the Name field.

Data type String
Default eis/*display name*

Important: Adhere to the following requirements for JNDI names:

- Do not assign duplicate JNDI names across different resource types (such as data sources versus J2C connection factories or JMS connection factories).
- Do not assign duplicate JNDI names for multiple resources of the same type in the same scope.

Description:

Specifies a text description of this connection factory.

Data type String

Connection factory interface:

Specifies the fully qualified name of the Connection Factory Interfaces supported by the resource adapter.

This is a required property. For new objects, the list of available classes is provided by the resource adapter in a drop-down list. After you create the connection factory, the field is a read only text field.

Data type Drop-down list or text

Category:

Specifies a string that you can use to classify or group this connection factory.

Data type String

Authentication alias for XA recovery:

Specifies the authentication alias that is used during XA recovery processing. If this alias name is changed after a server failure, the subsequent XA recovery processing uses the original setting that was in effect before the failure.

Select an alias from the list.

To define a new alias that is not displayed in the list:

1. Click **Apply**. Under Related Items, you now see a listing for Java Platform, Enterprise Edition (Java EE) Connector Architecture (J2C) authentication data entries.
2. Click **JAAS - J2C authentication data**.
3. Click **New**.
4. Define an alias.
5. Click **OK** and **Save**. The console now displays an alias collection page that lists all configured aliases. Above the table, this page also displays the name of your connection factory in the breadcrumb path.
6. Click the name of your J2C connection factory to return to the configuration panel for the connection factory that you are creating.
7. Select the new alias in the container-managed authentication alias list.
8. Click **Apply**.

If the resource adapter does not support XA transactions, this field is not displayed. The default value comes from the selected alias for application authentication, if specified.

If you have defined multiple security domains and multiple authentication aliases in the application server, you can click **Browse...** to select an authentication alias for the resource that you are configuring. Security domains allow you to isolate authentication aliases between servers. The tree view is useful in determining the security domain to which an alias belongs, and the tree view can help you determine the servers that is able to access each authentication alias. The tree view is tailored for each resource, so domains and aliases are hidden when you cannot use them.

The browse button is only accessible if at least one security domain is defined and assigned a scope that is applicable to the resource that is being edited. Additionally, that security domain must contain at least one JAAS J2C Authentication alias.

Data type Drop-down list

Component-managed authentication alias:

Specifies authentication data for component-managed signon to the resource.

Select an alias from the list.

To define a new alias that is not displayed in the list:

1. Click **Apply**. Under Related Items, you now see a listing for Java Platform, Enterprise Edition (Java EE) Connector Architecture (J2C) authentication data entries.
2. Click **JAAS - J2C authentication data**.
3. Click **New**.
4. Define an alias.
5. Click **OK** and **Save**. The console now displays an alias collection page that lists all configured aliases. Above the table, this page also displays the name of your connection factory in the breadcrumb path.
6. Click the name of your J2C connection factory to return to the configuration panel for the connection factory that you are creating.
7. Select the new alias in the container-managed authentication alias list.
8. Click **Apply**.

If you have defined multiple security domains and multiple authentication aliases in the application server, you can click **Browse...** to select an authentication alias for the resource that you are configuring. Security domains allow you to isolate authentication aliases between servers. The tree view is useful in determining the security domain to which an alias belongs, and the tree view can help you determine the servers that is able to access each authentication alias. The tree view is tailored for each resource, so domains and aliases are hidden when you cannot use them.

The browse button is only accessible if at least one security domain is defined and assigned a scope that is applicable to the resource that is being edited. Additionally, that security domain must contain at least one JAAS J2C Authentication alias.

Data type List

The alias that you configure for component-managed authentication does not apply to all clients that must access the secured resource. External Java clients with Java Naming and Directory Interface (JNDI) access can look up a Java 2 Connector (J2C) resource such as a data source or Java Message Service (JMS) queue. However, they are not permitted to take advantage of the component-managed authentication alias defined on the resource. This alias is the default value that is used when the getConnection() method does not specify any authentication data, like *user* and *password*, or a value for ConnectionSpec. If an external client needs a connection, it must assume responsibility for the authentication by passing it through arguments on the getConnection() call.

Mapping-configuration alias:

Specifies the authentication alias for the Java Authentication and Authorization Service (JAAS) mapping configuration that is used by this connection factory.

The **DefaultPrincipalMapping** JAAS configuration maps the authentication alias to the user ID and password. You can define and use other mapping configurations.

Note: Some mapping-configuration aliases do not use container-managed authentication aliases, so you cannot select a container-managed authentication alias if one of those mapping-configuration aliases is selected.

Data type Pick-list

Container-managed authentication alias:

Specifies authentication data, which is a JAAS - J2C authentication data entry, for container-managed signon to the resource. This setting can be disabled depending on the value that is selected for the Mapping-configuration alias setting.

Select an alias from the list.

To define a new alias that is not displayed in the list:

1. Click **Apply**. Under Related Items, you now see a listing for Java Platform, Enterprise Edition (Java EE) Connector Architecture (J2C) authentication data entries.
2. Click **JAAS - J2C authentication data**.
3. Click **New**.
4. Define an alias.
5. Click **OK** and **Save**. The console now displays an alias collection page that lists all configured aliases. Above the table, this page also displays the name of your connection factory in the breadcrumb path.

6. Click the name of your J2C connection factory to return to the configuration panel for the connection factory that you are creating.
7. Select the new alias in the container-managed authentication alias list.
8. Click **Apply**.

If you have defined multiple security domains and multiple authentication aliases in the application server, you can click **Browse...** to select an authentication alias for the resource that you are configuring. Security domains allow you to isolate authentication aliases between servers. The tree view is useful in determining the security domain to which an alias belongs, and the tree view can help you determine the servers that are able to access each authentication alias. The tree view is tailored for each resource, so domains and aliases are hidden when you cannot use them.

The browse button is only accessible if at least one security domain is defined and assigned a scope that is applicable to the resource that is being edited. Additionally, that security domain must contain as least one JAAS J2C Authentication alias.

Data type Pick-list

Authentication preference:

Specifies the authentication mechanisms defined for this connection factory.

This setting specifies which of the authentication mechanisms defined for the corresponding resource adapter applies to this connection factory. Common values, depending on the capabilities of the resource adapter, are: `KERBEROS`, `BASIC_PASSWORD`, and `None`.

If `None` is chosen, the application component is expected to manage authentication (<res-auth>Application</res-auth>). In this case, the user ID and password are taken from one of the following:
- The component-managed authentication alias
- UserName, Password Custom Properties
- Strings passed on the getConnection method

For example, if two authentication mechanism entries are defined for a resource adapter in the *ra.xml* document:
- <authentication-mechanism-type>BasicPassword</authentication-mechanism-type>
- <authentication-mechanism-type>Kerbv5</authentication-mechanism-type>

The authentication preference specifies the mechanism to use for container-managed authentication. An exception is issued during server startup if a mechanism that is not supported by the resource adapter is selected.

Data type Pick-list
Default BASIC_PASSWORD

J2C Connection Factory advanced settings:

Use this page to specify settings for a Java 2 Connector (J2C) connection factory.

You can access this administrative console page in one of two ways:
- **Resources** > **Resource Adapters** > **J2C connection factories** > ***J2C_connection_factory*** > **Advanced connection factory properties**
- **Resources** > **Resource Adapters** > ***resource_adapter*** > **J2C connection factories** > ***J2C_connection_factory*** > **Advanced connection factory properties**

Log missing transaction contexts:

Specifies whether the container logs that there is a missing transaction context when a connection is obtained.

Data type	Boolean
Default	True (enabled)

Cached handles:

Specifies whether cached handles are tracked by the container. Cached handles are handles that are held in `inst vars` in a bean.

Data type	Boolean
Default	False (clear)

Resource workload routing:

Use this topic to learn how to enable resource routing in your environment.

Note: Resource workload routing includes data source and connection factory fail over and subsequent fail back from a predefined alternate or backup resource. This function enables applications to easily recover from resource outages, such as database failures, without requiring you to embed alternate resource and configuration information. You can tailor the resource fail over and failback flexible configuration options to meet your environment-specific and application needs.

Configure an alternate resource

A data source and connection factory can fail over and fail back automatically when a specified or default failure threshold value is reached. When fail over occurs, the application switches from using the primary resource to using the alternate resource. Fail back occurs when the application switches back from the alternate resource to the primary resource.

The alternate resource is created the same way that other connection factories or data sources are created. The alternate resource configuration should mirror the primary resource configuration. For example, the alternate resource security configuration and the primary resource configuration, with respect to the application and resources, should mirror each other so that the application and database can access the required data. After the alternate resource is created, you can change the database values that are necessary for the alternate resource backend configuration. If the alternate resource is not compatible, it is likely that fail over will fail. If the resources are not compatible, the following errors might occur: tables or fields that do not exist, an expected record does not exist and unexpected resource errors exist. As a test option, before the alternate resource is configured to the primary data source, you can test the application by changing the JNDI name in the application from the primary JNDI name to the alternate JNDI name.

When the primary resource is used, the alternate resource is paused. Before the alternate resource is paused, the alternate resource can be available before the primary is used. Using the alternate before it is paused is not recommended unless there is a special reason the alternate needs to be accessed before the primary resource. An example of a special reason is testing the application for compatability.

An alternate resource cannot be used as a primary. When using the fail over feature with non-relational resource adapters that have back-ends that also support fail over, you must verify that fail over is not configured for these back-ends. Fail over works with non-relational resource adapters that have a ManagedConnection object that implements a testConnection method. The testConnection method is used to ping the alternate and primary resources for success before re-establishing a connection to the currently available resource. If the resource adapter does not implement a testConnection method or testConnection throws a `javax.resource.NotSupportedException` error, the fail over feature is disabled.

For resource adapters that do not meet the requirement for testConnection, partial fail over can be used. You must manually fail back using Mbeans to the primary resource when the primary resource is available. Partial fail over can be enabled by setting the property, enablePartialResourceAdapterFailoverSupport to `true`.

You are encouraged to test the suitability of this feature with your system environment and resources before enabling fail over support.

Mbean operations properties

failOverToAlternateResource

Values: `none`, `hold` or `automated`; default is `hold` without automated fail back.

Description: Manual fail over to alternate resource. This action is issued on the primary resource.

failBackToPrimaryResource

Values: `none`, `hold` or `automated`; default is automated with automated fail over.

Description: Manual fail back to primary resource. This action is issued on the primary resource.

Mbean attribute properties

resourceFailOver

Values: boolean

Description: False - Disables resource fail over. True - Enables resource fail over. This action is issued on the primary resource.

resourceFailBack

Values: boolean

Description: False - Disables resource fail back. True - Enables resource fail back. This action is issued on the primary resource.

populateAlternateResource

Values: boolean

Description: False - Disables populate alternate resource. True - Enables populate alternate resource. This action is issued on the alternate resource.

Custom properties

All properties for this feature must be created as new custom properties on the connection pool for a particular data source or connection factory. In the administrative console, navigate to the data source or connection factory that notification is to be enabled for. Click the **Connection pool properties** link. On the **Pool Properties** panel, click **Connection pool custom properties** link. The **Custom properties** panel for the resource connection pool displays. Click **New** to create the custom properties described as follows:

failureThreshold

Values: Must be an integer and > `0`.

Description: The failureThreshold property is only read if the failureNotificationActionCode or alternateResourceJNDIName property is set to valid value. If the failureThreshold property is not set or is set to an invalid number the default value of `5` is used. The integer value specified for the failureThreshold is the number of consecutive resource exceptions that must occur for a particular resource before notification is sent or failover occurs.

The following is an example of how this value works: If the failureThreshold property is set to `5` for data source B, then data source B must get five consecutive resource exceptions while attempting to establish connections, with no successful attempts in-between these failures, before notification is sent or the resource can fail over. An attempt to send the notification or fail over is made after five consecutive resource exceptions occur. However, in a multi-threaded environment, after the failure threshold value is reached, the timing of the notification or fail over might occur after additional resource exceptions.

Attention: Resource exception counters are not shared between resources. Resource exceptions must be consecutive to reach failure threshold.

alternateResourceJNDIName

Values: String value containing a direct JNDI name.

Description: An alternate connection factory or data source resource should be like the primary resource. Provide the JNDI name of the alternate resource to enable the fail over feature.

Advanced fail over properties

resourceAvailabilityTestRetryInterval

Values: int value, default is `10`.

Description: The test connection interval by default is `10` seconds. Every 10 seconds, the test connection thread attempts to test the primary resource. Depending on system resources, this value can be change from `1` - `MAXINIT` seconds.

enablePartialResourceAdapterFailoverSupport

Values: boolean value, default is `false`.

Description: If this value is `true`, fail over to the alternate resource occurs, but fail back to the primary is manual. This property can be set if the resource adapter being used does not meet the requirements for connection fail over, for example, it does not have testConnection implemented or it throws a not supported exception.

disableResourceFailOver

Values: boolean value, default is `false`.

Description: If this value is `true`, automatic fail over does not occur.

disableResourceFailBack

Values: boolean value, default is `false`.

Description: If this value is `true`, automatic fail back does not occur.

populateAlternateResource

Values: boolean value, default is `false`.

Description: If this value is `true`, the alternate resource is populated with connections to maximum connections. Every attempt is made to keep the alternate resource at maximum connections. If the database goes down for the alternate resource, the stale connections are removed and the populate thread repopulates the alternate resource when the database is available. You can dynamically enable and disable the populate alternate resource using the Mbean operations, disablePopulateAlternateResource and enablePopulateAlternateResource.

Attention: You might see performance gains during a failover with populate alternate resource enabled, but, the cost is high to keep the alternate resource populated. Most of the cost is in keeping twice the number of connections typically required for one data source. Because connections are large objects, keeping the connections uses additional memory resource on the server and extra resource on the database.

Data source resource definition in applications:

In support of the Java Enterprise Edition (Java EE) 6 specification, applications can define data sources in annotations or in the deployment descriptor. This topic reviews similarities and compatibility with WebSphere Application Server data sources defined at the server, node, cluster, or cell level. Optional features in data source definition are also discussed.

Standard properties for data source definition

Table 18. Standard properties for data source definition. Use this table to learn about standard properties for data source definitions

Annotation element	Descriptor element	Comments
name	name	JNDI name for the data source. The name must be in one of the java:global, java:app, java:module, or java:comp name spaces.
className	class-name	Fully qualified class name from the JDBC driver that implements javax.sql.XADataSource, javax.sql.ConnectionPoolDataSource, or javax.sql.DataSource.
databaseName	database-name	Value is supplied to JDBC driver.
description	description	Value is supplied to DataSource MBean.
initialPoolSize	initial-pool-size	Value of property is ignored. In WebSphere Application Server, initial pool size is always `0`.
isolationLevel	isolation-level	Equivalent to WebSphere Application Server data source custom property, webSphereDefaultIsolationLevel. This is a default transaction isolation level for new connections.
loginTimeout	login-timeout	Value is supplied to JDBC driver.
maxIdleTime	max-idle-time	Equivalent to WebSphere Application Server connection pooling property, unusedTimeout. This property is ignored in the client container where connection pooling is not provided.

Table 18. Standard properties for data source definition (continued). Use this table to learn about standard properties for data source definitions

Annotation element	Descriptor element	Comments
maxPoolSize	max-pool-size	Equivalent to WebSphere Application Server connection pooling property, maxConnections. This property is ignored in the client container where connection pooling is not provided.
maxStatements	max-statements	Defines the maximum number of statements for the connection pool. In WebSphere Application Server, each pooled connection has its own statement cache. Consequently, maxStatements is divided (equally, rounding down) between the maxPoolSize for the pool. If maxPoolSize is unlimited, then statement pooling is disabled.
minPoolSize	min-pool-size	Equivalent to WebSphere Application Server connection pooling property, minConnections. This property is ignored in the client container where connection pooling is not provided.
password	password	Default password for connection requests that do not specify a password. Consider using an authentication alias instead of hard-coding the user name and password into the application.
portNumber	port-number	Value is supplied to JDBC driver.
serverName	server-name	Value is supplied to JDBC driver.
transactional	transactional	In WebSphere Application Server, the property, transactional, controls whether the connection is enlisted in JTA transactions. When transactional=false, connections are not enlisted in JTA transactions, but you can still run transactions against the database using autocommit=true or connection.commit/rollback with autocommit=false. Equivalent to the opposite of the WebSphere Application Server data source custom property, nonTransactionalDataSource.
url	url	Value is supplied to the JDBC driver unless any of the following are also specified: databaseName, serverName, portNumber.
user	user	Default user name for connection requests that do not specify a user name. Consider using an authentication alias instead of hard-coding the user name and password into the application.

Table 18. Standard properties for data source definition (continued). Use this table to learn about standard properties for data source definitions

Annotation element	Descriptor element	Comments

Vendor properties and custom properties

JDBC driver vendor properties can be included in the data source definition. Most of the WebSphere Application Server custom properties can also be included in the data source definition.

With annotations, this is done through the properties element; for example,

```
@DataSourceDefinition
(
  name="java:app/env/myDataSource",
  className="org.apache.derby.jdbc.EmbeddedXADataSource40",
  databaseName="myDB",
  properties=
  {
    // Vendor properties for Derby Embedded JDBC driver:
    "createDatabase=create",
    "connectionAttributes=upgrade=true",

    // Custom properties for WebSphere Application Server:
    "connectionTimeout=60",
    "dataStoreHelperClass=com.ibm.websphere.rsadapter.DerbyDataStoreHelper",
    "validateNewConnection=true",
    "validateNewConnectionRetryCount=5"
  },
  serverName=""
)
```

The following example illustrates how the data source definition is included in the deployment descriptor:

```
<data-source>
 <name>java:app/env/myDataSource</name>
 <class-name>org.apache.derby.jdbc.EmbeddedXADataSource40</class-name>
 <database-name>myDB</database-name>
 <property><name>createDatabase</name><value>create</value></property>
 <property><name>connectionAttributes</name><value>upgrade=true</value></property>
 <property><name>connectionTimeout</name><value>60</value></property>
 <property><name>dataStoreHelperClass</name><value>com.ibm.websphere.rsadapter.DerbyDataStoreHelper</value></property>
 <property><name>validateNewConnection</name><value>true</value></property>
 <property><name>validateNewConnectionRetryCount</name><value>5</value></property>
 <server-name/>
</data-source>
```

The following is a list of WebSphere Application Server custom properties that can be configured in this manner:

- Connection pooling properties:
  - agedTimeout
  - authDataAlias
  - authMechanismPreference
  - connectionTimeout
  - defaultConnectionTypeOverride
  - globalConnectionTypeOverride
  - mappingConfigAlias
  - purgePolicy

  - reapTime
  - stuckThreshold
  - stuckTime
  - stuckTimerTime
  - surgeCreationInterval
  - surgeThreshold
  - testConnection
  - testConnectionInterval
  - XA_RECOVERY_AUTH_ALIAS
- Data source custom properties:
  - beginTranForResultSetScrollingAPIs
  - beginTranForVendorAPIs
  - connectionSharing
  - enableMultithreadedAccessDetection
  - errorDetectionModel
  - freeResourcesOnClose
  - oracleRACXARecoveryDelay (Oracle only)
  - preTestSQLString
  - userDefinedErrorMap
  - validateNewConnection
  - validateNewConnectionRetryCount
  - validateNewConnectionRetryInterval
  - validateNewConnectionTimeout

Resource references

It is recommended for applications to always use resource references when accessing data sources, which makes it easier for the deployer to override.

Connection sharing

By default, for data source definition, a connection request can share an existing in-use connection if it matches the originally requested settings for that connection (connectionSharing=MatchOriginalRequest). Alternately, connection sharing can be done by matching the connection request against the current state of the connection (connectionSharing=MatchCurrentState).

Life cycle

The life cycle of a data source definition is tied to the life cycle of the applications that define it. Consequently, you can update your application to change the data source definition without needing to restart the server. If multiple applications include the same data source definition, for example, both data source definitions have identical java:global names, identical set of properties configured, and identical values for properties, then all of the applications must be uninstalled before updating the data source definition and reinstalling the applications.

Conflicts between data source definitions

Applications, modules, and components should take care not to define data sources with the same java:global name as another application, because that process makes it impossible for the applications to coexist. Within an application, modules and components should take care not to define data sources with

the same java:app name as another module or component. The conflict causes the application installation to fail. Within a module, components should take care not to define data sources with the same java:module name as other components. The conflict causes the application installation to fail. Within the web module, components should take care not to define data sources with the same java:comp name as other components. The conflict causes the application installation to fail.

Bean validation in RAR modules:

WebSphere Application Server validates resource adapter archive (RAR) JavaBeans constraints in compliance with the Java Connector Architecture (JCA) version 1.6 specification.

Resource adapters can specify the validation requirements of configuration properties to the Application Server through annotations in the source code of the resource adapter, constraint specifications in a resource adapter validation descriptor, or a mixture of both. In specifying these constraints, resource adapters can use the built-in bean validation constraints supplied with the Application Server, custom bean validation constraints supplied either by the application developer or a third party, or a mixture of both. Resource adapter developers can apply constraints to the fields and JavaBeans-compliant properties of the following JCA types:

- ResourceAdapter
- ManagedConnectionFactory
- ActivationSpec
- AdministeredObject

At run time, the application server creates instances of bean types declared by the resource adapter. Each instance is validated immediately upon setting its configuration properties, before placing the instance into service.

When validating a RAR bean, the Application Server creates an instance of a validator factory according to the bean validation deployment descriptor discovered by the Application Server. A validator instance is then obtained from the factory and used to validate the bean instance.

If validation fails, the Application Server throws a constraint violation exception and reports all violations to the system log. The effects of the exception for each RAR bean type and problem determination information are documented in the topic, Troubleshooting bean validation in RAR modules.

Note: The Bean Validation specification requires that no more than one `validation.xml` is visible on the class path. This requirement is violated whenever two or more stand-alone RARs provide a validation descriptor. See the section, "RAR bean validation descriptor" in this topic, for more information. When more than one `validation.xml` is visible to the Application Server class loaders, the Application Server or application modules might fail to acquire the default ValidatorFactory and subsequently cannot perform bean validation. For example, the server cannot validate beans of a RAR embedded in an application whenever the embedded RAR lacks a validation configuration, and two or more stand-alone RARs provide configurations. To avoid trouble, install stand-alone RARs that provide a bean validation descriptor as isolated whenever possible.

Built-in constraint annotations

Note: Use built-in constraint annotations to specify the range and mandatory attributes of configuration properties rather than provide custom annotations for the same purpose. The following constraints are useful, but you can use all bean validation built-in constraints. See the topic Bean validation built-in constraints for a complete list of the constraints.

- @Min

  Specifies the minimum value of the configuration property decorated with this annotation. The value must be greater than or equal to the specified minimum.

- @Max

Specifies the maximum value of the configuration property decorated with this annotation. The value must less than or equal to the specified maximum.

- @Size

  Specifies the range of values of the configuration property decorated with this annotation. The value must be greater than or equal to the specified minimum and be less than or equal to the specified maximum.

- @NotNull

  Specifies the value of the configuration property decorated with this annotation must not be null. That is, the property is required.

The following example is a RAR bean class that is decorated with built-in constraint annotations.

The value of the serverName configuration property must not be null, and the value of the instanceCount property must be at least 1 when the Application Server creates and configures an instance of the MyConnector class. Otherwise, a constraint validation exception occurs and, in the case of ResourceAdapter bean, the resource adapter fails to start. See the topic Troubleshooting bean validation in RAR modules for more information.

```
package com.my.company;

@Connector(...)
public class MyConnector implements ResourceAdapter, Serializable
{
 @ConfigProperty(type=java.lang.String.class,defaultValue="WAS")
 private String serverName;

 @NotNull()
 public String getServerName() {return serverName;}

 private Integer instanceCount = 0;

 @Min(value=1)
 public Integer getInstanceCount() {return instanceCount;}
 ...
```

RAR bean validation descriptor

Bean validation constraints can be declared through an XML descriptor supplied by a RAR module. In the simplest case, a RAR validation descriptor consists of the validation configuration declared in the validation.xml file and zero or more XML files that declare RAR bean validation constraints. Files containing constraint declarations are specified in the constraint-mapping elements of the validation configuration (validation.xml).

You must package the validation descriptor in the META-INF directory of a RAR module. Any custom constraint annotation classes that are declared in the validation descriptor must also be packaged in the RAR module.

The following example is a simple RAR validation descriptor that declares constraint metadata like the code shown in the section, "Built-in constraint annotations."

```
<?xml version="1.0" encoding="UTF-8"?>
<validation-config
  xmlns="http://jboss.org/xml/ns/javax/validation/configuration"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xsi:schemaLocation="http://jboss.org/xml/ns/javax/validation/configuration validation-configuration-1.0.xsd">
<constraint-mapping>META-INF/constraints.xml</constraint-mapping>
</validation-config>
```

The constraints XML file is also located in the META-INF directory and looks like the following:

```
<constraint-mappings
 xmlns="http://jboss.org/xml/ns/javax/validation/mapping"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://jboss.org/xml/ns/javax/validation/mapping validation-mapping-1.0.xsd">
<default-package>com.my.company</default-package>
<bean class="MyConnector" ignore-annotations="true">
 <field name="serverName">
  <valid/>
  <!-- @NotNull() -->
```

```
  <constraint annotation="javax.validation.constraints.NotNull">
   <message>Value is not null</message>
  </constraint>
 </field>
 <field name="instanceCount">
  <valid/>
  <!-- @Min(1) -->
  <constraint annotation="javax.validation.constraints.Min">
    <message>Minimum possible value is 1</message>
    <element name="value">1</element>
   </constraint>
  </field>
 </bean>
<constraint-mapping>
```

The packaged RAR module, `MyResourceAdapter.rar`, looks like the following:

```
my/
  company/
    MyConnector.class
. . .
META-INF
  /validation.xml
  /constraints.xml
```

Third-party bean validation

WebSphere Application Server supports using different bean validation implementations. If a resource adapter requires a bean validation implementation different from the implementation that is provided by the product, and the RAR provides the bean validation implementation, you must package the JAR file that contains the bean validation implementation in the RAR module root directory.

The RAR module must also contain a single validation configuration descriptor (`validation.xml`), which can be packaged in the META-INF directory of the RAR module, or in the `META-INF/services` directory of the bean validation JAR file, but not both.

RAR bean validation configuration discovery

When validating RAR beans, the Application Server bootstraps the bean validation configuration, specific to the RAR, according to the bean validation descriptor supplied in the RAR META-INF directory. If the descriptor does not exist, the server bootstraps the configuration using the first validation descriptor discovered in the RAR class loading context, such as that supplied in a third-party bean validation that is packaged in the RAR. Finally, the server uses the default validation configuration provided by the product.

The server then creates a validator factory specific to the discovered bean validation configuration and uses this factory to create validator instances for validating the RAR bean instances. When you deploy a RAR that supplies a bean validation descriptor, you must take additional steps to ensure that the class loader that loads the RAR loads the bean validation descriptor and classes packaged in the RAR.

For an embedded RAR, after you have deployed the application that embeds the RAR, you must set the delegation mode of the application class loader to Parent-Last (Child-First). See the topic Configuring application class loaders for more information.

For a stand-alone RAR, you must install the RAR as an isolated resource provider. See the topic Resource Adapter settings for more information.

Troubleshooting bean validation in RAR modules:

RAR beans that fail validation are not placed into service. When constraint violations occur, applications encounter resource connectivity issues that are different according to the bean type and how the RAR is deployed. This topic explains how to understand, service, and prevent these known issues.

RAR bean constraint violations

WebSphere Application Server displays a constraint violation exception and reports all constraint violations to the system log when it validates RAR bean instances that violate one or more constraints. The cause of all constraint violation must be determined and resolved to restore full connectivity to the affected resource.

Problem determination starts with consulting the RAR provider documentation for the valid values of the configuration properties that are indicated in the violations. If the property values are invalid, you must reconfigure them according to the documentation and restart the resource adapter. If the adapter is embedded in an application, then restart the application to restart the adapter; if the adapter is stand-alone, then restart the application server.

If a valid configuration property value is indicated in a violation, then the constraint might be incorrectly specified for the bean, or the bean is incorrectly computing the property value. In these cases, the RAR vendor must correct the problem.

If the problem is caused by a faulty constraint definition (implementation), then the bean validation provider must correct the problem. In these cases, if the RAR is provided by IBM, or the RAR uses the bean validation implementation supplied by the Application Server, then contact IBM support to continue problem determination.

ResourceAdapter beans

ResourceAdapter beans are validated when the server starts a Java 2 Connector (J2C) resource adapter. When validation fails, the server rejects the ResourceAdapter instance and the resulting constraint violation exception causes the J2C resource adapter to fail. Applications cannot establish outbound connections to the resource, and the resource cannot deliver messages to applications. For an embedded adapter, the application that embeds the adapter fails to start. In-doubt transactions that involve the resource cannot be recovered.

The following example is a ResourceAdapter bean, MyConnector, at heap address 7efa7efa. Two validation constraints are violated. The constraint violation exception causes J2CResourceAdapter_1285109360562 to fail:

```
[9/29/10 10:51:24:125 CDT] 00000000 BeanValidatio E
 J2CA0238E: JavaBean com.my.company.adapter.MyConnector@7efa7efa failed Bean Validation due to one or more invalid
 configuration settings indicated in the following list of constraint violations:

. . .
```

ManagedConnectionFactory beans

ManagedConnectionFactory JavaBeans are validated during the initial Java Naming and Directory Interface (JNDI) lookup of a J2C connection factory.

When validation fails, the Application Server rejects the ManagedConnectionFactory instance and displays a naming exception to the application that performs the lookup. This exception indicates the causal constraint violation exception (javax.validation.ConstraintValidationException).

Applications cannot establish outbound connections to the resource. In-doubt transactions started over connections to the resource that were created by the connection factory cannot be recovered.

The following example is a ManagedConnectionFactory bean, MyMcf, at heap address 7dd07dd0, Two validation constraints are violated. The constraint violation exception causes the application to not obtain a connection factory that is required to create a connection to the resource, MyConnector:

```
[9/30/10 7:58:58:734 CDT] 00000023 BeanValidatio E
 J2CA0238E: JavaBean com.my.company.adapter.MyMcf@7dd07dd0 failed Bean Validation due to one or more invalid

 ...
 at javax.naming.InitialContext.lookup(
 at com.my.company.app.MyEjbImpl.testJbv(
. . .
```

ActivationSpec bean violations

ActivationSpec beans are validated when the applications starts. This is when the Application Server initially activates message endpoints bound to J2C activation specifications. These activation specifications name the bean class in their configuration. When validation fails, the endpoint fails to activate and the resulting constraint violation exception causes the application hosting the endpoint to fail.

Because the J2C resource adapter that contains the activation specification is started, applications can still establish connections to the resource. The resource can deliver messages to endpoints that have successfully activated. If the activation specification is defined within an embedded resource adapter, the server stops the adapter in the course of stopping the application. Failed transactional messages delivered by previous instances of the resource adapter that contains the activation specification cannot be recovered.

The following example is an ActivationSpec bean, MyActSpec, at heap address 51625162. Two validation constraints are violated. The log shows the constraint violation exception that causes the application, my_company_app, to fail:

```
[9/29/10 10:52:05:125 CDT] 00000009 BeanValidatio E
 J2CA0238E: JavaBean com.my.company.adapter.MyActSpec@51625162 failed Bean Validation due to one or more invalid
  configuration settings indicated in the following list of constraint violations:

AdministeredObject beans

AdministeredObject beans are validated when the server starts a J2C resource adapter that contains the administered object in its configuration. When validation fails, the server rejects the AdministeredObject instance and the resulting constraint violation exception causes the resource adapter to fail.

The following example is an AdministeredObject beans, MyAdminObj, at heap address 3a803a80. Two validation constraints are violated. The log shows the constraint violation exception that causes resource adapter to fail:

```
[9/29/10 10:51:25:125 CDT] 00000000 BeanValidatio E
 J2CA0238E: JavaBean com.my.company.adapter.MyAdminObj@3a803a80 failed Bean Validation due to one or more invalid
  configuration settings indicated in the following list of constraint violations:

JCA 1.6 support for annotations in RAR modules:

Note: The Java Connector Architecture (JCA) Version 1.6 specification adds support for Java annotations in resource archive (RAR) modules. Annotations are a means of specifying metadata, or configuration data, for a RAR module in the class files that make up the module.

Before JCA 1.6, this metadata was specified only in the deployment descriptor, but now you can specify this metadata using either a deployment descriptor or annotations. Metadata that is specified in annotations is merged into the deployment descriptor of a RAR module when it is updated, if the module is not marked metadata-complete in the deployment descriptor and if the module version is 1.6 or later.

The metadata-complete element defines whether the deployment descriptor for the resource adapter module is complete or whether the class files that are available to the module and packaged with the resource adapter should be examined for annotations that specify deployment information. If the metadata-complete is set to *true*, the application server deployment tool must ignore any annotations that specify deployment information, which might be present in the class files of the application. If metadata-complete is not specified, or is set to *false*, the deployment tool must examine the class files of the application for annotations, as specified by the JCA 1.6 Specification. If the deployment descriptor is not included, or is included but not marked metadata-complete, the deployment tool processes annotations.

Application servers must assume that metadata-complete is *true* for resource adapter modules with deployment descriptors that meet the requirements of JCA specification 1.5 and earlier. For a complete list of the supported annotations and their usage, consult the JCA specification.

Note: The JCA Version 1.6 specification also adds support for Bean Validation constraint annotations in RAR modules. You can specify Bean Validation constraint metadata for RAR JavaBeans by decorating your classes with Bean Validation constraint annotations or by supplying XML validation descriptors. The Application Server validates the constraints of all JCA 1.6 RAR JavaBeans instances before placing them into service at run time.

Connection factory JNDI name practices

Observe the conventions of the Java Naming and Directory Interface (JNDI) service in WebSphere Application Server when you create connection factory JNDI names.

Distributed computing environments often employ naming and directory services to obtain shared components and resources. Naming and directory services use name-to-object mappings to associate names with objects such locations, services, information, and resources. The Java Naming and Directory Interface (JNDI) provides a common interface that is used to access the various naming and directory services.

Naming your resources indirectly

When creating a connection factory or data source, a JNDI name is given by which the connection factory or data source can be looked up by a component. WebSphere Application Server uses an *indirect* name with the `java:comp/env` prefix:

- When you create a WebSphere Application Server data source, the default JNDI name is set to `jdbc/data_source_name`.
- When you create a connection factory, its default name is `eis/j2c_connection_factory_name`.

If you override these values by specifying your own, retain the `java:comp/env` prefix. An indirect name makes any resource-reference data associated with the application available to the connection management runtime, to better manage resources based on the res-auth, res-isolation-level, res-sharing-scope, and res-resolution-control settings.

Naming your resources for use with CMP

In addition, if you click the checkbox for the **Use this data source for container managed persistence (CMP)** option when you create the data source, another reference is created with the name of `eis/jndi_name_of_datasource_CMP`. For example, if a data source has a JNDI name of *jdbc/myDatasource*, the CMP JNDI name is *eis/jdbc/myDatasource_CMP*. This name is used internally by CMP and is provided simply for informational purposes.

Establishing custom finder SQL dynamic enhancement server-wide

Enable support for dynamic SQL enhancement of all custom finders, defined in all beans, by modifying the custom properties of your application server in the administrative console.

About this task

To establish this support on a server-wide basis (that is, dynamic SQL enhancement of all custom finders defined in all beans is enabled), use the following steps.

Procedure

1. Open the administrative console.
2. Select **Servers**.
3. Select **Application Servers**.
4. Select the server you want to configure.
5. In the Additional Properties area, select **Process Definition**.
6. In the Additional Properties area, select **Control** or **Servant**. Select **Control** to define the property in the Control, **Servant** to define the property in the Servant.
7. In the Additional Properties area, select **Java Virtual Machine**.
8. Select **Custom Properties**.
9. Select **com.ibm.websphere.ejbcontainer.customfinder.honorAccessIntent** and enter a value of **all**. If the property is not present in the list, create a new property name, enter the name *com.ibm.websphere.ejbcontainer.customfinder.honorAccessIntent* and the value **all**.

Establishing custom finder SQL dynamic enhancement on a set of beans

You can enable support for all custom finders defined on beans by modifying your application server's custom properties through the administrative console.

About this task

To establish this support for all custom finders defined on a set of beans use the following steps.

Procedure

1. Open the administrative console.
2. Select **Servers**.
3. Select **Application Servers**.
4. Select the server you want to configure.
5. Select **Server Infrastructure** > **Java and Process Management** > **Process Definition**.
6. Select **Java Virtual Machine**.
7. Select **Custom Properties**.
8. Select **com.ibm.websphere.ejbcontainer.customfinder.honorAccessIntent** and enter a value that corresponds to a list of beans that need this support, with each bean's name separated from the others by a colon (:). For example, *beanA:beanB:beanC*.

   If the property is not present in the list, create a new property name, enter the name *com.ibm.websphere.ejbcontainer.customfinder.honorAccessIntent* and enter the list as the value.

CMP connection factories collection

Use this page to view existing container managed persistence (CMP) connection factories settings.

These connection factories are used by a CMP bean to access any backend data store. A CMP connection factory is used by EJB model 2.x Entities with CMP version 2.x. Connection factories listed on this page are created automatically under the WebSphere Relational Resource Adapter when you check the box **Use this Data Source in container managed persistence (CMP)** in the General Properties area on the Data Source page. You cannot modify the settings for a CMP connection factory, and you cannot delete CMP connection factories from this collection. To remove the CMP connection factory object, you must navigate to the data source associated with the CMP connection factory and uncheck the **Use this Data Source for CMP** check box.

To view this administrative console page:

1. Click **Resources** > **Resource Adapters** > **Resource adapters**.
2. View the built-in resources. Click **Preferences**, select **Show built-in resources** and click **Apply**.
3. Click **WebSphere Relational Resource Adapter** > **CMP connection factories**

Name

Specifies the display name for the resource.

Data type String

JNDI Name

Specifies the JNDI name of the resource.

Data type String

Description

Specifies a description for the resource.

Data type String

Category
Specifies a category string which can be used to classify or group the resource.

Data type String

CMP connection factory settings
Use this page to view the settings of a connection factory that is used by a container-managed persistence (CMP) bean to access any database server. Because the connection factory is created and managed automatically, the settings of the connection factory cannot be modified.

To view this administrative console page:

1. Click **Resources** > **Resource Adapters** > **Resource adapters**.
2. Click **Preferences**, select **Show built-in resources** and click **Apply**.
3. Click **WebSphere Relational Resource Adapter** > **CMP Connection Factories** > ***connection_factory***.

Name:

Specifies the display name for the resource.

JNDI name:

Specifies the JNDI name of the resource.

Description:

Specifies a description for the resource.

Category:

Specifies a category string which can be used to classify or group the resource.

Authentication preference:

Specifies which of the authentication mechanisms that are defined for the corresponding resource adapter applies to this connection factory. This property is deprecated starting with version 6.0.

For example, if two authentication mechanism entries are defined for a resource adapter (*KerbV5* and *Basic Password*), this specifies one of those two types. If the authentication mechanism preference specified is not an authentication mechanism available on the corresponding resource adapter, it is ignored.

Data type String

Component-managed authentication alias:

References authentication data for component-managed signon to the resource.

Data type Drop-down list

Container-managed authentication alias:

References authentication data for container-managed signon to the resource.

Data type	Drop-down list

Configuring resource adapters

You can view a list of installed and configured resource adapters in the administrative console. Also, you can use the administrative console to install new resource adapters, create additional configurations of installed resource adapters, or delete resource adapter configurations.

Before you begin

A resource adapter is an implementation of the Java EE Connector Architecture (JCA) specification. The JCA specification provides access for applications to resources outside of the server or provides access for an enterprise information system (EIS) to applications on the server. It can provide application access to resources such as DB2, Customer Information Control System (CICS), Information Management Systems (IMS™), SAP, and PeopleSoft.

It can provide an EIS with the ability to communicate with message-driven beans that are configured on the server. Some resource adapters are provided by IBM; however, third-party vendors can provide their own resource adapters. A resource adapter implementation is provided in a resource adapter archive (RAR)file; this file has an extension,`RAR`. A resource adapter can be provided as a stand-alone adapter or as part of an application, in which case it is called an embedded adapter.

The Java Connector Architecture (JCA) Version 1.6 specification adds support for Java annotations and Bean Validation in RAR modules. For more information about annotation support and metadata, see the topic, JCA 1.6 support for annotations in RAR modules.

About this task

Use this task to configure a stand-alone resource adapter archive file. Embedded adapters are installed as part of the application installation. This panel can be used to work with either type adapter.

Procedure

1. Open the product administrative console.
2. Select **Resources** > **Resource adapters** > *resource_adapter*.
3. Set the scope setting. This field specifies the level to which this resource definition is visible. For general information, see the topic, Administrative console scope settings, in the Related Reference section. The Scope field is a read-only string field that shows where the particular definition for a resource adapter is located. This field is set either when the resource adapter is installed, which can only be at the node level, or when a new resource adapter definition is added.
4. Configure the description. This field specifies a text description of the resource adapter. Use a free-form text string to describe the resource adapter and its purpose.
5. Set the archive path. Use this field to specify the path to the RAR file containing the module for this resource adapter. This property is required.
6. Set the class path. The list of paths or JAR file names that together form the location for the resource adapter classes is set here. This includes any additional libraries needed by the resource adapter. The resource adapter code base is automatically added to the class path, but if anything outside the RAR is needed it can be specified here.
7. Set the native path. The list of paths that form the location for the resource adapter native libraries is set here. The resource adapter code base is automatically added to the class path, but if anything outside the RAR is needed it can be specified here.
8. Set the ThreadPool alias. The name of a thread pool that is configured in the server that is used by the resource adapter Work Manager is specified in this field. If there is no thread pool configured in the

server with this name, the default configured thread pool instance, named Default, is used. This property is only necessary if this resource adapter uses Work Manager. This field does not apply for the z/OS platform.

Resource adapters collection

Use this panel to perform the following actions on stand-alone resource adapters: view the list of installed resource adapters, install additional resource adapters, create additional configurations of already installed resource adapters and delete resource adapter configurations.

A resource adapter can be provided as a stand-alone adapter or as part of an application, in which case the resource adapter is referred to as an embedded adapter. Refer to related task, Installing resource adapters within applications, for more information on embedded resource adapters. A resource adapter is an implementation of the Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) specification. Enterprise applications can use a resource adapter to access resources outside of the application server including relational databases like DB2, online transaction processing (OLTP) systems like CICS, and enterprise information system (EIS) like SAP and PeopleSoft. A resource adapter can provide an EIS with the ability to communicate with message-driven beans (MDB) that are configured on the server. Resource adapters are provided by IBM or third party vendors. A resource adapter implementation is provided in a resource adapter archive file; this file has an extension of `.rar`.

To view this administrative console page, click **Resources** > **Resource Adapters** > **Resource adapters**.

To display a list of all of the resource adapters that are defined for a specific scope, select that scope.

To view the stand-alone resource adapters that are provided with the application server, select the **Show built-in resources** checkbox in the **Preferences** section.

To view additional information about, or to change the settings of a specific resource adapter, click the resource adapter name.

To perform an action on a specific resource adapter, select the checkbox beside the resource adapter name and click the appropriate button detailed below.

Install RAR:

Install a resource archive (RAR).

You can upload a RAR file from the local file system, or specify a RAR file on a remote file system. The RAR file must be installed at the node level.

New:

Create a copy of the selected resource archive which is already installed on the application server.

If you want to create a copy of an installed resource adapter, specify a server for the scope, and click **New**. You cannot create a copy of a resource adapter at the node scope. If you want to install a new resource adapter, click **Install RAR**.

Delete:

Delete the selected resource adapter.

Update RAR:

Update the selected resource adapter. Update a resource adapter archive (RAR) file when you determine that a resource adapter, or a set of resource adapters, needs to be updated with a different version or implementation.

Different versions or implementations of resource adapters can include different settings, therefore, updating your adapter might be beneficial if you require a specific set of configuration options. You can update the resource adapter for all of the nodes in a cell or all the nodes in a cluster. If some of your nodes are earlier than Version 7.0, the RAR update is not supported until those nodes are migrated to Version 7.0 or later.

Name:

Specifies the name of the resource adapter.

Description:

Specifies a text description of the resource adapter.

This description is a free-form text string to describe the resource adapter and its purpose.

Scope:

Specifies the level at which this resource adapter is visible. For general information, read about administrative console scope settings.

Some considerations that you should keep in mind for this particular panel are:

- Changing the scope enables you to see which resource adapter definitions exist at that level.
- Changing the scope does not have any effect on installation. Installations are always done under a scope of node, no matter what you set the scope to.
- When you create a new resource adapter from this panel, you must change the scope to what you want it to be before you click **New**.

Resource adapter settings:

Use this page to specify settings for a resource adapter.

A resource adapter is an implementation of the Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) specification that provides access for applications to resources outside of the server, provides access for applications to an enterprise information system (EIS), or provides access for an EIS to applications on the server. Resource adapters provide applications access to resources such as DB2, CICS, SAP and PeopleSoft. Resource adapters can provide an EIS with the ability to communicate with message driven beans that are configured on the server. Some resource adapters are provided by IBM; however, third party vendors can provide their own resource adapters. A resource adapter implementation is provided in a resource adapter archive file (RAR); this file has an extension of `.rar`. A resource adapter can be provided as a stand alone adapter or as part of an application, in which case the resource adapter is referred to as an embedded adapter.

The JCA Version 1.6 specification adds support for Java annotations in RAR modules. For more information on annotation support see the topic, JCA 1.6 support for annotations in RAR modules.

To view this administrative console page, click one of the following paths:

- **Resources** > **Resource Adapters** > **Resource adapters** > **New**.
- **Resources** > **Resource Adapters** > **Resource adapters** > ***resource_adapter***.
- **Applications** > **WebSphere enterprise applications** > ***enterprise_application*** > **Manage Modules** > ***connector_module*** > **Resource Adapter**.

- Install a new resource adapter archive:
  1. Click **Resources** > **Resource Adapters** > **Resource adapters** > **Install RAR**.
  2. Specify a full path for the local file system or remote file system, and click **Next**.

Scope:

Specifies the highest topological level at which application servers can use this adapter.

The Scope field is a read-only string field that specifies where the particular definition for a resource adapter is located. The Scope field is set when the resource adapter is installed, which can only be at the node level, or when a new resource adapter definition is added.

Name:

Specifies the name of the resource adapter definition.

This property is a required string containing no spaces that is a meaningful text identifier for the resource adapter.

Description:

Specifies a text description of the resource adapter.

This description is a free-form text string to describe the resource adapter and its purpose.

Archive path:

Specifies the path to the installed resource archive file that contains the module for this resource adapter.

You can only select RAR files that are installed on the nodes within the selected scope, preventing you from configuring a selection that might fail for some of your nodes.

Note: For resources at the cell scope, the RAR files that are available are those that are installed on each individual node in the entire cell. For resources at a cluster scope, the RAR files that are available are those that are installed on each individual node in that particular cluster.

This property is required.

Data type String

Class path:

Specifies a list of paths or Java archive file (JAR) names that together form the location for the resource adapter classes.

Class path entries are separated by using the ENTER key and must not contain path separator characters like ';' or ':'. Class paths can contain variable (symbolic) names that can be substituted using a variable map. Check your driver installation notes for specific JAR file names that are required.

Native library path:

Specifies an optional path to any native libraries, which are .dll or .so files.

Native path entries are separated by using the ENTER key and must not contain path separator characters like ';' or ':'. Native paths can contain variable (symbolic) names that can be substituted using a variable map.

Isolate this resource provider:

Specifies that this resource provider will be loaded in its own class loader. This allows different versions of the same resource provider to be loaded in the same Java Virtual Machine. Give each version of the resource provider a unique class path that is appropriate for that version.

Ensure that all copies of a resource adapter have the same value for this option. For example, if you create a resource adapter at the cluster scope, the value of this option will be taken from the resource adapter archive (RAR) that you copy. When you create the copy, you cannot modify the value for any instances of that RAR, which would be the copies at the node or cluster scope in this example. If you need to modify the value, you have to delete the copies of the RAR until there is only one instance of that particular RAR that is left.

Note: You cannot isolate a resource provider if you specify a native library path.

Thread pool alias:

Specifies the name of a thread pool that is part of the server configuration for this resource adapter. Set this property only if the resource adapter uses the work manager service.

If you input a thread pool name that does not exist in the server configuration, the application server uses the name DEFAULT.

Advanced resource adapter properties:

Use this page to specify advanced settings for resource adapters that comply with the Version 1.5 and 1.6 Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) specification.

A resource adapter is an implementation of the JCA specification that provides access for applications to an enterprise information system (EIS), like DB2, CICS, SAP and PeopleSoft, or provides access for an EIS to applications on the server. A resource adapter can also provide an EIS with the ability to communicate with message-driven beans that are configured on the server. Some resource adapters are provided by IBM, but third party vendors can provide their own resource adapters.

A resource adapter implementation is provided in a resource adapter archive file; this file has an extension of .rar. A resource adapter can be provided as a stand-alone adapter or as part of an application, in which case it is referred to as an embedded adapter.

To view this administrative console page, click **Resources** > **Resource Adapters** > **Resource adapters** > ***resource_adapter*** > **Advanced resource adapter properties**.

Restrict the JVM to allow only one instance of this resource adapter:

Prevents more than one instance of a resource adapter JavaBeans with a unique resource adapter implementation class name from existing in the same Java Virtual Machine (JVM). This field is only available on resource archives that allow definitions for activation specifications.

Note: Enabling this setting imposes a restrictive condition on the inbound communications. For example, if two applications embed the same resource adapter, only the first application to start will be able to access resources through its embedded resource adapter. If a stand-alone resource adapter is configured for a single instance, no applications that embed that same resource adapter will be able to access resources.

Data type	Boolean (checkbox)
Default	False (disabled)

Register this resource adapter with the high availability manager:

Specifies that the high availability (HA) manager will manage the lifecycle of a JCA resource adapter in a cluster. This option is only applicable to resource adapters with a version greater than JCA 1.0 and running on the Network Deployment version of WebSphere. Do not select this option without first consulting the product documentation for the resource adapter, because this option requires the resource adapter to support high availability of inbound messaging. This field is only available on resource archives that allow definitions for activation specifications.

Note: Enabling this setting imposes a restrictive condition on the inbound communications.

This setting can be implemented with:

- **Endpoint failover:** allows only one resource adapter in an HA group to receive messages across multiple servers. The result is that only one resource adapter can have endpoints active at one time.
- **Resource adapter instance failover:** allows only one resource adapter in an HA group to be started across multiple servers. Inbound or outbound communication is limited to one resource adapter in the cluster.

Data type	Boolean (checkbox with implementation options)
Default	False (disabled)

Directory conventions:

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This topic describes the conventions in use for WebSphere Application Server.

Default product locations - IBM i

These file paths are default locations. You can install the product and other components in any directory where you have write access. You can create profiles in any valid directory where you have write access. Multiple installations of WebSphere Application Server products or components require multiple locations.

app_client_root
: The default installation root directory for the Application Client for IBM WebSphere Application Server is the `/QIBM/ProdData/WebSphere/AppClient/V8/client` directory.

app_client_user_data_root
: The default Application Client for IBM WebSphere Application Server user data root is the `/QIBM/UserData/WebSphere/AppClient/V8/client` directory.

app_client_profile_root
: The default Application Client for IBM WebSphere Application Server profile root is the `/QIBM/UserData/WebSphere/AppClient/V8/client/profiles/`*`profile_name`* directory.

app_server_root
: The default installation root directory for WebSphere Application Server - Express is the `/QIBM/ProdData/WebSphere/AppServer/V8/Express` directory.

java_home

Table 19. Root directories for supported Java Virtual Machines.

This table shows the root directories for all supported Java Virtual Machines (JVMs).

JVM	Directory
32–bit IBM Technology for Java	/QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit
64–bit IBM Technology for Java	/QOpenSys/QIBM/ProdData/JavaVM/jdk60/64bit

plugins_profile_root
The default Web Server Plug-ins profile root is the /QIBM/UserData/WebSphere/Plugins/V8/webserver/profiles/*profile_name* directory.

plugins_root
The default installation root directory for Web Server Plug-ins is the /QIBM/ProdData/WebSphere/Plugins/V8/webserver directory.

plugins_user_data_root
The default Web Server Plug-ins user data root is the /QIBM/UserData/WebSphere/Plugins/V8/webserver directory.

product_library
product_lib
This is the product library for the installed product. The product library for each Version 8.0 installation on the system contains the program and service program objects (similar to .exe, .dll, .so objects) for the installed product. The product library name is QWAS8*x* (where *x* is A, B, C, and so on). The product library for the first WebSphere Application Server Version 8.0 product installed on the system is QWAS8A. The *app_server_root*/properties/product.properties file contains the value for the product library of the installation, was.install.library, and is located under the *app_server_root* directory.

profile_root
The default directory for a profile named *profile_name* for WebSphere Application Server - Express is the /QIBM/UserData/WebSphere/AppServer/V8/Express/profiles/*profile_name* directory.

shared_product_library
The shared product library, which contains all of the objects shared by all installations on the system, is QWAS8. This library contains objects such as the product definition, the subsystem description, the job description, and the job queue.

user_data_root
The default user data directory for WebSphere Application Server - Express is the /QIBM/UserData/WebSphere/AppServer/V8/Express directory.

The profiles and profileRegistry subdirectories are created under this directory when you install the product.

web_server_root
The default web server path is /www/*web_server_name*.

Updating a stand-alone resource adapter archive

Use the resource adapter archive (RAR) update wizard to update the stand-alone RAR files to a newer version. The application server uses the classes and other code that comprise a resource adapter archive to support the resource adapters that you configure.

Before you begin

A resource adapter must be installed on the application server, and you must have a new version of the resource adapter that is compatible with the old version. You can create the RAR file with an assembly tool, or the vendor for the resource adapter can provide the new version. If the new version of a RAR file is not compatible with the old version of the resource adapter, an update is not possible.

The Java Connector Architecture (JCA) Version 1.6 specification adds support for Java annotations in RAR modules. For more information on annotation support and metadata, see the topic JCA 1.6 support for annotations in RAR modules.

About this task

Update a RAR file when you determine that a resource adapter or a set of resource adapters needs to be updated with a different version. Different versions of resource adapters can include different settings, so updating your adapter might be beneficial if you require a certain set of configuration options. It is your choice to update the resource adapter for all the nodes in a cell or all the nodes in a cluster. If some of your nodes are earlier than Version 7.0, the RAR update is not supported until those nodes are migrated to Version 7.0. Updates to JCA 1.6 adapters are only applicable to a Version 8.0 node.

If you prefer to have more than one version of a resource adapter active in a given Java Virtual Machine (JVM), the update wizard does not provide the option of creating another version and keeping the old. In this case, you need to create an isolated resource adapter and configure it accordingly. Refer to the topic on configuring a resource adapter for more information.

Procedure

1. Save all configuration changes.
2. Back up your configuration settings with the backupConfig tool. The backupConfig tool is located in the `app_server_root/bin` directory. Read the topic on the backupConfig command for more information about how to use this command.
3. Stop any servers that contain the RAR file that is updated. Refer to the topic, Administering applications and their environment, for information about how to stop or start an application server.
4. Click **Resources** > **Resource Adapters** > **Resource Adapters**.
5. Select the check box next to the RAR file to update, and click **Update RAR**.
6. Specify the installation path for the RAR file, and click **Next**.
   - If your RAR file is located on the same workstation as your browser, select **Local file system**, and browse to find the file.
   - If your RAR file is located on the server workstation where the application server is installed, select **Remote file system**, and specify the fully qualified path to the file.
7. Review the configuration information that is provided for the RAR file. The following information is displayed for the RAR file:
   - Name
   - Current® RAR version
   - New RAR version
   - Scope
   - Any existing copies of the resource adapter. The resource adapters with an asterisk (*) are copies of the resource adapter and must also be updated at the same time.

   Click **Next** when you are finished.
8. Review the summary panel, and click **Finish** when you are satisfied with the configuration settings. When you click Finish, all the configuration changes are saved automatically. To revert to an older version of the resource adapter you must perform the update process again, and specify the older version of the RAR file.
9. Restart the servers that contain the updated RAR file.

What to do next

If you are not satisfied with the results, and you backed up your configuration with backupConfig tool, use the restoreConfig tool to restore your backup configuration. Read the topic on the restoreConfig command

for more information about how to use this command.

RARUpdate command group

Use the resource adapter archive (RAR) update wizard to upgrade the RAR module and property configuration of J2C Resource Adapters. The application server uses the classes and other code that comprise a resource adapter archive to support the resource adapters that you configure.

To avoid problems, use the administrative console RAR update wizard. For more information, see the topic Updating a resource adapter archive.

The RARUpdate command group contains the following commands:

- "compareResourceAdapterToRAR"
- "getNewRAObjectProperties"
- "findOtherRAsToUpdate" on page 246
- "updateRAR" on page 246

compareResourceAdapterToRAR

The compareResourceAdapterToRAR command determines whether a resource adapter is compatible with a new RAR file. A resource adapter may be updated with a RAR only when the two are compatible.

Target object

Resource adapter Object ID - The configuration object of the resource adapter that will be compared for update.

Result

The command returns true if the resource adapter is compatible with the specified RAR. It also displays the versions of the resource adapter and new RAR file. If the resource adapter is not compatible with the specified RAR, then the command returns false and provides a message explaining why they are not compatible.

Required parameters

-rarPath
The absolute path to a RAR file. (String, required)

Examples

Batch mode example usage:

```
AdminTask.compareResourceAdapterToRAR("Test Resource Adapter(cells/cell/nodes/node|resources.xml#J2CResourceAdapter_1169157308943)",
     '[-rarPath "c:\tra\rar\TRA.rar"]')
```

getNewRAObjectProperties

The getNewRAObjectProperties command obtains the list of new properties within a RAR file that may be configured when updating a resource adapter.

Target object

Resource adapter Object ID - The configuration object of the resource adapter that will be updated.

Result

You receive the list of new properties that may be configured on the resource adapter when updating a RAR.

Required parameters

-rarPath
The absolute path to a RAR file. (String, required)

-returnType
The type of value to return, "String" or "Hashtable". When returnType is "String", the command returns a String inteded for input to the updateRAR command; if returnType is "Hashtable", then the command returns a java.util.Hashtable which is intended for use with the Admin console. The returnType defaults to "String". (String, optional)

Examples

Batch mode example usage:

- Using Jython:

```
AdminTask.getNewRAObjectProperties('"Test Resource Adapter(cells/cell/nodes/node|resources.xml#J2CResourceAdapter_1169157308943)"',
     '[-rarPath c:/tra/RAR/TRA.rar -returnType String]')
```

findOtherRAsToUpdate

The findOtherRAsToUpdate command locates other resource adapters in the configuration that are similar to the resource adapter to be updated. The resulting resource adapters should also be updated.

Target object

Resource adapter Object ID - The configuration object of the resource adapter that will be compared for update.

Result

The command returns a list of resource adapter Object ID Strings that may be input as the target object of RARUpdate commands.

Examples

Batch mode example usage:

- Using Jython:

```
AdminTask.findOtherRAsToUpdate('"Test Resource Adapter(cells/cell/nodes/node|resources.xml#J2CResourceAdapter_1169157308943)"')
```

updateRAR

The updateRAR command updates the RAR and configuration of a resource adapter at a specific scope.

Target object

Resource adapter Object ID - The configuration object of the resource adapter that will be updated.

Result

This command returns a message of success or failure upon completion.

Required parameters

-rarPath
The absolute path to the new RAR file. (String, required)

Optional parameters

-ResourceAdapterProps
A list of [name value] pairs of new properties to set on the ResourceAdapter implementation class. You can specify the following parameters for this step:

-name The name of the resource adapter property. (String, optional)

-value The value of the resource adapter property. (String, optional)

-ConnectionFactoryProps
A list of [id name value] triplets of new properties to set on the connection factories in the resource adapter configuration. You can specify the following parameters for this step:

-id The Java Naming and Directory Interface (JNDI) name of the connection factory. (String, optional)

-name The name of the connection factory property. (String, optional)

-value The value of the resource adapter property. (String, optional)

-ActivationSpecProps
A list of [id name value] triplets of new properties to set on the activation specifications in the resource adapter configuration. You can specify the following parameters for this step:

-id The Java Naming and Directory Interface (JNDI) name of the activation specification. (String, optional)

-name The name of the activation specification property. (String, optional)

-value The value of the activation specification property. (String, optional)

-AdminObjectProps
A list of [id name value] triplets of new properties to set on the administered objects in the resource adapter configuration. You can specify the following parameters for this step:

-id The Java Naming and Directory Interface (JNDI) name of the activation specification. (String, optional)

-name The name of the administered object property. (String, optional)

-value The value of the administered object property. (String, optional)

Examples

Batch mode example usage:

- Using Jython:

```
AdminTask.updateRAR('"Test Resource Adapter(cells/cell/nodes/node|resources.xml#J2CResourceAdapter_1169157308943)"',
     '[-rarPath c:/tra/RAR/TRA.rar -ResourceAdapterProps [[RAProp1 RAProp1Val] [RAProp2 RAProp2Val]]
     -ConnectionFactoryProps [[eis/TRA_CF_1 CFProp1 CFProp1Val] [eis/TRA_CF_2 CFProp1 CFProp1Val2] [eis/TRA_DIF_CF CFProp2 CFProp2val]]
     -ActivationSpecProps [[eis/TRA_AS_1 ASProp1 ASProp1Val] [eis/TRA_AS_1 ASProp2 ASProp2Val] [eis/TRA_AS_2 ASProp3 ASProp3val] [eis/TRA_AS_2 ASProp4 ASProp4Val
     -AdminObjectProps [[eis/TRA_AO_1 AOProp1 AOProp1Val] [eis/TRA_AO_1 AOProp2 AOProp2Val] [eis/TRA_AO_2 AOProp1 AOProp1Val] [eis/TRA_AO_3 AOProp2 AOProp2Val]]]
```

Interactive mode example usage:

- Using Jython:

```
AdminTask.updateRAR('-interactive')
```

Mapping resource manager connection factory references to resource factories

You can use the administrative console to bind the resource manager connection factory references to one of the configured resource factories.

Before you begin

Before you can map the resource manager connection factory references to a configured resource factory, your enterprise application must contain configured resource references. You must use an assembly tool, such as Rational Application Developer, to assemble the application before deploying it through the administrative console.

Important: If your application does not contain resource references, the Resource references link does not display in the administrative console.

For more information on resource references, see the following topics:

- Creating or changing a resource reference
- Resource reference benefits

About this task

If the value of the res-auth element is `Container` within the deployment descriptor for your application, then you must specify the mapping configuration.

Procedure

1. Click **Applications** > **Enterprise applications >** *application_name*.
2. From Resources, select **Resource references**.
3. Select the application module and specify an authentication method for the selected connection factory reference binding. Select either **Use default method**, **Use custom login configuration** or **Use trusted connections**. If you select the **Use default method** option, the DefaultPrincipalMapping login configuration is selected. If you select the **Use trusted connections** option, then the TrustedConnectionMapping login configuration is selected. You must select an authentication data alias from the list.
4. After you make a selection, click **Apply** for the configuration to take effect.
5. If you select the **Use trusted connection option**, then you must select an authentication data alias from the menu list. The alias that is specified is what the application server uses to get the initial trusted connection.
6. Click **Apply**. The selected login configuration name and an **Mapping properties** button is displayed in the Login configuration field of the particular connection factory reference binding.
7. Click **Mapping properties > New** to specify the properties for your configuration. Click **OK** after specifying the properties on the Mapping properties panel.
8. If you select the **Use trusted connection** option, then you must select an authentication data alias from the menu list.
9. Click **Apply**. The **Mapping properties** button is displayed in the login configuration field of the particular connection factory reference binding.
10. Click **Mapping properties** to modify the properties of the trusted connection. See the topic, Setting the security properties for trusted connections, for information on tuning the mapping properties for the trusted connection.
11. Click **OK** and **Save** on the Resource references panel to save your changes to the master configuration.

Managing messages with message endpoints

Manage message delivery for message-driven beans (MDB) that are deployed as message endpoints. The message endpoints are managed beans (MBeans) for inbound resource adapters that are compliant with Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) Version 1.5.

About this task

The application server provides message endpoint MBeans to assist you in managing the delivery of a message to your message-driven beans that are acting as listeners on specific endpoints, which are destinations, and in managing the enterprise information system (EIS) resources that are utilized by these message-driven beans. Message-driven beans that are deployed as message endpoints are not the same as message-driven beans that are configured against a listener port. Message-driven beans that are used as message endpoints must be deployed using an ActivationSpecification that is defined within a resource adapter configuration for JCA Version 1.5.

With message endpoint MBeans, you can activate and deactivate specific endpoints within your applications to ensure that messages are delivered only to listening message-driven beans that are interacting with healthy EIS resources. This capability allows you to optimize the performance of your JMS applications in situations where an EIS resource is not behaving as expected. Message delivery to an endpoint typically fails when the message driven bean that is listening invokes an operation against a resource that is not healthy. For example, a messaging provider, which is an inbound resource adapter that is JCA Version 1.5 compliant, might fail to deliver messages to an endpoint when its underlying message-driven bean attempts to commit transactions against a database server that is not responding.

Note: Design your message-driven beans to delegate business processing to other enterprise beans. Do not access the EIS resources directly in the message-driven bean, but do so indirectly through a delegate bean.

Message endpoint MBeans alleviate two problems that are inherent to applications that provide message endpoints that access resources:

- Failed messages require additional processing, such as delivering them to the listening endpoint again or redirecting them to alternate destinations that process failed messages. In addition, a resource adapter might redeliver a message to an endpoint an infinite number of times.
- Message redirection requires the implementation of specialized destinations (queues and listeners) to process failed messages, as well as the logic to detect message failures. Message redirection is potentially error prone and computationally expensive due to its complexity.

The capability to deactivate (pause) and reactivate (resume) a specific message endpoint alleviates these problems by enabling the administrator to deactivate the endpoint from processing messages that are destined to fail. When the message endpoint is deactivated, you can repair the resource that is causing the problems and reactivate the endpoint to resume handling message requests. In the course of troubleshooting, you will not affect the resource adapter or the application that is hosting the endpoint.

If you are connecting to WebSphere MQ, you can also use the WAS_EndpointInitialState custom property in the activation specification to make the message endpoint start out in a deactivated state. When you set this property to Inactive, the message-driven bean connects with the destination, but does not start receiving messages. Use this setting to automatically deactivate a message endpoint when you know that certain tasks must be completed, services must be started, or checks must be carried out, before message handling begins. You activate the message endpoint in the same way as you would reactivate a message endpoint that you paused during its operation.

Procedure

1. Using the administrative console, navigate to the Message Endpoints panel for the application that is hosting the message endpoint.
   a. Select the **Applications** > **Application Types** > **Websphere enterprise applications** > ***application_name***.
   b. Select the **Runtime** panel.
   c. Select **Message Endpoints**. The panel lists the set of message endpoints that are hosted by the application.

2. Optional: Temporarily disable a message endpoint from handling messages and troubleshoot the problem.
   a. Deactivate the message endpoint by selecting the appropriate endpoint and clicking **Pause**.
   b. When the message endpoint is inactive, diagnose and repair the underlying cause of the delivery failures.
   c. Reactivate the message endpoint by selecting the appropriate endpoint and clicking **Resume**.
3. Optional: Activate a message endpoint that started out in a deactivated state. Select the appropriate endpoint and click **Resume**.

Results

The behavior you will observe when you deactivate (pause) a message endpoint using the message endpoint MBean is dependent upon a variety of factors, including the resource adapter that manages the message endpoint, the configuration of the message endpoint and the application server topology. Some specific examples of interest are as follows:

- **MDB listening on a non-durable topic (dependent on configuration):** The behavior that is implied by the deactivation (pause) of a message endpoint is often dependent upon the function that it is fulfilling. For example, if you have configured a message-driven bean to listen on a non-durable topic on the service integration bus, deactivating the message endpoint is analogous to stopping the application and will cause the subscription to be closed. This means that any messages that are published during the time that the message endpoint is paused will not be received by the message-driven bean.
- **Clustered message-driven bean (dependent on topology):** In this scenario a message-driven bean application has been deployed to a cluster of servers. A given message endpoint MBean controls only the behavior of the MDB in one server from the cluster, so will cause only one server to stop processing messages. Depending upon the messaging configuration and the specific resource adapter in use the messages that would have been consumed by the paused message endpoint may be consumed by the active message endpoints in the cluster, or they may remain unconsumed until the paused message endpoint is resumed.
- **Clustered message-driven bean, a non-clustered queue:** In this scenario, you have a cluster of servers with the same message-driven bean deployed to them. This is similar to the case, in which you have different message-driven beans with the same message selection criteria, except that in this case the message-driven beans are logically the same message-driven bean. Pausing the endpoint will cause only one of the servers to stop receiving messages, and the other message-driven beans will receive all the messages; none of the messages will be orphaned. To stop all of the endpoints, you must direct each server in the cluster to stop the local message endpoint.
- **Clustered message-driven bean, clustered queue:** In this scenario, each message-driven bean is pulling messages from a different partition of the queue. Messaging through WebSphere MQ and the Service Integration Bus have similar, but different, capabilities. If you are using WebSphere MQ, then pausing one endpoint will not allow the other instances of the message-driven bean to receive the messages. In the Service Integration Bus, messages from a paused endpoint will be redirected to the other message-driven beans.

Manage message endpoints

Use this panel to manage situations where messaging providers fail to deliver messages to their intended destinations. For example, a provider might fail to deliver messages to a message endpoint when its underlying message driven bean attempts to commit transactions against a database server that is not responding.

To view this administrative console panel:

1. Select the **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name***.
2. Select the **Runtime** panel. You will only see the Runtime panel if you have an application installed that is hosting message-driven beans.

3. Select **Message Endpoints**. The panel lists the set of message endpoints that are hosted by the application.

Name:

Specifies the name of the message endpoint.

Click the name of the message endpoint to view the configuration binding for the underlying endpoint message-driven bean and Activation Specification.

Running object scope:

Specifies the server where the endpoint is running.

For more information on scope, see the topic, Administrative console scope settings.

Status:

Indicates whether the message endpoint is active or inactive.

Click **Pause** to deactivate a message endpoint and stop it from handling messages.

Click **Resume** to reactivate a message endpoint that is inactive.

Configuring a JDBC provider and data source

For access to relational databases, applications use the Java Database Connectivity (JDBC) drivers and data sources that you configure for the application server.

Before you begin

Each vendor database requires different JDBC driver implementation classes for JDBC connectivity. A JDBC provider encapsulates those vendor-specific driver files. Through the data source that you associate with the JDBC provider, an application server obtains and manages the physical connections for transactions between applications and the database.

Attention: If you are accessing a DB2 database, IBM Optim pureQuery Runtime is an alternative to JDBC. For more information on pureQuery, see the topic, Task overview: IBM Optim pureQuery Runtime, in the related links section.

Before starting this task, determine the version of data source that you need according to the API specification of your applications.

- *Data sources (WebSphere Application Server Version 4)* are for use with the Enterprise JavaBeans (EJB) 1.0 specification and the Java Servlet 2.2 specification.
- Data sources of the latest standard version are for use with applications that implement the more advanced releases of these specifications.

Procedure

1. Verify that all of the necessary JDBC driver files are installed on your application server. Consult the article, Data source minimum required settings, by vendor for that information. If you opt to configure a user-defined JDBC provider, check your database documentation for information about the driver files.
2. Create a JDBC provider.

   When you create a JDBC provider from the administrative console, see the topic, Configuring a JDBC provider using the administrative console.

   OR

Using the wsadmin scripting client, see the topic, Configuring a JDBC provider using the scripting.

OR

Using the Java Management Extensions (JMX) API, see the topic, Creating a JDBC provider and data source using the JavaManagement Extensions API.

3. Create a data source.

   From the administrative console, see the topic, Creating a data source using the administrative console.

   OR

   Using the wsadmin scripting client, see the topic, Configuring new data sources using scripting. For V4 data sources, see the topic, Configuring new WAS40 data sources using scripting.

   OR

   Using the JMX API, see the topic, Creating a JDBC provider and data source using the JavaManagement Extensions API.

   Required properties: Different database vendors require different properties for implementations of their JDBC drivers. Set these properties on the WebSphere Application Server data source. Because Application Server contains templates for many vendor JDBC implementations, the administrative console surfaces the required properties and prompts you for them as you create a data source. However, if you script your data access configurations, you must consult the article Data source minimum required settings, by vendor, for the required properties and settings options.

4. Optional: Configure custom properties. Like the required properties, custom properties for specific vendor JDBC drivers must be set on the Application Server data source. Consult your database documentation for information about available custom properties. To configure a custom class to facilitate the handling of database properties that are not recognized natively by the Application Server, refer to the topic, Developing a custom DataStoreHelper class.

   You can also learn about optional data source properties in the Application Programming Guide and Reference for Java for your version of DB2 for z/OS if you use the DB2 Universal JDBC Driver provider.

5. Bind resource references to the data source. See the article, Data source lookups for enterprise beans and web modules.
6. Test the connection (for non-container-managed persistence usage). See the topic, Test connection service.

Results

If you use the DB2 JDBC Universal Driver, you might experience data source failures that the application server JVM log does not document. Check the DB2 database log or the WebSphere Application Server JDBC trace log (if JDBC trace was active). You might find that a bad authentication credential is the cause of failure. Currently the DB2 JDBC Universal Driver does not identify or surface the errors that are produced by non-valid authentication credentials in a proper or consistent way.

Even if you receive information about a bad credential, check the database and JDBC trace logs. These logs provide more reliable, detailed error data on authentication failures.

Note: The JDBC trace log exists only if the JDBC trace service is active during server start up. Activate the service in the administrative console. For more information, see the topic, Enabling trace at server startup. Specify **WAS.database** as the trace group and select **com.ibm.ws.db2.logwriter** as the trace string.

Data source minimum required settings, by vendor

These properties vary according to the database vendor requirements for Java Database Connectivity (JDBC) driver implementations. You must set the appropriate properties on every data source that you configure.

Use these tables for quick reference on the JDBC providers that represent your JDBC driver classes. Each table corresponds to a specific database vendor, product, and platform.

Following the tables are links to detailed requirements for creating data sources that correspond to each JDBC provider that the application server supports . The list includes information about connection properties that are required by the database and any optional properties that the JDBC driver supports. Use the administrative console or the wsadmin scripting tool to define these properties on your data sources.

Table 20. Apache Derby JDBC providers. Use the table for quick reference on database-specific JDBC providers.

Apache Derby		
JDBC provider	**Transaction support**	**Version and other considerations**
Derby JDBC Provider	One-phase	• Does not support Version 4 data sources • Configurable only in nodes at version 6.0.2 and later • Not for use in clustered environment: accessible from a single JVM only
Derby JDBC Provider (XA)	One and two phase	• Does not support Version 4 data sources • Configurable only in nodes at version 6.0.2 and later • Not for use in clustered environment: accessible from a single JVM only
Derby JDBC Provider 40	One-phase	• Configurable only in nodes at version 7.0 and later • Does not support Version 4 data sources
Derby JDBC Provider 40 (XA)	One and two phase	• Configurable only in nodes at version 7.0 and later • Does not support Version 4 data sources
Derby Network Server Using Derby Client	One-phase	• Does not support Version 4.0 data sources. • Configurable only in nodes at version 6.1 and later • *Can be used in clustered environment:* a database instance can be accessed by multiple JVMs • Only for use with Apache Derby databases that run on the same node as the application server

Table 20. Apache Derby JDBC providers (continued). Use the table for quick reference on database-specific JDBC providers.

Apache Derby		
JDBC provider	**Transaction support**	**Version and other considerations**
Derby Network Server Using Derby Client (XA)	One and two phase	• Does not support Version 4 data sources • Configurable only in nodes at version 6.1 and later • *Can be used in clustered environment:* a database instance can be accessed by multiple JVMs • Only for use with Apache Derby databases that run on the same node as the application server
Derby Network Server Using Derby Client 40	One-phase	• Configurable only in nodes at version 7.0 and later • Does not support Version 4 data sources
Derby Network Server Using Derby Client 40 (XA)	One and two phase	• Configurable only in nodes at version 7.0 and later • Does not support Version 4 data sources

Table 21. DB2 on AIX, HP-UX, Linux, Solaris, and Windows systems JDBC providers. Use the table for quick reference on database-specific JDBC providers.

DB2 on AIX, HP-UX, Linux, Solaris, and Windows systems		
JDBC provider	**Transaction support**	**Version and other considerations**
DB2 Using IBM JCC Driver	One-phase	• Configurable in nodes that are at version 7.0 and later.
DB2 Using IBM JCC Driver (XA)	One and two phase	• Configurable in nodes that are at version 7.0 and later.
DB2 Universal JDBC Provider	One-phase	N/A
DB2 Universal JDBC Provider (XA)	One and two phase	N/A

Table 22. DB2 UDB for iSeries JDBC providers. Use the table for quick reference on database-specific JDBC providers.

DB2 UDB for iSeries		
JDBC provider	**Transaction support**	**Version and other considerations**
DB2 UDB for iSeries (Native)	One-phase	Recommended when you run the application server on iSeries.
DB2 UDB for iSeries (Native XA)	One and two phase	Recommended when you run the application server on iSeries.
DB2 UDB for iSeries (Toolbox)	One-phase	N/A
DB2 UDB for iSeries (Toolbox XA)	One and two phase	N/A

Table 23. DB2 on z/OS JDBC providers. Use the table for quick reference on database-specific JDBC providers.

DB2 on z/OS		
JDBC provider	**Transaction support**	**Version and other considerations**
DB2 Using IBM JCC Driver	One-phase	Configurable in version 7.0 and later nodes.
DB2 Using IBM JCC Driver (XA)	One and two phase	Configurable version 7.0 and later nodes.
DB2 Universal JDBC Provider	One-phase when connecting to the application server that is on AIX, HP-UX, Linux, Solaris, Windows, and iSeries systems	
DB2 Universal JDBC Provider (XA)	One and two phase	

Table 24. Informix JDBC providers. Use the table for quick reference on database-specific JDBC providers.

Informix		
JDBC provider	**Transaction support**	**Version and other considerations**
Informix Using IBM JCC Driver	One phase	This provider is configurable in nodes that are at version 7.0 and later.
Informix Using IBM JCC Driver (XA)	One and two phase	This provider is configurable in nodes that are at version 7.0 and later.
Informix JDBC Driver	One-phase	N/A
Informix JDBC Driver (XA)	One and two phase	N/A
Informix using IBM DB2 JDBC Universal Driver	One phase	This provider is configurable in nodes that are at version 7.0 and later.
Informix using IBM DB2 JDBC Universal Driver (XA)	One and two phase	This provider is configurable in nodes that are at version 7.0 and later.

Table 25. Microsoft SQL Server JDBC providers. Use the table for quick reference on database-specific JDBC providers.

Microsoft SQL Server		
JDBC provider	**Transaction support**	**Version and other considerations**
Microsoft SQL Server JDBC Driver	One-phase	N/A
Microsoft SQL Server JDBC Driver (XA)	One and two phase	N/A
DataDirect ConnectJDBC Provider type 4 driver for MS SQL Server	One-phase	N/A
DataDirect ConnectJDBC Provider, type 4 driver, for MS SQL Server (XA)	One and two phase	N/A

Table 26. Oracle JDBC providers. Use the table for quick reference on database-specific JDBC providers.

Oracle		
JDBC provider	**Transaction support**	**Version and other considerations**
Oracle JDBC Driver	One-phase	Must use the ojdbc6.jar driver to connect to any version of Oracle database.

Table 26. Oracle JDBC providers (continued). Use the table for quick reference on database-specific JDBC providers.

Oracle		
JDBC provider	**Transaction support**	**Version and other considerations**
Oracle JDBC Driver(XA)	One and two phase	Must use the ojdbc6.jar driver to connect to any version of Oracle database.

Table 27. Sybase JDBC providers. Use the table for quick reference on database-specific JDBC providers.

Sybase		
JDBC provider	**Transaction support**	**Version and other considerations**
Sybase JDBC 4 Driver	One-phase	jConnect v7.0
Sybase JDBC 4 Driver (XA)	One and two phase	jConnect v7.0
Sybase JDBC 3 Driver	One-phase	jConnect v6.05
Sybase JDBC 3 Driver (XA)	One and two phase	jConnect v6.05
Sybase JDBC 2 Driver	One-phase	jConnect v5.5
Sybase JDBC 2 Driver (XA)	One and two phase	jConnect v5.5

Detailed requirements

The following list identifies required class files and connection properties per JDBC provider.

After you determine the JDBC provider that suits your application and environment, ensure that you acquire the corresponding JDBC driver at a release level supported by this version of the application server. Consult the IBM support website for supported hardware and software.

Use the following links to navigate to the requirements list. Each link corresponds to a specific database vendor, product, and platform.

- Apache Derby or Cloudscape 10.x
- DB2 Universal Database for iSeries
- Informix
- Microsoft SQL Server
- Oracle
- Sybase

Data source minimum required settings for Apache Derby:

These properties vary according to the database vendor requirements for JDBC driver implementations. You must set the appropriate properties on every data source that you configure. These settings are for Apache Derby and Cloudscape data sources.

You can configure the following types of providers:

- Derby JDBC Provider
- Derby JDBC Provider (XA)
- Derby JDBC Provider 40
- Derby JDBC Provider 40 (XA)
- Derby Network Server using Derby Client
- Derby Network Server using Derby Client (XA)

- Derby Network Server using Derby Client 40
- Derby Network Server using Derby Client 40 (XA)
- **Derby JDBC Provider**

  The Derby JDBC driver provides JDBC access to the Apache Derby database by using the framework that is already embedded in the application server. You cannot use any Version 4.0 data sources with this provider.

  This provider:

  – Is configurable only in nodes at version 6.0.2 and later
  – Supports one phase data source with the following class:

    `org.apache.derby.jdbc.EmbeddedConnectionPoolDataSource`
  – Requires the JDBC driver file:
    - derby.jar

      The full path name is ${DERBY_JDBC_DRIVER_PATH}/derby.jar. When you create a connection through the application server, the environment variables are set automatically.
  – Requires the following DataStoreHelper class:

    `com.ibm.websphere.rsadapter.DerbyDataStoreHelper`
  – Requires the following properties:

    databaseName
    The name of the database from which the data source obtains connections. If you do not specify a fully qualified path name, the application server uses the default location of *app_server_root*/derby or the equivalent default for AIX, HP-UX, Linux, or Solaris system environments. An example for the database path name is:

    If no database exists for the path name that you want to specify, configure the custom property, `createDatabase`, to a value of `create` to create the database dynamically.
- **Derby JDBC Provider (XA)**

  The Derby JDBC driver (XA) provides JDBC access to the Apache Derby database by using the framework that is already embedded in the application server.

  This provider:

  – Does not support use Version 4.0 data sources.
  – Is configurable only in nodes at version 6.0.2 and later
  – Supports the two-phase data source with the following class:

    `org.apache.derby.jdbc.EmbeddedXADataSource`
  – Requires JDBC driver file:
    - derby.jar

      The full path name is ${DERBY_JDBC_DRIVER_PATH}/derby.jar. When you create a connection through the application server, the environment variables are set automatically.
  – Requires the following DataStoreHelper class:

    `com.ibm.websphere.rsadapter.DerbyDataStoreHelper`
  – Does not require a valid authentication alias.
  – Requires the following properties:

    databaseName
    The name of the database from which the data source obtains connections. If you do not specify a fully qualified path name, the application server uses the default location of *app_server_root*/derby or the equivalent default for AIX, HP-UX, Linux, or Solaris system environments. An example for the database path name is:

    If no database exists for the path name that you want to specify, configure the custom property, `createDatabase`, to a value of `create` to create the database dynamically.

- **Derby JDBC Provider 40**

  The Derby JDBC Provider 40 provides JDBC access to the Apache Derby database by using the framework that is already embedded in the application server.

  This provider:

  – Is configurable only in nodes at version 7.0 and later.
  – Does not support Version 4.0 data sources.
  – Supports one phase data source with the following class:

    `org.apache.derby.jdbc.EmbeddedConnectionPoolDataSource40`
  – Requires the JDBC driver file:
    - derby.jar

      The full path name is ${DERBY_JDBC_DRIVER_PATH}/derby.jar. When you create a connection through the application server, the environment variables are set automatically.
  – Requires the following DataStoreHelper class:

    `com.ibm.websphere.rsadapter.DerbyDataStoreHelper`
  – Requires the following properties:

    databaseName

    The name of the database from which the data source obtains connections. If you do not specify a fully qualified path name, the application server uses the default location of *app_server_root*/derby or the equivalent default for AIX, HP-UX, Linux, or Solaris system environments. An example for the database path name is:

    If no database exists for the path name that you want to specify, configure the custom property, `createDatabase`, to a value of `create` to create the database dynamically.

- **Derby JDBC Provider 40 (XA)**

  The Derby JDBC Provider 40 (XA) provides JDBC access to the Apache Derby database by using the framework that is already embedded in the application server.

  This provider:

  – Is configurable only in nodes at version 7.0 and later.
  – Does not support Version 4.0 data sources.
  – Supports one phase data source with the following class:

    `org.apache.derby.jdbc.EmbeddedXADataSource40`
  – Requires the JDBC driver file:
    - derby.jar

      The full path name is ${DERBY_JDBC_DRIVER_PATH}/derby.jar. When you create a connection through the application server, the environment variables are set automatically.
  – Requires the following DataStoreHelper class:

    `com.ibm.websphere.rsadapter.DerbyDataStoreHelper`
  – Requires the following properties:

    databaseName

    The name of the database from which the data source obtains connections. If you do not specify a fully qualified path name, the application server uses the default location of *app_server_root*/derby or the equivalent default for AIX, HP-UX, Linux, or Solaris system environments. An example for the database path name is:

    If no database exists for the path name that you want to specify, configure the custom property, `createDatabase`, to a value of `create` to create the database dynamically.

- **Derby Network Server using Derby Client**

  Use this provider to access only Apache Derby databases that run on the same node as the application server.

This provider:

– Does not support Version 4.0 data sources.
– Is configurable only in nodes at version 6.1 and later
– Uses the following one phase data source for the Derby Network Server using Derby Client provider:
  `org.apache.derby.jdbc.ClientConnectionPoolDataSource`
– Requires the following JDBC driver file:
  - derbyclient.jar
– Requires DataStoreHelper class:
  `com.ibm.websphere.rsadapter.DerbyNetworkServerDataStoreHelper`
– Requires the following property:

  databaseName
  The name of the database from which the data source obtains connections. If you do not specify a fully qualified path name, the application server uses the default location of *app_server_root*/derby or the equivalent default for AIX, HP-UX, Linux, or Solaris system environments. An example for the database path name is:

  If no database exists for the path name that you want to specify, configure the custom property, `createDatabase`, to a value of `create` to create the database dynamically.

- **Derby Network Server using Derby Client (XA)**

  Use this provider to access only Apache Derby databases that run on the same node as the application server.

  This provider:

  – Does not support Version 4.0 data sources.
  – Is configurable only in nodes at version 6.1 and later
  – Uses the following XA data source for this Derby Network Server using Derby Client provider:
    `org.apache.derby.jdbc.ClientXADataSource`
  – Requires the following JDBC driver file:
    - derbyclient.jar
  – Requires the DataStoreHelper class:
    `com.ibm.websphere.rsadapter.DerbyNetworkServerDataStoreHelper`
  – Requires the following property:

    databaseName
    The name of the database from which the data source obtains connections. If you do not specify a fully qualified path name, the application server uses the default location of *app_server_root*/derby or the equivalent default for AIX, HP-UX, Linux, or Solaris system environments. An example for the database path name is:

    If no database exists for the path name that you want to specify, configure the custom property, `createDatabase`, to a value of `create` to create the database dynamically.

- **Derby Network Server using Derby Client 40**

  Use this provider to access only Apache Derby databases that run on the same node as the application server.

  This provider:

  – Is configurable only in nodes at version 7.0 and later
  – Does not support Version 4.0 data sources.
  – Uses the following one phase data source for the Derby Network Server using Derby Client provider:
    `org.apache.derby.jdbc.ClientConnectionPoolDataSource40`
  – Requires the following JDBC driver file:
    - derbyclient.jar

– Requires DataStoreHelper class:
  `com.ibm.websphere.rsadapter.DerbyNetworkServerDataStoreHelper`
– Requires the following property:

  databaseName
  The name of the database from which the data source obtains connections. If you do not specify a fully qualified path name, the application server uses the default location of *app_server_root*/derby or the equivalent default for AIX, HP-UX, Linux, or Solaris system environments. An example for the database path name is:

  If no database exists for the path name that you want to specify, configure the custom property, `createDatabase`, to a value of `create` to create the database dynamically.

- **Derby Network Server using Derby Client 40 (XA)**

  Use this provider to access only Apache Derby databases that run on the same node as the application server.

  This provider:
  – Is configurable only in nodes at version 7.0 and later
  – Does not support Version 4.0 data sources.
  – Uses the following one phase data source for the Derby Network Server using Derby Client provider:
    `org.apache.derby.jdbc.ClientXADataSource40`
  – Requires the following JDBC driver file:
    - derbyclient.jar
  – Requires DataStoreHelper class:
    `com.ibm.websphere.rsadapter.DerbyNetworkServerDataStoreHelper`
  – Requires the following property:

    databaseName
    The name of the database from which the data source obtains connections. If you do not specify a fully qualified path name, the application server uses the default location of *app_server_root*/derby or the equivalent default for AIX, HP-UX, Linux, or Solaris system environments. An example for the database path name is:

    If no database exists for the path name that you want to specify, configure the custom property, `createDatabase`, to a value of `create` to create the database dynamically.

Data source minimum required settings for DB2 Universal Database for IBM i:

These properties vary according to the database vendor requirements for JDBC driver implementations. You must set the appropriate properties on every data source that you configure. These settings are for a DB2 UDB data source.

What type of configuration do you have?

- "DB2 UDB for iSeries with the application server for AIX, HP-UX, IBM i, Linux, Solaris, or Windows"

DB2 UDB for iSeries with the application server for AIX, HP-UX, IBM i, Linux, Solaris, or Windows

You can configure the following types of providers:

- DB2 UDB for iSeries (Native)
- DB2 UDB for iSeries (Native XA)
- DB2 UDB for iSeries (Toolbox)
- DB2 UDB for iSeries (Toolbox XA)
- **DB2 UDB for iSeries (Native)**

The iSeries Developer Kit for Java contains this Type 2 JDBC driver that is built on top of the iSeries DB2 Call Level Interface (CLI) native libraries.

This provider:

– Is for local DB2 connections on iSeries. It is not recommended for remote access.
– Supports the one-phase data source:

  `com.ibm.db2.jdbc.app.UDBConnectionPoolDataSource`
– Requires the following JDBC driver files:
  - db2_classes16.jar - for nodes that are running at Version 7.0 or later. The location of the jar file is `/QIBM/Proddata/java400/jdk6/lib/ext/db2_classes16.jar`.
  - db2_classes.jar - for nodes that are running at Version 6.1 or earlier. The location of the jar file is `/QIBM/ProdData/Java400/ext/db2_classes.jar`.
– Requires the following DataStoreHelper class:

  `com.ibm.websphere.rsadapter.DB2AS400DataStoreHelper`
– Does not require an authentication alias.
– Requires the following properties:
  - **databaseName** - The name of the relational database to which the data source connections are established. This name must appear in the iSeries Relational Database Directory. The default is *LOCAL.

• **DB2 UDB for iSeries (Native XA)**

The iSeries Developer Kit for Java contains this XA-compliant Type 2 JDBC driver built on top of the iSeries DB2 Call Level Interface (CLI) native libraries.

This provider:

– Is for local DB2 connections on iSeries. It is not recommended for remote access.
– Supports the following two-phase data source:

  `com.ibm.db2.jdbc.app.UDBXADataSource`
– Requires the following JDBC driver files:
  - db2_classes16.jar - for nodes that are running at Version 7.0 or later. The location of the jar file is `/QIBM/Proddata/java400/jdk6/lib/ext/db2_classes16.jar`.
  - db2_classes.jar - for nodes that are running at Version 6.1 or earlier. The location of the jar file is `/QIBM/ProdData/Java400/ext/db2_classes.jar`.
– Requires the following DataStoreHelper class:

  `com.ibm.websphere.rsadapter.DB2AS400DataStoreHelper`
– Does not require an authentication alias.
– Requires the following properties:
  - **databaseName** - The name of the relational database to which the data source connections are established. This name must appear in the iSeries Relational Database Directory. The default is *LOCAL.

• **DB2 UDB for iSeries (Toolbox)**

This JDBC driver, also known as iSeries Toolbox driver for Java, is provided in the DB2 for iSeries database server.

This provider:

– Is for remote DB2 connections on iSeries. Use this driver instead of the IBM Developer Kit for Java JDBC Driver to access remote DB2 UDB for iSeries systems.
– Supports the following one-phase data source:

  `com.ibm.as400.access.AS400JDBCConnectionPoolDataSource`
– Requires the following JDBC driver files:
  - jt400.jar
– Requires the following DataStoreHelper class:

com.ibm.websphere.rsadapter.DB2AS400DataStoreHelper

– Does not require an authentication alias if the application server and DB2 UDB for iSeries are installed in the same server. If they are installed in different servers, the user ID and password are required.
– Requires the following properties:
  - **serverName** - The name of the server from which the data source obtains connections. Example: *myserver.mydomain.com*.

- **DB2 UDB for iSeries (Toolbox XA)**

  This XA compliant JDBC driver, also known as iSeries Toolbox XA compliant driver for Java, is provided in the DB2 for iSeries database server.

  This provider:

  – Is for remote DB2 connections on iSeries. Use this driver instead of the IBM Developer Kit for Java JDBC Driver to access remote DB2 UDB for iSeries systems.
  – Supports the following two-phase data source:

    com.ibm.as400.access.AS400JDBCXADataSource

  – Requires the following JDBC driver files:
    - jt400.jar
  – Requires the following DataStoreHelper class:

    com.ibm.websphere.rsadapter.DB2AS400DataStoreHelper

  – Does not require an authentication alias if the application server and DB2 UDB for iSeries are installed in the same server. If they are installed in different servers, the user ID and password are required.
  – Requires the following properties:
    - **serverName** - The name of the server from which the data source obtains connections. Example: *myserver.mydomain.com*.

Data source minimum required settings for Informix:

These properties vary according to the database vendor requirements for JDBC driver implementations. You must set the appropriate properties on every data source that you configure. These settings are for Informix data sources.

You can configure the following types of providers:

- Informix JDBC Driver
- Informix JDBC Driver (XA)
- Informix Using IBM JCC Driver
- Informix Using IBM JCC Driver (XA)
- Informix Using IBM DB2 JDBC Universal Driver
- Informix Using IBM DB2 JDBC Universal Driver (XA)
- **Informix JDBC Driver**

  The Informix JDBC Driver is a Type 4 JDBC driver that provides JDBC access to the Informix database.

  Informix JDBC Driver supports one phase data source:

  com.informix.jdbcx.IfxConnectionPoolDataSource

  Requires the following JDBC driver files:

  ifxjdbc.jar
  ifxjdbcx.jar

  Requires the following DataStoreHelper class:

  com.ibm.websphere.rsadapter.InformixDataStoreHelper

Requires a valid authentication alias.

Requires the following properties:

– **serverName**

The name of the Informix instance on the server. Example: ol_myserver.

– **portNumber**

The port on which the instances listen. Example: 1526.

– **ifxIFXHOST**

Either the IP address or the host name of the machine that is running the Informix database to which you want to connect. Example: myserver.mydomain.com.

To support IPv6: On AIX and Solaris, IBM Informix Dynamic Server 10.00 with fix pack 1 supports the IPv6 standard. To enable IPv6 on your WebSphere Application Server connection with one of these Informix releases, input your full IPv6 host name for the ifxIFXHOST property.

– **databaseName**

The name of the database from which the data source obtains connections. Example: Sample.

– **informixLockModeWait**

Although not required, this property enables you to set the number of seconds that Informix software waits for a lock. By default, Informix code throws an exception if it cannot immediately acquire a lock. Example: 2.

• **Informix JDBC Driver (XA)**

The Informix JDBC Driver (XA) is a Type 4 JDBC driver that provides XA-compliant JDBC access to the Informix database.

Informix JDBC Driver (XA) supports two phase data source:

```
com.informix.jdbcx.IfxXADataSource
```

Requires the following JDBC driver files:

```
ifxjdbc.jar
ifxjdbcx.jar
```

To use SQLJ: This provider also requires driver file ifxsqlj.jar if you plan to use SQLJ for queries.

Requires the following DataStoreHelper class:

```
com.ibm.websphere.rsadapter.InformixDataStoreHelper
```

Requires a valid authentication alias.

Requires the following properties:

– **serverName**

The name of the Informix instance on the server. Example: ol_myserver.

– **portNumber**

The port on which the instances listen. Example: 1526.

– **ifxIFXHOST**

Either the IP address or the host name of the machine that is running the Informix database to which you want to connect. Example: myserver.mydomain.com.

To support IPv6: On AIX and Solaris, IBM Informix Dynamic Server 10.00 with fix pack 1 supports the IPv6 standard. To enable IPv6 on your WebSphere Application Server connection with one of these Informix releases, input your full IPv6 host name for the ifxIFXHOST property.

– **databaseName**

The name of the database from which the data source obtains connections. Example: Sample.

– **ifxIFX_XASPEC**

Turn on this property when multiple users access the same database. Activating the property enforces tight coupling of XA transactions within the same global transaction ID, and requires the transactions to share lock space.

These parameters help prevent transaction management errors from occurring in the case of multiple client requests.

Turn on the ifxIFX_XASPEC property by assigning it the value of `Y` or `y`; either character works because the setting is not case-specific. Turn the property off by assigning it the value of `N` or `n`. WebSphere Application Server ignores all other values. Your setting for the property overrides the Informix database system setting.

– **informixLockModeWait**

Although not required, this property enables you to set the number of seconds that Informix software waits for a lock. By default, Informix code throws an exception if it cannot immediately acquire a lock. Example: 2.

- **Informix Using IBM JCC Driver**

The Informix IBM JCC Driver is a one-phase commit provider for Informix that uses the IBM Data Server Driver for JDBC and SQLJ. The IBM Data Server Driver is JDBC 4.0 compliant and is the next generation of the Universal JCC driver.

This provider is configurable in version 7.0 and later nodes.

The following one-phase data source is supported:

```
com.ibm.db2.jcc.DB2ConnectionPoolDataSource
```

The following JDBC driver files are required:

```
db2jcc4.jar
db2jcc_license_cu.jar
db2jcc_license_cisuz.jar
```

as well as the following DataStoreHelper class:

```
com.ibm.websphere.rsadapter.InformixJccDataStoreHelper
```

This provider requires a valid authentication alias.

The following properties are required:

– **serverName** - The TCP/IP address or host name for the Informix server.

– **portNumber** - The TCP/IP port number where the Informix server resides.

– **databaseName** - The name of the database from which the data source obtains connections. Example: *Sample*.

- **Informix Using IBM JCC Driver (XA)**

The Informix IBM JCC Driver (XA) is a two-phase commit provider for Informix that uses the IBM Data Server Driver for JDBC and SQLJ. The IBM Data Server Driver is JDBC 4.0 compliant and is the next generation of the Universal JCC driver.

This provider is configurable in version 7.0 and later nodes.

The following two-phase data source is supported:

```
com.ibm.db2.jcc.DB2XADataSource
```

The following JDBC driver files are required:

```
db2jcc4.jar
db2jcc_license_cu.jar
db2jcc_license_cisuz.jar
```

as well as the following DataStoreHelper class:

```
com.ibm.websphere.rsadapter.InformixJccDataStoreHelper
```

Note: If you plan to use SQLJ for queries, this provider also requires driver file `ifxsqlj.jar`.

This provider requires a valid authentication alias.

The following properties are required:

– **serverName** - The TCP/IP address or host name for the Informix server.

– **portNumber** - The TCP/IP port number where the Informix server resides.

– **databaseName** - The name of the database from which the data source obtains connections. Example: *Sample*.

Note: You cannot use Informix XA data sources with ANSI databases if SQL statements are issued in local transactions instead of global transactions. This scenario might occur within the application code or within a component of Application Server such as scheduler. The following message might be logged if you are experiencing this problem:

```
java.sql.SQLException: Already in transaction.
       at com.informix.util.IfxErrMsg.getSQLException(IfxErrMsg.java:398)
       at com.informix.jdbc.IfxSqli.a(IfxSqli.java:3247)
       at com.informix.jdbc.IfxSqli.E(IfxSqli.java:3556)
       at com.informix.jdbc.IfxSqli.dispatchMsg(IfxSqli.java:2382)
       at com.informix.jdbcx.IfxXASqli.receiveMessage(IfxXASqli.java:120)
       at com.informix.jdbc.IfxSqli.X(IfxSqli.java:7926)
       at com.informix.jdbc.IfxSqli.a(IfxSqli.java:854)
       at com.informix.jdbc.IfxSqli.executeCommand(IfxSqli.java:749)
       at com.informix.jdbc.IfxResultSet.b(IfxResultSet.java:293)
       at com.informix.jdbc.IfxStatement.c(IfxStatement.java:1269)
       at com.informix.jdbc.IfxStatement.b(IfxStatement.java:423)
       at com.informix.jdbc.IfxStatement.executeUpdate(IfxStatement.java:277)
       at com.informix.jdbc.IfxSqliConnect.setTransactionIsolation(IfxSqliConnect.java:2565)
```

To avoid this issue:

– Switch to a non-ANSI database.

– If the error is triggered by an application, update the application such that it always runs in a global transaction.

- **Informix Using IBM DB2 JDBC Universal Driver**

  The Informix JDBC Driver is a Type 4 JDBC driver that is JDBC 3.0 compliant and provides access to the Informix database.

  This provider supports the following one-phase data source:

  ```
  com.ibm.db2.jcc.DB2ConnectionPoolDataSource
  ```

  The following JDBC driver files are required:

  ```
  db2jcc.jar
  db2jcc_license_cu.jar
  db2jcc_license_cisuz.jar
  ```

  as well as the following DataStoreHelper class:

  ```
  com.ibm.websphere.rsadapter.InformixJccDataStoreHelper
  ```

  This provider requires a valid authentication alias.

  The following properties are required:

  – **serverName** - The TCP/IP address or host name for the Informix server.

  – **portNumber** - The TCP/IP port number where the Informix server resides.

  – **databaseName** - The name of the database from which the data source obtains connections. Example: *Sample*.

- **Informix Using IBM DB2 JDBC Universal Driver (XA)**

  The Informix Using JDBC Driver (XA) is a Type 4 JDBC driver that is JDBC 3.0 compliant and provides XA-compliant JDBC access to the Informix database.

  This provider supports the following two-phase data source:

  ```
  com.ibm.db2.jcc.DB2XADataSource
  ```

  The following JDBC driver files are required:

  ```
  db2jcc.jar
  db2jcc_license_cu.jar
  db2jcc_license_cisuz.jar
  ```

  as well as the following DataStoreHelper class:

  ```
  com.ibm.websphere.rsadapter.InformixJccDataStoreHelper
  ```

This provider requires a valid authentication alias.

The following properties are required:

– **serverName** - The TCP/IP address or host name for the Informix server.
– **portNumber** - The TCP/IP port number where the Informix server resides.
– **databaseName** - The name of the database from which the data source obtains connections. Example: *Sample*.

Note: You cannot use Informix XA data sources with ANSI databases if SQL statements are issued in local transactions instead of global transactions. This scenario might occur within the application code or within a component of Application Server such as scheduler. The following message might be logged if you are experiencing this problem:

```
java.sql.SQLException: Already in transaction.
       at com.informix.util.IfxErrMsg.getSQLException(IfxErrMsg.java:398)
       at com.informix.jdbc.IfxSqli.a(IfxSqli.java:3247)
       at com.informix.jdbc.IfxSqli.E(IfxSqli.java:3556)
       at com.informix.jdbc.IfxSqli.dispatchMsg(IfxSqli.java:2382)
       at com.informix.jdbcx.IfxXASqli.receiveMessage(IfxXASqli.java:120)
       at com.informix.jdbc.IfxSqli.X(IfxSqli.java:7926)
       at com.informix.jdbc.IfxSqli.a(IfxSqli.java:854)
       at com.informix.jdbc.IfxSqli.executeCommand(IfxSqli.java:749)
       at com.informix.jdbc.IfxResultSet.b(IfxResultSet.java:293)
       at com.informix.jdbc.IfxStatement.c(IfxStatement.java:1269)
       at com.informix.jdbc.IfxStatement.b(IfxStatement.java:423)
       at com.informix.jdbc.IfxStatement.executeUpdate(IfxStatement.java:277)
       at com.informix.jdbc.IfxSqliConnect.setTransactionIsolation(IfxSqliConnect.java:2565)
```

Data source minimum required settings for Microsoft SQL Server:

These properties vary according to the database vendor requirements for Java Database Connectivity (JDBC) driver implementations. You must set the appropriate properties on every data source that you configure. These settings are for Microsoft SQL Server data sources.

The application server also supports two options for setting isolation level in Microsoft SQL Server: SNAPSHOT and READ_COMMITTED_SNAPSHOT.

Table 28. Isolation levels in Microsoft SQL Server. The following table describes these isolation levels and configuration considerations.

JDBC provider	Microsoft SQL Server feature	Configuration consideration
Microsoft SQL Server JDBC Driver	SNAPSHOT isolation level	Set the isolation level constant by invoking the setTransactionIsolation method with one of the following attributes: • conn.setTransactionIsolation (com.microsoft.sqlserver.jdbc. SQLServerConnection. TRANSACTION_SNAPSHOT) • conn.setTransactionIsolation(*value_of_constant*)
	READ_COMMITTED_SNAPSHOT isolation level	This isolation level is an implementation of the Read committed isolation level. The policy enforces optimistic locking for read operations with Microsoft SQL Server. 1. Configure the isolation level on the database. 2. Invoke the setTransactionIsolation method with the conn.setTransactionIsolation (java.sql.Connection. TRANSACTION_READ_COMMITTED) attribute.

Table 28. Isolation levels in Microsoft SQL Server (continued). The following table describes these isolation levels and configuration considerations.

JDBC provider	Microsoft SQL Server feature	Configuration consideration
DataDirect ConnectJDBC type 4 driver for Microsoft SQL Server	SNAPSHOT isolation level	This isolation level implements optimistic locking for transactions in which Microsoft SQL Server serializes the data. Configure the ALLOW_SNAPSHOT_ISOLATION setting on the database, and then set the isolation level in one of two ways: • By isolation level constant. Invoke the setTransactionIsolation method with one of the following attributes: – conn.setTransactionIsolation (com.ddtek.jdbc.extensions. ExtConstants.TRANSACTION_SNAPSHOT) – conn.setTransactionIsolation(16) • By the custom data source property: – Set the data source custom property snapshotSerializable to `true`. – Invoke the setTransactionIsolation method with the conn.setTransactionIsolation (java.sql.Connection. TRANSACTION_SERIALIZABLE) attribute:
	READ_COMMITTED_SNAPSHOT isolation level	This isolation level is an implementation of the Read committed isolation level. The policy enforces optimistic locking for read operations with Microsoft SQL Server. 1. Configure the isolation level on the database. 2. Invoke the setTransactionIsolation method with the conn.setTransactionIsolation (java.sql.Connection. TRANSACTION_READ_COMMITTED) attribute.

Consult the Backward Compatibility for Microsoft SQL Server components web page for a complete list of deprecated items, as well as backward compatibility provisions, for Microsoft SQL Server.

You can configure the following types of providers:

- Microsoft SQL Server JDBC Driver
- Microsoft SQL Server JDBC Driver (XA)
- DataDirect ConnectJDBC type 4 driver for Microsoft SQL Server
- DataDirect ConnectJDBC type 4 driver for Microsoft SQL Server (XA)
- **Microsoft SQL Server JDBC Driver**

  The Microsoft SQL Server JDBC driver supports this data source:

  `com.microsoft.sqlserver.jdbc.SQLServerConnectionPoolDataSource`

  The JDBC provider requires the following Java archive (JAR) files:

  `sqljdbc4.jar`

  The JDBC provider requires the following DataStoreHelper class:

  `com.ibm.websphere.rsadapter.MicrosoftSQLServerDataStoreHelper`

  The JDBC provider requires a valid authentication alias.

  The JDBC driver requires the following properties:

  serverName
  Specifies the name of the server in which Microsoft SQL Server resides. Example: myserver.mydomain.com

  portNumber
  Specifies the TCP/IP port that Microsoft SQL Server uses for communication. Port 1433 is the default.

databaseName
Specifies the name of the database from which the data source obtains connections. Example: Sample.

- **Microsoft SQL Server JDBC Driver (XA)**

  This JDBC provider supports this data source:

  com.microsoft.sqlserver.jdbc.SQLServerXADataSource

  The JDBC provider requires the following Java archive (JAR) files:

  sqljdbc4.jar

  The JDBC provider requires the following DataStoreHelper class:

  com.ibm.websphere.rsadapter.MicrosoftSQLServerDataStoreHelper

  The JDBC provider requires a valid authentication alias.

  The JDBC driver requires the following properties:

  serverName
  Specifies the name of the server in which Microsoft SQL Server resides. Example: myserver.mydomain.com

  portNumber
  Specifies the TCP/IP port that Microsoft SQL Server uses for communication. Port 1433 is the default.

  databaseName
  Specifies the name of the database from which the data source obtains connections. Example: Sample.

- **DataDirect ConnectJDBC type 4 driver for Microsoft SQL Server**

  DataDirect ConnectJDBC type 4 driver for Microsoft SQL Server is a Type 4 JDBC driver that provides JDBC access to the Microsoft SQL Server databases. This provider is for use only with the Connect JDBC driver purchased from DataDirect Technologies.

  This JDBC provider supports the following data source:

  com.ddtek.jdbcx.sqlserver.SQLServerDataSource

  Requires JDBC driver files:

  sqlserver.jar

  Requires **DataStoreHelper** class:

  com.ibm.websphere.rsadapter.ConnectJDBCDataStoreHelper

  Requires a valid authentication alias.

  Requires properties:

  – **serverName** The name of the server in which Microsoft SQL Server resides. Example: *myserver.mydomain.com*
  – **portNumber** The TCP/IP port that Microsoft SQL Server uses for communication. Port 1433 is the default.
  – **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

- **DataDirect ConnectJDBC type 4 driver for Microsoft SQL Server (XA)**

  DataDirect ConnectJDBC type 4 driver for Microsoft SQL Server (XA) is a Type 4 JDBC driver which provides XA-compliant JDBC access to the Microsoft SQL Server databases. This provider is for use only with the Connect JDBC driver purchased from DataDirect Technologies.

  This JDBC provider supports this data source:

  com.ddtek.jdbcx.sqlserver.SQLServerDataSource.

  Requires JDBC driver files:

  sqlserver.jar

  Requires **DataStoreHelper** class:

  com.ibm.websphere.rsadapter.ConnectJDBCDataStoreHelper

  Requires a valid authentication alias.

Requires properties:
– **serverName** The name of the server in which Microsoft SQL Server resides. Example: *myserver.mydomain.com*
– **portNumber** The TCP/IP port that Microsoft SQL Server uses for communication. Port 1433 is the default.
– **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

Data source minimum required settings for Oracle:

These properties vary according to the database vendor requirements for JDBC driver implementations. You must set the appropriate properties on every data source that you configure. These settings are for Oracle data sources.

You can configure the following types of providers:
- Oracle JDBC Driver
- Oracle JDBC Driver (XA)
- **Oracle JDBC Driver**

  The Oracle JDBC Driver provides JDBC access to the Oracle database. This JDBC driver supports both Type 2 JDBC access and Type 4 JDBC access.

  This provider:
  – Supports one-phase data source:

    `oracle.jdbc.pool.OracleConnectionPoolDataSource`
  – Requires the following JDBC driver files:
    - ojdbc6.jar.

      Note: Be aware of the following:
      - Oracle does not support the use of `ojdbc5.jar` in an environment with the Java SE Development Kit Version 6 or later.
      - In mixed node environments, the data source wizard in the administrative console allows you to choose a class path for `ojdbc6.jar` or `ojdbc5.jar`.
      - For Oracle trace, use `ojdbc`*`version`*`_g.jar`.
  – Requires the following DataStoreHelper class:

    `com.ibm.websphere.rsadapter.Oracle11gDataStoreHelper`

    Note: You must use the Oracle11gDataStoreHelper with the `ojdbc6.jar` driver file, regardless of whether you use an Oracle 11g or Oracle 10g database server.
  – Requires a valid authentication alias.
  – Requires properties:

    URL The URL that indicates the database from which the data source obtains connections. For example:

    `jdbc:oracle:thin:@//`*`myServer`*`:1521/`*`myDatabase`*

    where *myServer* is the server name, *1521* is the port that the server uses for communication, and *myDatabase* is the database name.
- **Oracle JDBC Driver (XA)**

  The Oracle JDBC Driver (XA) provides XA-compliant JDBC access to the Oracle database. This JDBC driver supports both Type 2 JDBC access and Type 4 JDBC access.

  This provider:
  – Supports two-phase data source:

    `oracle.jdbc.xa.client.OracleXADataSource`
  – Requires the following JDBC driver files:
    - `ojdbc6.jar`

Note: Be aware of the following notes regarding the use of these driver files:
- Oracle does not support the use of `ojdbc5.jar` in an environment with the Java SE Development Kit Version 6 or later.
- In mixed node environments, the data source wizard in the administrative console allows you to choose a class path for `ojdbc6.jar` or `ojdbc5.jar`.
- For Oracle trace, use `ojdbc`*`version`*`_g.jar`.

– Requires the following DataStoreHelper class:

  `com.ibm.websphere.rsadapter.Oracle11gDataStoreHelper`

  Note: You must use the Oracle11gDataStoreHelper with the `ojdbc6.jar` driver file, regardless of whether you use an Oracle 11g or Oracle 10g database server.
– Requires a valid authentication alias.
– Requires properties:

  URL Indicates the database from which the data source obtains connections. For example:

  `jdbc:oracle:thin:@//`*`myServer`*`:1521/`*`myDatabase`*

  where *myServer* is the server name, *1521* is the port that the server uses for communication, and *myDatabase* is the database name.

Data source minimum required settings for Sybase:

These properties vary according to the database vendor requirements for JDBC driver implementations. You must set the appropriate properties on every data source that you configure. These settings are for Sybase data sources.

What types of providers can you configure?

You can configure the following types of providers:
- Sybase JDBC 4 Driver
- Sybase JDBC 4 Driver (XA)
- Sybase JDBC 3 Driver
- Sybase JDBC 3 Driver (XA)
- Sybase JDBC 2 Driver
- Sybase JDBC 2 Driver (XA)

Sybase JDBC 4 Driver

The Sybase JDBC 4 Driver is a Type 4 JDBC driver that provides JDBC access to the Sybase database.

This provider:
- Uses jConnect Version 7.0
- Supports one phase data source:

  `com.sybase.jdbc4.jdbc.SybConnectionPoolDataSource`
- Requires the following JDBC driver files:

  `jconn4.jar`
- Requires the following DataStoreHelper class:

  `com.ibm.websphere.rsadapter.SybaseDataStoreHelper`
- Requires a valid authentication alias.
- Requires the following properties:
  – **serverName** - The name of the database server. Example: *myserver.mydomain.com*.
  – **databaseName** - The name of the database from which the data source obtains connections. Example: *Sample*.
  – **portNumber** - The TCP/IP port number through which all communications to the server take place. Example: *5000*.

– **connectionProperties** - A custom property required for applications containing EJB 2.0 enterprise beans. Value: `SELECT_OPENS_CURSOR=true` (Type: java.lang.String)

Sybase JDBC 4 Driver (XA)

The Sybase JDBC 4 Driver (XA) is a Type 4 JDBC driver that provides XA-compliant JDBC access to the Sybase database.

This provider:
- Uses jConnect Version 7.0
- Supports two phase data source:
  `com.sybase.jdbc4.jdbc.SybXADataSource`
- Requires JDBC driver files:
  `jconn4.jar`
- Requires the following DataStoreHelper class:
  `com.ibm.websphere.rsadapter.SybaseDataStoreHelper`
- Requires a valid authentication alias.
- Requires the following properties:
  – **serverName** - The name of the database server. Example: *myserver.mydomain.com*
  – **databaseName** - The name of the database from which the data source obtains connections. Example: *Sample*.
  – **portNumber** - The TCP/IP port number through which all communications to the server take place. Example: *5000*.
  – **connectionProperties** - A custom property required for applications containing EJB 2.0 enterprise beans. Value: `SELECT_OPENS_CURSOR=true` (Type: java.lang.String)

Sybase JDBC 3 Driver

The Sybase JDBC 3 Driver is a Type 4 JDBC driver that provides JDBC access to the Sybase database.

This provider:
- Uses jConnect Version 6.05
- Supports one phase data source:
  `com.sybase.jdbc3.jdbc.SybConnectionPoolDataSource`
- Requires the following JDBC driver files:
  `jconn3.jar`
- Requires the following DataStoreHelper class:
  `com.ibm.websphere.rsadapter.SybaseDataStoreHelper`
- Requires a valid authentication alias.
- Requires the following properties:
  – **serverName** - The name of the database server. Example: *myserver.mydomain.com*.
  – **databaseName** - The name of the database from which the data source obtains connections. Example: *Sample*.
  – **portNumber** - The TCP/IP port number through which all communications to the server take place. Example: *5000*.
  – **connectionProperties** - A custom property required for applications containing EJB 2.0 enterprise beans. Value: `SELECT_OPENS_CURSOR=true` (Type: java.lang.String)

Sybase JDBC 3 Driver (XA)

The Sybase JDBC 3 Driver (XA) is a Type 4 JDBC driver that provides XA-compliant JDBC access to the Sybase database.

This provider:
- Uses jConnect Version 6.05

- Supports two phase data source:
  `com.sybase.jdbc3.jdbc.SybXADataSource`
- Requires JDBC driver files:
  `jconn3.jar`
- Requires the following DataStoreHelper class:
  `com.ibm.websphere.rsadapter.SybaseDataStoreHelper`
- Requires a valid authentication alias.
- Requires the following properties:
  - **serverName** - The name of the database server. Example: *myserver.mydomain.com*
  - **databaseName** - The name of the database from which the data source obtains connections. Example: *Sample*.
  - **portNumber** - The TCP/IP port number through which all communications to the server take place. Example: *5000*.
  - **connectionProperties** - A custom property required for applications containing EJB 2.0 enterprise beans. Value: `SELECT_OPENS_CURSOR=true` (Type: java.lang.String)

Sybase JDBC 2 Driver

The Sybase JDBC 2 Driver is a Type 4 JDBC driver that provides JDBC access to the Sybase database.

This provider:
- Uses jConnect Version 5.5
- Supports one phase data source:
  `com.sybase.jdbc2.jdbc.SybConnectionPoolDataSource`
- Requires the following JDBC driver files:
  `jconn2.jar`
- Requires the following DataStoreHelper class:
  `com.ibm.websphere.rsadapter.SybaseDataStoreHelper`
- Requires a valid authentication alias.
- Requires the following properties:
  - **serverName** - The name of the database server. Example: *myserver.mydomain.com*.
  - **databaseName** - The name of the database from which the data source obtains connections. Example: *Sample*.
  - **portNumber** - The TCP/IP port number through which all communications to the server take place. Example: *5000*.
  - **connectionProperties** - A custom property required for applications containing EJB 2.0 enterprise beans. Value: `SELECT_OPENS_CURSOR=true` (Type: java.lang.String)

Sybase JDBC 2 Driver (XA)

The Sybase JDBC 2 Driver (XA) is a Type 4 JDBC driver that provides XA-compliant JDBC access to the Sybase database.

This provider:
- Uses jConnect Version 5.5
- Supports two phase data source:
  `com.sybase.jdbc2.jdbc.SybXADataSource`
- Requires JDBC driver files:
  `jconn2.jar`
- Requires the following DataStoreHelper class:
  `com.ibm.websphere.rsadapter.SybaseDataStoreHelper`
- Requires a valid authentication alias.
- Requires the following properties:
  - **serverName** - The name of the database server. Example: *myserver.mydomain.com*

– **databaseName** - The name of the database from which the data source obtains connections. Example: *Sample*.
– **portNumber** - The TCP/IP port number through which all communications to the server take place. Example: *5000*.
– **connectionProperties** - A custom property required for applications containing EJB 2.0 enterprise beans. Value: `SELECT_OPENS_CURSOR=true` (Type: java.lang.String)

Configuring a JDBC provider using the administrative console

To create connections between an application and a relational database, the application server uses the driver implementation classes that are encapsulated by the Java Database Connectivity (JDBC) provider.

Before you begin

Each JDBC provider is essentially an object that represents vendor-specific JDBC driver classes to the application server, for establishing access to that particular vendor database. JDBC providers are prerequisites for data sources, which supply applications with the physical connections to a database. Consult the JDBC provider table to identify the appropriate JDBC provider for your database and application requirements.

About this task

Configure at least one JDBC provider for each database server that you plan to use at a particular scope within your application server environment.

Procedure

1. Open the administrative console.
2. Click **Resources** > **JDBC** > **JDBC Providers**.
3. Select the scope at which applications can use the JDBC provider. The scope that you select becomes the scope of any data source that you associate with this provider. You can choose a cell, node, cluster, or server. For more information about scope and how it can affect resources, see the information center topic on administrative scope settings.
4. Click **New**. This action causes the **Create a new JDBC Provider** wizard to launch.
5. Use the first drop-down list to select the database type of the JDBC provider that you must create.

   The User-Defined option: Select **User-Defined** for your database type if you encounter either of the following scenarios:
   - You do not see your database type.
   - You cannot select the JDBC provider type that you need in the next step.

   The user-defined selection triggers the wizard panel to display your provider type as a user-defined JDBC provider, and your implementation type as user-defined. Consult your database documentation for the JDBC driver class files, data source properties, and so on, that are required for your user-defined provider. You must supply this information about the next two panels:
   - database class path
   - database-specific properties
6. Select your JDBC provider type if it is displayed in the second drop-down list. Select **Show Deprecated** to trigger the display of both current and deprecated providers. If you cannot find your provider in this expanded list, then select **User-Defined** from the previous list of database types.
7. From the third drop-down list, select the implementation type that is necessary for your application. If your application does not require that connections support two-phase commit transactions, choose **Connection Pool Data Source**. Choose **XA Data Source**, however, if your application requires

connections that support two-phase commit transactions. Applications that use this data source configuration have the benefit of container-managed transaction recovery.

After you select an implementation type, the wizard fills the name and the description fields for your JDBC provider. You can type different values for these fields; they exist for administrative purposes only.

8. Click **Next** to see the **Enter database class path information** wizard panel.
9. In the class path field, type the full path location of the database JDBC driver class files. Your class path information becomes the value of the WebSphere environment variable that is displayed on this panel, in the form of ${*DATABASE*_JDBC_DRIVER_PATH}. The application server uses the variable to define your JDBC provider; this practice eliminates the must specify static JDBC class paths for individual applications. Remember that if you do not provide the full, correct JDBC driver class path for the variable, your data source ultimately fails. If the field already displays a fully qualified class path, you can accept that variable definition by completing the rest of this wizard panel and clicking **Next**.

   Note: The application server supports multiple versions of the selected JDBC driver for the DataDirect ConnectJDBC type 4 driver for MS SQL Server. Each version of the JDBC driver has a unique class path. Select the appropriate version of the JDBC driver so the class path is populated correctly.
10. Use the Native library path field to specify additional class files that your JDBC driver might require to function properly on your application server platform. Type the full directory path name of these class files.

    gotcha: If you are using an Oracle OCI driver as your JDBC provider, you must specify the path to where the native libraries are stored. If you do not specify a native library path, the first time you try to connect using this provider, class loader errors occur.
11. Click **Next** to see a summary of your JDBC provider settings.
12. Click **Finish** if you are satisfied with the JDBC provider configuration. You now see the JDBC provider collection panel, which displays your new JDBC provider in a table along with other providers that are configured for the same scope.

What to do next

The next step is to create a data source to associate with your JDBC provider. For detailed information, see the information center topic on configuring a data source using the administrative console.

Remember: If you modify configuration of a JDBC provider, like the class path, native library path, or custom properties, click **OK** and then restart every application server within the scope of that JDBC provider. Otherwise, the new configuration does not work and you receive data source failure messages.

JDBC provider collection:

Use this page to view JDBC providers. The JDBC provider object encapsulates the specific JDBC driver implementation class for the data sources that you define and associate with the provider.

To view this administrative console page, click **Resources** > **JDBC** > **JDBC providers** .

Name:

Specifies a text identifier for this provider.

For example, this field can be *DB2 JDBC Provider (XA)*.

Data type String

Scope:

Specifies the scope of the JDBC provider; if you use any scope other than the default of *Node*, the provider might not be available in other scope contexts. Data sources that are created with this JDBC provider inherit this scope.

Description:

Specifies a text string describing this provider.

Data type String

JDBC provider settings:

Use this page to modify the settings for a JDBC provider.

To view this administrative console page, click **Resources** > **JDBC** > **JDBC providers** > ***JDBC_provider***.

Important: If you use this page to modify the class path or native library path of an existing JDBC provider: After you apply and save the new settings, you must restart every application server within the scope of that JDBC provider for the new configuration to work. Otherwise, you receive a data source failure message.

Scope:

Specifies the scope of the JDBC provider; data sources that are created with this JDBC provider inherit this scope.

Name:

Specifies the name of the resource provider.

Data type String

Description:

Specifies a text description for the resource provider.

Data type String

Class path:

Specifies a list of paths or JAR file names which together form the location for the resource provider classes.

For example:

- *QIBM/ProdData/Java400/ext/db2_classes.jar* for iSeries platforms.

Class path entries are separated by using the ENTER key and must not contain path separator characters (such as ';' or ':'). Class paths contain variable (symbolic) names which you can substitute using a variable map. Check the driver installation notes for the specific required JAR file names.

Data type String

Native Library Path:

Specifies a list of paths that forms the location for the resource provider native libraries.

Native path entries are separated by using the ENTER key and must not contain path separator characters (such as ';' or ':'). Native paths can contain variable (symbolic) names which you can substitute using a variable map.

Data type String

Isolate this resource provider:

Specifies that this resource provider will be loaded in its own class loader. This allows different versions or implementations of the same resource provider to be loaded in the same Java Virtual Machine. Give each version of the resource provider a unique class path that is appropriate for that version or implementation.

Note: Be aware of the following:

- You cannot isolate a resource provider if you specify a native library path. The Application Server will define a value for the native library path for some JDBC providers; this behavior is intended to help you configure your provider when a native library path is necessary. If you do not require the native library path, delete the value, and you will be able to select the option to isolate the resource provider.
- If you are running a mixed cell environment, the application server will remove any isolated JDBC providers from nodes that are running at versions earlier than 7.0 if the provider is scoped for a version 7.0 cell, and you have not migrated the provider from an older release. If you want to use isolated resources at the cell level, do not use the resources in nodes that are running at versions earlier than 7.0. Define a resource at the node level, or avoid using the resource in nodes that are earlier than version 7.0, because this will result in a "Naming not found" exception when the application server attempts to perform a lookup on an isolated resource at the cell level.

Implementation class name:

Specifies the Java class name of the JDBC driver implementation.

This class is available in the driver file mentioned in the class path description above.

For example, *com.ibm.db2.jdbc.app.UDBXADataSource* for iSeries platforms.

Note: If you modify the implementation class name of the JDBC provider after you have created the provider, you might disconnect the provider from the template used to create it. As a result, data sources created from this JDBC provider do not have an associated template; you must manually configure a working data source through setting custom properties.

Data type String

JDBC provider summary:

JDBC providers are prerequisites for data sources, which supply applications with the physical connections to a database.

Use these tables for quick reference on database-specific JDBC providers.

Table 29. Apache Derby JDBC providers. Use the table for quick reference on database-specific JDBC providers.

Apache Derby		
JDBC provider	**Transaction support**	**Version and other considerations**
Derby JDBC Provider	One-phase	• Does not support Version 4 data sources • Configurable only in nodes at version 6.0.2 and later • Not for use in clustered environment: accessible from a single JVM only
Derby JDBC Provider (XA)	One and two phase	• Does not support Version 4 data sources • Configurable only in nodes at version 6.0.2 and later • Not for use in clustered environment: accessible from a single JVM only
Derby JDBC Provider 40	One-phase	• Configurable only in nodes at version 7.0 and later • Does not support Version 4 data sources
Derby JDBC Provider 40 (XA)	One and two phase	• Configurable only in nodes at version 7.0 and later • Does not support Version 4 data sources
Derby Network Server Using Derby Client	One-phase	• Does not support Version 4.0 data sources. • Configurable only in nodes at version 6.1 and later • *Can be used in clustered environment:* a database instance can be accessed by multiple JVMs • Only for use with Apache Derby databases that run on the same node as the application server
Derby Network Server Using Derby Client (XA)	One and two phase	• Does not support Version 4 data sources • Configurable only in nodes at version 6.1 and later • *Can be used in clustered environment:* a database instance can be accessed by multiple JVMs • Only for use with Apache Derby databases that run on the same node as the application server
Derby Network Server Using Derby Client 40	One-phase	• Configurable only in nodes at version 7.0 and later • Does not support Version 4 data sources

Table 29. Apache Derby JDBC providers (continued). Use the table for quick reference on database-specific JDBC providers.

Apache Derby		
JDBC provider	**Transaction support**	**Version and other considerations**
Derby Network Server Using Derby Client 40 (XA)	One and two phase	• Configurable only in nodes at version 7.0 and later • Does not support Version 4 data sources

Table 30. DB2 on AIX, HP-UX, Linux, Solaris, and Windows systems JDBC providers. Use the table for quick reference on database-specific JDBC providers.

DB2 on AIX, HP-UX, Linux, Solaris, and Windows systems		
JDBC provider	**Transaction support**	**Version and other considerations**
DB2 Using IBM JCC Driver	One-phase	• Configurable in nodes that are at version 7.0 and later.
DB2 Using IBM JCC Driver (XA)	One and two phase	• Configurable in nodes that are at version 7.0 and later.
DB2 Universal JDBC Provider	One-phase	N/A
DB2 Universal JDBC Provider (XA)	One and two phase	N/A

Table 31. DB2 UDB for iSeries JDBC providers. Use the table for quick reference on database-specific JDBC providers.

DB2 UDB for iSeries		
JDBC provider	**Transaction support**	**Version and other considerations**
DB2 UDB for iSeries (Native)	One-phase	Recommended when you run the application server on iSeries.
DB2 UDB for iSeries (Native XA)	One and two phase	Recommended when you run the application server on iSeries.
DB2 UDB for iSeries (Toolbox)	One-phase	N/A
DB2 UDB for iSeries (Toolbox XA)	One and two phase	N/A

Table 32. DB2 on z/OS JDBC providers. Use the table for quick reference on database-specific JDBC providers.

DB2 on z/OS		
JDBC provider	**Transaction support**	**Version and other considerations**
DB2 Using IBM JCC Driver	One-phase	Configurable in version 7.0 and later nodes.
DB2 Using IBM JCC Driver (XA)	One and two phase	Configurable version 7.0 and later nodes.
DB2 Universal JDBC Provider	One-phase when connecting to the application server that is on AIX, HP-UX, Linux, Solaris, Windows, and iSeries systems	
DB2 Universal JDBC Provider (XA)	One and two phase	

Table 33. Informix JDBC providers. Use the table for quick reference on database-specific JDBC providers.

Informix		
JDBC provider	**Transaction support**	**Version and other considerations**
Informix Using IBM JCC Driver	One phase	This provider is configurable in nodes that are at version 7.0 and later.
Informix Using IBM JCC Driver (XA)	One and two phase	This provider is configurable in nodes that are at version 7.0 and later.
Informix JDBC Driver	One-phase	N/A
Informix JDBC Driver (XA)	One and two phase	N/A
Informix using IBM DB2 JDBC Universal Driver	One phase	This provider is configurable in nodes that are at version 7.0 and later.
Informix using IBM DB2 JDBC Universal Driver (XA)	One and two phase	This provider is configurable in nodes that are at version 7.0 and later.

Table 34. Microsoft SQL Server JDBC providers. Use the table for quick reference on database-specific JDBC providers.

Microsoft SQL Server		
JDBC provider	**Transaction support**	**Version and other considerations**
Microsoft SQL Server JDBC Driver	One-phase	N/A
Microsoft SQL Server JDBC Driver (XA)	One and two phase	N/A
DataDirect ConnectJDBC Provider type 4 driver for MS SQL Server	One-phase	N/A
DataDirect ConnectJDBC Provider, type 4 driver, for MS SQL Server (XA)	One and two phase	N/A

Table 35. Oracle JDBC providers. Use the table for quick reference on database-specific JDBC providers.

Oracle		
JDBC provider	**Transaction support**	**Version and other considerations**
Oracle JDBC Driver	One-phase	Must use the ojdbc6.jar driver to connect to any version of Oracle database.
Oracle JDBC Driver(XA)	One and two phase	Must use the ojdbc6.jar driver to connect to any version of Oracle database.

Table 36. Sybase JDBC providers. Use the table for quick reference on database-specific JDBC providers.

Sybase		
JDBC provider	**Transaction support**	**Version and other considerations**
Sybase JDBC 4 Driver	One-phase	jConnect v7.0
Sybase JDBC 4 Driver (XA)	One and two phase	jConnect v7.0
Sybase JDBC 3 Driver	One-phase	jConnect v6.05
Sybase JDBC 3 Driver (XA)	One and two phase	jConnect v6.05
Sybase JDBC 2 Driver	One-phase	jConnect v5.5
Sybase JDBC 2 Driver (XA)	One and two phase	jConnect v5.5

Configuring a data source using the administrative console

Application components use a data source to access connection instances to a relational database.

Before you begin

The application server supports two different versions of data source. Determine the data source for your environment according to the enterprise bean and servlet specification levels that are the basis of your applications:

- *Data sources (WebSphere Application Server Version 4)* are for use with the Enterprise JavaBeans (EJB) 1.0 specification and the Java Servlet 2.2 specification.
- Data sources of the latest standard version are for use with applications that implement the more advanced releases of these specifications.

About this task

When you create a data source, you associate it with a Java Database Connectivity (JDBC) provider that is configured for access to a specific vendor database. The application server requires both objects for your applications to make calls to that particular database and receive data from it. The data source provides connection management capabilities that physically make possible these exchanges between your applications and the database.

Procedure

1. Open the administrative console.
2. Access the necessary console panel. Use one of the following paths:
   - Click **Resources** > **JDBC** > **Data sources**.
   - Click **Resources** > **JDBC** > **Data sources (**WebSphere Application Server Version 4)
   - Click **Resources** > **JDBC** > **JDBC providers** > ***jdbc_provider*** > **Data sources**
   - Click **Resources** > **JDBC** > **JDBC providers** > ***jdbc_provider*** > **Data sources (**WebSphere Application Server Version 4) .
3. Select the scope at which applications can use the data source. You can choose a cell, node, cluster, or server. For more information, see the topic on scope settings.

   Version 4 only: From this point onward, the steps for creating WebSphere Application Server Version 4 data sources differ from the steps for creating data sources of the latest standard version. To configure a Version 4 data source:
   - Click **New** to proceed to the console panel for defining required properties.
   - On this properties panel specify values for the fields that are grouped under the heading **Configuration**. The application server requires these properties to implement your JDBC driver classes.
   - Save your configuration by clicking **OK**. You are now finished with the primary data source configuration tasks.
   - Define other properties that your database vendor might require, or offer as options, for using the JDBC driver. The application server calls them custom properties, and requires that you set them on the data source. Begin by clicking the **Custom Properties** link that is now displayed on the administrative console panel. Consult your database documentation to learn about these required and optional properties.
4. Click **New**. This action causes the **Create a data source** wizard to launch and display the **Enter basic data source information** panel. The first field is the scope field, which is read-only. This field displays your previous scope selection.
5. Type a data source name in the **Data source name** field. This name identifies the data source for administrative purposes only.

6. Type a Java Naming and Directory Interface (JNDI) name in the **JNDI name** field. The application server uses the JNDI name to bind resource references for an application to this data source. Follow these requirements when you specify JNDI names:
   - Do not assign duplicate JNDI names across different resource types, such as data sources versus J2C connection factories or JMS connection factories.
   - Do not assign duplicate JNDI names for multiple resources of the same type in the same scope.

   For more information on JNDI, consult the topic on naming.
7. Click **Next** to see the **Select JDBC provider** panel. The **Select JDBC provider** panel is skipped if you do not have any JDBC providers that are configured at the current scope.
8. Select an existing JDBC provider, or create a new provider.
   - Select an existing JDBC provider.
     a. Click **Select an existing JDBC provider**.
     b. Select a JDBC driver from the drop-down list.
     c. Click **Next**. You now see the panel entitled **Enter database specific properties for the data source**.
   - Create a new JDBC provider.
     a. Click **Create new JDBC provider**.
     b. Click **Next** to see the **Create JDBC provider** panel.
     c. Use the first drop-down list to select the database type of the JDBC provider that you need to create.

        The User-Defined option: Select **User-Defined** for your database type if you encounter either of the following scenarios:
        – You do not see your database type.
        – You cannot select the JDBC provider type that you need in the next step.

        The user-defined selection triggers the wizard panel to display your provider type as a User-defined JDBC provider, and your implementation type as User-defined. Consult your database documentation for the JDBC driver class files, data source properties, and so on that are required for your user-defined provider. You must supply this information on the next two wizard panels:
        – database class path information
        – database-specific properties

     d. If the JDBC provider type is displayed in the second drop-down list, select your JDBC provider type. Select **Show Deprecated** to trigger the display of both current and deprecated providers. If you cannot find your provider in this expanded list, then select **User-Defined** from the previous list of database types.
     e. From the third drop-down list, select the implementation type that is necessary for your application. If your application does not require that connections support two-phase commit transactions, choose **Connection Pool Data Source**. Choose **XA Data Source**, however, if your application requires connections that support two-phase commit transactions. Applications that use this data source configuration have the benefit of container-managed transaction recovery.

        After you select an implementation type, the wizard fills the name and the description fields for your JDBC provider. You can type different values for these fields; they exist for administrative purposes only.
     f. Click **Next** after you have defined your database type, provider type, and implementation type. Now you see the wizard panel Enter database class path information.

g. In the class path field, type the full path location of the database JDBC driver class files. Your class path information becomes the value of the WebSphere environment variable that is displayed on this panel, in the form of ${*DATABASE*_JDBC_DRIVER_PATH}. The application server uses the variable to define your JDBC provider; this practice eliminates the need to specify static JDBC class paths for individual applications. Remember that if you do not provide the full, correct JDBC driver class path for the variable, your data source ultimately fails. If the field already displays a fully qualified class path, you can accept that variable definition by completing the rest of this wizard panel and clicking **Next**.

h. Use the **Native library path** field to specify additional class files that your JDBC driver might require to function properly on your application server platform. Type the full directory path name of these class files.

i. Click **Next**. You now see the **Enter database specific properties for the data source** panel.

9. Complete all of the fields on the **Enter database specific properties for the data source** panel.
   - Click **Use this data source in container managed persistence (CMP)** if container managed persistence (CMP) enterprise beans must access this data source.
   - Any other property fields that are displayed on this wizard panel are specific to your database type. See the topic, Data source minimum required settings, by vendor, for information on these property settings. The article addresses both current and deprecated JDBC providers that are pre-defined in the application server.

     User-defined data sources: This wizard panel does not display additional property fields for data sources that correspond with your user-defined JDBC providers. However, from the JDBC driver class files that you installed, the application server can generally extract the necessary data source property names. The application server defines them as data source custom properties, displays them on a custom properties console panel, and assigns them default values. Consult your database documentation about setting these properties and any other requirements for your user-defined data source. After you create the data source, navigate to the corresponding custom properties collection panel in the administrative console by clicking **Data sources** > ***data_source*** > **Custom properties**. Review the property default values and modify them if necessary.

10. Optional: Configure the security aliases for the data source. You can select none for any of the authentication methods, or choose one of the following types:
    - **Component-managed authentication alias** - specifies an authentication alias to use when the component resource reference res-auth value is Application. To define a new alias, navigate to **Related Items** > **J2EE Connector Architecture (J2C) authentication data entries**. A component-managed alias represents a combination of ID and password that is specified in an application for data source authentication. Therefore, the alias that you set on the data source must be identical to the alias in the application code.

      a. Use the drop-down list to select an existing component-managed authentication alias.

      b. To create a new alias, click the links that are provided. This action closes the data source wizard and triggers the administrative console to display the J2C authentication data panel. Click **New** to define a new alias. Click **OK** to save your settings and view the new alias on the J2C authentication data panel. Restart the data source wizard by navigating back to the data source collection panel, selecting the appropriate scope, and clicking **New**.

      For more information on Java 2 Connector (J2C) security, see the topic on managing Java 2 Connector Architecture authentication data entries.
    - **Mapping-configuration alias** - is used only in the absence of a login configuration on the component resource reference. The specification of a login configuration and the associated properties on the component resource reference is the preferred way to define the authentication

strategy when the res-auth value is set to Container. If you specify the DefaultPrincipalMapping login configuration, the associated property is a JAAS - J2C authentication data entry alias.

- **Container-managed authentication alias** - is used only in the absence of a login configuration on the component resource reference. The specification of a login configuration and the associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is set to `Container`.

Note: If you have defined security domains in the application server, you can click **Browse...** to select an authentication alias for the resource that you are configuring. Security domains support isolating authentication aliases between servers. The tree view is useful in determining the security domain to which an alias belongs, and the tree view can help you determine the servers that are able to access each authentication alias. The tree view is tailored for each resource, so domains and aliases are hidden when you cannot use them.

11. Click **Next** to view the **Summary** panel, and review any information for the data source. If any information is not correct, you can click **Previous** to go back and correct it.
12. Click **Finish** to save the configuration and exit the wizard. You now see the **Data sources** panel, which displays your new configuration in a table along with other data sources that are configured for the same scope.

What to do next

You can override the default values for some data source properties. You can also configure additional properties that your database vendor might require or offers as options. Consult your database documentation about these settings. The following topics in this information center inform you of how to use the administrative console to assign the property values:

- “Connection pool settings” on page 205
- Tuning connection pools
- “WebSphere Application Server data source properties” on page 289
- “Java EE resource provider or connection factory custom properties collection” on page 296

Disabling statement pooling:

Disable statement pooling when performing some Data Definition Language (DDL) operations, which might not be compatible with statement pooling. DDL operations, such as dropping and recreating tables, are not compatible with statement pooling when using the IBM Informix database. DDL operations invalidate the pooled statements or cause them to produce unexpected results.

About this task

Complete the following steps to use the administrative console to disable statement pooling. Statement pooling is disabled by specifying a value of zero for the statement cache size setting for your datasource.

Procedure

1. From the administrative console, select **Resources** > **JDBC** > **Data sources** > ***datasource_name***.
2. Under Additional properties, click **WebSphere Application Server data source properties**.
3. Enter a value of zero (0) in the Statement cache size field.
4. Click **OK**, and then click **Save**.

Data source collection:

Use this page to view configured data sources, which are the resources that provide connections to your relational database.

You can access this administrative console page in one of two ways:

- **Resources** > **JDBC** > **Data sources**.
- **Resources** > **JDBC** > **JDBC providers** > ***JDBC_provider*** > **Data sources**.

Version requirement: If you are using the Enterprise JavaBeans (EJB) 1.0 specification and the Java Servlet 2.2 specification, you must use the **Data sources (WebSphere Application Server Version 4)** console page.

Name:

Specifies the display name of this data source.

Click a data source name to edit the data source configuration settings.

Data type String

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name for this data source.

Data type String

Scope:

Specifies the scope of the JDBC provider that encapsulates the driver implementation classes to support this data source. Only applications that are installed within this scope can use this data source.

Provider:

Specifies the JDBC provider that encapsulates the appropriate classes.

Description:

Specifies a text description of the data source.

Data type String

Category:

Specifies a string that you can use to classify or group a data source.

Data type String

Data source settings:

Use this panel to edit the properties of a data source.

You can access this administrative console page in one of two ways:

- **Resources** > **JDBC** > **Data sources** > ***data_source***
- **Resources** > **JDBC** > **JDBC providers** > ***JDBC_provider*** > **Data sources** > ***data_source***

Note: If your application uses an Enterprise JavaBeans (EJB) 1.1 or a Java Servlet 2.2 module, use the **Data sources (WebSphere Application Server V4)** > ***data_source*** console page.

Test connection:

Activates the test connection service for validating application connections to the data source.

Before you click **Test connection**, set your data source properties and click **Apply**.

Scope:

Specifies the scope of the JDBC provider that supports this data source. Only applications that are installed within this scope can use this data source.

Provider:

Specifies the resource adapter that WebSphere Application Server uses for this connection factory.

Provider can be set only when you create a new connection factory. The list shows all the existing resource adapters that are defined at the relevant scope. Select one from the list if you want to use an existing resource adapter as Provider.

Name:

Specifies the display name for the data source.

Valid characters for this name include letters and numbers, but NOT most of the special characters. For example, you can set this field to `Test Data Source`. But any name starting with a period (•) or containing special characters (\ /,: ; " *? < > | = + & % ' ` @) is not a valid name.

Data type String

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name.

Distributed computing environments often employ naming and directory services to obtain shared components and resources. Naming and directory services associate names with locations, services, information, and resources.

Naming services provide name-to-object mappings. Directory services provide information about objects and the search tools required to locate those objects.

There are many naming and directory service implementations, and the interfaces to them vary. JNDI provides a common interface that is used to access the various naming and directory services.

For example, you can use the name`jdbc/markSection`.

If you leave this field blank a JNDI name is generated from the name of the data source. For example, a data source name, `markSection`, generates a JNDI name of `jdbc/markSection`.

After you set this value, save it, and restart the server, you can see this string when you run the memory dump name space tool.

Data type String

Use this data source in container-managed persistence (CMP):

Specifies if this data source is used for container-managed persistence of enterprise beans.

This option triggers creation of a CMP connection factory, which corresponds to this data source, for the relational resource adapter.

Data type	Boolean
Default	True (enabled)

Description:

Specifies a text description for the resource.

Data type	String

Category:

Specifies a category string you can use to classify or group the resource.

Data type	String

Data store helper class name:

Specifies the name of the DataStoreHelper implementation class that extends the capabilities of your selected JDBC driver implementation class to perform database-specific functions.

The application server provides a set of DataStoreHelper implementation classes for each of the JDBC provider drivers that it supports. These implementation classes are in the package com.ibm.websphere.rsadapter. For example, if your JDBC provider is DB2, then your default DataStoreHelper class is com.ibm.websphere.rsadapter.DB2DataStoreHelper. The administrative console page you are viewing, however, might make multiple DataStoreHelper class names available to you in a drop-down list; be sure to select the one required by your database configuration. Otherwise, your application might not work correctly. If you want to use a DataStoreHelper class that is not listed in the drop-down list, select **Specify a user-defined DataStoreHelper**, and type a fully qualified class name. See the information center for instructions on creating a custom DataStoreHelper class.

Data type	Drop-down list or string (if **user-defined DataStoreHelper** is selected)

Authentication alias for XA recovery:

This field is used to specify the authentication alias that you must use during XA recovery processing. If this alias name is changed after a server failure, the subsequent XA recovery processing uses the original setting that was in effect before the failure.

Select an alias from the list.

To define a new alias that is not displayed in the list:

1. Click **Apply**. Under Related Items, you now see a listing for Java Platform, Enterprise Edition (Java EE) Connector Architecture (J2C) authentication data entries.
2. Click **J2EE Connector Architecture (J2C) authentication data entries**.
3. Click **New**.
4. Define an alias.

5. Click **OK** and **Save**. The console now displays an alias collection page that lists all of your configured aliases. Above the table, this page also displays the name of your connection factory in the breadcrumb path.
6. Click the name of your J2C connection factory to return to the configuration panel for the connection factory that you are creating.
7. Select the new alias in the Container-managed authentication alias list.
8. Click **Apply**.

The database identity for the XA recovery authentication alias on a data source must have authorization to do XA recovery. Depending on the authorization schema for your installation, this level of authorization might be different from the level of authorization that the identity must use to access database tables for an application.

If the resource adapter does not support XA transactions, this field does not display. The default value for this field is derived from the selected alias for application authentication, if one is specified.

If you have defined multiple security domains and multiple authentication aliases in the application server, you can click **Browse...** to select an authentication alias for the resource that you are configuring. The Browse button is only accessible if at least one security domain is defined and assigned a scope which is applicable to the resource that is being edited. Additionally, that security domain must contain at least one Java Authentication and Authorization Service (JAAS) Java 2 Connector (J2C) Authentication alias.

Security domains allow you to isolate authentication aliases between servers. The tree view is useful in determining the security domain to which an alias belongs, and the tree view can help you determine the servers that are able to access each authentication alias. The tree view is tailored for each resource, so domains and aliases that you cannot use do not display.

Data type Drop-down list

Component-managed authentication alias:

This alias is used for database authentication at run time.

If your database is not secured, setting database authentication is not required. This is not recommended for a production environment.

Note: If you have a database that does not support user ID and password, like Cloudscape, do not set the alias in the component-managed authentication alias or container-managed authentication alias fields. Otherwise, you see the warning message in the system log to indicate that the user and password are not valid properties. This message is only a warning message; the data source is still created successfully.

Select an alias from the list.

To define a new alias that is not displayed in the list:

1. Click **Apply**. Under Related Items, you now see a listing for Java Platform, Enterprise Edition (Java EE) Connector Architecture (J2C) authentication data entries.
2. Click **J2EE Connector Architecture (J2C) authentication data entries**.
3. Click **New**.
4. Define an alias.
5. Click **OK** and **Save**. The console now displays an alias collection page that lists all of your configured aliases. Above the table, this page also displays the name of your connection factory in the breadcrumb path.

6. Click the name of your J2C connection factory to return to the configuration panel for the connection factory that you are creating.
7. Select the new alias in the Container-managed authentication alias list.
8. Click **Apply**.

If you have defined multiple security domains and multiple authentication aliases in the application server, you can click **Browse...** to select an authentication alias for the resource that you are configuring. The Browse button is only accessible if at least one security domain is defined and assigned a scope which is applicable to the resource that is being edited. Additionally, that security domain must contain at least one JAAS J2C Authentication alias.

If you do not set an alias through the component-managed authentication or otherwise, and your database requires the user ID and password to get a connection, an exception occurs during run time.

Data type Drop-down list

Container-managed authentication alias:

Specifies authentication data, which is a JAAS - J2C authentication data entry, for container-managed signon to the resource. Depending on the value that is selected for the **Mapping-configuration alias** setting, you can disable this setting.

Select an alias from the list.

To define a new alias that is not displayed in the list:

1. Click **Apply**. Under Related Items, you now see a listing for J2EE Connector Architecture (J2C) authentication data entries.
2. Click **JAAS - J2C authentication data**.
3. Click **New**.
4. Define an alias.
5. Click **OK** and **Save**. The console now displays an alias collection page that lists all of your configured aliases. Above the table, this page also displays the name of your connection factory in the breadcrumb path.
6. Click the name of your J2C connection factory to return to the configuration panel for the connection factory that you are creating.
7. Select the new alias in the Container-managed authentication alias list.
8. Click **Apply**.

If you have defined multiple security domains and multiple authentication aliases in the application server, you can click **Browse...** to select an authentication alias for the resource that you are configuring. The Browse button is only accessible if at least one security domain is defined and assigned a scope which is applicable to the resource that is being edited. Additionally, that security domain must contain at least one JAAS J2C Authentication alias.

Security domains allow you to isolate authentication aliases between servers. The tree view is useful in determining the security domain to which an alias belongs, and the tree view can help you determine the servers that can access each authentication alias. The tree view is tailored for each resource, so domains and aliases that you cannot use do not display.

Data type Drop-down list

Mapping-configuration alias:

Specifies the authentication alias for the Java Authentication and Authorization Service (JAAS) mapping configuration that is used by this connection factory.

The **DefaultPrincipalMapping** JAAS configuration maps the authentication alias to the user ID and password. You can define and use other mapping configurations.

Data type Drop-down list

Common and required data source properties: These properties are specific to the data source that corresponds to your selected JDBC provider. They are either required by the data source, or are especially useful for the data source. You can find a complete list of the properties required for all supported JDBC providers in the information center.

WebSphere Application Server data source properties:

Use this page to set advanced data source properties in the application server. These properties activate and configure services that the application server applies to data sources to customize connections within an application server. These properties do not affect connections within the database.

To access this administrative console page complete one of the following paths:

- **Resources** > **JDBC** > **Data sources** > ***data_source*** > **WebSphere Application Server data source properties**
- **Resources** > **JDBC** > **JDBC providers** > ***JDBC_provider*** > **Data sources** > ***data_source*** > **WebSphere Application Server data source properties**
- **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Application scoped resources** > ***data_source*** > **WebSphere Application Server data source properties**.

Statement cache size:

Specifies the number of statements that can be cached per connection. The application server caches a statement after you close that statement.

The WebSphere Application Server data source optimizes the processing of prepared statements and callable statements by caching those statements that are not used in an active connection. Both statement types help maximize the performance of transactions between your application and data store.

- A prepared statement is a precompiled SQL statement that is stored in a PreparedStatement object. The application server uses this object to run the SQL statement multiple times, as required by your application run time, with values that are determined by the run time.
- A callable statement is an SQL statement that contains a call to a stored procedure, which is a series of precompiled statements that perform a task and return a result. The statement is stored in the CallableStatement object. The application server uses this object to run a stored procedure multiple times, as required by your application run time, with values that are determined by the run time.

If the statement cache is not large enough, useful entries are discarded to make room for new entries. To determine the highest value for your cache size to avoid any cache discards, add the number of uniquely prepared statements and callable statements, as determined by the SQL string, concurrency, and the scroll type, for each application that uses this data source on a particular server. This value is the maximum number of possible statements that can be cached on a given connection over the life of the server. Setting the cache size to this value means that you never have cache discards. In general, configure a larger cache for applications with a greater number of statements.

You can also use the Tivoli Performance Viewer to minimize cache discards. Use a standard workload that represents a typical number of incoming client requests, use a fixed number of iterations, and use a standard set of configuration settings.

Note: The higher the statement cache, the more system resources are delayed. Therefore, if you set the number too high, you might lack resources because your system cannot open multiple prepared statements.

If there is a particular statement that you do not want the application server to cache, configure the statement poolability hint to `false`. The application server does not cache a statement if the poolability hint is set to `false`. The application specifies the statement poolability hints at run time.

In test applications, tuning the statement cache improves throughput from 10% to 20%. However, because of potential resource limitations, this tuning process might not always be possible.

Data type	Integer
Default	Default values depend on the database. Typically, this value is 10. For Informix versions 7.3, 9.2, 9.3, and 9.4, without the respective latest fixes, the default value must be 0. A default value of 0 means that there is no cache statement.

Enable multithreaded access detection: If checked, the following warning message is entered in the WebSphere Application Server system out log if multiple threads attempt to concurrently use the same connection handle. You can use this property to debug connection problems if you think the problems might be caused by multiple threads trying to use the same connection handle. Having multiple threads concurrently using the same connection handle is a programming model violation.

```
J2CA0167W: An attempt to concurrently use the same connection handle by multiple threads has
been detected. The connection handle is: {0}.
```

Enable database reauthentication: Indicates that the exact match on connections retrieved out of the application server connection pool (the connection pool search criteria does not include a user name and password) cannot exist. Instead, the connection reauthentication is done in the doConnectionSetupPerTransaction() of the DataStoreHelper class. The application server does not provide a connection reauthentication implementation at run time. Therefore, when you check this box, you must extend the DataStoreHelper class to provide implementation of the doConnectionSetupPerTransaction() method where the reauthentication occurs. If you do not complete this process, the application server might return unusable connections. For more information, read the API documentation for the com.ibm.websphere.rsadapter.DataStoreHelper#doConnectionSetupPerTransaction method.

Connection reauthentication can help improve performance by reducing opening and closing connections, particularly for applications that frequently request connections with different user names and passwords.

Note: You cannot enable database reauthentication if you select TrustedConnectionMapping for the mapping configuration alias.

Enable JMS one-phase optimization support: When you check this option, the application server uses Java Message Service (JMS) to get optimized connections from this data source. This property prevents Java database connectivity (JDBC) applications from sharing connections with container-managed persistence (CMP) applications. This option is not available if the JDBC provider of the data source is an XA provider.

Manage cached handles: Specifies whether the container tracks cached handles, which are connection handles that an application component holds active across transaction and method boundaries. You can use this property to debug connection problems, but tracking handles can cause large performance issues during run time.

If the **Manage cached handles** property is selected in the administrative console, and you clear it, the field is no longer visible for resources that are at Version 7.0 or greater of the application server. This field is only displayed if the manageCachedHandles property is set to `true` in the resources.xml file. To make the field available, change the value for the manageCachedHandles entry from `false` to `true` in the resources.xml file, or enter the following Jython command from the wsadmin tool:

```
AdminConfig.modify(myDataSourceVariable, '[[manageCachedHandles "true"]]')
```

Note: For any resources that are running at Version 6.x of the application server, the **Manage cached handles** property is always visible. For example, if you have a node that is at Version 6.1, the entry in the resources.xml file does not affect how the field is displayed in the administrative console.

For a different method to debug problems, use the multi-thread and cross-component diagnostic alerts to detect violations in the Java Connector Architecture (JCA) programming model. To enable these alerts, select those options from **Servers** > **Application servers** > ***application_server*** > **Performance** > **Performance and Diagnostic Advisor Configuration** > **Performance and Diagnostic Advice configuration** panel. These alerts force the connection manager to manage cached handles, detect the connection conditions, and send alerts.

Note: For these alerts to be active, you must also select **Enable Performance and Diagnostic Advisor Framework (Runtime Performance Advisor)** from the **Servers** > **Application servers** > ***application_server*** > **Performance** > **Performance and Diagnostic Advisor Configuration** panel.

Log missing transaction context: Specifies whether the container issues an entry to the activity log when an application obtains a connection without a transaction context. These are exceptions to the Java Platform, Enterprise Edition (Java EE) programming model connection requirements.

Non-transactional data source: Specifies that the application server does not enlist the connections from this data source in global or local transactions. Applications must explicitly call setAutoCommit(false) on the connection if they want to start a local transaction on the connection, and they must commit or roll back the transaction that they started.

Note: Set this property to `true` in rare circumstances, except when a Java Persistence API (JPA) application requires both JTA and non-JTA data sources. The non-JTA data source requires this property to be set to `true`.

Use WebSphere Application Server exception checking model:

Specifies that the application server uses the error mapping facility that is defined in the data store helper to identify errors. The application server does not replace exceptions that are thrown by the JDBC driver with exceptions that are defined in the error map of the data store helper.

Use WebSphere Application Server exception mapping model:

Specifies that the application server uses the error mapping facility that is defined in the data store helper to identify errors, and the application server replaces the exceptions that are thrown by the JDBC driver with exceptions that are defined in the error map of the data store helper.

Note: This error detection model functions with JDBC Version 3.0 and earlier.

Validate new connections: Specifies whether the connection manager tests newly created connections to the database.

Number of retries: Specifies the number of times you want to retry making the initial connection to a database after the first pretest operation fails.

Retry interval: If you select **Validate new connections**, this option specifies the length of time, in seconds, that the application server waits before retrying to make a connection if the initial attempt fails.

Validate existing pooled connections: Specifies whether the connection manager tests the validity of pooled connections before returning them to applications.

Retry interval: If you select **Pretest existing pooled connections**, this option specifies the length of time, in seconds, to allot to the JDBC driver for validating a connection.

Validation by JDBC driver:

Specifies that the application server uses the JDBC driver to validate the connections. The JDBC provider must support JDBC 4.0 or greater to use this option. This option is available only if either **Validate new connections** or **Validate existing pooled connections** is selected.

gotcha: For an Oracle data source, **Validation by JDBC Driver** displays on the administrative console only after the validateNewConnectionTimeout property is added to the custom properties of WebSphere Application Server data source properties. The validateNewConnectionTimeout property is used for JDBC 4.0 driver validation and can be specified with the administrative console.

Timeout: Specifies the timeout in seconds for testing connections, either new or pooled by the application server, to the database. If the timeout expires before validating then the connection is considered unusable. If retries are configured, the full value of the timeout applies to each retry. A value of 0 indicates the JDBC driver does not impose a timeout on validation attempts.

Note: This option is only available for JDBC drivers that are JDBC 4.0 compliant.

Validation by SQL string (deprecated):

Specifies an SQL statement that the application server sends to the database to test the connection. Use a query that is likely to have low impact on performance. This option is available only if either **Validate new connections** or **Validate existing pooled connections** is selected.

Optimize for get/use/close connection pattern with heterogenous pooling:

Optimizes the data source for applications that use the get/use/close connection pattern. This optimization enables the connection pool for the data source to share connections that are in the same transaction. With this optimization pattern, you can share one connection during a transaction even if connections use different connection properties.

If you use the heterogeneous pooling feature, you must first extend the data source definition so that you can specify different custom properties or applications to override non-core properties for the data source. For more information about extending data sources, see the information on extending DB2 data source definitions at the application level.

Note: This field is only available for DB2 data sources.

Retry interval for client reroute: Specifies the amount of time, in seconds, between retries for automatic client reroute.

Note: This field is only available for DB2 data sources.

Maximum retries for client reroute: Specifies the maximum number of connection retries that are attempted by the automatic client reroute function if the primary connection to the server fails. The property is only used when **Retry interval for client reroute** is set.

Note: This field is only available for DB2 data sources.

Alternate server names: Specifies the list of alternate server name or names for the DB2 server. If more than one alternate server name is specified, the names must be separated by commas. For example:

```
host1,host2
```

Note: This field is only available for DB2 data sources.

Alternate port numbers: Specifies the list of alternate server port or ports for the DB2 server. If more than one alternate server port is specified, the ports must be separated by commas. For example:

```
5000,50001
```

Note: This field is only available for DB2 data sources.

Client reroute server list JNDI name: Specifies the JNDI name that is used to bind the DB2 client reroute server list into the JNDI name space. The DB2 database server uses this name to look up the alternate server name list when the alternate server information is not already in memory. This option is not supported for type 2 data sources.

Note: This field is only available for DB2 data sources.

Unbind client reroute list from JNDI: Used with test connection only. When set to `true`, the Client reroute server list JNDI name is unbound from the JNDI name space after a test connection is issued.

Note: This field is only available for DB2 data sources.

Data source (WebSphere Application Server V4) collection:

Use this page to view the settings of a WebSphere Application Server Version 4.0 data source.

These data sources use the WebSphere Application Server Version 4.0 Connection Manager architecture. All Enterprise JavaBeans (EJB) 1.x modules must use a WebSphere Application Server Version 4.0 data source.

You can access this administrative console page in one of two ways:

- **Resources** > **JDBC** > **Data sources(WebSphere Application Server V4)**.
- **Resources** > **JDBC** > **JDBC providers** > ***JDBC_provider*** > **Data sources(WebSphere Application Server V4)**.

Name:

Specifies a text identifier of the data source.

Data type String

JNDI Name:

Specifies the Java Naming and Directory Interface (JNDI) name of the data source.

Data type String

Scope:

Specifies the scope of the JDBC provider that encapsulates the driver implementation classes to support this data source. Only applications that are installed within this scope can use this data source.

Provider:

Specifies the JDBC provider that encapsulates the appropriate classes.

Description:

Specifies a text description of the data source.

Data type String

Category:

Specifies a text string that you can use to classify or group the data source.

Data type String

Data source (WebSphere Application Server Version 4) settings:

Use this page to create a Version 4.0 style data source. This data source uses the WebSphere Application Server Version 4.0 connection manager architecture. All Enterprise JavaBeans (EJB) 1.x modules must use a Version 4.0 data source.

You can access this administrative console page in one of two ways:

- **Resources** > **JDBC** > **Data sources(WebSphere Application Server V4)** > ***data_source***.
- **Resources** > **JDBC** > **JDBC providers** > ***JDBC_provider*** > **Data sources(WebSphere Application Server V4)** > ***data_source***.

Scope:

Specifies the scope of the JDBC provider that encapsulates the driver implementation classes to support this data source. Only applications that are installed within this scope can use this data source.

Provider:

Specifies the JDBC provider that WebSphere Application Server uses for this data source.

The list shows all of the existing JDBC providers that are defined at the relevant scope. Select one from the list if you want to use an existing JDBC provider as Provider.

Create new provider:

Provides the option of configuring a new JDBC provider for the new data source.

Create New Provider is displayed only when you create, rather than edit, a data source.

If you click **Create New Provider** the **Create a new JDBC provider** wizard launches. Complete all of the wizard panels and click **Finish**. The administrative console now displays the Data sources (WebSphere Application Server V4) configuration page again, where you see the new JDBC provider name in the Provider field.

Name:

Specifies the display name for the resource.

For example, you can set this field to `Test Data Source`.

Data type String

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name.

Distributed computing environments often employ naming and directory services to obtain shared components and resources. Naming and directory services associate names with locations, services, information, and resources.

Naming services provide name-to-object mappings. Directory services provide information about objects and the search tools required to locate those objects.

There are many naming and directory service implementations, and the interfaces to them vary. JNDI provides a common interface that is used to access the various naming and directory services.

For example, you can use the name `jdbc/markSection`.

If you leave this field blank a JNDI name is generated from the name of the data source. For example, a data source name of markSection generates a JNDI name of `jdbc/markSection`.

After you set this value, save it, and restart the server, you can see this string when you run the memory dump name space tool.

Data type String

Description:

Specifies a text description for the resource.

Data type String

Category:

Specifies a category string that you can use to classify or group the resource.

Data type String

Database name:

Specifies the name of the database of the data source to access.

For example, you can call the database `SAMPLE`.

Data type String

Default user ID:

Specifies the user name to use for connecting to the database.

For example, you can use the ID `db2admin`.

Data type String

Default password:

Specifies the password used for connecting to the database.

For example, you can use the password `db2admin`.

Data type String

Java EE resource provider or connection factory custom properties collection:

Use this page to view the custom properties of a Java Platform, Enterprise Edition (Java EE) resource provider or connection factory.

You can configure custom property collections for numerous resource types. According to the resource type with which a collection is associated, your ability to add, delete, and modify individual properties and settings varies. Begin the configuration process by clicking the **Required** field to sort those column values in descending order. All of the required (true) values are then sorted at the beginning of the page. Be sure to set all required properties.

Note: The following list displays three custom properties that are deprecated in WebSphere Application Server Version 6.10. The product now offers these properties as pre-configured options, which are the replacement properties in the following list. To avoid runtime error messages, permanently disable the original custom properties by deleting them from the table on this administrative console page.

- validateNewConnection -- replaced by **Pretest new connection**
- validateNewConnectionRetryCount -- replaced by **Number of retries**
- validateNewConnectionRetryInterval -- replaced by **Retry interval**

To set the replacement properties, click **Data sources** > ***data_source*** > **WebSphere Application Server data source properties** in the administrative console.

Name:

Specifies the property name.

Data type String

Value:

Specifies the property value.

Data type Variable; see “Custom property settings” on page 297 for more information.

Description:

Specifies text to describe any bounds or well-defined values for this property.

Data type String

Required:

Specifies whether this property is required for the resource provider.

Data type Boolean or check box

Custom property settings:

Use this page to specify the attributes of custom properties that might be required for resource providers and resource factories.

According to the resource type with which a property collection is associated, your ability to modify individual property settings varies. Therefore, consider the following descriptions as a general reference for custom property settings. (The administrative console page that you are using to configure your custom property might only allow you to modify a subset of the following settings.)

You can access this administrative console page through several different paths, depending on the type of resource to which the custom properties belong, for example: **Resources** > **Resource Adapters** > **Resource adapters** > ***resource_adapter*** > **Custom Properties**.

Note: The following list displays three custom properties that are deprecated in WebSphere Application Server Version 6.10. The product now offers these properties as pre-configured options, which are the replacement properties in the following list. To avoid runtime error messages, permanently disable the original custom properties by deleting them from the table on this administrative console page.

- validateNewConnection -- replaced by **Pretest new connection**
- validateNewConnectionRetryCount -- replaced by **Number of retries**
- validateNewConnectionRetryInterval -- replaced by **Retry interval**

To set the replacement properties, click **Data sources** > ***data_source*** > **WebSphere Application Server data source properties** in the administrative console.

Required:

Specifies that a value must be provided for this property of the resource, otherwise a warning occurs. If you are creating a new custom property, this field is not available.

Data type Check box

Name:

Specifies the name associated with this property, for example, *PortNumber*, *ConnectionURL*.

Data type String

Value:

Specifies the value associated with this property of the resource.

Data type Determined by the Type field. If the Type is `java.lang.String`, the text entered into the Value field is interpreted as a string. Similarly, if the Type is `java.lang.Integer`, the Value field is interpreted as numeric. This means that the text that is entered for the Value field must be able to be interpreted as indicated by the Type field, otherwise an error occurs. For example, attempting to create a property with a Type of `java.lang.Integer` and a Value of *someValue* results in an error. Only a numeric value can be properly interpreted for any of the available numeric types.

Description:

Specifies text to describe any bounds or well-defined values for this property.

Data type String

Type:

Specifies the fully qualified Java data type of this property.

There are specific types that are valid:
- java.lang.Boolean
- java.lang.String
- java.lang.Integer
- java.lang.Double
- java.lang.Byte
- java.lang.Short
- java.lang.Long
- java.lang.Float

Data type Drop-down list

Custom Properties (Version 4) collection:

Use this page to view properties for a WebSphere Application Server Version 4.0 data source.

You can access this administrative console page in one of two ways:
- **Resources** > **JDBC** > **Data Sources (WebSphere Application Server V4)** > *data_source* > **Custom Properties**
- **Resources** > **JDBC** > **JDBC Providers** > *JDBC_provider* > **Data Sources (WebSphere Application Server V4)** > *data_source* > **Custom Properties**

Name:

Specifies the name of the custom property

Data type String

Value:

Specifies the value of the custom property.

Data type Integer

Description:

Specifies text to describe any bounds or well-defined values for this property.

Data type String

Required:

Specifies properties that are required for this resource.

Data type String

Custom property (Version 4) settings:

Use this page to add properties for a WebSphere Application Server Version 4.0 data source.

To view this administrative console page, click **Resources** > **JDBC** > **JDBC Providers**> *JDBC_provider* > **Data Sources (WebSphere Application Server V4)** > *data_source* > **Custom Properties** > *custom_property*.

Required:

Specifies properties that are required for this resource.

Data type Check box

Name:

Specifies the name associated with this property (PortNumber, ConnectionURL, etc).

Data type String

Value:

Specifies the value associated with this property in this property set.

Data type Integer

Description:

Specifies text to describe any bounds or well-defined values for this property.

Data type String

Type:

Specifies the fully qualified Java type of this property (java.lang.Integer, java.lang.Byte).

Data type String

ResourceManagement command group for the AdminTask object

You can use the Jython or Jacl scripting languages to configure resource providers with the wsadmin tool. The commands and parameters in the ResourceManagement group can be used to define and display properties for resource providers.

The ResourceManagement command group for the AdminTask object includes the following commands:

- "setResourceProperty"
- "showResourceProperties" on page 301

setResourceProperty

Use the setResourceProperty command to set the value of a specified property defined on a resource provider such as JDBCProvider or a connection factory such as DataSource or JMSConnectionFactory. If the property with specified key is defined already, then this command overrides the value. If no property with a specified key is defined, this command will add the property with specified key and value.

Target object

The configuration object ID of a resource provider or a connection factory.

Required parameters

-propertyName
Specifies the name of the property. (String, required)

-propertyValue
Specifies the value of a property. (String, required)

Optional parameters

-propertyType
Specifies the type of the property. The default value is java.lang.String. (String, optional)

-propertyDescription
Specifies the description of the defined property. (String, optional)

Sample output

The command does not return output.

Examples

Batch mode example usage:

- Using Jacl:

```
$AdminTask setResourceProperty {-propertyName test.property -propertyValue testValue}
```

- Using Jython string:

```
AdminTask.setResourceProperty('[-propertyName test.property -propertyValue testValue]')
```

- Using Jython list:

```
AdminTask.setResourceProperty(['-propertyName', 'test.property', '-propertyValue', 'testValue'])
```

Interactive mode example usage:

- Using Jacl:

```
$AdminTask setResourceProperty {-interactive}
```

- Using Jython:

```
AdminTask.setResourceProperty('-interactive')
```

showResourceProperties

Use the showResourceProperties command to list all of the property values that are defined on a resource provider such as JDBC provider or a connection factory such as data source or JMS connection factory.

Target object

The configuration object ID of a resource provider or a connection factory.

Required parameters

None.

Optional parameters

-propertyName
Specifies the name of the property. If you specify the property name, the value of the specified property name is returned. If you do not specify the property name, all property values will be listed. Each element in the list is a property name value pair. (String, optional)

Sample output

The command returns the property values that are defined on the resource provider or the connection factory that you specified.

Examples

Batch mode example usage:

- Using Jacl:

```
$AdminTask showResourceProperties {-propertyName test.property}
```

- Using Jython string:

```
print AdminTask.showResourceProperties('[-propertyName test.property]')
```

- Using Jython list:

```
print AdminTask.showResourceProperties(['-propertyName', 'test.property'])
```

Interactive mode example usage:

- Using Jacl:

```
$AdminTask showResourceProperties {-interactive}
```

- Using Jython:

```
print AdminTask.showResourceProperties('-interactive')
```

Creating and configuring a JDBC provider and data source using the JMX API

If your application requires access to a relational database using the Java Database Connectivity (JDBC) API, you can create the necessary JDBC provider and data source objects using the Java Management Extensions (JMX) API exclusively. Alternatively, you can use the JMX API in combination with the wsadmin scripting tool.

About this task

bprac: If you are using the JMX API to create a data source, you should use one of the product-provided templates if one exists for your specific JDBC provider. The product provides a template for every supported JDBC provider. See the topic, Data source minimum required settings, by vendor, for a list of all of the supported JDBC providers. When you use the administrative console to select one of the provided templates, the administrative console prompts you for values for all of the required properties for that data source. See the topic, Configuring a JDBC provider and data source, for

more information about how to use the administrative console to create a data source. If you decide to use the wsadmin scripting tool to create a data source, see the topic, Data source minimum required settings, by vendor, for a list of the required settings.

Example

Using the JMX API to create the configuration objects necessary to access relational databases. This code sample demonstrates how to use the WebSphere Application Server MBeans to create and configure the objects which are required to access a relational database from an enterprise application. These objects include: a JDBC provider, either XA or non-XA capable, a data source, an authentication alias, and optionally a Container Managed Persistence (CMP) connection factory. Details of configuring these options can be found in the header comments of the following source code. The sample also demonstrates how to use the data source MBean to reload the configuration changes into the running server.

/**
 * This sample code demonstrates the use of the WebSphere JMX APIs to create
 * a DB2 jdbc provider and data source with an authentication alias.
 * This sample code may be configured to:
 * - Create either node or server scoped objects
 * - Create either an XA or non-XA jdbc provider
 * - Create a connection factory so the data source may be used by CMP beans,
 * otherwise the data source may be used by BMP beans, session beans, or
 * servlets
 * These are configured by setting the value of class constants
 * (see "Program configuration settings" below)
 * The jdbc provider, data source and CMP connection factory (if configured)
 * are created using predefined templates, which is a best practice.
 * Note: there are templates which will create both the jdbc provider and a
 * data source at once, this sample intentionally creates both objects
 * separately for thoroughness
 *
 * To compile and run this program, put the admin client bundle
 * was_install_root\runtimes\com.ibm.ws.admin.client_8.0.0.jar
 * on the classpath in addition to the classfile that was obtained when
 * this source file was built.
 *
 * Once compiled, this program is run in it's own JVM and
 * uses the WebSphere Admin Client API to interact with a WebSphere
 * Application Server either locally or remotely to create the
 * JDBC resources discussed above.

        ObjectName queryName =
            new ObjectName("WebSphere:type=" + beanName + ",*");
        Set names = adminClient.queryNames(queryName, null);
        if (!names.isEmpty()) {
            mBean = (ObjectName) names.iterator().next();
        }
        return mBean;
    }
}
```

Example: Creating a JDBC provider and data source using Java Management Extensions API and the wsadmin scripting tool:

The following sample code is a JACL (wsadmin - scripting tool) script used to create a data source.

Use this script to create only data sources for which the product does *not* provide a template. For every JDBC provider WebSphere Application Server supports, the product provides a corresponding data source template. See the topic, Creating configuration objects using the wsadmin tool, for instructions on how to use the `createUsingTemplate` command to establish these data sources. For a complete list of supported JDBC providers (and therefore a complete list of data sources that must be created using a template), refer to the topic, Data source minimum required settings, by vendor.

This script sets up the following sample JDBC objects:
- Creates a data source *fvtDS_1*
- Creates a 4.0 data source *fvtDS_3*
- Creates a container-managed persistence (CMP) data source linked to *fvtDS_1*

Attention: If you later modify the class path or native library path of the JDBC provider associated with your data source, you must restart every application server within the scope of that JDBC provider for the new configuration to work. Otherwise, you receive a data source failure message.

```
#AWE --  Set up XA DB2 data sources, both Version 4.0 and  Connector architecture (JCA)-compliant data sources

#UPDATE THESE VALUES:
#The classpath that will be used by your database driver
set driverClassPath "c:/sqllib/java/db2java.zip"

set server "server1"

set fvtbase "c:/wssb/fvtbase"

#Users and passwords..

```

Using the DB2 Universal JDBC Driver to access DB2 for z/OS

The z/OS operating system requires that you configure the DB2 Universal JDBC Driver and your database to ensure interoperability. Within WebSphere Application Server, configure a Java Database Connectivity (JDBC) provider object and a data source object to implement the driver capabilities for your applications.

Before you begin

The available versions of the DB2 Universal JDBC Driver to connect with DB2 on z/OS are as follows:

- The DB2 Universal JDBC Driver in DB2 UDB for z/OS Version 8. This version supports both driver Types 2 and 4.
- The DB2 Universal JDBC Driver for DB2 UDB for OS/390® and z/OS Version 7, as documented in APAR PQ80841. This version supports both driver Types 2 and 4.
- The DB2 Universal JDBC Driver with the feature *z/OS Application Connectivity to DB2 for z/OS*, which provides Type 4 connectivity only. If you install this version of the driver, you must configure a DB2 Universal JDBC Driver provider (XA) to access remote DB2 databases.

Consult the DB2 service updates for available enhancements on the version that use.

Migration tip: If you are replacing the DB2 for 390 and z/OS Legacy JDBC driver with the DB2 Universal JDBC Driver, you can migrate your existing JDBC provider settings. See the topic Migrating from the JDBC/SQLJ Driver for OS/390 and z/OS to the DB2 Universal JDBC Driver in the Information Management Software for z/OS Solutions Information Center for more information.

Procedure

1. Install the driver class files and any necessary native files in an available HFS directory.

   Native files are class files that some versions of the DB2 Universal JDBC Driver require for running on the z/OS operating system.

2. Configure the driver and database for interoperability

   a. Bind the required DB2 packages

      Any application that executes SQL statements in DB2 for z/OS, the Universal JDBC driver must first bind with DB2 the packages that represent the SQL statements to be executed.

      The specific details of the bind utility and bind process are described by the readme file provided with the installed DB2 Universal JDBC Driver. Refer to this readme file for details on how to set up and perform the required binding.

      The utility requires the server name or IP address, the port number, and the database name (the database location on z/OS) for the target DB2. To get this information, issue a DB2 **-DISPLAY DDF** command on the target DB2 system. This command displays the IPADDR (IP address), the SQL DOMAIN (server name), the TCPPORT number, and the LOCATION (database name/location) for you to use as input to the utility.

      You must perform the bind process for each target DB2 accessed using the DB2 Universal JDBC Driver.

   b. Set up to handle in-doubt transactions

      Perform this setup once for each target DB2 for z/OS Version 7 location that is accessed using the DB2 Universal JDBC Driver Type 4 XA support.

      DB2 for z/OS Version 7 does not implement Java Platform, Enterprise Edition (Java EE) XA support, therefore, the Type 4 driver XA processing uses DB2 V7 two-phase commit protocol and a table in each location (database) to store a list of global transactions that are in doubt or finished but not committed.

      This table must be set up at each DB2 V7 location that is accessed. To do the set up, use the In-Doubt Utility, which is included as part of the installed DB2 Universal JDBC Driver. The utility creates the SYSIBM.INDOUBT Table that stores information about In-Doubt Global Transactions. This utility also binds the package T4XAIndbtPkg, which contains the SQL statements to insert and delete from the SYSIBM.INDOUBT Table. The T4XAIndbtPkg package is written with SQLJ.

      This installation process requires that the target DB2 subsystem is configured with DDF enabled for incoming TCP/IP connections.

      1) To enable DDF on the target DB2, issue the DB2 **-START DDF** command on that system.
      2) This utility requires the server name or IP address and the port number for the target DB2 V7. To obtain this information, issue a DB2 **-DISPLAY DDF** command on the target DB2 V7 system. The IPADDR (IP address), the SQL DOMAIN (server name), and the TCPPORT number that can be used as input to the utility are displayed.

      To find more detailed information about the In-Doubt utility, refer to the *DB2 Universal Database™ for z/OS Version 7 Application Programming Guide and Reference for Java™* publication. You can download it from the Library section of the DB2 Universal Database for z/OS Version 7 product information web pages. Within this publication, search for discussion about the utility under **`DB2T4XAIndoubtUtil`**, which is the official name of the In-Doubt utility.

      Note: The previously described setup for in-doubt transactions is ***not*** a requirement for DB2 FOR z/OS Version 8 servers because DB2 FOR z/OS Version 8 natively supports XA commands over DRDA® and manages the In-Doubt Global Transactions internally.

   c. Define a db2.jcc.propertiesFile

      A db2.jcc.propertiesFile for use by DB2 Universal JDBC Driver Type 2 processing under WebSphere Application Server for z/OS can be created and specified as input to the driver. This runtime properties file is for use in specifying various runtime options that the DB2 Universal JDBC Driver uses for Type 2 connectivity. These options are specified as properties in the form of

parameter=value. Refer to the README file packaged with the installed DB2 Universal JDBC Driver for a detailed description of each of the properties.

This file is not required; however, if it is not provided, universal driver default processing is performed.

Of specific interest is the db2.jcc.ssid property. This property specifies the DB2 subsystem identifier (not location name), to be used by the DB2 Universal JDBC Driver Type 2 processing as the local subsystem name to which it connects. If this property is not provided, the driver uses the subsystem identifier that it finds in the DSNHDECP load module. If the installation wants to use the DSNHDECP load module to specify the subsystem identifier, this load module must be included in a `steplib` data set in the servant region PROCs associated with each server that uses the DB2 identified by the subsystem ID. Refer to the readme file packaged with the universal driver for more information about using this load module. If that DSNHDECP load module does not accurately reflect the wanted subsystem, or if multiple subsystems might be using a generic DSNHDECP, the db2.jcc.ssid property must be specified.

Although the db2.jcc.propertiesFile is not required, if you choose to define the file, you must specify the fully qualified HFS file name as a JVM System property as follows:

- **db2.jcc.propertiesFile = <fully-qualified-hfs-filename>**

The driver-general properties are typically specific to a driver load, for example, server, rather than all servers using the JDBC provider, therefore, it is best to set this JVM property at the server level. To define the **db2.jcc.propertiesFile=** property to the server level using the WebSphere Application Server for z/OS administrative console:

1) Under the WebSphere Application Server for z/OS administrative console, go to **Servers** > **Application Servers**, then click the server to which you want to add the JVM property.
2) On the selected server page, expand **Java and Process Management** and click **Process Definition** > **Servant**.
3) On the Servant page, click **Additional Properties**, then click **Java Virtual Machine**.
4) On the Java Virtual Machine page, click **Additional Properties**, then click **Custom Properties**.
5) On the Custom Properties page, scroll down and click **New** to configure a new JVM property for the selected server. The name of the property is **db2.jcc.propertiesFile**. The value of the property is the fully qualified HFS file name that you created and initialized with the DB2 Universal JDBC Driver properties. The Type 2 driver uses these properties for the selected server
6) Click **Ok**.
7) Click **Save** to save the new JVM property.

3. Define a JDBC provider for the DB2 Universal JDBC Driver. The JDBC provider object encapsulates the driver classes for implementation in WebSphere Application Server.
   a. From the WebSphere Application Server for z/OS administrative console, click **Resources** > **JDBC** > **JDBC Providers**.
   b. Select the *scope* at which applications can use the JDBC provider. This scope becomes the scope of any data source that you associate with this provider. You can choose a cell, node, cluster, or server. For more information, see the topic, administrative console scope settings.
   c. Click **New**. This action causes the **Create a new JDBC Provider** wizard to launch.
   d. Use the first drop-down list to select DB2 for z/OS as your database type.
   e. Select the DB2 Universal JDBC Driver provider as your JDBC provider type in the second drop-down list.
   f. From the third drop-down list, select the implementation type that is necessary for your application.

      If your application does not require that connections support two-phase commit transactions, and you plan to use type 4 connectivity, choose **Connection Pool Data Source**. If you use the connection pool data source with type 2 connectivity, however, Application Server on z/OS uses RRS to process *both* one-phase and two-phase transactions.

Restriction: Do not select **Connection Pool Data Source** if your installation has the z/OS Application Connectivity to DB2 for z/OS feature defined to WebSphere Application Server for z/OS. Only the XA implementation of the DB2 Universal JDBC Driver supports this feature.

Choose **XA Data Source** if you plan to use driver type 4, and your application requires connections that support two-phase commit transactions. Use only driverType 4 connectivity for the XA data source.

After you select an implementation type, the wizard fills the name and the description fields for your JDBC provider. You can type different values for these fields; they exist for administrative purposes only.

g. Click **Next** after you have defined your database type, provider type, and implementation type. Now you see the wizard page Enter database class path information.

   Typically you do not need to change the class path that already populates the field. (That class path is the value of the WebSphere environment variable that is displayed on this page, in the form of ${*DATABASE*_JDBC_DRIVER_PATH}.) Most likely you also do not need to change the native library path or the data source implementation class name.

h. Click **Next** to see a summary of your JDBC provider settings.

i. Click **Finish** if you are satisfied with the entire JDBC provider configuration. The JDBC provider collection page displays, which shows your new JDBC provider in a table along with other providers that are configured for the same scope.

4. Define a data source. WebSphere Application Server uses the data source object to obtain database connections and manage those connections.

   a. From the WebSphere Application Server for z/OS administrative console, access the page for the data source version that your applications require. If you need support for two-phase transactions, use only a data source of the latest standard version. Version 4 data sources do not support connections that participate in two-phase transactions.

      Navigate to the appropriate page in one of two ways:

      - Click **Resources** > **JDBC** > **Data sources**, or **Data sources (WebSphere Application Server Version 4)**.
      - Click **Resources** > **JDBC** > **JDBC providers** > *JDBC_provider* > **Data sources**, or **Data sources (WebSphere Application Server Version 4)**.

   b. Select the *scope* at which applications can use the data source. You can choose a cell, node, cluster, or server. For more information, see the topic Administrative console scope settings.

      Version 4 only: From this point onward, the steps for creating data sources (WebSphere Application Server Version 4) differ from the steps for creating data sources of the latest standard version. To configure a Version 4 data source complete the following steps:

      - Click **New** to proceed to the console page for defining required properties.
      - On this properties page specify values for the fields that are grouped under the heading **Configuration**. Application Server requires these properties to implement your JDBC driver classes; see the topic, Data source minimum required settings, by vendor to learn about acceptable values.
      - Save your configuration by clicking **OK**. You are now finished with the primary data source configuration tasks.
      - Optional: Define additional properties that are supported by the DB2 Universal JDBC provider. Application Server calls them *custom properties*, and requires that you set them on the data source as well. Begin by clicking the Custom Properties link that is now displayed on the administrative console page. You can learn about optional data source properties in the *Application Programming Guide and Reference for Java* for your version of DB2 for z/OS.

c. Click **New**. This action causes the **Create a data source** wizard to launch and display the Enter basic data source information page. The first field is the scope field, which is read-only. This field displays your previous scope selection.

d. Type a data source name in the Data source name field. This name identifies the data source for administrative purposes only.

e. Type a Java Naming and Directory Interface (JNDI) name in the JNDI name field. WebSphere Application Server uses the JNDI name to bind application resource references to this data source. For more information about JNDI, see the topic, Naming.

f. Configure a component-managed alias to secure your data source if you plan to implement driverType 4 connectivity with the DB2 Universal JDBC Driver. If you plan to use driverType 2 connectivity, you do not have to set an alias. In this case the connection manager uses a default authentication alias, which is the user identity of a thread when that thread delivers a getConnection request.

   A component-managed alias consists of an ID and password that are specified in an application for data source authentication. Therefore, the alias that you set on the data source must be identical to the alias in the application code. For more information about Java 2 Connector (J2C) security, see the topic, Managing Java 2 Connector Architecture authentication data entries.

   To set a component-managed alias, either select an existing alias or create a new one.

   - Use the drop-down list to select an existing component-managed authentication alias.
   - To create an alias, click the **create a new one** link. This action closes the data source wizard and triggers the administrative console to display the J2C authentication data collection page. Click **New** to define a new alias. Click **OK** to save your settings and view the new alias on the J2C authentication data collection page. Restart the data source wizard by navigating back to the data source collection page, selecting the appropriate scope, and clicking **New**.

g. Click **Next** to see the wizard page Select JDBC provider.

h. Either select an existing JDBC provider, or create a provider.

   To select an existing JDBC provider:

   1) Click **Select an existing JDBC provider**.
   2) Select a JDBC driver from the drop-down list.
   3) Click **Next**. You now see the page entitled Enter database-specific properties for the data source.

   To create a JDBC provider:

   1) Click **Create new JDBC provider**.
   2) Click **Next** to see the Create JDBC provider page.
   3) Use the first drop-down list to select DB2 for z/OS as your database type.
   4) Select the DB2 Universal JDBC Driver provider as your JDBC provider type in the second drop-down list.
   5) From the third drop-down list, select the implementation type that is necessary for your application.

      If your application does not require that connections support two-phase commit transactions, choose **Connection Pool Data Source**. Both driverType 2 and driverType 4 connectivity implementations of the DB2 Universal JDBC Driver support connection pool data sources.

      Restriction: Do not select this provider if your installation has the z/OS Application Connectivity to DB2 for z/OS feature defined to WebSphere Application Server for z/OS. Only the XA implementation of the DB2 Universal JDBC Driver supports this feature.

      Choose **XA Data Source** if your application requires connections that support two-phase commit transactions. Applications that use this data source configuration have the benefit of container-managed transaction recovery. Use only driverType 4 connectivity for the XA implementation.

After you select an implementation type, the wizard fills the name and the description fields for your JDBC provider. You can type different values for these fields; they exist for administrative purposes only.

6) Click **Next** after you have defined your database type, provider type, and implementation type. Now you see the wizard page Enter database class path information.

   Typically you do not need to change the class path that already populates the field. (That class path is the value of the WebSphere environment variable that is displayed on this page, in the form of ${*DATABASE*_JDBC_DRIVER_PATH}.) Most likely you also do not need to change the native library path or the data source implementation class name.

7) Click **Next**. You now see the page entitled Enter database-specific properties for the data source.

i. Click **Use this data source in container managed persistence (CMP)** if container managed persistence (CMP) enterprise beans must access this data source.

j. Specify all the remaining properties, as they are required for implementation of the DB2 Universal JDBC Driver. These properties include:

   - Database name, which is the location name of the target database used when establishing connections with this data source
   - driverType, which is the JDBC connectivity type used by the data source
   - Server name, which is the TCP/IP address or host name for the Distributed Relational Database Architecture™ (DRDA) server.

     This property is required only if driverType is set to 4. This property is not used if driverType is set to 2.
   - Port number, which is the TCP/IP port number where the DRDA server resides.

     Provide a value for this property only if driverType is set to 4. Do not set this property if driverType is set to 2.

k. Click **Finish** to save the configuration and exit the wizard. The Data source collection page displays, which shows your new configuration in a table along with other data sources that are configured for the same scope.

What to do next

You can override the default values for some data source properties. Click your new data source link in the table to view the general configuration page for required data source properties. You can also define additional properties that are supported by the DB2 Universal JDBC Driver. Application Server requires that you set them as custom properties on the data source. Learn about optional data source properties in the *Application Programming Guide and Reference for Java* for your version of DB2 for z/OS.

Extended data source properties:

Use this page to set the extended data source properties for a DB2 database. You can use these properties to allow an application to extend the custom properties for a data source or override any non-core properties that already exist for that data source.

To access this administrative console page:

- For applications that do not use container-managed persistence click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Resource references**
- For applications that use container-managed persistence click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Provide default data source mapping for modules containing 2.x entity beans**.

For data sources that use the DB2 Universal JDBC driver or DB2 Using IBM JCC Driver, click **Extended properties...** in the **Target Resource JNDI Name** column.

gotcha: If you include multiple values for an extended data source property, you must enclose those values in quotation marks.

Name: Specifies the name (or key) for the property.

Each property name must be unique. If the same name is used for multiple properties, the value specified for the first property that has that name is used.

Do not start your property names with `was`, because this prefix is reserved for properties that are predefined in the application server.

Data type String

Value:

Specifies the property value.

Data type Variable

Configuring two resource reference files on the same data source:

You can configure two resource reference files on the same data source. This allows you to extend the custom properties for the data source to be extended to include two different schema names (currentSQLId on z/OS or currentSchema name in the custom properties) that can be used to exploit the capabilities of the application server.

About this task

When an EntityManager is created, the application server obtains a connection to the database. When you are using a pessimistic transaction, the EntityManager will retain that connection until the EntityManager is closed. When there are two EntityManagers that extend the data source definitions, the `openjpa.jdbc.TransactionIsolation` property might cause a problem with the transaction. This property can be found in the `persistence.xml` file in the following entry:

```
property name="openjpa.jdbc.TransactionIsolation" value="read-committed"
```

In order to satisfy this request, Java Persistence API (JPA) will obtain a connection and immediately call `setTransactionIsolation(READ_COMMITTED)`. When you have two EntityManagers share a single physical connection to the database, the first EntityManager creates a connection to the database and involves that connection in a transaction. When the second EntityManager creates a connection, it is not able to change the isolation level.

You can avoid this problem by creating two resource reference files in the same data source. You can create the resource references with Rational Application Developer or by editing the XML files. You will need to make changes to the `ejb-jar.xml`, `ibm-ejb-jar-bnd.xml`, `ibm-ejb-jar-ext.xml`, `persistence.xml` files.

Note: For IBM Optim PureQuery Runtime, if this is an XA data source you must define a new custom property on the data source where *property_name* = `downgradeHoldCursorsUnderXa` and boolean value = `true`.

See the following sections for information on how to accomplish this:

- Configure two resource reference files on the same data source using Rational Application Developer.
- Configure two resource reference files on the same data source by editing the XML files.

Procedure

- Configure two resource reference files on the same data source using Rational Application Developer.
  1. Edit the `ejb-jar.xml` file
     a. Create the deployment descriptor if it doesn't already exist:
        1) Go to the context menu of the Enterprise Java beans (EJB) project and select **Java EE** > **Generate Deployment Descriptor Stub**.
     b. Edit the deployment descriptor:
        1) Go to the project's META-INF directory and select the `ejb-jar.xml` file.
     c. Add the enterprise bean's element to the deployment descriptor if it doesn't already exist:
        1) In the left hand pane, select **EJB Project node**. Click **Add**.
        2) In the dialog, select **Enterprise Beans**. Click **OK**.
     d. Add the session bean to the deployment descriptor if it's not already there:
        1) In the left pane, select **Enterprise Beans**. Click **Add**.
        2) Select **Session Bean**. Click **OK**.
        3) Enter the name of the session bean in the dialog. Click **OK**.
        4) In the right-side pane, enter the `EJB Class`, the business local, and the business remote interfaces.
     e. Add the resource reference elements to the session bean:
        1) Select the session bean in the left pane and click **Add**.
        2) Select **Resource Reference**. Click **OK**.
        3) In the **Add Resource Reference** dialog, enter the name, type, authentication and sharing scope fields. Click **OK**.
        4) Repeat for the second resource reference.
     f. Save the editor
  2. Edit the `ibm-ejb-jar-bnd.xml` file
     a. Create the WebSphere EJB bindings descriptor if it doesn't already exist
        1) Go to the context menu of the Enterprise JavaBeans (EJB) project and select **Java EE** > **Generate WebSphere Bindings Deployment Descriptor**.
     b. Edit the bindings descriptor:
        1) In the project's META-INF directory, select the `ibm-ejb-jar-bnd.xml` file.
     c. Add a binding element for the session bean to the bindings descriptor:
        1) In the left pane, select **EJB Jar Bindings** node and click **Add**.
        2) In the dialog, select **Session** and click **OK**.
        3) In the right pane, enter the name of the session bean.
     d. Add the bindings for the resource references to the session bean:
        1) In the left pane, select the session bean and click **Add**.
        2) In the dialog, select **Resource Reference** and click **OK**.
        3) In the left pane, select the resource reference.
        4) In the right pane, enter the name and binding name for the reference
        5) Repeat for the second resource reference.
     e. Save the editor
  3. Edit the `ibm-ejb-jar-ext.xml` file.
     a. Create the WebSphere EJB extensions descriptor if it doesn't already exist:
        1) Go to the context menu of the Enterprise JavaBeans (EJB) project and select **Java EE** > **Generate WebSphere Extensions Deployment Descriptor**.
     b. Edit the extensions descriptor:

1) In the project's META-INF directory, select the `ibm-ejb-jar-ext.xml` file.

c. Add an extensions element for the session bean to the extensions descriptor:
   1) In the left pane, select the **EJB Jar Extensions** node and click **Add**.
   2) In the dialog, select **Session** and click **OK**.
   3) In the right pane, enter the name of the session bean.

d. Define the isolation level for the resource references:
   1) In the left pane, select the session bean and click **Add**.
   2) In the dialog, select **Resource Reference** and click **OK**.
   3) In the left pane, select the resource reference.
   4) In the right pane, enter the name and the isolation level.
   5) Repeat for the second resource reference.

e. Save the editor

4. Edit the `persistence.xml` file.
   a. Add JPA support to the EJB project, which will create the persistence.xml file:
      1) From the project's context menu, select **Properties**.
      2) In the left pane, select the **Project Facets** node.
      3) In the right pane, check the box beside **Java Persistence**.
      4) Click **OK**.
   b. Edit the `persistence.xml` file:
      1) In the project's META-INF directory, select the `persistence.xml` file
   c. The created `persistence.xml` file already contains a persistence unit definition. Edit this `persistence.xml` file
      1) In the left pane, select the **Persistence Unit** node. Set the name, JTA data source and exclude the unlisted classes fields.
   d. Create a new persistence unit definition in the file:
      1) In the left pane, select the **Persistence** node and click **Add** .
      2) In the dialog, select **Persistence Unit** and click **OK**.
      3) In the left pan, select the **Persistence Unit** node. Set the name, JTA data source and exclude the unlisted classes fields.
   e. Add classes to the persistence unit:
      1) In the left pane, select the persistence unit node and click **Add** .
      2) In the dialog, select **Class** and click **OK**.
      3) In the right pane, enter the name of the class.
      4) Repeat for each class.
   f. Add properties to the persistence unit
      1) If there is not already a **Properties** element in the file, select the persistence unit node in the left pane and click **Add**.
      2) In the dialog, select **Properties** and click **OK**.
      3) In the left pane, select the **Properties** node and click **Add**.
      4) In the dialog, select **Property** and click **OK**.
      5) In the right pane, enter the name and value for the property
      6) Repeat the previous three steps to add the additional properties.
   g. Save the editor

- Configure two resource reference files on the same data source by editing the XML files.
  1. Edit the `ejb-jar.xml` file:

```
<?xml version="1.0" encoding="UTF-8"?>
<ejb-jar id="ejb-jar_ID" metadata-complete="false" version="3.0" xmlns="http://java.sun.com/xml/ns/javaee"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://java.sun.com/xml/ns/javaee http://java.sun.com/xml/ns/javaee/ejb-jar_3_0.xsd">
    <enterprise-beans>
        <session>
            <ejb-name>NewOrderSessionFacadeBean</ejb-name>
            <business-local>neworder session.ejb3.NewOrderSessionFacade</business-local>
            <business-remote>neworder session.ejb3.NewOrderSessionFacadeRemote</business-remote>
            <ejb-class>neworder session.ejb3.NewOrderSessionFacadeBean</ejb-class>
            <session-type>Stateless</session-type>
   <resource-ref>
    <description></description>
    <res-ref-name>jdbc/ERWWDataSourceV5</res-ref-name>
    <res-type>javax.sql.DataSource</res-type>
    <res-auth>Container</res-auth>
    <res-sharing-scope>Shareable</res-sharing-scope>
   </resource-ref>
   <resource-ref>
    <description></description>
    <res-ref-name>jdbc/ERWWDataSourceV5_HP</res-ref-name>
    <res-type>javax.sql.DataSource</res-type>
    <res-auth>Container</res-auth>
    <res-sharing-scope>Shareable</res-sharing-scope>
   </resource-ref>
        </session>
     </enterprise-beans>
</ejb-jar>
```

2. Edit the `ibm-ejb-jar-bnd.xml` file:

```
<?xml version="1.0" encoding="UTF-8"?>
<ejb-jar-bnd xmlns="http://websphere.ibm.com/xml/ns/javaee"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-ejb-jar-bnd_1_0.xsd"
 version="1.0">
 <session name="NewOrderSessionFacadeBean" simple-binding-name="ejb/session/NewOrderSessionFacadeBean">
  <resource-ref name="jdbc/ERWWDataSourceV5" binding-name="jdbc/ERWWDataSourceV5"></resource-ref>
  <resource-ref name="jdbc/ERWWDataSourceV5_HP" binding-name="jdbc/ERWWDataSourceV5"></resource-ref>
 </session>
</ejb-jar-bnd>
```

3. Edit the `ibm-ejb-jar-ext.xml` file:

```
<?xml version="1.0" encoding="UTF-8"?>
<ejb-jar-ext xmlns="http://websphere.ibm.com/xml/ns/javaee"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:schemaLocation="http://websphere.ibm.com/xml/ns/javaee http://websphere.ibm.com/xml/ns/javaee/ibm-ejb-jar-ext_1_0.xsd"
 version="1.0" metadata-complete="true">
 <session name="NewOrderSessionFacadeBean">
  <resource-ref name="jdbc/ERWWDataSourceV5"
   isolation-level="TRANSACTION_READ_COMMITTED" />
  <resource-ref name="jdbc/ERWWDataSourceV5_HP"
   isolation-level="TRANSACTION_READ_COMMITTED" />
 </session>
</ejb-jar-ext>
```

4. Edit the `persistence.xml` file:

```
<?xml version="1.0" encoding="UTF-8"?>
<persistence xmlns="http://java.sun.com/xml/ns/persistence" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 version="1.0" xsi:schemaLocation=
"http://java.sun.com/xml/ns/persistence http://java.sun.com/xml/ns/persistence/persistence_1_0.xsd">
    <persistence-unit name="NewOrderSessionEJB3">
        <jta-data-source>java:comp/env/jdbc/ERWWDataSourceV5</jta-data-source>
        <class>warehouseejb3.WarehouseJPA</class>
        <class>districtejb3.DistrictJPA</class>
        <class>customerejb3.CustomerJPA</class>
        <class>stockejb3.StockJPA</class>
        <class>orderejb3.OrderJPA</class>
        <class>orderlineejb3.OrderlineJPA</class>
        <class>neworderejb3.NewOrderJPA</class>
        <exclude-unlisted-classes>true</exclude-unlisted-classes>
        <properties>
  <property name="openjpa.LockManager" value="pessimistic"/>
  <property name="openjpa.ReadLockLevel" value="read"/>
  <property name="openjpa.WriteLockLevel" value="write"/>
  <property name="openjpa.LockTimeout" value="30000"/>
     <property name="openjpa.FetchBatchSize" value="1" />
     <property name="openjpa.jdbc.TransactionIsolation" value="read-committed" />
     <property name="openjpa.Log" value="none"/>
     </properties>
    </persistence-unit>
    <persistence-unit name="ItemEJB3">

        <class>itemejb3.ItemJPA</class>
```

```
        <exclude-unlisted-classes>true</exclude-unlisted-classes>
        <properties>
  <property name="openjpa.LockManager" value="pessimistic"/>
  <property name="openjpa.ReadLockLevel" value="read"/>
  <property name="openjpa.WriteLockLevel" value="write"/>
  <property name="openjpa.LockTimeout" value="30000"/>
     <property name="openjpa.FetchBatchSize" value="1" />
     <property name="openjpa.jdbc.TransactionIsolation" value="read-committed" />
     <property name="openjpa.Log" value="none"/>
     </properties>
    </persistence-unit>
</persistence>
```

Configuring Oracle Real Application Cluster (RAC) with the application server

Oracle Real Application Cluster (RAC) is a "share-everything" database architecture in which two or more Oracle RAC nodes are clustered together and share the same storage. The RAC nodes are connected together with a high-speed interconnect that enables fast communication between the Oracle nodes. The nodes can exchange various categories of data block ownership information during startup, lock information, exchange transaction information and data, and so on.

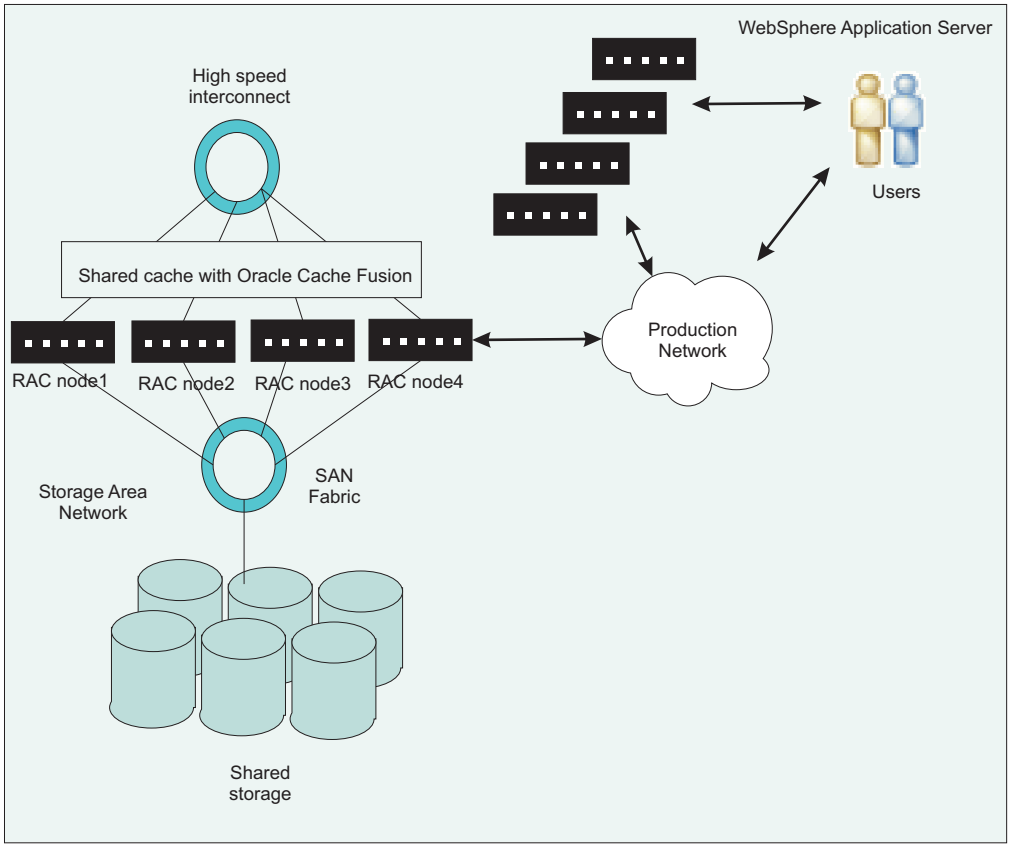
About this task

Using the Oracle JDBC driver, you can configure failover support, load balancing, or both, in an Oracle Real Application Clusters (RAC) environment. Oracle RAC is an option of an Oracle database that brings together two or more computers to form a clustered database that behaves as a single system. In a RAC database, Oracle processes that are running in separate nodes access the same data from a shared disk storage. First introduced in Oracle Version 9i, RAC provides both high availability and flexible scalability.

A typical Oracle RAC cluster consists of the following:

- **Cluster nodes** – 2 to *n* nodes or hosts, running the Oracle database server.
- **Network Interconnect** – a private network used for cluster communications and cache fusion. This is typically used for transferring database blocks between node instances.
- **Shared Storage** – used to hold the database system and data files. The shared storage is accessed by the cluster nodes.
- **Production network** – used by clients and application servers to access the database.

The following figure depicts a typical configuration for Oracle RAC:



Here are two of the many features that Oracle RAC provides:

- *Oracle Notification Service (ONS)* allows for Oracle RAC to communicate the status for the nodes, which are typically UP and DOWN events, to the Oracle JDBC driver and the driver's connection cache. To take advantage of ONS, you must configure the application server to use Oracle's connection caching instead of the application server's connection pooling feature. Read the topic Configuring Oracle connection caching in the application server for more information on this process.
- *Distributed Transaction Processing (DTP)* is a feature that was introduced in Oracle 10gR2. When this feature is enabled, Oracle will ensure that all in-flight prepared transactions that belong to a DTP service for failed RAC instances are pushed to disk. Then, Oracle will restart the DTP service on any of the RAC instances that are still operational.

For more information on Oracle RAC and how it works with the application server, refer to *Building a high availability database environment using WebSphere middleware: Part 3: Handling two-phase commit in WebSphere Application Server using Oracle RAC* on the developerWorks® website.

Procedure

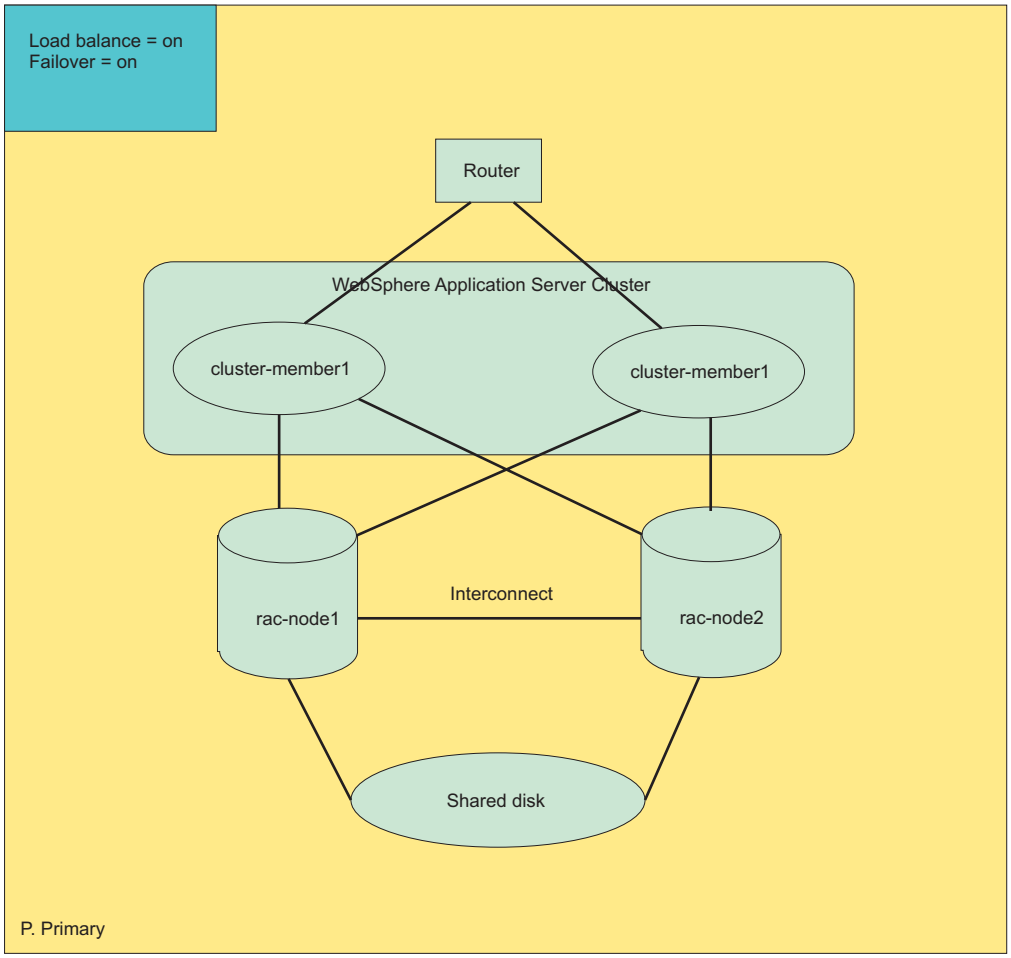
- "Configuring a simple RAC configuration in an application server cluster."
- "Configuring Oracle connection caching in the application server" on page 323.
- "Configuring two-phase commit distributed transactions with Oracle RAC" on page 324.

Configuring a simple RAC configuration in an application server cluster:

Oracle Real Application Cluster (RAC) is a "share-everything" database architecture that can provide high availability and load balancing. A typical configuration for an Oracle RAC contains two or more Oracle RAC nodes that are clustered together and share the same storage.

About this task

This figure depicts a typical RAC physical topology in a cluster environment for the application server, and both the failover and load balancing are enabled:



In the figure above, the application server cluster consists of two members: cluster-member1 and cluster-member2. The Oracle RAC physical configuration contains two nodes: rac-node1 and rac-node2. The RAC nodes can be located in the same physical machine with the cluster members, or they could be placed in entirely different machines. The actual placement does not impact the fundamental qualities of the services provided by RAC. To achieve both high availability and load-balancing, you can specify the Oracle data source URL for both cluster members in the application server with the required properties.

Procedure

1. Navigate to the Oracle data source. Click **Resources** > **JDBC** > **Data sources** > ***oracle_data_source***. If you don't already have an Oracle data source, create a new data source by clicking **New** and completing the wizard. For the URL, substitute the properties in the next step.
2. Set the URL for the Oracle database with the required configuration parameters.

```
jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS_LIST=
                  (ADDRESS=(PROTOCOL=TCP)(HOST=rac-node1)(port=1521))
                  (ADDRESS=(PROTOCOL=TCP)(HOST=rac-node2)(port=1521)))
                  (FAILOVER=on)(LOAD_BALANCE=on)
                  (CONNECT_DATA=(SERVER=DEDICATED)
                  (SERVICE_NAME=<service_name>)))
```

Note: Be aware of these configuration options:

- If you are not using Oracle services, then *service_name* will be the database name in the example. If you are using Oracle services, then *service_name* will be the name of the services.
- The example has FAILOVER and LOAD_BALANCE turned on. To turn one or both of these features off, change `on` to `off` in the above example.

3. Click **Apply** or **OK**.

Configuring Oracle connection caching in the application server:

You can elect to configure an Oracle data source to use the Oracle connection caching feature instead of using the application server connection pooling. Connection caching for Oracle databases is similar to connection pooling in the application server.

About this task

Currently, Oracle supports connection caching only with data sources that use the oracle.jdbc.pool.OracleDataSource implementation class, instead of the oracle.jdbc.pool.OracleConnectionPoolDataSource or oracle.jdbc.xa.client.OracleXADataSource classes. By default, the Oracle JDBC providers in the application server are configured to use the oracle.jdbc.pool.OracleConnectionPoolDataSource for non-XA data sources, or oracle.jdbc.xa.client.OracleXADataSource for XA data sources. To enable Oracle connection caching, you must configure and use a new JDBC provider in the application server that implements the oracle.jdbc.pool.OracleDataSource class.

Note: Oracle connection caching does not support XA.

Procedure

1. Create a data source and user-defined JDBC provider.
   a. Click **Resources** > **JDBC** > **Data sources**
   b. Select a server from the **Scope** drop-down list.
   c. Click **New**.
   d. Enter the name and JNDI name for the data source. Click **Next**.
   e. Create a JDBC provider. Select **Create new JDBC provider**, and click **Next**.
   f. Define the required properties for the JDBC provider. Use the following configuration settings:
      - **Database type:** User-defined
      - **Implementation class name:** oracle.jdbc.pool.OracleDataSource

      Click **Next**.
   g. Enter the class path for `ojdbc6.jar`, and click **Next**.
   h. For **Data store helper class name**, enter `com.ibm.websphere.rsadapter.Oracle11gDataStoreHelper`. Click **Next**.
   i. Define the security aliases for this data source, and click **Next**.
   j. Finish the wizard.
   k. Save the configuration changes.
2. Configure the data source that you created.
   a. Click the name of the data source. The configuration panel displays.
   b. Select **Custom properties**, and create or modify the properties for this data source. Enter or update the following custom properties:

Name	Value
disableWASConnectionPooling	true **gotcha:** You must also set the maximumPoolSize attribute to `0` on WebSphere Application Server connection pool settings to allow Oracle to control the pool boundaries.
connectionCachingEnabled	true
connectionCacheName	*your_cache_name*
removeExistingOracleConnectionPoolIfExists	true **Note:** The removeExistingOracleConnectionPoolIfExists property must be set to `true` so the application server removes any existing Oracle connection pools with an identical name. Otherwise, the Oracle data source fails the getConnection method if the pool name that is created has a name that is identical to an existing pool. For example, if you run a test connection, the test connection process creates an Oracle connection pool that prevents the application server from working properly at run time.
URL	*Oracle_URL*

Note: The order in which the custom properties are set is important. The setting order can be an issue because the application server passes the properties as a collection and the order is not guaranteed. If you encounter this issue, contact Oracle and reference Oracle bug #6638862.

3. Click **Apply** or **OK**.
4. Save the changes to the application server configuration.
5. Restart the application server.

Results

Oracle does not display a message if the pool creation fails, and a normal connection is returned instead. You can confirm that the Oracle connection pool is created by using the administrative console test connection function for the data source. First, turn on trace with the trace string, "RRA=all", for the server that runs your application. Then, issue a test connection. Issue a second test connection. Both test connections should work. Examine the trace log.

If the Oracle connection pool was created successfully, the trace shows that the second test connection detected that the Oracle connection cache exists because of the first test connection, and was successful in removing it so that it can be created again by the second test.

Configuring two-phase commit distributed transactions with Oracle RAC:

Real Application Cluster (RAC) configurations for Oracle 10g have an inherent issue with the transaction manager when Oracle attempts to recover two-phase commit distributed transactions that span over multiple Oracle RAC nodes. A problem can occur when one node fails, and Oracle opens up the other surviving nodes for business before the Oracle RAC completes the necessary recovery action for the node that has failed. The application server's ability to maintain transaction affinity provides you the ability to circumvent this issue.

About this task

Errors can occur when the recovery process attempts to commit or rollback a transaction branch through a RAC node that was previously active but later failed. The transaction manager would receive the following exception:

```
ORA- 24756: transaction does not exist
```

If this error is encountered, the Oracle database administrator might need to manually resolve the in-doubt transaction by forcing a rollback or commit process. If you do not desire a manual intervention, however, you might want to configure an automatic and transparent strategy for transaction recovery.

If the in-doubt transaction is not resolved, any subsequent transactions will receive the following exception:

```
ORA-01591 lock held by in-doubt distributed transaction
```

The result is that portions of the database will not be usable.

The key to a transparent recovery strategy is to eliminate the possibility of a global transaction spanning more than one transaction branch over multiple RAC nodes. A transaction branch corresponds to a database connection that is enlisted in a global transaction. If all connections in a global two-phase commit transaction originate from the same node, transaction recovery problems should not arise. Configure an Oracle RAC with the application server to prevent errors with two-phase transactions.

The application server maintains transaction affinity for incoming connections, and you can take advantage of this feature to configure automatic recovery for Oracle RAC with two-phase commit transactions. If you implement this configuration, all connections from a given application server will be received from the same Oracle node, and the connections will finish on that same node. This configuration will avoid situations in which transactions span multiple nodes, and you should not experience a recovery problem if one or more Oracle nodes go down.

Procedure

- You can elect to manually resolve the in-doubt transaction.
  1. Get the orphaned transaction ID. Issue the following command:

     ```
     sql > select state, local_tran_ID, Global_tran_Id from dba_2pc_pending where state = "prepared"
     ```
  2. Roll back all of the transaction IDs that are in the prepared phase.

     ```
     sql > rollback force '';
     ```
- Configure an automatic strategy for transaction recovery.
  1. Create an Oracle service that has only one primary node. Creating the service with one primary node will ensure that load balancing is disabled. You can also specify one or more alternate nodes with the -a parameter. Run this command to create the service:

     ```
     srvctl add service -d <database_name> -s <service_name> -r <primary nodes> -a <alternate_nodes>
     ```
  2. Enable Distributed Transaction Processing (DTP) on the Oracle service. DTP was first introduced in Oracle 10gR2. Each DTP service is a singleton service that is available on only one Oracle RAC instance. Run this command:

     ```
     execute dbms_service.modify_service (service_name => '<service_name>' , dtp => true);
     ```
  3. Configure each cluster member in the application server to use the Oracle DTP service.

Results

If you configured an automatic recovery strategy, the DTP service will start automatically on the preferred instance. However, if the database is restarted, the DTP service will not start automatically. You can start the DTP service using this command:

```
srvctl start service -d  -s
```

If a RAC node stops working, Oracle will not failover the DTP service until the Oracle RAC cleanup and recovery is complete. Even if the Oracle nodes come back up, the Oracle DTP service will not return to the freshly restarted RAC node. Instead, you will have to manually move the service to the restarted RAC node.

When you configure DTP on the Oracle service, you have transferred load balancing from the Oracle JDBC provider to the application server. The workload will be distributed by the application server instead of Oracle, which is why you created services that do not implement load balancing and only use one primary node. This configuration prevents situations in which transaction processes span multiple RAC nodes and alleviates recovery problems that can arise when one or more RAC nodes fail.

Configuring client reroute for applications that use DB2 databases

The client reroute feature enables you to configure your client applications for a DB2 universal database to recover from a communication loss, and the applications can continue to work with minimal interruption. Rerouting is central to the support of continuous operations, but rerouting is only possible when there is an alternate location that is identified to the client connection.

Before you begin

This task assumes the following:

- You have a DB2 data source defined in the application server. See the topic, Configuring a data source using the administrative console, for information about creating a data source.
- The DB2 data source to which your application connects is running one of the following:
  - DB2 for z/OS Version 9.1 or later
  - DB2 Database for Linux, UNIX, and Windows Version 9.5 or later
- You have implemented the DB2 database with a redundant setup or the ability to fail the DB2 server to a standby node.

About this task

Client reroute for DB2 allows you to provide an alternate server location, in case the connection to the database server fails. If you decide to use client reroute with the persistence option, the alternate server information persists across Java Virtual Machines (JVMs). In the event of an application server crash, the alternate server information is not lost when the application server is restored and attempts to connect to the database.

Without any configuration on the client side, a JDBC driver for DB2 supports the client reroute capability, if it is enabled, when the driver makes an initial connection to the DB2 server. When the JDBC driver connects to a DB2 server that has an alternate server configured, the primary server sends information about the alternate server to the JDBC driver. If the connection to the primary server fails, the JDBC driver is able to reroute connections to the alternate server. If the client process crashes, however, the alternate server information is lost, and the client needs to connect to the primary server again. If the client cannot make an initial connection to the primary server, the client has no knowledge of the alternate server and cannot reroute.

To overcome this problem, you can configure a DB2 data source in the application server with the **Alternate server name** and **Alternate port number** fields, or with the clientRerouteAlternateServerName and clientRerouteAlternatePortNumber data source custom properties, to support client reroute even on the initial connection attempt. If the JDBC driver is not able to connect to the primary DB2 server, the information that is necessary for a client reroute is already present, and the JDBC driver can reroute the connection to an alternate server.

Attention: The data source custom property, enableClientAffinitiesList, changes the semantics of the clientRerouteAlternateServerName and clientRerouteAlternatePortNumber properties.
To learn more about these properties, see the DB2 information center topic, Common IBM Data Server

Driver for JDBC and SQLJ properties for all supported database products. To learn more about client affinity, see the topic, .Configuring client affinity for applications that use DB2 databases.

Additionally, if you have configured a DB2 data source as a Type 4 JDBC driver, you can use the **Client reroute server list JNDI name** field, or the clientRerouteServerListJNDIName data source custom property, to enable persistence of the client reroute state. Typically, when a connection is rerouted and the JDBC driver has connected to the alternate DB2 server, the alternate server sends information about its own alternate server to the JDBC driver. The JDBC driver will then have the information that is required to reroute the connection again if the alternate DB2 server is not available. Effectively, the server that was originally the alternate server is now the primary server, and a new alternate server has been established. If you enable persistence for client reroute, this new state can be remembered. If the application server crashes and is restarted, the JDBC driver can connect to the DB2 server that was considered the primary server at the time of the crash. Without the persistence feature, the JDBC driver would have to start from the original server configuration and attempt to connect to the server that was originally considered the primary server.

You can use the automatic client rerouting feature within the following DB2 configurable environments:

- Enterprise Server Edition (ESE) with the data partitioning feature (DPF)
- Data Propagator (DPROPR)-style replication
- High availability cluster multiprocessor (HACMP™)
- High availability disaster recovery (HADR).

Procedure

1. In the administrative console, click **Resources** > **JDBC** > **Data sources** > ***data_source***.
2. Click **WebSphere Application Server data source properties**.
3. In the **DB2 automatic client reroute options** section, fill in the fields to enable client rerouting. Complete the following fields:

   Alternate server names
   Specifies the list of alternate server name or names for the DB2 server. If more than one alternate server name is specified, the names must be separated by commas. For example:

   ```
   host1,host2
   ```

   Alternate port numbers
   Specifies the list of alternate server port or ports for the DB2 server. If more than one alternate server port is specified, the ports must be separated by commas. For example:

   ```
   5000,50001
   ```

   Note: Ensure that an equal number of entries must be specified for both alternate ports and hosts. Otherwise, a warning is displayed and client reroute is not enabled.
4. Optional: Enable client reroute with the persistence option.
   a. Complete the field for **Client reroute server list JNDI name**. The field specifies the JNDI name that is used to bind the DB2 client reroute server list into the JNDI name space. The DB2 database server uses this name to look up the alternate server name list when the alternate server information is not already in memory.

      Note: Be aware of the following:
      - This option is not supported for Type 2 data sources. If you use a DB2 data source that is configured as a Type 2 JDBC driver, the JDBC driver uses a catalog to persist the client reroute information. If this property is configured with a Type 2 driver, the application server will issue a warning.
      - Use different JNDI names among different data sources. Otherwise, when you delete a data source, and the JNDI entry is removed from the name space, the other data sources that share the JNDI entry will be affected.

5. Configure the retry count and interval for the client reroute function. Complete these two fields:

   Retry interval for client reroute
   Specifies the amount of time, in seconds, between retries for automatic client reroute.

   Maximum retries for client reroute
   Specifies the maximum number of connection retries that are attempted by the automatic client reroute function if the primary connection to the server fails. The property is only used when **Retry interval for client reroute** is set.

   Attention: If you do not specify a value for these properties, DB2 failover processing (client rerouting) does not occur.
6. Click **OK** and save the changes.
7. Restart the application server.

What to do next

If you later want to remove the client reroute information that is bound in JNDI, you can do so by deleting the data source. You can also use the unbind feature with the test connection service to delete the JNDI binding for the client reroute function from the application server's JNDI name space without deleting the data source.

To delete the JNDI binding for client reroute:
1. Select **Unbind client reroute list from JNDI**.
2. Click **OK**.
3. Save the configuration.
4. Click **Test connection** for the data source.
5. Deselect **Unbind client reroute list from JNDI**.
6. Click **OK**.
7. Save the configuration.

Configuring client affinities for applications that use DB2 databases

The client affinities feature is an alternative to automatic client reroute when enabling your data source to use other servers when a connection fails. In this client-only method, the client determines the order that alternate servers run during failover. For more information about client affinities, see the topic, Client affinities for DB2 Database for Linux, UNIX, and Windows, in the DB2 information center.

Before you begin

This task assumes that:
- You have a DB2 data source defined in the application server. See the topic, Configuring a data source using the administrative console, for information about creating a data source.
- The DB2 data source to which your application connects is running one of the following databases:
  - DB2 for z/OS Version 9.1 or later
  - DB2 Database for Linux, UNIX, and Windows Version 9.5 or later
- You have implemented the DB2 database with a redundant setup or the ability to fail the DB2 server to a standby node.

About this task

In WebSphere Application Server, client affinities allows the DB2 data source on the client or application server to control the order of servers that are tried during initial connection processing.

For WebSphere Application Server, the data source custom property, enableClientAffinitiesList, is used to enable client affinities. If you want to use the administrative console to configure client affinities, use the DB2 automatic client reroute options section of the WebSphere Application Server data source properties panel to configure the following properties: Alternate server names, Alternate port numbers, Retry interval for client reroute, and Maximum retries for client reroute. You can also use the Custom properties panel to configure other client affinities properties as needed, including enableSeamlessFailover and affinityFailbackInterval.

The data source custom property, enableClientAffinitiesList, changes the semantics of the clientRerouteAlternateServerName and clientRerouteAlternatePortNumber properties.

Attention:

To learn more about these properties, see the DB2 information center topic, Configuration of client affinities for Java clients for DB2 Database for Linux, UNIX, and Windows connections.

To configure client affinities in the application server, complete the following steps:

Procedure

1. Configure a JDBC provider as usual with the JCC driver for DB2 in the class path.
2. Create a data source that uses the JDBC provider that was created in step 1. The server name and port information must be the name of the preferred primary server from your DB2 WLB environment.
3. After the data source is created, navigate to its primary panel in the administrative console by clicking **Resources** > **JDBC** > **Data sources** > ***data_source***.
4. Click **WebSphere Application Server data source properties** located under Additional Properties.
5. Scroll down to the section DB2 automatic client reroute options.
6. In the DB2 automatic client reroute options section, configure the Alternate server names, Alternate port numbers, Retry interval for client reroute, and Maximum retries for client reroute.
7. Click **OK**, and save the changes.
8. Navigate back to the data source primary panel, and click **Custom properties** located under Additional Properties.
9. On the Custom properties panel, configure other client affinities properties as needed, including enableClientAffinitiesList, enableSeamlessFailover and affinityFailbackInterval. Read about the configuration of client affinities for Java clients for DB2 Database for Linux, UNIX, and Windows connections, in the DB2 information center, for the recommended values for these properties.
10. Click **OK** and save the changes.
11. Restart the application server.

Verifying a data source connection

Many connection problems can be easily fixed by verifying configuration parameters. There are steps that you must complete to enable a successful connection.

About this task

If your connection is still not successful after completing these steps and reviewing the applicable information, check the SystemOut.log for warning or exception messages. Then use the technical support search function to find known problems. See the IBM Suggests section of this topic for a link to the IBM support and downloads page, which contains the search function.

Procedure

1. Create the authentication data alias. See the topic, Managing Java 2 Connector Architecture authentication data entries.
2. Create the JDBC provider. See the topic, Configuring JDBC providers using the administrative console.

3. Create a data source. See the topic, Configuring a data source using the administrative console
4. Save the data source.
5. Verify the connectivity if you created an authentication alias. To verify connectivity, restart the server for which you must verify connectivity.

   If you are using scripting or Java Management Extensions (JMX) to create the authentication alias, you can use the updateAuthDataCfg MBean. You can use this MBean method to refresh the authentication data in each server where it is needed. When you create a data source and the data source has not been used, you can use the updateAuthDataCfg MBean method. After a data source is used, its contents are instantiated in the server memory and generally cannot be changed.

   For more information about the updateAuthDataCfg MBean method, see the SecurityAdmin MBean documentation under Reference > Programming interfaces > Mbean interfaces.
6. Test the connection.

   You can test your connection from the data source collection view or the data source details view. Access either view in the administrative console, and then select a connection from the list. Click **Test Connection** on the connection. See the topic, Test the connection service.

Test connection service

WebSphere Application Server provides a test connection service for validating data source configurations. The testConnection operation instantiates the data source configuration, gets a connection, and then immediately closes the connection.

If you associate your data sources with WebSphere variables, see the topic, Creating, editing, and deleting WebSphere variables, to verify that you configure them correctly. A `variable cannot be found` exception results from attempted use of a data source that is invoked through an incorrectly defined variable.

Activating the test connection service

There are three ways to activate the test connection service: through the administrative console, the wsadmin tool, or a Java stand-alone program. Each process invokes the same methods on the same MBean.

Administrative console

WebSphere Application Server allows you to test a connection from the administrative console by simply pushing a button: the *Data source collection*, *Data source settings*, *Version 4 data source collection*, and *Version 4 data source settings* pages all have **Test Connection** buttons. After you define and save a data source, you can click this button to ensure that the parameters in the data source definition are correct. On the collection page, you can select several data sources and test them all at once. Note that there are certain conditions that must be met first. For more information, see the topic, Testing a connection with the administrative console.

Note: The following exception occurs when you click Test Connection to connect a Sybase data source from the administrative console.

```
Test connection failed for data source isagent on server server1 at node
svtaix24Node01 with the following exception: java.lang.Exception:
java.sql.SQLException: JZ006: Caught IOException: java.net.ConnectException: A
remote host refused an attempted connect operation.DSRA0010E: SQL State = JZ006,
Error Code = 0
```

This exception occurs when the Sybase data source port number is not matched to the port configured in Sybase server. The default port number is 5000. Check the port number of your Sybase server in the interfaces file under `/<sybase install directory>`.

WsAdmin tool

The wsadmin tool provides a scripting interface to a full range of WebSphere Application Server administration activities. Because the Test Connection functionality is implemented as a method on an MBean, and wsadmin can invoke MBean methods, wsadmin can be utilized to test connections to data sources. You have two options for testing a data source connection through wsadmin:

The *AdminControl* object of wsadmin has a testConnection operation that tests the configuration properties of a data source object. For information, see the topic, Testing a connection using wsadmin.

You can also test a connection by invoking the MBean operation. Use the example in the topic, Example: Testing data source connection using wsadmin, as a guide for this technique.

Java stand-alone program

Finally, you can test a connection by executing the `testConnection` method on the `DataSourceCfgHelper` MBean. This method allows you to pass the configuration ID of the configured data source. The Java program connects to a running Java Management Extensions (JMX) server to access the MBean. In a base installation of Application Server, you connect to the JMX server running in the application server, usually on port 8880.

The return value from this invocation is either 0, a positive number, or an exception. 0 indicates that the operation completed successfully, with no warnings. A positive number indicates that the operation completed successfully, with the number of warnings. An exception indicates that the test of the connection failed.

Example: Testing a connection using testConnection(ConfigID).

The following sample code creates a data source instance and an associated connection instance, and tests them to ensure database connectivity.

This program uses JMX to connect to a running server and invoke the *testConnection* method on the *DataSourceCfgHelper* MBean. The acronym *ND* in a comment line indicates that the following code applies to WebSphere Application Server WebSphere Application Server, Network Deployment. The word *Base* in a comment line indicates that the following code applies to WebSphere Application Server.

```
/**
 * Description
 * Resource adapter test program to make sure that the MBean interfaces work.
 * Following interfaces are tested
 *
 *  ---  testConnection()
 *
 *
 * We need following to run
 * C:\src>java -Djava.ext.dirs=C:\WebSphere\AppServer\lib;C:\WebSphere\AppServer\java\jre\lib\ext testDSGUI
 * must include jre for log.jar and mail.jar, else get class not found exception
 *
 *
 */

 ex.printStackTrace(System.out);
  }
 }
}
```

Tip: Ensure that you run the test connection service at the same level as an existing data source. For example, do not run the test connection service at the node level if your data source is configured on the server level. If the test connection service and the data source configuration do not exist on the same level, a failure to load exception might result. In this situation, source the db2profile script on the machine and ensure that the environment contains pointers to the DB2 native libraries. The db2profile script exists in the root directory of the DB2 user ID.

Testing a connection with the administrative console

After you have defined and saved a data source, you can click the **Test Connection** button to ensure that the parameters in the data source definition are correct.

Before you begin

About this task

You can select multiple data sources on the data source collection page and test them as a group. Be sure that the following conditions are met before using the Test Connection button:

Procedure

- If you are testing a connection using a WebSphere Application Server Version 4.0 type of data source, ensure that the *user* and *password* information is set.
- Designate variables appropriately.
  - WebSphere Application Server automatically sets environment variables for Java database connectivity (JDBC) driver class paths on the IBM i platform. Application Server names the variable according to your driver, either ${OS400_NATIVE_JDBC_DRIVER_PATH} or ${OS400_TOOLBOX_JDBC_DRIVER_PATH}. In the administrative console, you designate the complete path location of your driver as the value of the environment variable. See the “JDBC provider settings” on page 275 article for more information.
  - If you download the latest JTOpen version of the jt400.jar file, use one of two placement strategies to keep the value of your environment variable accurate. You can place the file in the same directory that you specify for the ${OS400_TOOLBOX_JDBC_DRIVER_PATH} variable. Alternatively, you can place the jt400.jar file in a different directory and change the value of ${OS400_TOOLBOX_JDBC_DRIVER_PATH} to this different path.
- Restart the application server after you define or edit WebSphere variables.
- Restart the application server after you create or edit an authentication alias for the data source.
- You can now test a connection to the data source. On the data source collection page in the administrative console, select the data source and click **Test Connection** .

A Test Connection operation can have three different outcomes, each resulting in a different message being displayed in the messages panel of the page on which you press the Test Connection button.

1. The test can complete successfully, meaning that a connection is successfully obtained to the database using the configured data source parameters. The resulting message states: Test Connection for data source *DataSourceName* on process *ProcessName* at node *NodeName* was successful.
2. The test can complete successfully with warnings. This means that while a connection is successfully obtained to the database, warnings were issued. The resulting message states: Test Connection for data source *DataSourceName* on process *ProcessName* at node *NodeName* was successful with warnings. View the JVM Logs for more details.

   The **View the JVM Logs** text is a hyperlink that takes you to the JVM Logs console screen for the process.
3. The test can fail. A connection to the database with the configured parameters is not obtained. The resulting message states: Test Connection failed for data source *DataSourceName* on process *ProcessName* at node *NodeName* with the following exception: *ExceptionText*. View the JVM Logs for more details.

   Again, the text for **View the JVM Logs** is a hyperlink to the appropriate logs screen.

Testing a connection using wsadmin

The AdminControl object of the wsadmin scripting tool has a testConnection operation that tests the configuration properties of a data source object.

Before you begin

About this task

The testConnection operation takes a data source *configuration ID* as an argument.

Note: This invocation cannot accept user IDs and passwords that must be defined in the database itself. This invocation can be used only for databases that do not require a user ID and password to make a connection (such as DB2 on a Windows machine), or for data sources that have a component-managed or container-managed authentication alias set on the data source object.

Procedure

1. Start the getid() method for your data source.
2. Set the value of the *configuration ID* to a variable.

   ```
   set myds [$AdminConfig getid /JDBCProvider:mydriver/DataSource:mydatasrc/]
   ```

   where *JDBCProvider:mydriver/DataSource:mydatasrc* is the data source you want to test. After you have the configuration ID of the data source, you can test the connection to the database.
3. Test the connection to the database. Use the following command:

   ```
   $AdminControl testConnection $myds
   ```

Configuring connection validation timeout

You can configure a timeout for connection validation by the Java Database Connectivity (JDBC) driver through a data source custom property in the data source configuration panels.

About this task

You can choose between validating connections with the JDBC driver or by having the application server run a SQL query. Select one or both of the following connection pretest attributes:

- Validate new connections
- Validate existing pooled connections

By default, connection validation is disabled. When you save the configuration for the data source, the administrative console supplies only the option that is selected. The administrative console will select validation by timeout or validation by a query, but if validation is not enabled then the application server will select neither option.

Procedure

1. Open the administrative console.
2. Go to the **WebSphere Application Server Data Source properties** panel for the data source.
   a. Select **Resources** > **JDBC** > **Data Sources** > ***data_source***
   b. Select **WebSphere Application Server Data Source properties**.
3. Go to the **Connection Validation Properties** section.
4. Select the type of connections that the application server will validate.
   - Select **Validate new connections**. This option specifies that the connection manager tests newly created connections to the database.
   - Select **Validate existing pooled connections**. This options specifies that the connection manager tests the validity of pooled connections before returning them to applications.
   - You can also select both options

     Note: You must make a selection here. If you do not select one or both of these options, you will not be able to select **Validation by JDBC Driver**. The **Validation by JDBC Driver** timeout feature is only available for JDBC providers that comply with the JDBC 4.0 specification.

     For an Oracle datasource, **Validation by JDBC Driver** appears on the administrative console only after the validateNewConnectionTimeout property is added to the custom properties of WebSphere Application Server datasource properties. The validateNewConnectionTimeout property is used for JDBC 4.0 driver validation and can be specified using administrative console.

   .
5. Click **Validation by JDBC Driver**. The application server issues a warning if **Validation by JDBC driver** is configured and the JDBC driver does not implement JDBC 4.0, or if the Connection.isValid method raises an error.

   Note: Connection validation by SQL query is deprecated. Use validation by JDBC Driver instead.
6. Enter the timeout value in the input box. The timeout value is in seconds.

   Note: If retries are configured, meaning the retry interval is not set to 0, for **Validate new connections** or **Validate existing pooled connections**, then the full value of the timeout applies to each retry. For each retry, the application server waits for the retry interval. Then the JDBC driver uses the full value of the timeout to validate the connection
7. Save the data source configuration.

What to do next

If you are modifying an existing data source, restart your server for this change to go into effect. If this is a new data source, restarting the server is not necessary.

Resource references

Use this page to designate how the resource references of application modules map to the actual resources that are configured for the application.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Resource references**.

You can also view this page during the **Map resource references to resources** step when you install an application.

- If your application uses any of the following resource types, you can set or reset their mapping configurations:
  - Default messaging JMS queues destinations
  - Default messaging JMS topic destinations
  - Data source
  - Generic JMS connection factory
  - Mail session
  - J2C connection factory
  - JMS queue connection factory for the JMS provider of WebSphere MQ
  - JMS queue destination for WebSphere MQ
  - JMS topic connection factory for WebSphere MQ
  - JMS topic destination for WebSphere MQ
  - Unified JMS connection factory for WebSphere MQ
  - URL configuration
- The page is composed of sections that correspond to each applicable resource type. Each section heading is the class name for the resource. If your application contains only one applicable resource type, you see only one section.
- Each section contains a table. Each table row depicts a resource reference within a specific module of your application.
- The rows contain the JNDI names of resource mapping targets for your references *only* if you bound them together during application assembly. You can modify those bindings on this administrative console page.
- To set your mappings:
  1. Select a row. If you want to apply the same mapping to multiple rows, complete the steps in the section, Set multiple JNDI names.
  2. Click **Browse** to view a new page listing of all resources that are available mapping targets for your application references.
  3. Select a resource and click **Apply**. The console displays the Resource references page again. The JNDI name of the selected resource mapping displays in the Target Resource JNDI Name field.
  4. Repeat the previous steps as necessary.
  5. If you are editing the resource references of an existing enterprise application, click **OK**. You now return to the general configuration page for your enterprise application. If you are installing the application and have completed the **Map resource references to resources** step, continue to the next step.
- **For data sources and connection factories:** Sections for these resource types contain an additional set of steps for modifying your security settings. Use the last column in the displayed table to view the authorization type for each resource configuration per application module. You can modify the corresponding authentication method only if the authorization type is container. Container-managed authorization indicates that the product performs signon to the resource rather than the enterprise bean code. The reconfiguring process differs slightly for each authentication method option:
  - When you want to assign no authentication method to a resource:
    1. Determine which resource configurations to designate with no authentication method.
    2. Select the appropriate table rows.
    3. Click **Modify Resource Authentication Method** and select **None** from the authentication method options that are displayed above the table.
    4. Click **Apply**.

– When you want to assign the WebSphere Application Server DefaultPrincipalMapping login configuration to a resource:
  1. You must apply this option to each resource individually if you want to designate different authentication data aliases. See the topic, J2EE connector security, for more information about the default mapping configuration.
  2. Select the appropriate table rows.
  3. Click **Modify Resource Authentication Method** and select **Use default method** from the list of authentication method options that are displayed above the table.
  4. Select an authentication data entry or alias from the list.
  5. Click **Apply**.
– When you want to assign a trusted context to a resource:
  1. You must have a data source that is running at least DB2 Version 9.1 for z/OS, and the data source must have trusted context enabled.
  2. You must have a data source server that is running at least DB2 Version 9.1 for z/OS, and the data source must have trusted context enabled.
  3. Select the appropriate table rows that have trusted context enabled.
  4. Click **Modify Resource Authentication Method** and select **Use trusted connections** from the authentication method options that are displayed above the table.
  5. Select an authentication alias from the list that matches an alias that is already defined in the DB2 data source. If you do not have an alias defined that is suitable, you must define a new alias.
  6. Click **Apply**.
  7. To edit the properties of the custom login configuration, click **Mapping Properties** in the table cell.
– When you want to assign a custom Java Authentication and Authorization Service (JAAS) login configuration to a resource:
  1. See the topic, J2EE connector security, for more information about custom JAAS login configurations.
  2. Select the appropriate table row.
  3. Click **Modify Resource Authentication Method** and select **Use custom login configuration** from the authentication method options that are displayed above the table.
  4. Select an application login configuration from the list.
  5. Click **Apply**.
  6. To edit the properties of the custom login configuration, click **Mapping Properties** in the table cell.

Set multiple JNDI names

Use this option to set the same JNDI name on multiple resources with one operation.

Click **Set multiple JNDI names** to display a menu of JNDI names. If you make a selection from this list, it is applied to the **Target Resource JNDI Name** field of all the selected rows of the table.

Modify Resource Authentication Method

Use this panel to toggle the display of a panel above the table rows.

This use of this panel is described in the **For data sources and connection factories** section.

Extended Properties

Use this panel to set additional properties on the selected resource.

Select a single table row and click **Extended Properties** to set additional properties on the selected resource. For more details on using this function, see the documentation on extending DB2 data source definitions at the application level.

Select
Select the check boxes of the rows that you want to edit.

Module
The name of a module in the application.

Bean
The name of an enterprise bean that is contained by the module.

URI
Specifies location of the module relative to the root of the application EAR file.

Resource Reference
The name of a resource reference that is used in the enterprise bean, if applicable, and is declared in the deployment descriptor of the application module.

Target Resource JNDI name
The Java Naming and Directory Interface (JNDI) name of the resource that is the mapping target of the resource reference.

Data type String

Login configuration
This column applies to data sources and connection factories only and refers to the authorization type and the authentication method for securing the resource.

Mapping-configuration alias
This panel allows you to select a mapping configuration alias for the resource that you are configuring. This panel is only available when security domains are defined. Security domains allow you to isolate mapping configuration aliases between servers. The tree view is useful in determining the security domain to which an alias belongs, and the tree view can help you determine the servers that will be able to access each authentication alias. The tree view is tailored for each resource, so domains and aliases are hidden when you cannot use them. For example, a cell-scoped security domain will be hidden from the tree if all servers and clusters in the tree have defined their own security domain. If you are looking for an alias that is not visible in the tree, it is because the alias cannot be used by any servers that have visibility to this resource. In this case, you must define the alias at the global scope or in a different security domain that is visible to this resource.

To view this administrative console panel:

1. You must have a security domain defined in the application server.
2. Click one of the following paths in the administrative console:
   - **Resources** > **JDBC** > **Data sources** > ***data_source***. Click **Browse...** in the security section for **Component-managed authentication alias** or **Container-managed authentication alias**.
   - **Resources** > **JDBC** > **JDBC Providers** > ***jdbc_provider*** > **Data sources** > ***data_source***. Click **Browse...** in the security section for **Component-managed authentication alias** or **Container-managed authentication alias**.
   - **Resources** > **Resource Adapters** > **J2C connection factories** > ***j2c_connection_factory***. Click **Browse...** in the security section for **Component-managed authentication alias** or **Container-managed authentication alias**.

Note: Be careful when selecting an alias, because it is possible to select an alias that is only accessible by a subset of the servers that will use the resource. If you select a global alias, you are guaranteed that an alias by that name will be accessible to all users of the resource. If the alias has been overridden in a security domain, however, that alias will be used instead of the global one. The tree view includes icons to help you select the proper alias:

-  The alias is accessible by all servers that can access this resource.
-  There is at least one server that cannot access the alias. Check the tree view to see if this is OK for the application that will be using this resource.
-  The alias is defined in multiple places.

Select a J2C authentication alias

Use this panel to select a Java 2 Connector (J2C) authentication alias for the resource that you are configuring. This panel is available only when at least one security domain is defined and assigned a scope that is applicable to the resource that is being edited. Additionally, that security domain must contain at least one JAAS J2C Authentication alias. Security domains isolate J2C authentication aliases between servers.

The tree view is useful in determining the security domain to which an alias belongs, and the tree view can help you determine the servers that are able to access each authentication alias. The tree view is tailored for each resource, so domains and aliases are hidden when you cannot use them. For example, a cell-scoped security domain is hidden from the tree if all servers and clusters in the tree have defined their own security domain. If you are looking for an alias that is not visible in the tree, it is because the alias cannot be used by any servers that have visibility to this resource. In this case, you must define the alias at the global scope or in a different security domain that is visible to this resource.

To view this administrative console panel:

1. Read the preceding introduction for conditions under which this panel is accessible.
2. Click one of the following paths in the administrative console:
   - **Resources** > **JDBC** > **Data sources** > ***data_source***. Click **Browse...** in the security settings section for the applicable authentication classes.
   - **Resources** > **JDBC** > **JDBC providers** > ***jdbc_provider*** > **Data sources** > ***data_source***. Click **Browse...** in the security settings section for the applicable authentication classes.
   - **Resources** > **Resource Adapters** > **J2C connection factories** > ***j2c_connection_factory***. Click **Browse...** in the security settings section for the applicable authentication classes.
   - **Resources** > **Resource Adapters** > **J2C activation specifications** > ***j2c_activation_specification***. Click **Browse...** in the security settings section for the applicable authentication classes.
   - **Resources** > **JMS** > **Connection factories** > ***connection_factory***. Click **Browse...** in the security settings section for the applicable authentication classes.
   - **Resources** > **JMS** > **JMS providers** > ***jms_provider*** > **[Additional properties] Queue connection factories** > ***connection_factory***. Click **Browse...** in the security settings section for the applicable authentication classes.
   - **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application*** > **[Modules] Manage Modules** > ***module*** > **[Additional Properties] Resource Adapter** > **[Additional Properties] J2C connection factories** > ***connection_factory***. Click **Browse...** in the security settings section for the applicable authentication classes.
   - **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application*** > **[Modules] Manage Modules** > ***module*** > **[Additional Properties] Resource Adapter** > **[Additional Properties] J2C activation specifications** > ***activation_spec***. Click **Browse...** in the security settings section for the applicable authentication classes.

Note: Be careful when selecting an alias, because it is possible to select an alias that is only accessible by a subset of the servers that use the resource. If you select a global alias, you are guaranteed that an alias by that name is accessible to all users of the resource. If the alias has been overridden in a security domain, however, that alias is used instead of the global one. The tree view includes icons to help you select the proper alias:

- The alias is accessible by all servers that can access this resource.
- There is at least one server that cannot access the alias. Check the tree view to see if this is OK for the application that will be using this resource.
- The alias is defined in multiple places.

Considerations for isolated resource providers

There are some design considerations that you should be aware of when working with resource providers that you have specified to be isolated in their own class loaders.

Be aware of the following issues that you need to address if you isolate a resource provider in it's own class loader:

- **Client container**

  The client container does not manage the class path of resource providers, so resource providers that are isolated will not be supported in the client container.
- **Multiple resource provider versions per application**

  If an application refers to resources from multiple versions or implementations of the same resource provider, then all of the resource providers that are referenced must be isolated.
- **References to isolated resource provider classes**

  If a module directly refers to classes that are loaded by an isolated resource provider, which means the module has import statements of resource provider classes, the following restrictions are in place:
  - The module can only refer to resources from one version or implementation of an isolated resource provider. This is an inherent class loading restriction, because a module class loader can only refer to one version of a class.
  - The module cannot perform direct JNDI lookup without the use of Java EE resource reference meta-data. This restriction is required, because without resource reference metadata the application server has no mechanism to link the class loader of the module to the class loader of the isolated resource provider.

  The relational resource adapter does not generally allow direct access to resource provider classes, so these restrictions will typically only affect modules that implement the com.ibm.websphere.rsadapter.WSCallHelper class. For mail providers, these restrictions will most likely be in place, because the javax.mail API relies heavily on classes rather than interfaces. Therefore, the implementation details are necessarily part of the API.

Implicitly set client information

If you track client information in your database, you can choose one of two ways to pass WebSphere Application Server client data on database connections.

You can choose to *explicitly* pass the information about connections by calling an IBM proprietary API, setClientInformation(Properties), on the `com.ibm.websphere.rsadapter.WSConnection` object within your application code. The `com.ibm.websphere.rsadapter.WSConnection` object is located in the *plugins_root*`/com.ibm.ws.runtime.jar` file. In some cases, however, you might want WebSphere Application Server to handle the passing of client information to database connections. This method of setting the client information is referred to as *implicit*. You might choose the implicit method because:

- You want to keep your application free of proprietary APIs, or

- Your application uses container-managed persistence (CMP), in which case you cannot use the proprietary API to set client information on database connections.

The WebSphere Application Server trace facility provides the capability for setting client information implicitly. You can designate one of two special trace groups to enable or disable client information passing: “WAS.clientinfo trace” or “WAS.clientinfopluslogging trace” on page 343.

Possible runtime scenarios

- Connection sharing

  In the case of connection sharing, WebSphere Application Server sets the client information on the first acquired connection handle only. If connection sharing is enabled and two or more `getConnection` methods are called (resulting in two handles on the same connection), only the first `getConnection` call causes the client information to pass to the backend database. This scenario does not apply to the explicit process of passing client information; in such cases every `setClientInformation` method is relayed to the database regardless of connection sharing.
- Implicit/explicit co-existence

  When you use both the explicit and implicit procedures for relaying client information, some combination of the explicitly set data and implicitly set data is combined, but the explicit setting usually takes precedence. For example, if the application sets the client accounting information to "myAccountingInfo", the final accountingInfo string that is passed to the backend database looks something like the following sample code:

  ```
  000325_WSRdbManagedConnectionImpl@1234_myAccountingInfo:
  ```

  Where `000325` is the thread ID and `WSRdbManagedConnectionImpl@1234` is the WebSphere connection instance.
- Client information reset

  When you configure Application Server to pass client information, it does reset client information when a connection is returned to the pool, but *only* if the WAS.clientinfo and WAS.clientinfopluslogging trace mechanisms are disabled (that is, WAS.clientinfo=all=disabled:WAS.clientinfopluslogging=all=disabled).

  In the explicit case, however, the reset operation is done only when the application issues `setClientInformation(null)` on the WSConnection connection.

WAS.clientinfo trace

By default, the implicit mechanism is disabled. You can turn on this mechanism dynamically, without stopping and starting your application server, or statically by setting the WebSphere Application Server trace group *WAS.clientinfo=all=enabled*.

The information implicitly collected and set on the database connection consists of the *user name*, *user location* and *application name*.

Important: User name and user location can be implicitly collected and set only on the database connection if you enable Java 2 security.

user name
: The name of the user that initiates the application request. This option is collected and passed to the backend database (when supported). Information here is collected by calling the `WSSecurityHelper.getFirstCaller` method.

user location
: The name of the location of the user, in the form of cell:node:server. This option is collected and passed to the backend database (when appropriate). Information here is collected by calling the `WSSecurityHelper.getFirstServer` method.

application name
The name of the application running. This value is the output of the `getApplication` method from the Java EE Name object. This value is collected regardless of the Global Security setting.

WAS.clientinfopluslogging trace

When debugging database problems, such as deadlocks, there is a set of information that may help with the debugging effort. This information is typically obtained by enabling a WebSphere Relational Resource Adapter (RRA) trace, and an Enterprise JavaBeans (EJB) container trace. However, there are some cases where timing is an issue when reproducing a given problem. Having too much tracing information can alter the behavior of the application, such as change the timing, and the problem might no longer occur.

Because of this situation, a new trace group is provided where only a minimum set of information is collected. This trace group is WAS.clientinfopluslogging. This function sets the client information implicitly on the connection, just like the WAS.clientinfo trace, and, logs and traces important application activities. Those activities are:

- SQL strings that are run (such as, select userId from tabl1 where id=? for update).
- Start, commit, and rollback of transactions.
- EJB calls (such as, Create, Remove, findByPrimaryKey).

Enabling client information tracing with the administrative console

Use either of the methods outlined in this task to enable the passing and tracing of client information about a database connection.

About this task

Refer to the *Implicitly set client information* topic to determine which of the two available levels of client information passing and tracing is appropriate for your configuration. Once a level is selected, there are two methods of enabling it:

- Enable either of the WebSphere Application Server trace groups: WAS.clientinfo or WAS.clientinfopluslogging. Enabling either of these trace groups enables client information passing for all data sources of the application server. If client information is only required for a specific data source, consider using the method below.
- Create a data source custom property to enable client information tracing. This method is functionally equivalent to enabling WAS.clientinfo as described above, except that it is enabled only on the specified data source. A data source custom property does not exist to provide the equivalent functionality of the WAS.clientinfopluslogging trace group. If that level of tracing is required, use that trace group setting instead.

Procedure

1. Open the administrative console.
2. If you choose to enable client information passing and tracing by using a trace group:
   a. Select **Troubleshooting**.
   b. Select **Log and Trace**.
   c. Select the server you want to use.
   d. Select **Diagnostic Trace**.
   e. Select **Change log detail levels**.
   f. Select the **Configuration** or **Runtime** tab. Changes made to the Configuration are applied after a server restart. Changes made to the Runtime are applied immediately.
   g. In the **Trace Specification** entry field, type either `WAS.clientinfo=all` or `WAS.clientinfopluslogging=all`. To deactivate either trace, replace `=all` with `=off` (without spacing between characters) or delete the trace string entry.

3. If you choose to enable client information passing by using a data source custom property:
   a. Select **Resources**.
   b. Select **JDBC** > **Data sources**.
   c. Select the datasource on which you want to enable client information tracing.
   d. Select **Custom Properties** under the **Additional Properties** section.
   e. Press **New...**.
   f. Enter `enableClientInformation` in the **Name** field.
   g. Enter `true` in the **Value** field.
   h. Optional: Enter a description in the **Description** field, if desired.
   i. Select **java.lang.Boolean** in the **Type** field.
4. Press **OK**.
5. Save the changes to the configuration when prompted to do so.

About Apache Derby

The Apache Derby package that is bundled with the application server is backed by full IBM Quality Assurance (QA).

Note: WebSphere Application Server supports direct customer use of the Apache Derby database in *test* environments only. The product does not support direct customer use of Apache Derby database in *production* environments.

Unlike versions 5.1.60x and earlier, Apache Derby is a pure Java database server. The Apache Derby code base, which the open source community calls Derby, is a product of the Apache Software Foundation (ASF) open source relational database project. Apache Derby includes the Derby base code without any modification to the underlying source code. You can investigate more incompatibilities about Derby code at the Apache Derby website.

Note: Earlier versions of Apache Derby cannot conduct two phase-commit transactions over the Network Server framework, but later versions of the Derby Client JDBC driver provides Apache Derby with support for XA transactions. Only the Network Server framework provides support for multiple Java virtual machines (JVMs), such as application servers, to access Apache Derby.

Apache Derby is equipped with the following .bat/sh tools:
- sysinfo: displays database version information
- ij: manipulates the database instances

  transition: Use ij as an alternative for the Cloudscape cview tool, which does not exist in Derby. When you run the ij tool, surround the dbname by double quotation marks (" ") if it includes the full path name; for example:

  ```
  ij> connect '"c:\temp;create=true"'
  ```

  This is ' " " ' without spaces.
- dblook: dumps DDL information
- networkServerControl: controls the networkServer process (can be used for functions such as ping and trace)
- startNetworkServer: starts the networkServer process
- stopNetworkServer: stops the networkServer process

Attention: If you use non-English characters in your Derby database name, you need to update the ij script to specify the file encoding property to the JVM: -Dfile.encoding=*XXXXXX*, where *XXXXXX* is the encoding used to create the non-English characters.

Managing resources through JCA lifecycle management operations

You can manage the run-time status of your data source and connection factory resources to perform some data access administrative tasks without restarting the application server. This topic outlines the process for managing those resources through the administrative console.

Before you begin

When you manage the run-time status of connection factories or data sources, you are applying Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) lifecycle management operations to the MBeans that are associated with these resources. The management operations are PAUSE and RESUME. Pausing an MBean halts outbound communication to the backend, such as a database. This action affects all applications that use the corresponding connection factory or data source on the same server.

About this task

With these management operations, you can perform some administrative tasks dynamically, without restarting your application server:

- Respond to a security threat, and prevent new connection requests from reaching the backend
- Perform maintenance on the backend
- Apply configuration changes to non-required properties of the connection factory or data source, such as turning JDBC trace on or off, or modifying preferences for collecting client information

Procedure

1. Navigate to the administrative console page that corresponds to the resource type that you want to manage.
   - For connection factories, use either of the following paths:
     - **Resources** > **Resource Adapters** > **J2C connection factories**
     - **Resources** > **Resource Adapters** > **Resource Adapters** > *resource_adapter* > **J2C connection factories**
   - For data sources, use either of the following paths:
     - **Resources** > **JDBC** > **Data sources**
     - **Resources** > **JDBC** > **JDBC providers** > *JDBC_provider* > **Data sources**
2. Select the connection factory or data source configurations that you want to manage, and click **Manage state**. The administrative console now displays the JCA lifecycle management page, which contains a table that depicts the full scope configuration of your previous selection.

   The table is comprised of three columns:
   - **JNDI name:** The Java Naming and Directory Interface (JNDI) name of the connection factory or data source configuration.
   - **Running object scope:** The server that is running the connection factory or data source MBean.
   - **Status:** The status of the connection factory or data source MBean.
3. Select the rows that represent each invocation of the resource, per running server, that you want to manage. Be aware that when you click your management operation, WebSphere Application Server applies it to every resource object in your selection.

   Restriction: If the MBean status of a row has a value of NOT_ACCESSED, you cannot apply JCA lifecycle management operations to that MBean. The NOT_ACCESSED state indicates that the MBean exists on the specified server, but no applications performed a JNDI namespace lookup on the corresponding connection factory or data source.
4. Click **Pause** or **Resume**. The status column of the table changes to reflect the new state of the MBean.

JCA life cycle management

Use this page to perform JCA life cycle management operations on data source and connection factory MBeans. With these management operations, you can control the runtime status of the corresponding data source and connection factory resources.

You can view this administrative console page in different locations, depending on whether you want to manage data sources or J2C connection factories. For example:

- For connection factories: Click **Resources** > **Resource adapters** > **J2C connection factories**. Select the connection factory configurations that you want to manage, and click **Manage state**.
- For data sources, click **Resources** > **JDBC** > **Data sources**. Select the data source configurations that you want to manage, and click **Manage state**.

Guidelines for using this administrative console page:

- The table displays a list of MBeans that correspond to the data sources or connection factories in your selection from the previous console page. These MBeans are compatible with Version 6.0.2 and later of the application server.
- You can only perform JCA life cycle management actions on MBeans that are in the active state. In this context, an MBean is considered active when an application performs a Java Naming and Directory Interface (JNDI) name space lookup on the corresponding data source or connection factory resource.
- Pausing an MBean halts outbound communication to the backend, such as a database. This action affects all applications that use the resource on the selected server.

Pause:

Specifies to pause the MBean that is selected. Pausing an MBean halts outbound communication to the back-end resource, and this action affects all applications that use the resource on the selected server.

Note: When an application attempts a connection to a paused data source, the connection manager raises an SQLException with an error code of com.ibm.websphere.rsadapter.WSDataSource.ERROR_CONNECTION_POOL_IS_PAUSED.

Resume:

Specifies to resume the MBean that is selected. Resuming an MBean enables outbound communication to the back-end resource. This action affects all applications that use the resource on the selected server.

Purge:

Specifies to purge the contents of the connection pool for the data source or connection factory that is specified. Purging the pool does not affect ongoing transactions.

Name (JNDI name):

Specifies the name of the connection factory or data source configuration, followed by the Java Naming and Directory Interface (JNDI) name in parenthesis.

Running object scope:

Specifies the server that is running the connection factory or data source MBean.

Status:

Specifies the state of the connection factory or data source MBean.

Possible values:

State	Indications
ACTIVE	• The resource that corresponds with the MBean is ready to provide an application with connections to a backend. • An application performed a JNDI namespace lookup on this resource. You can apply the JCA life cycle management operation of PAUSE to an MBean in this state.
PAUSED	• All outbound communication to the backend through the corresponding resource is stopped, as a result of a JCA life cycle management operation that was applied previously to the MBean. • An application performed a JNDI namespace lookup on the resource. You can apply the JCA life cycle management operation of RESUME to an MBean in this state.
NOT_ACCESSED	• The MBean exists on the specified server, but no applications performed a JNDI name space lookup on the corresponding connection factory or data source. You cannot apply JCA life cycle management operations to an MBean in this state.

Chapter 8. Administering Dynamic caching

This page provides a starting point for finding information about the dynamic cache service, which improves performance by caching the output of servlets, commands, web services, and JavaServer Pages (JSP) files.

Dynamic caching features include replication of cache entries, cache disk offload, Edge-Side Include caching, web services, and external caching. Use external caching to control caches outside of the application server.

Administering the dynamic cache service

Using the dynamic cache service

Use the dynamic cache service to improve application performance by caching the output of servlets, web services, and WebSphere Application Server commands into memory.

Before you begin

Develop a cache policy for your application. The cache policy defines rules for what responses to cache and the amount of time the responses should be held in the cache. Refer to the Configuring cacheable objects with the cachespec.xml file article for more information.

About this task

The dynamic cache service is enabled by default. You can configure the default cache instance, as follows:

Procedure

1. Click **Servers > Server Types > WebSphere® application servers > *server_name* > Container services > Dynamic cache service**.
2. Configure the default cache instance or follow the links to enable servlet or portlet caching. Refer to the Dynamic cache service settings article for more information about default cache settings.

Example

This example puts all of the steps together for configuring the dynamic cache service with the `cachespec.xml` file, showing the use of the cache ID generation rules, dependency IDs, and invalidation rules.

Suppose that a servlet manages a simple news site. This servlet uses the query parameter "action" to determine if the request views (query parameter "view") news or updates (query parameter "update") news (used by the administrator). Another query parameter "category" selects the news category. Suppose that this site supports an optional customized layout that is stored in the user's session using the attribute name "layout". Here are example URL requests to this servlet:

- http://*yourhost/yourwebapp*/newscontroller?action=view&category=sports (Returns a news page for the sports category)
- http://*yourhost/yourwebapp*/newscontroller?action=view&category=money (Returns a news page for the money category)
- http://*yourhost/yourwebapp*/newscontroller?action=update&category=fashion (Allows the administrator to update news in the fashion category)

The following steps illustrate how to configure the dynamic cache service for this example with the `cachespec.xml` file:

1. Define the <cache-entry> elements that are necessary to identify the servlet. In this case, the URI for the servlet is "newscontroller", so this is the cache-entry <name> element. Because this example caches a servlet or JavaServer Pages (JSP) file, the cache entry class is "servlet".

```
<cache-entry>
<name> /newscontroller </name>
<class>servlet  </class>
 </cache-entry>
```

2. Define cache ID generation rules. This servlet caches only when action=view, so one component of the cache ID is the parameter "action" when the value equals "view". The news category is also an essential part of the cache ID. The optional session attribute for the user's layout is included in the cache ID. The cache entry is now:

```
<cache-entry>
 <name> /newscontroller </name>
 <class>servlet  </class>
  <cache-id>
  <component id="action" type="parameter">
   <value>view</value>
   <required>true</required>
  </component>
  <component id="category" type="parameter">
   <required>true</required>
  </component>
  <component id="layout" type="session">
   <required>false</required>
  </component>
 </cache-id>
</cache-entry>
```

3. Define dependency ID rules. For this servlet, a dependency ID is added for the category. Later, when the category is invalidated due to an update event, all views of that news category are invalidated. Following is an example of the cache entry after adding the dependency ID:

```
<cache-entry>
 <name>newscontroller </name>
 <class>servlet  </class>
  <cache-id>
  <component id="action" type="parameter">
   <value>view</value>
   <required>true</required>
  </component>
  <component id="category" type="parameter">
   <required>true</required>
  </component>
  <component id="layout" type="session">
   <required>false</required>
  </component>
 </cache-id>
 <dependency-id>category
  <component id="category" type="parameter">
   <required>true</required>
  </component>
 </dependency-id>
</cache-entry>
```

4. Define invalidation rules. Because a category dependency ID is already defined, define an invalidation rule to invalidate the category when action=update. To incorporate the conditional logic, add "ignore-value" components into the invalidation rule. These components do not add to the output of the invalidation ID, but only determine whether or not the invalidation ID creates and runs. The final cache-entry now looks like the following:

```
<cache-entry>
 <name>newscontroller </name>
 <class>servlet  </class>
  <cache-id>
  <component id="action" type="parameter">
   <value>view</value>
   <required>true</required>
```

```
 </component>
 <component id="category" type="parameter">
  <required>true</required>
 </component>
 <component id="layout" type="session">
  <required>false</required>
 </component>
</cache-id>
<dependency-id>category
 <component id="category" type="parameter">
  <required>true</required>
 </component>
</dependency-id>
<invalidation>category
 <component id="action" type="parameter" ignore-value="true">
  <value>update</value>
  <required>true</required>
 </component>
 <component id="category" type="parameter">
  <required>true</required>
    </component>
</invalidation>
</cache-entry>
```

What to do next

You might want to enable dynamic cache disk offload. This option moves cache entries that are expired from memory to disk for potential future access. Refer to the Configuring dynamic cache disk offload for more information about enabling disk offload.

Dynamic cache service settings

Use this page to configure and manage the dynamic cache service settings.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > *server_name* > **Container services > Dynamic cache service**.

Enable service at server startup:

The dynamic servlet cache service starts when the server starts.

Attention: This option displays on WebSphere Application Server V6.1 servers but is not available on WebSphere Application Server V7.0 servers.

Enable servlet caching:

The dynamic servlet cache service starts when servlet caching is enabled in Web Container panel.

Enable portlet caching:

Start the dynamic portlet cache service by enabling servlet caching, then, enabling portlet fragment caching under Portlet Container panel.

Cache provider:

Specifies whether to configure the server to use the default dynamic cache provider or an alternate cache provider. If an alternate cache provider is available, it appears in the list of available cache providers.

gotcha: If WebSphere eXtreme Scale is available as an alternate cache provider, see the topics "Introduction: Dynamic cache," and "Configuring dynamic cache (DynaCache) to use the

WebSphere eXtreme Scale dynamic cache provider" for more information about setting up and using WebSphere eXtreme Scale with WebSphere Application Server.

Cache size:

Specifies a positive integer as the value for the maximum number of entries that the cache holds.

Enter a cache size value in this field that is between the range of 100 through 200,000.

Default priority:

Specifies the default priority for cache entries, determining how long an entry stays in a full cache.

Default	1
Range	1 to 255

Limit memory cache size:

Specifies the size of the memory cache.

Use this feature to constrain the cache in terms of the JVM heap. In addition to specifying the cache size in MB, dynamic cache also enables you to set a high watermark and low watermark for the cache heap that is consumed. When the cache heap memory reaches the high watermark, dynamic cache either discards or is evicted from the disk using the least recently used (LRU) algorithm, until the cache is brought down to the low watermark. This functionality of limiting the cache in terms of the JVM heap is only available if the objects that are put into the cache implement the sizeable interface. This interface has one method that returns the size of the object in bytes put into the cache. Dynamic cache uses the sizeable interface to estimate the heap size of the cache.

Default	-1 to disable limiting the memory cache size
Range	1 to maximum integer

Memory cache size:

Specifies a value for the maximum memory cache size in megabytes (MB).

High threshold:

Specifies a high watermark when the memory cache eviction policy starts. The threshold is expressed in terms of the percentage of the memory cache size in megabytes (MB). The default value is 95%

Values	1 to 100

Low threshold:

Specifies a low watermark when the memory cache eviction policy ends. The threshold is expressed in terms of the percentage of the memory cache size in megabytes (MB). The default value is 80%.

Values	1 to 100

Enable disk offload:

Specifies whether disk offload is enabled.

By default, the dynamic cache maintains the number of entries that are configured in memory. If new entries are created while the cache is full, the priorities that are configured for each cache entry, and a least recently used algorithm, are used to remove entries from the cache. In addition to having a cache entry removed from memory when the cache is full, you can enable disk offload to have a cache entry copied to the file system (the location is configurable). Later, if that cache entry is needed, it is moved back to memory from the file system.

Before you enable disk offload, consider the following:

- You cannot specify the number of cache entries that are offloaded to disk.
- You cannot specify the amount of disk space to use.

Offload location:

Specifies the location on the disk to save cache entries when disk offload is enabled.

If disk offload location is not specified, the default location, `${WAS_TEMP_DIR}/node/server name/_dynacache/cache JNDI name` is used. If disk offload location is specified, the node, server name, and cache instance name are appended. For example, `${USER_INSTALL_ROOT}/diskoffload` generates the location as `${USER_INSTALL_ROOT}/diskoffload/node/server name/cache JNDI name`. This value is ignored if disk offload is not enabled.

The default value of the ${WAS_TEMP_DIR} property is `${USER_INSTALL_ROOT}/temp`. If you change the value of the ${WAS_TEMP_DIR} property after starting WebSphere Application Server, but do not move the disk cache contents to the new location:

- The application server creates a disk cache file at the new disk offload location.
- If the Flush to disk setting is enabled, all of the disk cache content at the old location is lost when you restart the application server

When you are specifying a directory, consider the following:

- If you use the default directory and the disk fills up, WebSphere Application Server could possibly stall if it must write messages to log files, and there is no more space.
- Depending on the operating system, you might see disk full messages on the console.

Flush to disk:

Specifies if in-memory cached objects are saved to disk when the server is stopped. This value is ignored if **Enable disk offload** is not selected.

Default	false

Limit disk cache size in GB:

Specifies a value for the maximum disk cache size in GB. When you select this option, you can specify a positive integer value. Leaving this option blank indicates an unlimited size. This setting applies only if enable disk offload is specified for the cache.

Value	3 and above.

Limit disk cache size in entries:

Specifies a value for the maximum disk cache size in number of entries. When you select this option, you can specify a positive integer value. Leaving this option blank indicates an unlimited size. This setting applies only if enable disk offload is specified for the cache.

Value	0 to MAXINT. A value of 0 indicates unlimited size.

Limit disk cache entry size:

Specifies a value for the maximum size of an individual cache entry in MB. Any cache entry larger than this value, when evicted from memory, is not offloaded to disk. When you select this option, you can specify a positive integer value. Leaving this option blank indicates an unlimited size. This setting applies only if enable disk offload is specified for the cache.

Value	0 to MAXINT. A value of 0 indicates unlimited size.

Disk cache performance settings:

Specifies the level of performance that is required by the disk cache. This setting applies only if **enableDiskOffload** is specified for the cache. Performance levels determine how memory resources should be used on background activity such as cache cleanup, expiration, garbage collection, and so on. This setting applies only if enable disk offload is specified for the cache.

High performance and high memory usage	Indicates that all metadata is kept in memory.
Balanced performance and balanced memory usage	Indicates some metadata is kept in memory. This is the default performance setting and provides an optimal balance of performance and memory usage for most users.
Low performance and low memory usage	Indicates that limited metadata is kept in memory.
Custom performance	Indicates that the administrator explicitly configures the memory settings that are used to support the above background activity. The administrator sets these values using the **DiskCacheCustomPerformanceSettings** object.

Disk cache cleanup frequency:

Specifies a value for the disk cache cleanup frequency, in minutes. If this value is set to 0, the cleanup runs only at midnight. This setting applies only when the Disk Offload Performance Level is low, balanced, or custom. The high performance level does not require disk cleanup, and this value is ignored.

Value	0 to 1440

Maximum buffer for cache identifiers per metaentry:

Specifies a value for the maximum number of cache identifiers that are stored for an individual dependency ID or template in the disk cache metadata in memory. If this limit is exceeded the information is offloaded to the disk. This setting applies only when the disk offload performance level is CUSTOM.

Value	100 to MAXINT

Maximum buffer for dependency identifiers:

Specifies a value for the maximum number of dependency identifier buckets in the disk cache metadata in memory. If this limit is exceeded the information is offloaded to the disk. This setting applies only when the disk cache performance level is custom.

Value	100 to MAXINT

Maximum buffer for templates:

Specifies a value for the maximum number of template buckets that are in the disk cache metadata in memory. If this limit is exceeded the information is offloaded to the disk. This setting applies only when the disk cache performance level is custom.

Value	10 to MAXINT

Disk cache eviction algorithm:

Specifies the eviction algorithm that the disk cache uses to evict entries when the high threshold is reached. This setting applies only if enable disk offload is specified for the cache. This setting does not apply when the disk cache eviction policy is set to none.

None	No eviction policy, so the disk cache can grow until it reaches its limit at which time the dynamic cache service stops writing to disk
Random	When the disk size reaches a high threshold limit, the disk cache garbage collector wakes up and randomly picks entries on the disk and evicts them until the size reaches a low threshold limit.
Size	When the disk size reaches a high threshold limit, the disk cache garbage collector wakes up and picks the largest entries on the disk and evicts them until the disk size reaches a low threshold limit.

High threshold:

Specifies when the eviction policy runs. The threshold is expressed in terms of the percentage of the disk cache size in GB or entries. The lower value is used when limit disk cache size in GB and limit disk cache size in entries are specified. This setting does not apply when the disk cache eviction policy is set to none.

Values	1 to 100

Low threshold:

Specifies when the eviction policy ends. The threshold is expressed in terms of the percentage of the disk cache size in GB or entries. The lower value is used limit disk cache size in GB and limit disk cache size in entries are specified. This setting does not apply when the disk cache eviction policy is set to none.

Values	1 to 100

Configuring dynamic cache (DynaCache) to use the WebSphere eXtreme Scale dynamic cache provider

The dynamic cache engine is the default cache provider for the dynamic cache APIs and framework. However, dynamic cache allows WebSphere eXtreme Scale to act as its core caching engine. You can configure dynamic cache to use WebSphere eXtreme Scale as your cache provider instead of the default dynamic cache engine. Configuring dynamic cache to use WebSphere eXtreme Scale lets you leverage transactional support, improved scalability, high availability, and other WebSphere eXtreme Scale features without changing your existing dynamic cache caching code.

Before you begin

- Read the "Introduction: Dynamic cache" topic for an overview of WebSphere eXtreme Scale functionality.
- Determine whether using WebSphere eXtreme Scale is beneficial to the applications running in your application servers.

  The WebSphere eXtreme Scale features significantly increase the distributed capabilities of the dynamic cache function beyond what is offered by the default dynamic cache engine and data replication service. With WebSphere eXtreme Scale, you can create caches that are truly distributed between multiple servers, rather than just replicate and synchronize caches between the servers. WebSphere eXtreme Scale caches are transactional and highly available, ensuring that each server sees the same dynamic cache content. WebSphere eXtreme Scale also offers a higher quality of service for cache replication than what is provided through the data replication service (DRS).

  However, these advantages do not mean that the eXtreme Scale dynamic cache provider is the right choice for every application. Use the decision trees and feature comparison matrix provided in the See the topic Configuring the dynamic cache provider for WebSphere eXtreme Scale in the WebSphere eXtreme Scale Version 7.0 Information Center for a overview of this cache provider.

If you decide that is beneficial for your applications, use the information provided in the "Configuring the dynamic cache provider for WebSphere eXtreme Scale" section of the *WebSphere eXtreme Scale Version 7.0 Product Overview* to determine the appropriate WebSphere eXtreme Scale topology for your caching deployment.

If you use WebSphere eXtreme Scale, instead of the default dynamic cache engine, dynamic cache has the following limitations:

- No disk cache support. The following custom properties do not work:
  - com.ibm.ws.cache.CacheConfig.enableDiskOffload
  - com.ibm.ws.cache.CacheConfig.diskOffloadLocation
  - com.ibm.ws.cache.CacheConfig.flushToDiskOnStop
  - com.ibm.ws.cache.CacheConfig.htodCleanupFrequency
  - com.ibm.ws.cache.CacheConfig.htodDelayOffload
  - com.ibm.ws.cache.CacheConfig.htodDelayOffloadEntriesLimit
  - com.ibm.ws.cache.CacheConfig.htodDelayOffloadDepIdBuckets
  - com.ibm.ws.cache.CacheConfig.htodDelayOffloadTemplateBuckets
  - com.ibm.ws.cache.CacheConfig.diskCachePerformanceLevel
  - com.ibm.ws.cache.CacheConfig.diskCacheEvictionPolicy
  - com.ibm.ws.cache.CacheConfig.diskCacheHighThreshold
  - com.ibm.ws.cache.CacheConfig.diskCacheLowThreshold
  - com.ibm.ws.cache.CacheConfig.diskCacheSize
  - com.ibm.ws.cache.CacheConfig.diskCacheSizeInGB
  - com.ibm.ws.cache.CacheConfig.diskCacheEntrySizeInMB
  - com.ibm.ws.cache.CacheConfig.explicitBufferLimitOnStop
  - com.ibm.ws.cache.CacheConfig.lruToDiskTriggerTime
  - com.ibm.ws.cache.CacheConfig.lruToDiskTriggerPercent
- No DRS replication (push or push-pull support). The following custom properties will not work:
  - com.ibm.ws.cache.CacheConfig.enableReplicationAcks
  - com.ibm.ws.cache.CacheConfig.enableCacheReplication
  - com.ibm.ws.cache.CacheConfig.replicationDomain
  - com.ibm.ws.cache.CacheConfig.cacheEntryWindow
  - com.ibm.ws.cache.CacheConfig.cachePercentageWindow

  - com.ibm.ws.cache.CacheConfig.cacheInvalidateEntryWindow
  - com.ibm.ws.cache.CacheConfig.cacheInvalidatePercentWindow
  - com.ibm.ws.cache.CacheConfig.filterTimeOutInvalidation
  - com.ibm.ws.cache.CacheConfig.filterLRUInvalidation
- The alias API feature is not supported for Object cache.
- Event listener is supported. When firing any event, WebSphere eXtreme Scale always sets the sourceOfInvalidation to `REMOTE`.
- Disable dependency ID, com.ibm.ws.cache.CacheConfig.disableDependencyId, and templates, com.ibm.ws.cache.CacheConfig.disableTemplatesSupport, are not supported.
- No PMI support.
- The following CacheStatistic counters are supported:
  - CacheHits
  - CacheLruRemoves
  - CacheMisses
  - CacheRemoves
  - ExplictInvalidationsFromMemory
  - MemoryCacheEntries
  - TimeoutInvalidationsFromMemory
- NioMap - skipMemoryAndWriteToDisk will not work because the disk cache is not supported. In addition, the DistributedNioMapObject.release() is not called to release byteBuffer to the NIO buffer management.

Complete the following actions to enable the WebSphere eXtreme Scale dynamic cache provider.

Procedure

1. Install the WebSphere eXtreme Scale client, or the WebSphere eXtreme Scale client and server packages in your application server for the remote server and the other topologies respectively.
2. Designate the WebSphere eXtreme Scale dynamic cache provider as your cache provider.

   Each cache instance can be individually configured to use WebSphere eXtreme Scale. The dynamic cache engine is the default cache provider for a cache instance. Cache instances configured with WebSphere eXtreme Scale can coexist with cache instances configured with DRS.

   Complete one of the following actions to designate the WebSphere eXtreme Scale dynamic cache provider as your cache provider:

   a. Use the administrative console to designate the WebSphere eXtreme Scale dynamic cache provider as your cache provider.
      1) In the administrative console, click **Servers > Server Types > WebSphere application servers >** *server_name*.
      2) Under Container Services, click **Dynamic cache service** *server_name*, and then, in the **Cache provider** field, select `WebSphere eXtreme Scale dynamic cache provider .`
      3) Click **OK**.

   b. Add the cacheProviderName property to the cacheinstances.properties file that is bundled in an enterprise application, and set the property to `com.ibm.ws.objectgrid.dynacache.CacheProviderImpl`.

      For example, for cache.instance.26, you would add the following line to the cacheinstances.properties file:

      ```
      cache.instance.26.cacheProviderName = com.ibm.ws.objectgrid.dynacache.CacheProviderImpl
      ```

   c. Add the following Factory APIs to the code for an enterprise application:

```
Properties p = new Properties();
               ==>p.put(CacheConfig.CACHE_PROVIDER_NAME, CacheConfig.CACHE_PROVIDER_OBJECT_GRID);
               DistributedMap map1 = DistributedMapFactory.getMap("myMap", p);
               DistributedMap map2 = DistributedObjectCacheFactory.getMap("myMap2", p);
```

3. Configure the replication setting for the cache instance.

   With the WebSphere eXtreme Scale dynamic cache provider you can have local cache instances, and replicated cache instances.

   If you are only going to use local cache instances, go to the last step, and save your configuration changes. In a local cache the WebSphere eXtreme Scale container is co-located with the JVM; that is, the WebSphere eXtreme Scale container and WebSphere Application Server share the same JVM heap.

   If you are going to use replicated caches, complete one of the following actions, depending on how you have created the cache instance:

   a. On the **Java virtual machine > Custom properties** page in the administrative console, click **New** again. Enter `com.ibm.ws.cache.CacheConfig.enableCacheReplication` in the **Name** field, and `true` in the **Value** field, and then click **OK**.

   b. Add the enableCacheReplication property to the cacheinstances.properties file that is bundled in an enterprise application, and set the property to `true`. .

      For example, for cache.instance.26, you would add the following line to the cacheinstances.properties file:

      ```
      cache.instance.26.enableCacheReplication = true
      ```

   c. Add the following Factory APIs to the code for an enterprise application:

      ```
      Properties p = new Properties();
                     p.put(CacheConfig.CACHE_PROVIDER_NAME, CacheConfig.CACHE_PROVIDER_OBJECT_GRID);
                     ==>p.put(CacheConfig.ENABLE_CACHE_REPLICATION, "true");
                     DistributedMap map1 = DistributedMapFactory.getMap("myMap", p);
                     DistributedMap map2 = DistributedObjectCacheFactory.getMap("myMap2", p);
      ```

4. Configure the WebSphere eXtreme Scale replication topology.

   The only required configuration parameter for the WebSphere eXtreme Scale dynamic cache provider is the cache topology parameter.

   a. On the **Java virtual machine > Custom properties** page in the administrative console, click **New** again. Enter `com.ibm.websphere.xs.dynacache.topology` in the **Name** field, and one of the following values in the **Value** field:

      ```
      embedded
      embedded_partitioned
      remote
      ```

      gotcha: If you specify `embedded_partitioned`, you must also add the com.ibm.websphere.xs.dynacache.num_initial_containers custom property to your JVM settings, and set this property to an integer that is equal to or slightly less than the total number of server instances that are accessing this distributed cache instance.

   b. Add the com.ibm.websphere.xs.dynacache.topology property to the cacheinstances.properties file that is bundled in an enterprise application, and set the property to `true`. .

      For example, for cache.instance.26, you would add the following line to the cacheinstances.properties file:

      ```
      cache.instance.26.enableCacheReplication = embedded
      ```

      gotcha: If you specify `embedded_partitioned`, you must also add the com.ibm.websphere.xs.dynacache.num_initial_containers property to the cacheinstances.propertiesfile, and set this property to an integer that is equal to or slightly less than the total number of server instances that are accessing this distributed cache instance.

For example, if a dynamic cache service is shared between grid members, then the variable should be set to the number of grid members.

c. Add the following Factory APIs to the code for an enterprise application:

```
Properties p = new Properties();
                p.put(CacheConfig.CACHE_PROVIDER_NAME, CacheConfig.CACHE_PROVIDER_OBJECT_GRID);
                p.put(CacheConfig.ENABLE_CACHE_REPLICATION, "true");
                ==>p.put("com.ibm.websphere.xs.dynacache.topology", "embedded");
                ==>p.put("com.ibm.websphere.xs.dynacache.num_initial_containers", "3");
                DistributedMap map1 = DistributedMapFactory.getMap("myMap", p);
                DistributedMap map2 = DistributedObjectCacheFactory.getMap("myMap2", p);
```

See the topic Configuring the dynamic cache provider for WebSphere eXtreme Scale in the WebSphere eXtreme Scale Version 7 Information Center for more information about the `embedded`, `embedded_partitioned`, and `remote` settings.

5. Configure the eXtreme Scale catalog service grid.

   When you run a catalog service grid, you must set the catalog.services.cluster custom property for the catalog service endpoints.

   See the topic Starting the catalog service process in a WebSphere Application Server environment in the WebSphere eXtreme Scale Version 7 Information Center for a description of how to start the catalog service process in a WebSphere Application Server environment.

   a. In the administrative console, click **System administration > Cell > Custom properties > New**.

   b. Enter `catalog.services.cluster` in the **Name** field, and the appropriate *server_name*:*host_name*:*client_port*:*peer_port*:*listener_port* value in the **Value** field.

      - *server_name* is the fully qualified name of the WebSphere process, such as the cell name, node name, or server name, of the server that hosts the catalog service. Example: `cellA\node1\nodeagent`
      - *host_name* is the name of the hosting server.
      - *client_port* is the port that is used for peer catalog grid communication.
      - *peer_port* is the port that is used for peer catalog grid communication.
      - *listener_port* is the listener port. This port must match the BOOTSTRAP_ADDRESS value that is defined in the server configuration.

      Following is an example of a valid value:

      ```
      cellA\node1\nodeagent:host.local.domain:6600:6601:2809,cellA\node2\
      nodeagent:host.foreign.domain:6600:6601:2809
      ```

   c. Click **OK**.

6. Click **Save** to save all of your configuration changes.
7. Restart all the application servers that you configured to use WebSphere eXtreme Scale.
8. Configure custom key objects.

   When you are using custom objects as keys, the objects must implement the Serializable or Externalizable interface. If you are using custom objects with the embedded or embedded partitioned topologies, you must place the objects on the shared library path, in the same way that you do if you are using the default dynamic cache provider. For more information, see the topic Using the DistributedMap and DistributedObjectCache interfaces for the dynamic cache.

   If you are using the remote topology, you must place the custom key objects on the CLASSPATH for the stand-alone WebSphere eXtreme Scale containers. See the steps to start a container process in the *WebSphere eXtreme Scale Version 7.0 Administration Guide* for more information. This publication is available on the WebSphere eXtreme Scale library page

9. Configure eXtreme Scale container servers.

   The cached data is stored in WebSphere eXtreme Scale containers. These containers can run inside or outside of a WebSphere Application Server process. The eXtreme Scale provider automatically creates containers inside a WebSphere Application Server process when you are using embedded or embedded partitioned topologies for a cache instance. No further configuration is needed for these topologies.

When you use the remote topology, you must start up stand-alone eXtreme Scale containers before you start the WebSphere Application Server instances that access the cache instance. The *WebSphere eXtreme Scale Version 7.0 Administration Guide* documents the steps that you need to complete to start stand-alone containers.

gotcha: Make sure that all the containers for a specific dynamic cache point to the same catalog service endpoints.

The dynacache-remoteobjectgrid. xml and dynacache-remote-definition.xml configuration files for the stand-alone eXtreme Scale Dynamic Cache provider containers are located in the *install_root*/customLibraries/ ObjectGrid/dynacache/etc directory if WebSphere eXtreme Scale is installed on top of the WebSphere Application Server, or in the *install_root*/ObjectGrid/dynacache/etc directory if you are using a stand-alone version of WebSphere eXtreme Scale. Make copies of these files to edit and use when launching stand-alone containers for the eXtreme Scale dynamic cache provider. The value specified for the numIntitialContainers parameter in the dynacache-remote-deployment.xml file should be based on the number of container processes being run.

The following example illustrates a UNIX-based command line entry that launches a stand-alone container for the WebSphere eXtreme Scale dynamic cache provider:

```
startOgServer.sh container1 -objectGridFile ../dynacache/etc/dynacache-remoteobjectgrid.
xml -deploymentPolicyFile ../dynacache/etc/dynacache-remotedeployment.
xml -catalogServiceEndpoints MyServer1.company.com:2809
```

gotcha: The set of container processes needs to have enough free memory to service all the dynamic cache instances configured to use the remote topology. Any WebSphere Application Server process that shares the same or equivalent values for catalog.services.cluster must use the same set of stand-alone containers. The number of containers and number of machines they reside on needs to be sized appropriately. See the topic Capacity planning and high availability in the *WebSphere eXtreme Scale Version 7.0 Product Overview* for additional details. This publication is available on the WebSphere eXtreme Scale library page.

10. Verify that the WebSphere eXtreme Scale dynamic cache provider is correctly configured.

    If the WebSphere eXtreme Scale dynamic cache provider is correctly configured, the system log contains a number of messages similar to the following messages:

    ```
    DYNA1001I: WebSphere Dynamic cache instance named "{0}" initialized successfully using cache provider "{1}".
    DYNA1071I: The cache provider \"{0}\" is being used.
    ```

    If the configuration and initialization of the cache instance with WebSphere eXtreme Scale fails the dynamic cache runtime reverts to the default dynamic cache cache provider, and you should see messages similar to the following message in the system log.

    ```
    DYNA1066E: Unable to initialize the cache provider \"{0}\".
    The Dynamic cache will be used to create the cache instance \"{1}\"
    instead of the configured cache provider.
    ```

Dynamic caching with Asynchronous Request Dispatcher:

Asynchronous Request Dispatcher (ARD) improves servlet response time when slow operations are logically separated and performed concurrently with other operations that are required to complete the response.

Servlet caching works with ARD include requests, with certain caveats. The dynamic caching service does not support the ESI and ExternalCache features when ARD is enabled, due to complex and intractable buffering issues with third party content.

If the include request has been cached by the dynamic cache service, the include request returns immediately with the response data written to the top-level response data for the servlet.

In combination with the Remote Request Dispatcher (RRD), include request processing can also be offloaded to other members in the application server core group, thus reducing resource requirements on the original application server.

Configuring servlet caching

After a servlet is invoked and completes generating the output to cache, a cache entry is created containing the output and the side effects of the servlet. These side effects can include calls to other servlets or JavaServer Pages (JSP) files or metadata about the entry, including timeout and entry priority information. Configure servlet caching to save the output of servlets and JavaServer Pages (JSP) files to the dynamic cache.

Before you begin

To enable servlet caching, you must complete the tasks in the Using the dynamic cache service topic.

About this task

Unique entries are distinguished by an ID string that is generated from the HttpServletRequest object each time the servlet runs. You can then base servlet caching on:

- Request parameters and attributes of the Universal Resource Identifier (URI) that was used to invoke the servlet
- Session information
- Other options, including cookies

Because JavaServer Pages files are compiled into servlets, the dynamic cache function treats JavaServer Pages files the same as servlets, except in specifically documented situations.

Procedure

1. In the administrative console, click **Servers > Server Types > WebSphere application servers > *server_name* > Web container settings > Web container** in the console navigation tree.
2. Select **Enable servlet caching** under the Configuration tab.
3. Click **Apply** or **OK**.
4. Restart WebSphere Application Server. Refer to the Managing application servers topic for more information.

What to do next

Define the cache policy for your servlets by Configuring cacheable objects with the cachespec.xml file.

Dynamic caching with Asynchronous Request Dispatcher:

Asynchronous Request Dispatcher (ARD) improves servlet response time when slow operations are logically separated and performed concurrently with other operations that are required to complete the response.

Servlet caching works with ARD include requests, with certain caveats. The dynamic caching service does not support the ESI and ExternalCache features when ARD is enabled, due to complex and intractable buffering issues with third party content.

If the include request has been cached by the dynamic cache service, the include request returns immediately with the response data written to the top-level response data for the servlet.

In combination with the Remote Request Dispatcher (RRD), include request processing can also be offloaded to other members in the application server core group, thus reducing resource requirements on the original application server.

Configuring portlet fragment caching

After a portlet is invoked and completes generating the output to cache, a cache entry is created, containing the output and the side effects of the portlet. These side effects can include calls to other portlets or metadata about the entry, including timeout and entry priority information. Configure portlet fragment caching with the WebSphere Application Sever administrative console to save the output of portlets to the dynamic cache.

Before you begin

To enable portlet fragment caching, you must complete the steps in the Using the dynamic cache service topic.

About this task

Unique entries are distinguished by an ID string that generates from the PortletRequest object each time the portlet runs. You can then base portlet fragment caching on:

- Request parameters and attributes
- Session information
- Portlet-specific information, portlet session, portlet window ID, portlet mode, and portlet window state

Procedure

1. In the administrative console, click **Servers > Server Types > WebSphere application servers > *server_name* > Portlet container settings > Portlet container** > **Application servers >** *server_name* in the administrative console navigation tree.
2. Select **Enable portlet fragment cache** under the Configuration tab.
3. Click **Apply** or **OK**.
4. Restart WebSphere Application Server.

   See the *Setting up the application serving environment* PDF for more information.

What to do next

Define a cache policy for your portlets. Note that portlets are not cached unless an applicable caching policy is defined in a cachespec.xml file. Refer to the Configuring cacheable objects with the cachespec.xml file topic for general task information about defining a cache policy. Refer to the Configuring caching policies for portlets topic for information about defining portlet-specific aspects in a cache policy.

Configuring caching policies for portlets:

Fragment caching for portlets requires that you define a cache policy in a cachespec.xml file, either within the portlet web application archives (WAR) file or globally. If no caching policy is defined and applicable to a particular portlet, that porlet is not cached.

WebSphere Application Server caching policies provide a lot of flexibility for defining cache IDs and invalidation rules that match the specific requirements of individual portlets. The caching policies that you can define are not necessarily compliant with the caching behavior that is defined by the Java Portlet Specification. The following sections provide some recommendations on how you can exploit the features of cachespec.xml file, to define a caching policy that conforms to the specification.

Cache expiration. Portlets define cache expiration time in the `<expiration-cache>` element of the portlet.xml deployment descriptor. If this element is not present, or has a value of zero, the portlet is not cached. The cache expiration time for portlets is only defined in the deployment descriptor; any cache timeout values that are specified in a cachespec.xml file have no effect.

Caching scopes. Portlets are defined in the <caching-scope> element of the portlet.xml deployment descriptor, whether the portlet content should be shared across all users or whether it contains user-specific information and must be cached individually for each user. To maintain this setting in your caching policy definition, include the com.ibm.wsspi.portletcontainer.user_cache_scope attribute in your cache key, with the following cache key component:

```
<component id="com.ibm.wsspi.portletcontainer.user_cache_scope" type="attribute"/>
```

This attribute has the following values:

- The value, public, in a portlet that defines public cache scope.
- The current logon user ID in a portlet that defines private cache scope.
- Null (anonymous) in a portlet that defines private cache scope if no user is logged on.

If you want to cache portlet content for anonymous access, even in a portlet that defines private cache scope, add <required>false</required> to the cache key component. This implies that all anonymous browser access will retrieve the same cache content.

Portlet lifecycle methods. The Java Portlet Specification defines the four lifecycle phases: action, event, render and resource for running in a portlet. Only the render and resource phases produce content; the action and event phases invoke portlet activity without generating content and must not be cached. The lifecycle phase for a portlet call is available in the javax.portlet.lifecycle_phase request attribute. Check for the correct lifecycle by including the following cache key component:

```
<component id="javax.portlet.lifecycle_phase" type="attribute">
 <value>RENDER_PHASE</value>
</component>
```

This cache key component only caches render requests to the portlet. Cache additional resource requests by adding the RESOURCE_PHASE. In many cases, the best approach is to define a separate <cache-id> element for resource requests. The resource ID is available in the com.ibm.wsspi.portletcontainer.resource_id request attribute for caching key generation in resource requests.

Request parameters. Portlets can typically display multiple views. Render parameters distinguish which view displays. Each combination of parameters addresses a different view of the portlet. All views need to be cached separately; therefore, the full request parameter map should normally be included in the cache key. The com.ibm.wsspi.portletcontainer.all_parameters attribute provides a unique value for the content of the full request parameter map that can be used with the following cache key component:

```
<component id="com.ibm.wsspi.portletcontainer.all_parameters" type="attribute">
 <required>false</required>
</component>
```

If you write a cache policy for a specific portlet, and you know exactly which views of the portlet are addressed by which request parameters, it is usually more efficient to use specific <parameter> elements in the cache key to cache only the most important views of the portlet.

Other cache key components. Depending on your usage scenario, you will need to include other information in your cache key, if the returned content depends on it (for example, the portlet mode and window state, or the request locale in a multi-language portal). In a multi-device portal that supports different markup types, the returned content type should also be part of the cache key. The content type for a portlet is available in the com.ibm.wsspi.portletcontainer.response_contenttype request attribute.

Cache invalidation. The Java Portlet Specification states that action and event requests to a portlet must invalidate all currently cached content. The portlet caching definitions usually allow for caching multiple views of a portlet at the same time. To invalidate all of them, use the dependency ID mechanism of cachespec.xml.

Define a common dependency ID for all views that should be invalidated by an action. The common ID will usually only include the portlet window ID and the user scope, so that a portlet action does not affect private cache entries for other users:

```
<dependency-id>action
 <component id="" type="portletWindowId"/>
 <component id="com.ibm.wsspi.portletcontainer.user_cache_scope" type="attribute"/>
</dependency-id>
```

Define an invalidation rule that repeats the dependency ID and adds the current lifecycle method as a condition. It is essential to have the `ignore-value` attribute on the condition part. The lifecycle attribute must not be part of the returned invalidation ID, because that invalidation ID must match exactly with the dependency ID that is specified above.

```
<invalidation>action
 <component id="" type="portletWindowId"/>
 <component id="com.ibm.wsspi.portletcontainer.user_cache_scope" type="attribute"/>
 <component id="javax.portlet.lifecycle_phase" type="attribute" ignore-value="true">
  <value>ACTION_PHASE</value>
  <value>EVENT_PHASE</value>
 </component>
</invalidation>
```

Following the same pattern, specify more complex invalidation rules in caching policies for individual portlets, (for example, you can only invalidate a subset of the portlet views for specific actions that are determined by request parameters). The following example code describes a generic caching configuration that conforms to the behavior that is defined by the Java Portlet Specification:

Sample cachespec.xml file

```
<?xml version="1.0" ?>
<!DOCTYPE cache SYSTEM "cachespec.dtd">
<cache>
 <cache-entry>
  <class>portlet</class>
  <name>MyPortlet</name>
  <property name="consume-subfragments">true</property>
  <cache-id>
   <component id="" type="portletWindowId"/>
   <component id="com.ibm.wsspi.portletcontainer.user_cache_scope" type="attribute"/>

   <component id="" type="portletWindowState">
   <!-- minimized portlets are not cached -->
   <not-value>minimized</not-value>
  </component>
  <component id="" type="portletMode"/>

  <component id="" type="locale"/>
  <component id="com.ibm.wsspi.portletcontainer.response_contenttype" type="attribute"/>

  <component id="com.ibm.wsspi.portletcontainer.all_parameters" type="attribute">
   <required>false</required>
  </component>

  <component id="javax.portlet.lifecycle_phase" type="attribute">
   <value>RENDER_PHASE</value>
  </component>
 </cache-id>

 <dependency-id>action
  <component id="" type="portletWindowId"/>
  <component id="com.ibm.wsspi.portletcontainer.user_cache_scope" type="attribute"/>
 </dependency-id>

 <invalidation>action
  <component id="" type="portletWindowId"/>
```

```
  <component id="com.ibm.wsspi.portletcontainer.user_cache_scope" type="attribute"/>
  <component id="javax.portlet.lifecycle_phase" type="attribute" ignore-value="true">
   <value>ACTION_PHASE</value>
   <value>EVENT_PHASE </value>
  </component>
 </invalidation>

 </cache-entry>
</cache>
```

Configuring portlet fragment caching with the wsadmin tool

You can configure portlet fragment caching with scripting and the wsadmin tool.

Before you begin

Before starting this task, the wsadmin tool must be running. See the *Using the administrative clients* PDF for more information.

About this task

Important: If you use the wsadmin tool to enable portlet fragment caching, you must make sure that servlet caching is also enabled. Similarly if you use the wsadmin tool to disable portlet fragment caching, you must make sure that servlet caching is also disabled. The settings for these two caching functions must stay synchronized. If you enable or disable portlet fragment caching using the administrative console, synchronization is automatically taken care of for you.

Procedure

1. Locate the server object. The following example selects the first server found:

   Using Jacl:

   ```
   set s1 [$AdminConfig getid /Server:server1/]
   ```

   Using Jython:

   ```
   s1 = AdminConfig.getid('/Server:server1/')
   ```

2. List the web containers and assign them to the `wc` variable, for example:

   Using Jacl:

   ```
   set wc [$AdminConfig list PortletContainer $s1]
   ```

   Using Jython:

   ```
   wc = AdminConfig.list('PortletContainer', s1)
   ```

3. Set the enablePortletCaching attribute to `true` and assign it to the `serEnable` variable, for example:

   Using Jacl:

   ```
   set serEnable "{enablePortletCaching true}"
   ```

   Using Jython:

   ```
   serEnable = [['enablePortletCaching', 'true']]
   ```

4. Enable caching, for example:

   Using Jacl:

   ```
   $AdminConfig modify $wc $serEnable
   ```

   Using Jython:

   ```
   AdminConfig.modify(wc, serEnable)
   ```

Configuring caching for Struts and Tiles applications

Use this task to cache Struts and Tiles applications.

Before you begin

Before you configure Struts and Tiles caching, you should have a developed application. Find more information about developing Struts and Tiles applications on the Apache Struts Web Application Framework on the Apache website at http://struts.apache.org/.

About this task

Use this task when you want to cache data in Struts and Tiles applications.

Struts is an open source framework for building web applications using the Model-View-Controller (MVC) architecture. The Struts framework has a controller component and integrates with other technologies to provide the model and the view. Struts provide a control layer for the web application, which reduces construction time and maintenance costs.

The Tiles framework builds on the jsp:include feature and is bundled with the Struts web application framework. The Tiles framework reduces the duplication between JavaServer Pages (JSP) files and makes website layouts flexible and easy to maintain by assembling presentation pages from component parts.

Struts and Tiles caching is an extension of servlet and JSP caching, so the actions performed for each type of caching are very similar. Refer to the Configuring servlet caching topic for more information about servlet caching.

Procedure

1. Enable servlet and JSP caching. Enabling servlet caching automatically enables Struts and Tiles caching. Refer to the Configuring servlet caching topic for more information about servlet caching.
2. Develop the cache policy. A cache policy is required to cache a struts or tiles response.

   To develop a Struts cache policy:

   The Struts framework provides the controller component in the MVC-style application. The controller is a servlet called `org.apache.struts.action.ActionServlet.class`. In the `web.xml` file of the application, a servlet mapping of `*.do` is added for this Struts ActionServlet servlet so that every request for a Web address that ends with `.do` is processed. The ActionServlet servlet uses the information in the `struts-config.xml` file to decide which Struts action class runs the request for the specified resource.

   In the previous version of WebSphere Application Server, only one cache policy per servlet was supported. However, when you are using Struts, every request that ends in `.do` maps to the same ActionServlet servlet. To cache Struts responses, write a cache policy for the ActionServlet servlet based on its servlet path.

   For example, consider two Struts actions: `/HelloParam.do` and `/HelloAttr.do`. To cache the responses based on the id request parameter and the arg request attribute respectively, use the following cache policy:

```
<cache-entry>
 <class>servlet</class>
 <name>org.apache.struts.action.ActionServlet.class</name>
 <cache-id>
  <component id="" type="servletpath">
   <value>/HelloParm.do</value>
  </component>
 </cache-id>
 <cache-id>
  <component id="" type="servletpath">
   <value>/HelloAttr.do</value>
  </component>
  <component id="arg" type="attribute">
```

```
   <required>true</required>
  </component>
 </cache-id>
</cache-entry>
```

With the current version of WebSphere Application Server, you can map multiple cache policies for a single servlet. You can rewrite the previous cache policy as in the following example:

```
<cache-entry>
 <class>servlet>
 <name>/HelloParam.do</name>
 <cache-id>
  <component id="id" type="parameter">
   <required>true</required>
  </component>
</cache-entry>
<cache-entry>
 <class>servlet</class>
 <name>/HelloAttr.do</name>
 <cache-id>
  <component id="arg" type="attribute">
   <required>true</required>
  </component>
 </cache-id>
</cache-entry>
```

To develop a Tiles cache policy:

The Tiles framework is built on the jsp:include tag, so everything that applies to JSP caching also applies to Tiles. You must set the flush attribute to `true` in any fragments that are included using the tiles:insert tag for the fragments to be cached correctly. The extra feature in tiles caching over JSP caching is based on the tiles attribute. For example, you might develop the following layout.jsp template:

```
<html>
 <%String categoryId = request.getParameter("categoryId")+"test"; %>
 <tiles:insert attribute="header">
  <tiles:put name="categoryId" value="<%= categoryId %>" />
 </tile:insert>
 <table>
  <tr>
   <td width="70%" valign="top"><tiles:insert attribute="body" /> </td>
  </tr>
  <tr>
   <td colspan="2"><tiles:insert attribute="footer" /></td>
  </tr>
 </table>
</body>
</html>
```

The nested tiles:put tag specifies the attribute of the inserted tile. In the `layout.jsp` template, the categoryId attribute is defined and passed on to the tile that is inserted into the placeholder for the header. In the following example, the `layout.jsp` file is inserted into another JSP file:

```
<html>
<body>
<tiles:insert page="layout.jsp?categoryId=1002" flush="true">
 <tiles:put name="header" value="/header.jsp" />
 <tiles:put name="body" value="/body.jsp" />
 <tiles:put name="footer" value="/footer.jsp" />
</tiles:insert>
</body>
</html>
```

The categoryId tile attribute is passed on to the header.jsp file. The header.jsp file can use the <tiles:useAttribute> tag to retrieve the value of categoryId. To cache the header.jsp file based on the value of the categoryId attribute, you can use the following cache policy:

```
<cache-entry>
 <class>servlet</class>
 <name>/header.jsp</name>
 <cache-id>
  <component id="categoryId" type="tiles_attribute">
  <required>true</required>
  </component>
 </cache-id>
</cache-entry>
```

3. Ensure your cache policy is working correctly. You can modify the policies within the cachespec.xml file while your application is running. Refer to the Configuring cacheable objects with the cachespec.xml file topic for more information about cache policies.

Results

What to do next

Refer to the Task overview: Using the dynamic cache service to improve performance for more information about the dynamic cache.

Configuring dynamic cache disk offload

Use this task to configure dynamic cache disk offload, which saves cache entries that are deleted from the memory cache to disk.

About this task

By default, when the number of cache entries reaches the configured limit for a given application server, cache entries are removed from the memory cache, allowing newer entries to be stored in the cache. Use disk offload to copy the cache entries that are being removed from the memory cache to disk for potential future access.

Procedure

1. In the administrative console, click **Servers > Server Types > WebSphere application servers > *server_name* > Container services > Dynamic cache service** .
2. Select **Enable disk offload**.
3. After you enable the disk offload, you can set the Disk offload location. The disk offload location specifies where to save the cache entries on the disk. The disk offload location must be unique for any application servers that are defined on the same node. If you have multiple servers defined on the same node, make sure the disk offload location is different for each server.
4. Enable Flush to disk if you want cache objects that are in memory to be saved to disk when the server is stopped. Disk offload must be enabled if you choose this option. If you do not enable flush to disk, all the cache objects are deleted when the server stops.
5. Click **Apply** or **OK**.
6. Restart WebSphere Application Server.

Results

You enabled disk offload. Memory cache entries are moved to disk for potential future access.

When you have two or more application servers with servlet caching enabled and the application servers specify the same disk offload location for their caches through the dynamic cache service, the following exceptions might occur:

```
java.lang.NullPointerException
       at com.ibm.ws.cache.CacheOnDisk.readTemplate(CacheOnDisk.java:686)
       at com.ibm.ws.cache.Cache.internalInvalidateByTemplate(Cache.java:828)
```

or:

```
java.lang.NullPointerException
       at com.ibm.ws.cache.CacheOnDisk.readCacheEntry(CacheOnDisk.java:600)
       at com.ibm.ws.cache.Cache.getCacheEntry(Cache.java:341)
```

If one server is run as root and the other servers are run as non-root, this problem could occur. For example, if `server1` runs as root and `server2` runs as `wasuser` or `wasgroup`, the cache files in the disk offload location might be created with root permissions. This situation causes the applications running on the non-root servers to crash when they try to read or write to the cache.

Java virtual machine cache settings:

Use this page to set Java virtual machine (JVM) custom properties to maintain cache entries that are saved to disk.

You can set the custom properties globally to affect all cache instances, or you can set the custom property on a single cache instance. In most cases, set the properties on the individual cache instances. To set the custom properties on the default cache instance, use the global option. If you set the same property both globally and on a cache instance, the value that is set on the cache instance overrides the global value.

To configure the custom properties on a single object cache instance or servlet cache instance, perform the following steps:

1. In the administrative console, click one of the following paths:
   - To configure a servlet cache instance, click **Resources > Cache instances > Servlet cache instances >** *servlet_cache_instance_name* **> Custom properties > New**.
   - To configure an object cache instance, click **Resources > Cache instances > Object cache instances >** *object_cache_instance_name* **> Custom properties > New**.
2. Type the name of the custom property. When configuring these custom properties on a single cache instance, you do not use the full property path. For example, type `explictBufferLimitOnStop` to configure the `com.ibm.ws.cache.CacheConfig.explictBufferLimitOnStop` custom property.
3. Type a valid value for the property in the **Value** field.
4. Save the property and restart WebSphere Application Server.

To configure the custom property globally across all configured cache instances, perform the following steps:

1. In the administrative console, click **Servers > Application servers >** *server_name* **> Java and process management > Process definition > Java virtual machine > Custom properties > New**.
2. Type the name of the custom property (`com.ibm.ws.cache.CacheConfig.explictBufferLimitOnStop`) in the **Name** field.
3. Type a valid value for the property in the **Value** field.
4. Save the property and restart WebSphere Application Server.

Also use these properties to tune the delay offload function for the disk cache.

Important: Setting these custom properties using the **wsadmin** command is deprecated for WebSphere Application Server Version 7.0. Use the administrative console to set these properties. The individual property descriptions include information on how to use the administrative console to set these properties.

The delay offload function uses extra memory buffers for dependency IDs and templates to delay the disk offload and minimize the input and output operations. However, if most of your cache IDs are longer than 100 bytes, the delay offload function might use too much memory. Use any combination of the following properties to tune your configuration:

- To increase or decrease the in-memory limit of cache IDs for dependency ID and template buffers, use the `com.ibm.ws.cache.CacheConfig.htodDelayOffloadEntriesLimit` custom property.
- To disable the disk cache delay offload function, use the `com.ibm.ws.cache.CacheConfig.htodDelayOffload` custom property. Disabling this property saves all cache entries to disk immediately after removing them from the memory cache.

You can define the following Java virtual machine cache settings:

- "com.ibm.ws.cache.CacheConfig.explictBufferLimitOnStop"
- "com.ibm.ws.cache.CacheConfig.htodCleanupFrequency"
- "com.ibm.ws.cache.CacheConfig.htodDelayOffloadEntriesLimit" on page 371
- "com.ibm.ws.cache.CacheConfig.lruToDiskTriggerPercent" on page 371
- "com.ibm.ws.cache.CacheConfig.lruToDiskTriggerTime" on page 372

com.ibm.ws.cache.CacheConfig.explictBufferLimitOnStop:

Use this custom property when the flush-to-disk-on-stop feature is enabled. When the server is stopping, offloads are limited to the value specified for this property, pending removal of entries in the explicit invalidation buffer.

If this property is set to `0`, there is no limit to the number of offloads that can occur. Only positive integers are accepted as values for this property. If the number of entries in the explicit invalidation buffer is greater than the specified limit, all of the disk files for this specified cache instance are deleted after the server stops.

Important: You cannot use the administrative console to set this property.

com.ibm.ws.cache.CacheConfig.htodCleanupFrequency:

Use this property to change the amount of time between disk cache cleanup.

Important: Setting this custom property manually is deprecated for V6.1. Therefore, you should use the administrative console to set this property. To set this property in the administrative console, click one of the following paths:

- To configure a servlet cache instance, click **Resources > Cache instances > Servlet cache instances >** *servlet_cache_instance_name*.
- To configure an object cache instance, click **Resources > Cache instances > Object cache instances >** *object_cache_instance_name*.

Then:

1. Under Disk Cache setting, select the Enable disk offload field if it is not already selected.
2. Under Performance Settings, select Balanced performance and balanced memory usage or Custom.
3. In the Disk cache cleanup frequency field, specify an appropriate length of time, in minutes.

By default, the disk cache cleanup is scheduled to run at midnight to remove expired cache entries and cache entries that have not been accessed in the past 24 hours. However, if you have thousands of cache entries that might expire within one or two hours, the files that are in the disk cache can grow large and

become unmanageable. Use the `com.ibm.ws.cache.CacheConfig.htodCleanupFrequency` custom property to change the time interval between disk cache cleanup.

Units	minutes For example, a value of 60 means 60 minutes between each disk cache cleanup.
Default	0 The disk cache cleanup occurs at midnight every 24 hours.

com.ibm.ws.cache.CacheConfig.htodDelayOffloadEntriesLimit:

Use this property to specify the number of different cache IDs that can be saved in memory for the dependency ID and template buffers. Consider increasing this value if you have a lot of memory in your server and you want to increase the performance of your disk cache.

Important: Setting this custom property using the **wsadmin** command is deprecated for V7.0. Therefore, you should use the administrative console to set this property. To set this property in the administrative console, click one of the following paths:

- To configure a servlet cache instance, click **Resources > Cache instances > Servlet cache instances >** *servlet_cache_instance_name*.
- To configure an object cache instance, click **Resources > Cache instances > Object cache instances >** *object_cache_instance_name*.

Then:

1. Under Disk Cache setting, select the Enable disk offload field, if it is not already selected.
2. Under Disk Cache settings, select Limit disk cache size in entries, if it is not already selected.
3. In the Disk cache size field, specify the number of cache IDs that can be saved in memory for the dependency ID and template buffers.

Units	number of cache IDs For example, a value of 1000 means that each dependency ID or template ID can have up to 1000 different cache IDs in memory.
Default	1000
Minimum	100

com.ibm.ws.cache.CacheConfig.lruToDiskTriggerPercent:

Use this custom property to set the percentage of the memory cache size to be used as an overflow buffer when disk offload is enabled.

Cache entries in the overflow buffer are purged and asynchronously offloaded to disk at a frequency of *lruToDiskTriggerTime* milliseconds. If the memory overflow buffer is full, cache entries are offloaded to disk synchronously on the thread for the caller.

Units	integer, percentage
Lower bound	0
Upper bound	100

Scope	Configurable per cache instance.

com.ibm.ws.cache.CacheConfig.lruToDiskTriggerTime:

Use this custom property to set the frequency with which cache entries in memory are asynchronously offloaded to disk when the disk offload feature is enabled.

Units	integer, milliseconds
Lower bound	0
Upper bound	5000
Scope	Applicable to all cache instances.

Configuring Edge Side Include caching

The web server plug-in contains a built-in ESI processor. The ESI processor can cache whole pages, as well as fragments, providing a higher cache hit ratio. The cache implemented by the ESI processor is an in-memory cache, not a disk cache, therefore, the cache entries are not saved when the web server is restarted.

About this task

Edge Side Include (ESI) is configured through the `plugin-cfg.xml` file.

When a request is received by the web server plug-in, it is sent to the ESI processor, unless the ESI processor is disabled. It is enabled by default. If a cache miss occurs, a Surrogate-Capabilities header is added to the request and the request is forwarded to the WebSphere Application Server. If servlet caching is enabled in the application server, and the response is edge cacheable, the application server returns a Surrogate-Control header in response to the WebSphere Application Server plug-in.

The value of the Surrogate-Control response header contains the list of rules that are used by the ESI processor to generate the cache ID. The response is then stored in the ESI cache, using the cache ID as the key. For each ESI include tag in the body of the response, a new request is processed so that each nested include results in either a cache hit or another request that forwards to the application server. When all nested includes have been processed, the page is assembled and returned to the client.

The ESI processor is configurable through the WebSphere web server plug-in configuration file `plugin-cfg.xml`. The following is an example of the beginning of this file, which illustrates the ESI configuration options.

```
<?xml version-"1.0"?>
<Config>
  <Property Name="esiEnable" Value="true"/>
  <Property Name="esiMaxCacheSize" Value="1024"/>
  <Property Name="esiInvalidationMonitor" Value="false"/>
```

Procedure

- The first option, esiEnable, can be used to disable the ESI processor by setting the value to false. ESI is enabled by default. If ESI is disabled, then the other ESI options are ignored.
- The second option, esiMaxCacheSize, is the maximum size of the cache in 1K byte units. The default maximum size of the cache is 1 megabyte.

  If the first response has a Content-Length response header, the web server plug-in checks for the response size. If the size of the response body is larger than the available ESI caching space, the response passes through without being handled by ESI.

  Some parent responses have nested ESI includes. If a parent response is successfully stored in the ESI cache, and any subsequent nested include has a Content-length header that specifies a size larger than

the available space in the ESI cache, but smaller than the value specified for esiMaxCacheSize property, the plug-in ESI processor evicts other cache elements until there is enough space for the nested include in the ESI cache.

- The third option, esiInvalidationMonitor, specifies if the ESI processor should receive invalidations from the application server. ESI works well when the web servers following a threading model are used, and only one process is started. When multiple processes are started, each process caches the responses independently and the cache is not shared. This could lead to a situation where, the system's memory is fully used up by ESI processor. There are three methods by which entries are removed from the ESI cache: first, an entry expiration timeout occurs; second, an entry is purged to make room for newer entries; or third, the application server sends an explicit invalidation for a group of entries. For the third mechanism to be enabled, the esiInvalidationMonitor property must be set to true and the DynaCacheEsi application must be installed on the application server. The DynaCacheEsi application is located in the installableApps directory and is named DynaCacheEsi.ear. If the ESIInvalidationMonitor property is set to true but the DynaCacheEsi application is not installed, then errors occur in the web server plug-in and the request fails.
- This ESI processor is monitored through the CacheMonitor application. For the ESI processor cache to be visible in the CacheMonitor, the DynaCacheEsi application must be installed as described above, and the ESIInvalidationMonitor property must be set to true in the `plugin-cfg.xml` file.
- When WebSphere Application Server is used to serve static data, such as images and HTML on the application server, the URLs are also cached in the ESI processor. This data has a default timeout of 300 seconds. You can change the timeout value by adding the property com.ibm.servlet.file.esi.timeOut to the Java virtual machine (JVM) command line parameters. The following example shows how to set a one minute timeout on static data cached in the plug-in:

  ```
  -Dcom.ibm.servlet.file.esi.timeOut=60
  ```

  For information about configuring alternate URL, see the *Tuning guide* PDF.

Configuring alternate URL:

Alternate URL is a method for edge caching JavaServer Pages (JSP) files and servlet responses that you can not request externally. Dynamic cache provides support to recognize the presence of an Edge Side Include (ESI) processor and to generate ESI include tags and appropriate cache policies for edge fragments that can be cached. However, you must be able to externally request an edge fragment from the application server before it can be cached. In other words, if a user types the URL in their browser with the appropriate parameters and cookies for the fragment, WebSphere Application Server must be able to return the content for that fragment.

About this task

One of the standard Java Platform, Enterprise Edition (Java EE) programming architectures is the model-view-controller (MVC) architecture, where a call to a controller servlet might include one or more child JSP files to construct the view. When using the MVC programming model, the child JSP files are edge cached only if you can request these JSP files externally, which is not usually the case. For example, if a child JSP file uses one or more request attributes that are determined and set by the controller servlet, you cannot cache that JSP file on the edge. You can use alternate URL support to overcome this limitation by providing an alternate controller servlet URL used to invoke the JSP file.

The alternate URL for a JSP file or a servlet is set in the `cachespec.xml` file as a property with the name `alternate_url`. You can set the alternate URL either on a per cache-entry basis or on a per cache-id basis. It is valid only if the `EdgeCacheable` property is also set for that entry. If the `EdgeCacheable` property is not set, the `alternate_url` property is ignored. The following is a sample cache policy using the `alternate_url` property:

```
<cache-entry>
    <class>servlet</class>
    <name>/AltUrlTest2.jsp</name>
```

```
    <property  name="EdgeCacheable">true</property>
    <property  name="alternate_url">/alturlcontroller2</property>
        <cache-id>
            <timeout>600</timeout>
            <priority>2</priority>
        </cache-id>
</cache-entry>
```

What to do next

For more information on the `cachespec.xml` file, refer to the cachespec.xml file topic.

Configuring external cache groups

The dynamic cache can control caches outside of the application server, such as the Edge server, an IBM HTTP Server, or an HTTP Server ESI Fragment Processor plug-in.

About this task

When external cache groups are defined, the dynamic cache matches externally cacheable cache entries with those groups, and pushes cache entries and invalidations out to those groups. This allows WebSphere Application Server to manage dynamic content beyond the application server. The content can then be served from the external cache, instead of the application server, improving savings in performance.

Procedure

1. Open the administrative console.
2. Enable the dynamic cache.
   a. In the administrative console, click **Servers > Server Types > WebSphere application servers > *server_name* > Container services > Dynamic cache service**.
   b. Select **Enable service at server startup** to enable the dynamic cache each time the application server starts.
3. Define the external cache group that WebSphere Application Server should control.
   a. In the administrative console, click **Servers > Server Types > WebSphere application servers > *server_name* > Container services > Dynamic cache service > External cache groups**.
   b. Click **New** or choose an external cache group from the list.
4. Configure cache group members.
   a. Click **External cache groups** from the dynamic cache administrative console page. Then click **New** or choose an external cache group from the list.
   b. Click **External cache group members > New** or choose an external cache group member from the list.
   c. Type the configuration string in the Address field.
   d. Type the adapter bean name in the Adapter Bean Name field.
   e. Save the configuration.
   f. Click **Apply** or **OK**.

External cache group collection:

Use this page to define sets of external caches that are controlled by WebSphere Application Server on web servers such as IBM Edge Server and IBM HTTP Server.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > *server_name* > **Container services** > **Dynamic cache service** > **External cache groups**.

Name:

Specifies the external cache group name.

The external cache group name needs to match the ExternalCache property as defined in the servlet or JavaServer Pages (JSP) file cachespec.xml file.

When external caching is enabled, the cache matches pages with its Universal Resource Identifiers (URI) and pushes matching pages to the external cache. The entries can then be served from the external cache, instead of from the application server.

Type:

Specifies the external cache group type.

External cache group settings:

Use this page to configure sets of external caches that are controlled by WebSphere Application Server on web servers, such as IBM Edge Server and IBM HTTP Server.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > *server_name* > **Container services > Dynamic cache service** > **External cache groups** > *external_cache_group*.

Name:

Specifies the external cache group name.

The external cache group name must match the **ExternalCache** property as defined in the servlet or JavaServer Pages (JSPs) `cachespec.xml` file.

When external caching is enabled, the cache matches pages with its Universal Resource Identifiers (URIs) and pushes matching pages to the external cache. The entries can then be served from the external cache, instead of the application server. This ability creates a significant savings in performance.

External cache group member collection:

Use this page to define specific caches that are members of a cache group.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > *server_name* > **Container services > Dynamic cache service** > **External cache groups** > *external_cache_group* > **External cache group members**.

Address:

Specifies a configuration string that is used by the external cache adapter bean to connect to the external cache.

AdapterBeanName:

Specifies the adapter bean name.

Example adapter bean names that are supported in WebSphere Application Server are as follows:

Table 37. Adapter bean names.. Example adapter bean names

AFPA

Table 37. Adapter bean names. (continued). Example adapter bean names

AdapterBeanName: com.ibm.ws.cache.servlet.Afpa
Address: Port on which afpa listens
ESI
AdapterBeanName: com.ibm.websphere.servlet.cache.ESIInvalidatorServlet
IBM Web Traffic Express (WTE) (IBM Edge Server)
AdapterBeanName: com.ibm.websphere.edge.dynacache.WteAdapter
Address: hostname:port (host name and port on which WTE is listening)

External cache group member settings:

Use this page to define a single cache that is controlled by WebSphere Application Server.

To view this administrative console page, click **Servers > Server Types > WebSphere application servers >** ***server_name*** **> Container services > Dynamic cache service > External cache groups >** ***external_cache_group*** **> External cache group members >** ***external_cache_group_member***.

Advanced Fast Path Architecture adapter bean name:

Specifies the adapter bean name.

- **Adapter bean name**: specifies the adapter bean name. For example, you can use a bean name such as `com.ibm.ws.cache.servlet.Afpa`.
- **Address:** specifies the port on which AFPA listens.

Edge Side Include (ESI):

Specifies the adapter bean name.

- **Adapter bean name**: specifies the adapter bean name. For example, you can use a bean name such as `com.ibm.websphere.servlet.cache.ESIInvalidatorServlet`.
- **Address:** local host

IBM Web Traffic Express (IBM WebSphere Edge Server):

Specifies the adapter bean name.

- **Adapter bean name**: specifies the adapter bean name. For example, you can use a bean name such as `com.ibm.websphere.edge.dynacache.WteAdapter`.
- **Address:** hostname:port (host name and port on which WTE is listening).

Configuring high-speed external caching through the web server:

IBM HTTP Server for Windows 2003 operating systems contains a high-speed cache referred to as the *Fast Response Cache Accelerator*, or *cache accelerator*. The Fast Response Cache Accelerator is available on Windows 2003 operating systems and AIX platforms. However, support to cache dynamic content is only available on Windows 2003 operating systems. You can enable cache accelerator to cache static and dynamic content.

Before you begin

About this task

Enable cache accelerator for caching static content by adding the following directives to the `httpd.conf` configuration file, located in the IBM HTTP Server `conf` directory:

- AfpaEnable
- AfpaCache on
- AfpaLogFile "*app_server_root*\IBMHttpServer\logs\afpalog" V-ECLF

To enable cache accelerator for caching dynamic content, such as servlets and JavaServer Pages (JSP) files, configure WebSphere Application Server and IBM HTTP Server for distributed platforms:

Procedure

1. Configure WebSphere Application Server to enable Fast Response Cache Accelerator.
   a. Configure an external cache group on the application server:
      1) Click **Servers > Server Types > WebSphere application servers > *server_name* > Container services > Dynamic cache service > External cache groups**.
      2) Click **New** on the External cache group administrative console page to define an external cache group named `afpa` for each application server that uses the cache accelerator.
      3) In the **External cache group** field, type `afpa` and apply the changes.
   b. Add a member to the group with an adapter bean name of `com.ibm.ws.cache.servlet.Afpa`.
      1) Click **Afpa > External cache group members**.
      2) Click **New** on the External cache group members administrative console page.
      3) In the AdapterBean name field, type `com.ibm.ws.cache.servlet.Afpa`.
      4) In the Address field, enter an unused port number.
   c. Add a cache policy in the `cachespec.xml` file for the servlet or JSP file you want to cache. Add the following property to the cache policy:

      ```
      <property name="ExternalCache">afpa</property>
      ```
2. Enable cache accelerator on IBM HTTP Server for distributed platforms:
   a. Add the following directives to the end of the `httpd.conf` file:
      - AfpaEnable
      - AfpaCache on
      - AfpaLogFile "*app_server_root*\IBMHttpServer\logs\afpalog" V-ECLF
      -

        depfeat: IBM HTTP Server 1.3.x - LoadModule afpaplugin_module *app_server_root*\bin\afpaplugin.dll
      - IBM HTTP Server 2.0 - LoadModule afpaplugin_20_module *app_server_root*\bin\afpaplugin_20.dll
      - AfpaPluginHost *WAS_Hostname:port*, where *WAS_Hostname* is the host name of the application server and *port* is the port you specified in the Address field while configuring the external cache group member

   The LoadModule directive loads the IBM HTTP Server plug-in that connects the Fast Response Cache Accelerator to the WebSphere Application Server fragment cache. If multiple IBM HTTP Servers are routing requests to a single application server, add the directives above to the `httpd.conf` file of each of these IBM HTTP Servers for distributed platforms.

Disabling template-based invalidations during JSP reloads

By setting the Java virtual machine (JVM) `com.ibm.ws.cache.CacheConfig.disableTemplateInvalidation` custom property to **true**, the template-based invalidations are disabled during JSP reloads.

About this task

To set any of these JVM custom properties, complete the following steps:

Procedure

1. In the administrative console, click **Servers > Application servers >*server_name* > Process definition > Java virtual machine > Custom properties > New**.

2. Enter `com.ibm.ws.cache.CacheConfig.disableTemplateInvalidation` in the Name field.
3. Enter **true** in the Value field.
4. Save the property and restart WebSphere Application Server.

Dynamic cache provider for the JPA 2.0 second level cache

Learn to use the WebSphere Application Server dynamic cache service as a Java Persistence API (JPA) second level (L2) cache provider. JPA 2.0 has standardized the L2 cache interface. WebSphere Application Server supports the JPA standard. The dynamic cache service plugs in as a level 2 cache provider to JPA. This topic describes how the L2 cache boosts the performance of your JPA application, the advantages of using DynaCache as L2 cache provider and how to configure and monitor the dynamic cache service for your JPA application in the WebSphere Application Server environment.

Note: A dynamic cache JPA second level (L2) cache provider for JPA 2.0 shares entity states across various persistence contexts, transactions and users. When caching is enabled, entities that are not found in the persistence context are loaded from the L2 cache. L2 caching avoids database access for currently-loaded entities. For more details about L2 caching, view the JPA 2.0 specification.

Attention: L2 caching increases the memory consumption of the application, therefore, it is important to limit the size of the L2 cache. There is also a possibility of stale data for updated objects in a clustered environment. Configure L2 caching for read-mostly, infrequently modified entities. L2 caches are not recommended for frequently and concurrently updated entities.

JPA utilizes several configurable L2 caches to maximize performance. The JPA data cache is a cache of persistent object data that operates at the EntityManagerFactory level. When enabled, the data cache is checked before making a trip to the datastore. Data is stored in the cache when objects are committed and when persistent objects are loaded from the datastore. In addition to the data cache, JPA defines service provider interfaces for a query cache.

The query cache stores the object IDs that are returned by query executions. When you run a query, JPA assembles a key that is based on the query properties and the parameters that are used at launch time and checks for a cached query result. If one is found, the object IDs in the cached result are looked up, and the resulting persistence-capable objects are returned. Otherwise, the query is launched against the database and the object IDs that are loaded by the query are placed into the cache. The object ID list is not cached until the list that is returned at query launch time is fully traversed.

The WebSphere Dynamic cache cache provider provides an excellent alternative to the default concurrent data and query cache providers on WebSphere Application Server, due to the value-added features that the dynamic cache service brings, such as its own feature set and the capabilities that are inherited from WebSphere Application Server. The dynamic cache provides the following advantages:

- Cluster distributed cache synchronization and replication through WebSphere Application Server data replication service (DRS) and high-availability (HA) services.
- Sophisticated and advanced DataCache and QueryCache monitoring, tuning and administration of the cache. The L2 cache will inherit the entire ecosystem of the available dynamic cache tooling.
- Native servant region z/OS support.
- Performs equally, if not better, to the default cache provider.

The JPA standard provides aliases as a mechanism to easily configure JPA plug-ins. The dynamic cache level 2 cache provider for JPA 2.0 is typically configured with the *dynacache* alias. You can use the *dynacache* alias for setting the DataCache and QueryCache properties of JPA. If the QueryCache property is set to use *dynacache*, then the DataCache property will also use the *dynacache* alias. You can configure the QueryCache and DataCache properties to use different types of cache providers. You can set the QueryCache property to default and set the DataCache to use dynamic cache, or reverse. It is ideal to use the WebSphere Application Server dynamic cache service for the DataCache, QueryCache, and the DataCacheManager. If the DataCache is set to **dynacache**, then the RemoteCommitProvider does

nothing because DRS and HAM are leveraged to do the cache synchronization. You cannot enable the QueryCache property separately from the DataCache. The QueryCache property benefits from the availability of the DataCache property, where the entity data is cached.

Configuring the JPA dynamic cache L2 provider (basic method)

Enable the dynamic cache service as the level 2 cache provider for JPA 2.0 by setting some or all of the following properties to **dynacache**: OpenJPA openjpa.QueryCache, openjpa.DataCache, and the openjpa.DataCacheManager. This default configuration is a suitable default for most environments.

```
<property name="openjpa.DataCache" value="dynacache(CacheSize=1000)"/>
<property name="openjpa.QueryCache" value="dynacache"/>
<property name="openjpa.DataCacheManager" value="dynacache"/>
```

Table 38. Property names and aliases.. Fully-qualified property names and aliases for the dynamic cache.

Dynamic cache name	Property name	Alias
DataCache cache provider	com.ibm.ws.cache.openjpa. DynacacheDataCache	dynacache
QueryCache cache provider	com.ibm.ws.cache.openjpa. DynacacheQueryCache	dynacache
RemoteCommitProvider	com.ibm.ws.cache.openjpa. NoOpRemoteCommitProvider	none
DataCacheManager	com.ibm.ws.cache.openjpa. DynacacheDataCacheManager	dynacache

Configuring the JPA dynamic cache L2 provider (advanced method)

Configure the dynamic cache instance for the JPA 2.0 Level 2 data or query cache with additional or advanced configuration properties in the persistent unit (advanced method). Enable the dynamic cache service as the level 2 cache provider for JPA 2.0 by setting some or all of the following properties to **dynacache**: OpenJPA openjpa.QueryCache, openjpa.DataCache, and openjpa.DataCacheManager properties.

```
<property name="openjpa.DataCache" value="dynacache(CacheName="myJPACache",
                                                    CacheSize=1000,
                                                    EnableDiskOffload=true,
                                                    DiskCacheSizeInGB=4,
                                                    DiskOffloadLocation=c:\temp,
                                                    EnableCacheReplication=true)"/>
```

Table 39. Dynamic cache property names and values. Properties of the dynamic cache cache instance that can be configured in the persistent unit.

Dynamic cache custom properties	Default values
CacheName	default
CacheSize	2000
EnableDiskOffload	false
EnableCacheReplication	false
DiskCacheSizeInGB	not applicable
DiskOffloadLocation	not applicable
ReplicationType	1 , 2 or 4. 1 means NOT_SHARED, 2 is PUSH and 4 is PUSH_PULL

Important: The properties in the table are not mandatory. If not specified, the dynamic cache service assumes default values that are suitable for the majority of users.

The following example showcases the dynamic cache mbean operations in action to introspect the L2 cache:

```
wsadmin>set mbean [$AdminControl queryNames type=DynaCache,*]

wsadmin> $AdminControl invoke $mbean getCacheIDsInMemory {default \S}
66
71
10
A5614-67
```

```
wsadmin> $AdminControl invoke $mbean getJPACacheStatistics {OpenBooks openbooks.war OpenBooks default}
HIT_COUNT=0
TOTAL_HIT_COUNT=0
READ_COUNT=5
TOTAL_READ_COUNT=5
WRITE_COUNT=4
TOTAL_WRITE_COUNT=4

wsadmin> $AdminControl invoke $mbean getJPACacheStatistics {OpenBooks openbooks.war OpenBooks default openbook.domain.Customer}
HIT_COUNT=0
TOTAL_HIT_COUNT=0
READ_COUNT=0
TOTAL_READ_COUNT=0
WRITE_COUNT=1
TOTAL_WRITE_COUNT=1
```

You can also use the Extended Cache Monitor to view the contents of the cache ID and key values that are placed in the cache by the JPA runtime.

Using the dynamic cache L2 cache provider in a clustered environment

Customers can define a cache-instance in the customary way in WebSphere Application Server and then reference the name in the CacheName property of the JPA DataCache property value. You can define an object cache instance using the cacheinstances.properties file, DistributedMapFactory, or the administrative console.

All properties are optional and if they are not specified, defaults properties are assumed. If the cache instance does not exist, the dynamic cache service creates the cache instance. Advanced configuration for a QueryCache Dynacache instance is completed in a similar manner.

The JPA data cache operates in both single-JVM and multi-JVM environments. Multi-JVM caching is achieved through the use of the Data Replication Service (DRS) in a clustered WebSphere Application Server, Network Deployment environment.

For entities and queries in the dynamic cache DataCache and QueryCache instances that are replicated across servers in a WebSphere Application Server, Network Deployment environment using the Data Replication Service, configure a replication domain and associate the replication domain with the cache instance. The persistent unit must also have the openjpa.RemoteCommitProvider openJPA property set to **none**.

Replicate an OpenJPA L2 dynamic cache instance, as follows:

1. Create a replication domain in the administrative console and associate the replication domain with the baseCache cache instance on the dynamic cache service panel on all application servers that must share the distributed cache. The dynamic cache service uses this replication domain to replicate data across servers in the replication domain.
2. Configure the cache instance by setting the enableCacheReplication property to true when defining the configuration of the cache instance. If you do not specify the replicationType property, the cache instance is configured by default in the NOT_SHARED sharing mode, where only invalidations are propagated. You can configure the cache instance in the NOT_SHARED, PUSH and PUSH_PULL sharing types. Refer to the cache replication topic to learn more about this topic.
3. Set the `com.ibm.ws.cache.CacheConfig.createCacheAtServerStartup` JVM custom property to **true** on all the application servers in the replication domain. This custom property helps the JPA cache instances on servers bootstrap earlier and faster.
4. Create a shared library to make the entity classes available in the classpath of the application server by defining a shared library and associating it with the server classloader. This step is necessary for the dynamic cache service and DRS to deserialize the replicated entity objects. Refer to the Shared library collection, Managing shared libraries, and Associating shared libraries with servers topics for more information about shared libraries.
5. Set the openjpa.RemoteCommitProvider to **none**.

You might also use other RemoteCommitProvider implementations that are included with JPA 2.0 with dynamic cache, specifically the following implementations:

- org.apache.openjpa.event.SingleJVMRemoteCommitProvider (configured with the "sjvm" alias)
- org.apache.openjpa.event.TCPRemoteCommitProvider
- org.apache.openjpa.event.JMSRemoteCommitProvider

Read more about remote and offline operation in the JPA documentation.

Attention: Configure dynamic cache with DRS for replication of JPA data and QueryCache objects and using the NoOp RemoteCommitProvider property in a distributed or clustered environment.

Troubleshooting the JPA L2 cache

Look for the following messages in the log file when using the dynamic cache service as a JPA cache provider:

```
# Significant dynamic cache OpenJPA messages in the SystemOut.log file
DYNA1081I: OpenJPA L2 DataCache Dynacache instance \"{0}\" created or retrieved successfully for persistent unit \"{1}\".

# Applicable only if QueryCache is enabled
DYNA1080I: OpenJPA L2 QueryCache Dynacache instance \"{0}\" created or retrieved successfully for persistent unit \"{1}\".
```

Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

Chapter 9. Administering EJB applications

This page provides a starting point for finding information about enterprise beans.

Based on the Enterprise JavaBeans (EJB) specification, enterprise beans are Java components that typically implement the business logic of Java 2 Platform, Enterprise Edition (J2EE) applications as well as access data.

Deploying EJB 3.x enterprise beans

EJB module settings

Use this page to configure and manage a specific deployed EJB module.

Note: You cannot start or stop an individual EJB module for modification. You must start or stop the appropriate application entirely.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > **application_name** > **Manage Modules** > **module_name**.

Attention: If an application is running, changing an application setting causes the application to restart. On stand-alone servers, the application restarts after you save the change. On multiple-server products, the application restarts after you save the change and files synchronize on the node where the application is installed. To control when synchronization occurs on multiple-server products, deselect **Synchronize changes with nodes** on the Console preferences page.

URI

Specifies location of the module relative to the root of the application EAR file. The URI must match the URI of a ModuleRef URI in the deployment descriptor of the deployed application (EAR).

Alternate deployment descriptor

Specifies an alternate deployment descriptor for the module as defined in the application deployment descriptor according to the Java Platform, Enterprise Edition (Java EE) specification.

Starting weight

Specifies the order in which modules are started when the server starts. The module with the lowest starting weight is started first.

If the application deployment descriptor specifies the `<initialize-in-order>true</initialize-in-order>` element, the default starting weights reflect the order that is specified in the deployment descriptor. Otherwise, the defaults are determined based on module type (RAR modules start before EJB modules, which start before web modules).

Data type	Integer
Default	5000
Range	Greater than 0

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This topic describes the conventions in use for WebSphere Application Server.

Default product locations - IBM i

These file paths are default locations. You can install the product and other components in any directory where you have write access. You can create profiles in any valid directory where you have write access. Multiple installations of WebSphere Application Server products or components require multiple locations.

app_client_root
The default installation root directory for the Application Client for IBM WebSphere Application Server is the `/QIBM/ProdData/WebSphere/AppClient/V8/client` directory.

app_client_user_data_root
The default Application Client for IBM WebSphere Application Server user data root is the `/QIBM/UserData/WebSphere/AppClient/V8/client` directory.

app_client_profile_root
The default Application Client for IBM WebSphere Application Server profile root is the `/QIBM/UserData/WebSphere/AppClient/V8/client/profiles/`*`profile_name`* directory.

app_server_root
The default installation root directory for WebSphere Application Server - Express is the `/QIBM/ProdData/WebSphere/AppServer/V8/Express` directory.

java_home

Table 40. Root directories for supported Java Virtual Machines.

This table shows the root directories for all supported Java Virtual Machines (JVMs).

JVM	Directory
32–bit IBM Technology for Java	`/QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit`
64–bit IBM Technology for Java	`/QOpenSys/QIBM/ProdData/JavaVM/jdk60/64bit`

plugins_profile_root
The default Web Server Plug-ins profile root is the `/QIBM/UserData/WebSphere/Plugins/V8/webserver/profiles/`*profile_name* directory.

plugins_root
The default installation root directory for Web Server Plug-ins is the `/QIBM/ProdData/WebSphere/Plugins/V8/webserver` directory.

plugins_user_data_root
The default Web Server Plug-ins user data root is the `/QIBM/UserData/WebSphere/Plugins/V8/webserver` directory.

product_library
product_lib
This is the product library for the installed product. The product library for each Version 8.0 installation on the system contains the program and service program objects (similar to `.exe`, `.dll`, `.so` objects) for the installed product. The product library name is `QWAS8`*x* (where *x* is A, B, C, and so on). The product library for the first WebSphere Application Server Version 8.0 product installed on the system is `QWAS8A`. The *`app_server_root`*`/properties/product.properties` file contains the value for the product library of the installation, `was.install.library`, and is located under the *`app_server_root`* directory.

profile_root
The default directory for a profile named *profile_name* for WebSphere Application Server - Express is the `/QIBM/UserData/WebSphere/AppServer/V8/Express/profiles/`*`profile_name`* directory.

shared_product_library
The shared product library, which contains all of the objects shared by all installations on the system, is `QWAS8`. This library contains objects such as the product definition, the subsystem description, the job description, and the job queue.

user_data_root
The default user data directory for WebSphere Application Server - Express is the `/QIBM/UserData/WebSphere/AppServer/V8/Express` directory.

The `profiles` and `profileRegistry` subdirectories are created under this directory when you install the product.

web_server_root
The default web server path is /www/*web_server_name*.

Deploying EJB modules

When you deploy an Enterprise JavaBeans (EJB) module, you install that module on a server that has been configured to support deployed modules.

Before you begin

Assemble one or more EJB modules, assemble one or more web modules, and assemble them into a Java EE application.

For an overview about the changes to the EJB deployment model for EJB 3.x, see the topic EJB 3.x deployment overview.

Procedure

1. Prepare the deployment environment. See the topic Preparing to host applications.
2. Update the configuration for each EJB module as needed for the deployment environment.
3. Required: If a module has dependencies on Java 5-specific extensions, such as generics, annotations, and so on, then you must run the EJBDeplolycommand-line tool separately and before installing the module or application containing it. This is because the administrative console and the wsadmin command-line tool do not allow for specifying the ejbdeploy -complianceLevel 5.0 option.

   It is only necessary to run the EJBDeploy tool for EJB 2.1 modules containing entity beans.
4. Address potential interoperability issues.

   There can be unexpected results if a WebSphere stack product, or another product, that runs on a version of Application Server that does not support EJB 3.x attempts to remotely invoke a method on an EJB 3.x compliant enterprise bean on a separate server that is running a version Application Server that supports EJB 3.x. If these products attempt to invoke a method through the enterprise bean's EJB 3.x remote business interface, they might encounter exceptions that were introduced in EJB 3.x that will be pushed back to the environment that is not EJB 3.x compliant.

   This scenario could also be an issue for an administrator of an environment that includes a combination of stack products that contain a mixture of EJB 3.x compliant and non-compliant instances of Application Server.

   The following is a list of the exception classes that have been introduced in EJB 3.0:

   - javax.ejb.ConcurrentAccessException
   - javax.ejb.EJBAccessException
   - javax.ejb.EJBTransactionRequiredException
   - javax.ejb.EJBTransactionRolledbackException
   - javax.ejb.NoSuchEJBException

   a. Ensure that Application Server is updated to 7.0.0.3.
   b. Manually copy the <*app_server_root*>/runtimes/ejb3exceptions.jar file from Application Server to a directory on each of the stack products installations, or other product installations, that you will use as the EJB 3.x client.

c. Ensure that the directory that contains the ejb3exceptions.jar file is in the class path. One possible location for the JAR file that would satisfy this requirement is the <*app_server_root*>/lib directory on a server that is not EJB 3.x compliant.

   Note: Just like the EJB thin client jars, if an update becomes available, users must copy the ejb3exceptions.jar file again after installing the version of the WebSphere Application Server containing the updated version.

5. Deploy the application. See the topic Deploying and administering enterprise applications.

What to do next

If you specify that the EJBDeploy tool be run during application installation and the installation fails with a NameNotFoundException message, ensure that the input Java archive (JAR) or enterprise archive (EAR) file does not contain source files. Either remove the source files or include all dependent classes and resource files on the class path. If there are source files in the input JAR or EAR file, the EJB deployment tools runs a rebuild before generating the deployment code.

If the module deploys successfully, test and debug the module. See the topic Diagnosing problems (using diagnosis tools).

EJB 3.0 and EJB 3.1 deployment overview

Learn about the Enterprise JavaBeans (EJB) 3.0 and 3.1 deployment model, including *Just-In-Time* (JIT) deployment.

All Java Enterprise Edition (Java EE) application server products have some form of EJB deployment phase in which your application is customized to run in that particular implementation of the application server. Typically, this is accomplished by a deployment tool that is specific to the application server and generates code to bridge your EJB interface and implementation code to the application server's implementation for an EJB container. Some application server products' deployment tools alter the bytecodes of your application classes, rather than generating code, but the end result is similar.

Application Server bridges your EJB interface with its implementation by generating code that encapsulates your EJB implementation classes, connecting them to Application Server's EJB container. This enables the EJB container to host your enterprise beans and provide services to them. If one or more of your enterprise beans has remote interfaces defined, Application Server generates additional code to provide the remote function.

For more information about packaging your EJB module, see the topic that covers the EJB 3.x module packaging overview.

EJBDeploy Tool

Historically, EJB deployment in the Application Server product has been performed by the EJBDeploy tool, which is included with WebSphere Application Server and packaged with the development tools for the WebSphere products.

The EJBDeploy tool introspects the external interfaces for your enterprise beans, generates the wrapper code as .java files, and compiles the code using the javac compiler to produce .class files that are packaged in your EJB module with your application code. The EJBDeploy tool also runs the rmic tool against the remote EJB interfaces in the application, producing additional *stub* and *tie* class files that interact with the Remote Method Invocation over Internet Inter-ORB Protocol (RMI-IIOP) Object Request Broker (ORB), providing remote object support.

For modules previous to EJB 3.0, you ran the EJBDeploy tool when you installed the application on Application Server or before you installed the application from the command-line tool or a development tool.

Just-In-Time (JIT) deployment

EJB 3.0 support in Application Server introduced a new feature called JIT deployment.

With JIT deployment, the EJB container dynamically generates the wrapper, stub, and tie classes in-memory when the application is running. Additionally, the web container and application client containers dynamically generate the stub class that is required for remote EJB invocations.

Effectively, this means that you do not need to process EJB 3.0 or 3.1 modules, web modules that invoke EJB 3.0 or 3.1 beans, or client modules that invoke EJB 3.0 or 3.1 beans through the EJBDeploy tool before you run them in Application Server.

createEJBStubs tool

In most cases the Just-In-Time deployment feature can dynamically generate the RMI-IIOP stub classes that are required for invocation of remote EJB interfaces. There are some instances in which these stub classes are not dynamically generated. For EJB 3.0 or 3.1 clients that are not running inside an EJB 3.x enabled web container, EJB container, or client container, you must generate the stub classes with the createEJBStubs tool and ensure that the generated stubs are available in the client environment's class path. Typically, you would accomplish this by copying the generated stubs to the location where the client's business interface class resides.

The createEJBStubs tool must be used to generate client-side stubs for the following environments:

- "Bare" Java Standard Edition (SE) clients, where a Java SE Java Virtual Machine (JVM) is the client environment.
- Containers in Application Server environments prior to Version 7 that do not have the Feature Pack for EJB 3.0 applied.
- Environments that are not WebSphere Application Server environments.

Interoperability

There can be unexpected results if a WebSphere stack product, or another product, that runs on a version of Application Server that does not support EJB 3.0 or 3.1 attempts to remotely invoke a method on an EJB 3.x compliant enterprise bean on a separate server that is running a version Application Server that supports EJB 3.0 or 3.1. If these products attempt to invoke a method through the enterprise bean's EJB 3.x remote business interface, they might encounter exceptions that were introduced in EJB 3.0 that will be pushed back to the environment that is not EJB 3.x compliant.

This scenario could also be an issue for an administrator of an environment that includes a combination of stack products that contain a mixture of EJB 3.x compliant and non-compliant instances of Application Server.

The following is a list of the exception classes introduced in EJB 3.0:

- javax.ejb.ConcurrentAccessException
- javax.ejb.EJBAccessException
- javax.ejb.EJBTransactionRequiredException
- javax.ejb.EJBTransactionRolledbackException
- javax.ejb.NoSuchEJBException

Refer to the EJB module deployment step to address potential interoperability issues.

EJB 2.x Modules

EJB 2.x modules that have been converted to be EJB 3.0 or EJB 3.1 modules should have all WebSphere Application Server generated files (including stub and tie classes) removed prior to EJB deployment in the Application Server product.

EJBDEPLOY relationships – troubleshooting tips

Use this information to troubleshoot information for EJBDEPLOY problems.

The converter that is defined for the primary key is not invoked on its foreign key value

The mapping for primary key fields to database columns may use a converter to transform the key values. If a container-managed persistence (CMP) bean uses a converter to map its primary key, and that bean has a relationship where the bean at the other end holds a foreign key, the mapping for the foreign key will not use the converter.

The following errors might occur, indicating that the converter defined for the primary key is not invoked on its foreign key value. During the run of the ejbDeploy command , you receive the following message:

```
No type mapping defined for Java datatype1 to Database datatype2
```

During run time, the application does not find the CMP bean at the other end of the relationship.

To work around this limitation, define your own foreign key in the database table, and create a mapping that uses the same converter as defined for the primary key on the enterprise beans at the other end of its relationship.

Directory conventions

References in product information to *app_server_root*, *profile_root*, and other directories imply specific default directory locations. This topic describes the conventions in use for WebSphere Application Server.

Default product locations - IBM i

These file paths are default locations. You can install the product and other components in any directory where you have write access. You can create profiles in any valid directory where you have write access. Multiple installations of WebSphere Application Server products or components require multiple locations.

app_client_root
: The default installation root directory for the Application Client for IBM WebSphere Application Server is the `/QIBM/ProdData/WebSphere/AppClient/V8/client` directory.

app_client_user_data_root
: The default Application Client for IBM WebSphere Application Server user data root is the `/QIBM/UserData/WebSphere/AppClient/V8/client` directory.

app_client_profile_root
: The default Application Client for IBM WebSphere Application Server profile root is the `/QIBM/UserData/WebSphere/AppClient/V8/client/profiles/`*`profile_name`* directory.

app_server_root
: The default installation root directory for WebSphere Application Server - Express is the `/QIBM/ProdData/WebSphere/AppServer/V8/Express` directory.

java_home

Table 41. Root directories for supported Java Virtual Machines.

This table shows the root directories for all supported Java Virtual Machines (JVMs).

JVM	Directory
32–bit IBM Technology for Java	/QOpenSys/QIBM/ProdData/JavaVM/jdk60/32bit
64–bit IBM Technology for Java	/QOpenSys/QIBM/ProdData/JavaVM/jdk60/64bit

plugins_profile_root
The default Web Server Plug-ins profile root is the /QIBM/UserData/WebSphere/Plugins/V8/webserver/profiles/*profile_name* directory.

plugins_root
The default installation root directory for Web Server Plug-ins is the /QIBM/ProdData/WebSphere/Plugins/V8/webserver directory.

plugins_user_data_root
The default Web Server Plug-ins user data root is the /QIBM/UserData/WebSphere/Plugins/V8/webserver directory.

product_library
product_lib
This is the product library for the installed product. The product library for each Version 8.0 installation on the system contains the program and service program objects (similar to .exe, .dll, .so objects) for the installed product. The product library name is QWAS8*x* (where *x* is A, B, C, and so on). The product library for the first WebSphere Application Server Version 8.0 product installed on the system is QWAS8A. The *app_server_root*/properties/product.properties file contains the value for the product library of the installation, was.install.library, and is located under the *app_server_root* directory.

profile_root
The default directory for a profile named *profile_name* for WebSphere Application Server - Express is the /QIBM/UserData/WebSphere/AppServer/V8/Express/profiles/*profile_name* directory.

shared_product_library
The shared product library, which contains all of the objects shared by all installations on the system, is QWAS8. This library contains objects such as the product definition, the subsystem description, the job description, and the job queue.

user_data_root
The default user data directory for WebSphere Application Server - Express is the /QIBM/UserData/WebSphere/AppServer/V8/Express directory.

The profiles and profileRegistry subdirectories are created under this directory when you install the product.

web_server_root
The default web server path is /www/*web_server_name*.

Administering entity beans

Enterprise beans back up and recovery best practices

The following items should be considered for backup when using enterprise beans.

Database data

Enterprise beans often use a database for back-end persistence. Container-managed persistence (CMP) entity beans always use a database for back-end persistence. This data should be backed up the same as any of your business data.

The collection for container-managed entity beans persistence is determined by either the schema name specified during deployment, or the schema specified on the data source associated with the enterprise bean. Any persistent store used by session and bean-managed beans is defined by the bean implementation. For database tables, you can choose to save the entire collection or an individual table as shown with the following commands, respectively:

```
SAVLIB LIB(EJB) DEV(*SAVF) SAVF(WSALIB/WSASAVF)
SAVOBJ OBJ(MYBEANTBL) LIB(EJB) DEV(*SAVF) OBJTYPE(*FILE) SAVF(WSALIB/WSASAVF)
```

It might be possible to save database objects while the product is active, if the save operation can obtain a snapshot of the data store. You may have to shut down if a snapshot cannot be obtained. This occurs if there are requests that obtain locks or have open transactions against the database being saved.

Enterprise JavaBeans (EJB) source code, class files, and deployed code

When you deploy enterprise beans, a WebSphere Application Server-specific implementation of the enterprise beans is generated. Save these deployed Java(TM) Archive (JAR) files to avoid redeploying, and to preserve any binding information that was specified during the application installation. The JAR files, application code and configuration, such as bindings, are located by default in the *profile_root*/installedApps directory. By saving this directory, you save your installed applications, including HTML, servlets, JavaServer Pages(TM) (JSP(TM)) files, and enterprise beans. Normally, each application is located in a separate subdirectory, so you can choose to save all applications or a subset.

Note: The commands below have been wrapped for display purposes. Enter each as a single command.

This command saves all installed applications:

```
SAV DEV('/QSYS.lib/wsalib.lib/wsasavf.file')
 OBJ(('/profile_root/installedApps'))
```

This command saves the sampleApp application only:

```
SAV DEV('/QSYS.lib/wsalib.lib/wsasavf.file')
 OBJ(('/profile_root/installedApps/cellName/sampleApp.ear'))
```

If you have located utility or general purpose classes in other directories, such as /*profile_root*/lib/app or /*profile_root*/lib/ext, be sure to include those locations in your backup plan as well.

Administrative configuration

For more information, see the topic Introduction: Administrative configuration data.

Managing EJB containers

Each application server can have a single Enterprise JavaBeans (EJB) container; one is created automatically for you when the application server is created. The following steps are to be performed only as needed to improve performance after the EJB application has been deployed.

Procedure

1. Adjust EJB container settings.
2. Adjust EJB cache settings.

What to do next

If adjustments do not improve performance, consider adjusting access intent policies for entity beans, reassembling the module, and redeploying the module in the application.

EJB containers

An Enterprise JavaBeans (EJB) container provides a run-time environment for enterprise beans within the application server. The container handles all aspects of an enterprise bean's operation within the application server and acts as an intermediary between the user-written business logic within the bean and the rest of the application server environment.

One or more EJB modules, each containing one or more enterprise beans, can be installed in a single container.

The EJB container provides many services to the enterprise bean, including the following:

- Beginning, committing, and rolling back transactions as necessary.
- Maintaining pools of enterprise bean instances ready for incoming requests and moving these instances between the inactive pools and an active state, ensuring that threading conditions within the bean are satisfied.
- Most importantly, automatically synchronizing data in an entity bean's instance variables with corresponding data items stored in persistent storage.

By dynamically maintaining a set of active bean instances and synchronizing bean state with persistent storage when beans are moved into and out of active state, the container makes it possible for an application to manage many more bean instances than could otherwise simultaneously be held in the application server's memory. In this respect, an EJB container provides services similar to virtual memory within an operating system.

WebSphere Application Server provides significant flexibility in the management of database data with entity beans. The Entity EJBs Activate at and Load at configuration settings specify how and when to load and cache data from the corresponding database row data of an enterprise bean. These configuration settings provide the capability to specify enterprise bean caching Options A, B or C, as specified in the EJB 1.1 specifications. You can configure these settings with assembly tools. To read more about how to use the assembly tools see the assembly tool information center.

Option A provides maximum enterprise bean performance by caching database data outside of the transaction scope. Generally, Option A is only applicable where the EJB container has exclusive access to the given database. Otherwise, data integrity is compromised. Option B provides more aggressive caching of Entity EJB object instances, which can result in improved performance over Option C, but also results in greater memory usage. Option C is the most common real-world configuration for Entity EJBs and is the default setting.

The `Activate at` setting specifies the point at which an enterprise bean is activated and placed in the cache. Removal from the cache and passivation are also governed by this setting. Valid values are `Once` and `Transaction`. The `Once` setting indicates that the bean is activated when it is first accessed in the server process, and passivated (and removed from the cache) at the discretion of the container, for example when the cache becomes full. The `Transaction` setting indicates that the bean is activated at the start of a transaction and passivated (and removed from the cache) at the end of the transaction. The default value is `Transaction`.

The `Load at` setting specifies when the bean loads its state from the database. The value of this property implies whether the container has exclusive or shared access to the database. Valid values are `Activation` and `Transaction`. Activation indicates the bean is loaded when it is activated and implies that the container has exclusive access to the database. Transaction indicates that the bean is loaded at the start of a transaction and implies that the container has shared access to the database. The default is `Transaction`. The settings of the `Activate at` and `Load at` properties govern which commit options are used. For Option A (exclusive database access), use `Activate at = Once` and `Load at = Activation`. This option reduces database input/output by avoiding calls to the ejbLoad function, but serializes all

transactions accessing the bean instance. Option A can increase memory usage by maintaining more objects in the cache, but can provide better response time if bean instances are not generally accessed concurrently by multiple transactions.

Important: When using WebSphere WebSphere Application Server, Network Deployment and workload management is enabled, Option A cannot be used.

You must use settings that result in the use of Options B or C. For Option B (shared database access), use `Activate at = Once` and `Load at = Transaction`. Option B can increase memory usage by maintaining more objects in the cache. However, because each transaction creates its own copy of an object, there can be multiple copies of an instance in memory at any given time (one per transaction), requiring the database be accessed at each transaction. If an enterprise bean contains a significant number of calls to the ejbActivate function, using Option B can be beneficial because the required object is already in the cache. Otherwise, this option does not provide significant benefit over Option A. For Option C (shared database access), use `Activate at = Transaction` and `Load at = Transaction`. This option can reduce memory usage by maintaining fewer objects in the cache. However, there can be multiple copies of an instance in memory at any given time (one per transaction). This option can reduce transaction contention for enterprise bean instances that are accessed concurrently but not updated.

This product supports the cloning of stateful session bean home objects among multiple application servers. However, it does not support the cloning of a specific instance of a stateful session bean. Each instance of a particular stateful session bean can exist in just one application server and can be accessed only by directing requests to that particular application server. State information for a stateful session bean cannot be maintained across multiple members of a server cluster. However, enabling stateful session bean failover and configuring the EJB container to use memory-to-memory replication does enable stateful session bean failover to be replicated to other servers in the cluster so that failover can occur to the backup server if the primary server for a stateful session bean stops for some reason. For more information about stateful session bean failover, see Stateful session bean failover for the EJB container.

By default, an EJB container runs in the **quick start** mode. The EJB container startup logic delays the loading and processing of all EJB types *except* Message Driven Beans, because message driven beans must exist before messages are posted for them; Startup Beans, which must be processed when the server starts; and EJB types that you specify to initialize when the server starts. .

All other EJB initialization is delayed until the first use of the EJB type. When using local interfaces, the first use is when you perform an InitialContext.lookup method for the type. For remote interfaces, it is when you call the first method on an EJB or its Home.

EJB container settings

Use this page to configure and manage the EJB container of this application server.

To view this administrative console page, click **Servers** > **WebSphere application servers** > **server** > **EJB Container Settings** > **EJB container**.

Passivation directory

Specifies the directory into which the container saves the persistent state of passivated stateful session beans. This directory must already exist. It is not automatically created.

Stateful session beans with an activation policy of TRANSACTION are passivated at the end of the transaction in which they are enlisted, and stateful session beans with an activation policy of ONCE (default) are passivated when the number of active bean instances becomes greater than the cache size specified in the container configuration. When a stateful bean is passivated, the container serializes the bean instance to a file in the passivation directory and discards the instance from the bean cache. If, at a later time, a request arrives for the passivated bean instance, the container retrieves it from the

passivation directory, deserializes it, returns it to the cache, and dispatches the request to it. If any step fails (for example, if the bean instance is no longer in the passivation directory), the method invocation fails.

Inactive pool cleanup interval

Specifies the interval at which the container examines the pools of available bean instances to determine if some instances can be deleted to reduce memory usage. This setting is for all bean pools. **Attention:** Stateful session beans are NOT pooled, so this applies to stateless session and entity bean pools.

Data type	Integer
Default	30000
Units	Milliseconds
Range	0 to 2 147 483 647

Default data source JNDI name

Specifies the JNDI name of a data source to use if no data source is specified during application deployment. This setting is not applicable for EJB 2.x-compliant CMP beans.

Servlets and enterprise beans use *data sources* to obtain these connections. When configuring a container, you can specify a default data source for the container. This data source becomes the default data source used by any entity beans installed in the container that use container-managed persistence (CMP).

The default data source for a container is secure. When specifying it, you must provide a user ID and password for accessing the data source.

Specifying a default data source is optional if each CMP entity bean in the container has a data source specified in its configuration. If a default data source is not specified and a CMP entity bean is installed in the container without specifying a data source for that bean, applications cannot use that CMP entity bean.

Enable stateful session bean failover using memory-to-memory replication

Specifies that failover is enabled for *all* stateful session beans installed in this EJB container.

This checkbox is disabled until you define a replication domain. This selection has a hyperlink to help you configure the replication settings. If no replication domains are configured, the link takes you to a panel where you can create one. If at least one domain is configured, the link takes you to a panel where you can select the replication settings to be used by the EJB container.

Data type	Checkbox
Default	Unselected
Range	Selected or unselected.

Initial state

Specifies the execution state requested when the server first starts.

Data type	String
Default	Started
Range	Valid values are `Started` and `Stopped`

EJB container system properties

In addition to the settings that are accessible from the administrative console, you can set EJB system properties using command-line scripting.

You can use the properties page to define the following EJB container system properties:

- “com.ibm.websphere.ejbcontainer.allowEarlyInsert”
- “com.ibm.websphere.ejbcontainer.checkEJBApplicationConfiguration”
- “com.ibm.websphere.ejbcontainer.declaredUncheckedAreSystemExceptions” on page 395
- “com.ibm.websphere.ejbcontainer.defaultStatefulSessionTimeout” on page 395
- “ com.ibm.websphere.ejbcontainer.EE5Compatibility ” on page 395
- “com.ibm.websphere.ejbcontainer.limitSetRollbackOnlyBehaviorToInstanceFor” on page 396
- “com.ibm.websphere.ejbcontainer.poolSize” on page 396

com.ibm.websphere.ejbcontainer.allowEarlyInsert

This property is applicable to container managed persistence (CMP) 1.1 beans only. By default, the EJB container creates the entity bean representation in the database only after the method, ejbPostCreate(...), is called.

Note: CMP beans are not supported in EJB 3.x modules.

Some applications might rely on method, ejbCreate(...), to have created the entity bean in the database. For such a requirement, setting the JVM property, com.ibm.websphere.ejbcontainer.allowEarlyInsert, to `true` overrides the default behavior.

com.ibm.websphere.ejbcontainer.checkEJBApplicationConfiguration

Specifies a server-wide setting that indicates the container should complete additional application configuration validation to ensure the application is consistent with the Java Platform, Enterprise Edition (Java EE) specification.

Note: You can also specify this property as an application custom property.

This property is intended for use during development of an application to assist in identifying improper configurations, which might result in unexpected behavior. For example, applying the javax.ejb.Asynchronous annotation to an interface is not supported by the specification and is typically ignored. When this property is enabled, an error is logged, and an exception occurs when the bean is processed. This failure is useful during development to understand why the methods are not working asynchronously.

Additional configuration validation is completed and might result in multiple configuration warnings and errors being logged when this property is enabled. Typically, this additional validation is for scenarios that incur extra overhead to run, which is unnecessary for stable applications on a production server. For minor deviations from the specification, only warnings are logged. For more significant issues, an error is logged, and the application cannot run until the error is corrected.

Note: When the com.ibm.websphere.ejbcontainer.checkEJBApplicationConfiguration property is enabled, some of the issues that were reported as warnings are displayed as errors, which prevents the application from starting.

Note: The embeddable container and servers configured for development mode perform the additional validation that is associated with this property; however, all identified issues are reported as warnings, rather than errors, unless this property is specifically enabled.

com.ibm.websphere.ejbcontainer.declaredUncheckedAreSystemExceptions

This property enables you to indicate whether exceptions that are declared on the throws clause of an EJB method should are treated as application exceptions or as system runtime exceptions. When this property is set to `true`, these exceptions are treated like system runtime exceptions, and causes an EJBException to be issued on the client side.

If this property is not specified, or if this property is set to `false`, exceptions that are declared on the throws clause of an EJB method are treated as application exceptions.

The default value for this property is false.

transition: In Version 7, the default value for this property is true.

com.ibm.websphere.ejbcontainer.defaultStatefulSessionTimeout

Specifies a server-wide timeout for stateful session beans, which indicates how long a stateful session bean is retained by the server.

Note: The property applies only to EJB 3.1 modules and later.

This is a system property that you can add directly to the server.xml file or as a generic JVM argument using the administrative console.

The property is specified in minutes, the only valid unit. The default value is 10 minutes. A value of zero specifies that the server uses the default value of 10 minutes. A negative value is not valid. Any zero or greater value is valid. If a non-valid value is specified, a warning is issued to SystemOut, and the default value is used.

The stateful session bean timeout duration can be specified on a *per-bean* basis using annotations or xml. If a timeout duration is explicitly specified for a particular bean, this takes precedence over any server-wide timeout setting.

If no bean-specific timeout duration exists for a particular bean, then the server-wide timeout setting is applied to that bean.

If no bean-specific timeout duration exists for a particular bean, and no server-wide timeout setting exists, then the default timeout setting is applied to that bean.

com.ibm.websphere.ejbcontainer.EE5Compatibility

Specifies a server-wide setting that indicates the EJB container provides default behaviors that are consistent with the Java Enterprise Edition (Java EE) 5.0 specification.

This is a system property that you can add directly to the server.xml file or as a generic JVM argument using the administrative console.

The Java EE specification includes improvements to the EJB programming model that have resulted in minor changes to some default behaviors. In general, these changes provide more intuitive or more reliable behavior. However, if an application has been written to rely on one or more of the Java EE 5.0 behaviors, this system property might be set to revert the EJB container back to the Java EE 5.0 default behaviors.

Setting the property to true overrides the following behaviors:

- @ApplicationException annotations are not inherited. Starting with the Java EE 6.0 specification, the default behavior for the @ApplicationException annotation was changed, indicating that the annotation

is inherited by subclass exception classes. When this system property is specified, the @ApplicationException annotation is not inherited by subclass exception classes. Alternatively, you can change the @ApplicationException declaration to specify 'inherited=false'.

- Concurrent access to stateful session beans is prohibited, and results in the exception, javax.ejb.ConcurrentAccessException. Starting with the Java EE 6.0 specification, the default behavior for stateful session concurrency was changed to allow concurrent access, though each concurrent request is serialized by the container, blocking access to the bean instance indefinitely until the instance lock may be obtained. When this system property is specified, all stateful session beans that do not have an explicit access-timeout value specified assume the default access-timeout value of 0 (the Java EE 5.0 default). Alternatively, you can modify the stateful session bean to define an access-timeout value of 0.
- The Java type, Class, and any subclass of Enum are treated as resource environment references instead of simple environment entries. Starting with the Java EE 6.0 specification, the Java type, Class, and any subclass of Enum were added to the set of supported simple environment entry types. In prior versions of Java EE, these types would have been treated as resource environment references and a binding would have been required in the `ibm-ejb-jar-bnd.xml` file or `ibm-web-bnd.xml` file. Now that these data types are supported as simple environment entries, a platform-specific binding is no longer required. Instead, you can specify the value directly in the deployment descriptor. When this system property is specified, applications that use the javax.annotation.Resource annotation for the Java type, Class, or any subclass of Enum is treated as resource environment references, and the referenced value will be obtained using the binding file information. Installing the application is not effected by this property, and therefore, binding information is not entered during installation. Instead, you must manually enter the binding information in the binding file.

com.ibm.websphere.ejbcontainer.extendSetRollbackOnlyBehaviorToInstanceFor

This property allows the user to specify application names in which they want to have the EJBs in their EJB 3.x modules demonstrate the pre-EJB 3.0 setRollbackOnly behavior.

The pre-EJB 3.0 setRollbackOnly behavior is described in “Changing applications to WebSphere "version specific" setRollbackOnly behavior” on page 398.

com.ibm.websphere.ejbcontainer.limitSetRollbackOnlyBehaviorToInstanceFor

This property allows the user to specify application names in which they want to have the EJBs in their EJB 3.x modules demonstrate the EJB 3.x setRollbackOnly behavior.

The EJB 3.x setRollbackOnly behavior is described in “Changing applications to WebSphere "version specific" setRollbackOnly behavior” on page 398.

com.ibm.websphere.ejbcontainer.poolSize

Specifies the size of the pool for the specified bean type. This property applies to stateless, message-driven, and entity beans. If you do not specify a default value, the container default value, 50 and 500, are used.

Set the pool size for a given entity bean as:

beantype=[*H*]*min*,[*H*]*max* [:*beantype*=[*H*]*min*,[*H*]*max*...]

The *beantype* element is the Java EE name of the bean, formed by concatenating the application name, the **#** character, the module name, the **#** character, and the name of the bean, that is, the string assigned to the `<ejb-name>` field in the deployment descriptor of the bean. The *min* and *max* elements are the minimum and maximum pool sizes for that bean type. Do not specify the square brackets shown in the previous prototype; they denote optional additional bean types that you can specify after the first bean type. Each bean type specification is delimited by a colon (:).

Use an asterisk (*) as the value of *beantype* to indicate that all bean types are to use those values unless overridden by an exact bean-type specification somewhere else in the string; for example:

```
*=30,100
```

To specify a default value, omit either the *min* or *max* value but retain the comma (,) between the two values; for example:

Note: The following example displayed on multiple lines for publication purposes.

```
SMApp#PerfModule#TunerBean=54,
   :SMApp#SMModule#TypeBean=100,200
```

You can specify the bean types in any order within the string.

You can designate the maximum configured EJB pool size as a *hard limit* by inserting the character, *H,* directly in front of the *max* value. Without the *H character*, the maximum value indicates how many EJB instances can be pooled and does not limit the number of EJB instances that can be created or in use. Inserting the *H* character before the max value indicates a hard limit, and the EJB container blocks creation of more instances when that limit is reached. Further threads must wait until an instance becomes available or until the transaction times out.

You can designate the minimum configured EJB pool size as a *hard limit* by inserting the character, *H,* directly in front of the *min* value. Without the *H* character, the minimum value indicates how many EJB instances are maintained in the pool when the EJB type is not actively in use, but does not preload the pool when the application is started. Typically, the minimum pool size is not reached until the minimum number of EJB instances has been accessed concurrently by the application. Inserting the *H* character before the min value indicates a hard limit, and the EJB container preloads the pool with the minimum number of EJB instances when the application is started.

For example, if you want to indicate that no more than 200 EJB instances are created, and that additional requests must wait for an instance and might time out while waiting, then enter:

```
SMApp#SMModule#TypeBean=100,H200
```

If you want to indicate that the EJB container preloads the pool with a minimum of 100 EJB instances when the application is started, then enter:

```
SMApp#SMModule#TypeBean=H100,200
```

Note: The hard limit indicator is only available to EJB Version 2.0 or later stateless session beans.

Changing enterprise bean types to initialize at application start time using the administrative console

All Enterprise JavaBeans (EJB) types within a server can be forced to initialize at application start time by setting a system property within the administrative console.

About this task

If the value of this property is set to **true**, then all beans within the server are initialized at each application's start time.

However, by default, the product's EJB container delays the initialization (loading of classes and processing of deployment descriptor metadata) of most EJB types until they are needed during run time. This delay helps to speed up the application start time.

Procedure

1. Open the administrative console.
2. Select **Servers**.
3. Select **Application Servers**.
4. Select the server you want to configure.
5. In the Server Infrastructure area, select **Java and Process Management**.
6. In the Server Infrastructure area, select **Process Definition**.
7. In the Additional Properties area, select **Java Virtual Machine**.
8. In the Additional Properties area, select **Custom Properties**.
9. Select the **New** box.
10. In the **Name** entry field, type *com.ibm.websphere.ejbcontainer.initializeEJBsAtStartup*.
11. In the **Value** entry field, type *true*. Entering *true* causes all Enterprise JavaBeans to initialize when your application starts. Entering *false* causes initialization of all beans to be delayed.

    Note: Setting com.ibm.websphere.ejbcontainer.initializeEJBsAtStartup to either true or false takes precedence over any *Start EJB at Application Start* settings made on individual EJB types.
12. Select **OK**.

What to do next

This task can also be done by using an assembly tool.

Changing applications to WebSphere "version specific" setRollbackOnly behavior

Use this task to allow post-EJB 3.0 applications to exhibit the pre-EJB 3.0 behavior and to allow pre-EJB 3.0 applications to exhibit post-EJB 3.0 behavior. The steps in this task that provide this processing behavior are based on a very specific processing scenario, which is explained below.

About this task

Processing Scenario: The basis for this task is the following processing scenario.

An EJB method is invoked which starts a global transaction. Within the execution of this method another EJB method is invoked that continues to run within the same transaction. During the execution of this method, the setRollbackOnly() method is invoked. The EJB Container behavior when this scenario is encountered is dictated by the EJB Specification. However, this behavior was required to change in the WebSphere Application Server for EJB 3.0 support.

Section 13.6.2.8 of JSR 220: Enterprise JavaBeans™,Version 3.0 EJB Core Contracts and Requirements document, as well as previous versions of the EJB specification, indicates that

"If the container initiated the transaction immediately before dispatching the business method to the instance (as opposed to the transaction being inherited from the caller), the container must note that the instance has invoked the setRollbackOnly method. When the business method invocation completes, the container must roll back rather than commit the transaction. If the business method has returned normally or with an application exception, the container must pass the method result or the application exception to the client after the container performed the rollback." also section 14.3.11 states: "However, the container should not throw the javax.ejb.EJBException or java.rmi.RemoteException or if the container performs a transaction rollback because the instance has invoked the setRollbackOnly method on its EJBContext object. In this case, the container must rollback the transaction and pass the business method result or the application exception thrown by the business method to the client."

Historically, the WebSphere Application Server has interpreted the above sections of the specification to dictate that the setRollbackOnly behavior should only applied if the transaction was marked as RollbackOnly within the method that began the transaction. However, the Compatibility Test Suite for the EJB 3.0 specification requires that a transaction marked as RollbackOnly exhibit the above setRollbackOnly behavior, regardless of whether the transaction was marked as RollbackOnly within the method that began the transaction, or within another method within the same transaction that was invoked from the original EJB method.

To illustrate this requirement, consider the following example:

- An application invokes a method, `art`, on EJB A with Container Managed Transaction support, TX_REQUIRED.
- The container begins a transaction and invokes the method.
- Method `A.art()` invokes a method, `bob`, on EJB B with Container Managed Transaction support, TX_REQUIRED.
- Within `B.bob()` the setRollbackOnly method is invoked on the transaction and then completes.

Behavior prior to EJB 3.0: Since the transaction is not initiated with the `B.bob()` method, a TranactionRolledbackException is thrown to `A.art()` and eventually to the client application.

Behavior introduced in EJB 3.0 and beyond: Method `B.bob()` returns normally to method `A.art()`. Method `A.art()` performs a rollback on the transaction and return the results to the client with no exception thrown to the client application, as indicated by the EJB specification.

Since this processing introduces a change in behavior for applications that are migrated to EJB 3.0 or beyond from a previous version, the following JVM system properties are available to change this behavior to suit your requirements:

- `com.ibm.websphere.ejbcontainer.limitSetRollbackOnlyBehaviorToInstanceFor` : This property allows the user to specify application names in which they want to have the EJBs in their EJB 3.0 modules demonstrate the pre-EJB 3.0 setRollbackOnly behavior described above.
- `com.ibm.websphere.ejbcontainer.extendSetRollbackOnlyBehaviorBeyondInstanceFor` : This property allows the user to specify application names in which they want to have the EJBs in their pre-EJB 3.0 modules demonstrate the EJB 3.0 setRollbackOnly behavior described above.

The values of these properties are set to the application names (*appName1:appName2:appName3*) that need to demonstrate the desired behavior.

Procedure

1. Open the administrative console.
2. Select **Servers**.
3. Select **Server Types**.
4. Select **WebSphere application servers**.
5. Select the server that you want to configure.
6. Under Server infrastructure, select **Java and Process Management > Process Definition**.
7. Under Additional properties, select **Java virtual machine > Custom properties > New**.
8. In the **Name** entry field, type the JVM system property.
   com.ibm.websphere.ejbcontainer.limitSetRollbackOnlyBehviorToInstanceFor or
   com.ibm.websphere.ejbcontainer.extendSetRollbackOnlyBehaviorBeyondInstanceFor
9. In the **Value** entry field, type **(appName1:appName2:appName3....).** . Names of the application(s) that the behavior should apply.
10. Select **OK**.
11. Save the configuration.

12. Restart the server.

EJB cache settings

Use this page to configure and manage the cache for a specific Enterprise JavaBeans (EJB) container. To avoid errors from attempting to overload the cache, determine the cache absolute limit. Multiply the number of enterprise beans active in any given transaction by the total number of concurrent transactions expected. Then, add the number of active session bean instances. This value is the limit that the cache will hold. You can use the Tivoli Performance Viewer to view bean performance information.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > **server** > **EJB Container Settings** > **EJB cache settings**.

Cleanup interval

Specifies the interval at which the container attempts to remove unused items from the cache in order to reduce the total number of items to the value of the cache size. This setting applies to the cache only.

The cache manager tries to maintain some unallocated entries that can be allocated quickly as needed. A background thread attempts to free some entries while maintaining some unallocated entries. If the thread runs while the application server is idle, when the application server needs to allocate new cache entries, it does not pay the performance cost of removing entries from the cache. In general, increase this parameter as the cache size increases.Timeouts are specified according to the transaction type:

- Container-managed transactions: The bean provider configures the timeout attribute in the deployment desecriptor.
- Bean-managed transaction: An application calls the UserTransaction.setTransactionTimeout method in the codes.

Data type	Integer
Units	Milliseconds
Range	0 to 2 147 483 647
Default	3000

Cache size

Specifies the number of buckets in the active instance list within the EJB container.

A bucket can contain more than one active enterprise bean instance, but performance is maximized if each bucket in the table has a minimum number of instances assigned to it. When the number of active instances within the container exceeds the number of buckets, that is, the cache size, the container periodically attempts to reduce the number of active instances in the table by passivating some of the active instances. For the best balance of performance and memory, set this value to the maximum number of active instances expected during a typical workload.

Data type	Integer
Units	Buckets in the hash table
Range	Greater than 0. The container selects the next largest prime number equal to or greater than the specified value.
Default	2053

Container interoperability

Container interoperability describes the ability of the product clients and servers at different versions to successfully negotiate differences in native Enterprise JavaBeans (EJB) finder methods support and Java EE compliance.

Interoperability of the handle formats in WebSphere Application Server, Version 5 and Version 5.0.1

Applications that attempt to persist handles to enterprise beans and **EJBHome** needed to subclass ObjectInputStream in WebSphere Application Server, Version 5. This action was required so that the subclass ObjectInputStream could utilize the context class loader to resolve the classes for enterprise beans and EJBHome stubs.

In addition, handles created and persisted in WebSphere Application Server, Version 5 only work with objects that have an unchanged remote interface. If the remote interface is changed, the handle is no longer valid because the stub is serialized inside the handle and its serial Version UID changes if the remote interface changes.

This release introduces a new handle persistence mechanism that avoids the implementation drawbacks of the previous version. However, if handles are used for this WebSphere Application Server deployment, you should consider the following issues when applying this update, future WebSphere Application Server Fix Packs and EJB Container cumulative fixes for WebSphere Application Server, Version 5.

If a WebSphere Application Server, Version 5 persisted handle or home handle is encountered by a WebSphere Application Server, Version 5.0.1 system, it can be read and utilized. In addition, it will be converted to WebSphere Application Server, Version 5.0.1 format if it is re-persisted. The WebSphere Application Server, Version 5.0.1 format cannot be read by a WebSphere Application Server, Version 5 system unless PQ72184 is applied.

Problems arise when handles are persisted and shared across systems that are not at the WebSphere Application Server, Version 5.0.1 level or later. However, a Version 5 system can receive a handle from Version 5.0.1 remotely through a call to get a handle on an enterprise bean or a getHomeHandle on an **EJBHome**. The remote call will succeed, however, any attempt to persist it on the Version 5 system will have the same limitations regarding the use of ObjectInputStream and changes in remote interface invalidating the persisted handle.

When your application stores handles persistently and shares this persistence with multiple clients or application servers, apply WebSphere Application Server, Version 5.0.1 or PQ72184 to both the client and server systems at the same time. Failure to do so can result in the inability of these systems to read the handle data stored by upgraded systems. Also, handles stored by the WebSphere Application Server, Version 5 can force the applications of the updated system to still subclass `ObjectInputStream`. Applications using the WebSphere Application Server Enterprise, Version 5 scheduler and process choreographer, are affected by these changes. These users should update their Version 5 systems at the same time with either Version 5.0.1 or PQ72184.

If the applications store handles in the session context, or locally in a file on the same system, that is not shared by other applications, on different systems, they might be able to update their systems individually, rather than all at once. If Client Container and thin client applications do not share persisted handle data, they can be updated as needed as well. However, handles created and persisted in WebSphere Application Server, Version 5, Version 4.0.3 and later (with the property flag set), or Version 3.5.7 and later (with the property flag set) are not usable if either the home or the remote interface changes.

If any WebSphere Application Server, Version 3.5.7 or Version 4.0.3 and later enables the system property com.ibm.websphere.container.portable to **true**, any handles to objects on that server have the same interoperability limitations. In addition, if any WebSphere Application Server, Version 3.5.7 and later or Version 4.0.3 applications store a handle obtained from a WebSphere Application Server, Version 5 or Version 5.0.1, the same restrictions apply, regarding the need to subclass ObjectInputStream and the usability of handles after a change to the remote interface is made.

Replication of the Http Session and Handles

This note applies to you if you place Handles to Homes or Enterprise JavaBeans, or EJB or EJBHome references in the Http Session in your application and you use Http Session Replication. If you intend to replicate a mixed environment of Version 5.0.0 and Version 5.0.1 or 5.0.2 machines you should first apply the latest Version 5.0.0 container cumulative e-fix to the Version 5.0.0 machines before allowing the Version 5.0.1 or 5.0.2 server into the typology. The reason for this is that Version 5.0.0 servers are not able to understand the persisted Handle format used on the Version 5.0.1 and 5.0.2 server. This is similar to the case of Version 5.0.0 and Version 5.0.1 or 5.0.2 systems trying to use a shared database, mentioned above. But in this case, it is the Http Session object and not the database providing the persistence.

Top Down Deployment Mapping

The size of the Handle objects has grown due to the fix put in to allow serialization and deserialization to occur without the previous requirements of subclassing the ObjectInputStream and so on. Top down deployment of an object that contains EJB and EJBHome references create a database table ddl that has a field of 1000 bytes of VARCHAR for BITDATA which will contain the Handle. It might be that your object's Handle does not fit in the 1000 byte default field, and you might need to adjust this to a higher value. You might try increments of 250 bytes, that is, 1250, 1500, and so on.

Configuring a timer service

You can configure and manage the EJB timer service for a specific EJB container.

About this task

WebSphere Application Server implements the Enterprise JavaBeans (EJB) Timer Service. Based on your business needs, you can use persistent timers or non-persistent timers. Persistent timers are helpful if you are creating a timer for a time-based event that requires assurance of timer existence beyond the life cycle of the server to persist through server shutdowns and restarts. Previously started persistent timers automatically start when your server starts, and they require a database instance.

Non-persistent timers do not use a data store and are canceled when the application server is stopped or fails to remain in an active state. Non-persistent timers exist only on the server where the timer is created.

Both persistent and non-persistent timers require a work manager. Persistent timers use the work manager that is used by the scheduler service. Non-persistent timers use the server default work manager by default, but can be configured to use another work manager using EJB timer scripting. Non-persistent timers do not use the scheduler service.

You can configure and manage the EJB timer service for persistent and non-persistent timers in the administrative console. The configuration for persistent and non-persistent timers is not mutually exclusive. Your application might contain both persistent and non-persistent timers.

Procedure

1. Click **Servers** > **Application servers** > **server_name** > **EJB Container settings** > **EJB timer service settings**.
2. Configure the persistent EJB timer support.
3. If you want to use the internal, or pre-configured, scheduler instance, select **Use internal EJB timer service scheduler instance**. If you choose not to change the default settings, this instance for the scheduler is associated with an Apache Derby database. If you choose to customize the pre-configured instance, complete the following actions:
   a. To change the data source, enter your **Data source JNDI name**. You can use any supported database, such as DB2 or Oracle.
   b. Enter your chosen **Data source alias**.

c. Enter your chosen **Table prefix** if you want to have several server processes use the same database, but different tables.
d. Enter a **Poll interval** value in milliseconds.
e. If you want more timers to run concurrently, enter a new value for **Number of timer threads**.

For more details, see information about timer service settings.

4. If you want to configure your own scheduler instance instead of using the pre-configured internal one, select **Use custom scheduler instance**. You might want to use your own instance to:
   - Change scheduler service configuration options not available for customization on this panel
   - Keep EJB timer tasks in the same database tables as your other tasks
   - Have a single scheduler instance handle all the EJB timers in a cluster. This way, an *ejbTimer* task created on one cluster member can run on a different cluster member.

   To use your own instance, you must:
   a. Configure a scheduler instance through the scheduler service graphical user interface. See the using schedulers documentation for information about how to do this.
   b. Select your **Scheduler JNDI name** from the list.
5. Configure the non-persistent timer support. Support for non-persistent timers is configured in addition to (not instead of) support for persistent timers.
   a. Enter your chosen **Maximum number of retries**.
   b. Enter your chosen **Time interval between retries**.
   c. Select the **Share thread pool configured for persistent timers** or the **Create a separate thread pool for non-persistent timers** option. If you choose the **Create a separate thread pool for non-persistent timers** option, enter your chosen **Number of timer threads**.
6. Optional: Configure data caching for your EJB timers. Caching allows the application server to reuse timer data without having to query the database each time that data is required. See the topic on caching data for a timer service for information on configuring this feature.
7. Click **Apply**.
8. Click **OK**.

Caching data for a timer service

If you want to optimize database access and SQL calls for an EJB timer service, you can enable the application server to cache data for that timer. Caching allows the application server to reuse timer data without having to query the database each time that data is required.

About this task

By allowing the application server to cache data for an Enterprise JavaBeans (EJB) timer service, you can minimize the number of SQL statements that would be generated for calls to methods on the timer interface. When this feature is enabled, data for the timer will be cached in the timer object when you create that timer object.

The specification for enterprise beans requires that an SQL call to the database be made for each call to the javax.ejb.Timer interface, so that the application can ensure that the EJB timer is using the most current data that is available. If these methods are called often, or you have many EJB timers that call any one of these methods, the application server would be generating many SQL statements in a very short amount of time. In some cases, you might find that strict adherence to this requirement is detrimental to performance and causing more overhead than is warranted.

For example, consider a case in which a timer expires only at 12:00 AM every Monday morning. During the course of the week, any applications that call methods on the timer interface will result in the creation of an SQL call, but the call will always return the same data. In addition, when an application calls the ejbTimeout method for a timer, the data that is associated with that timer cannot change; the timer's data

that is stored in the database cannot be updated while an ejbTimeout method is running for that timer. Therefore, any subsequent method calls that applications make during the timeout period will cause the generation of an unnecessary SQL call and a wasted trip to the database.

If you enable caching for timer data, however, the application server will only query the database the first time a configured method is called. For any subsequent calls to one of the configured methods, the application server will use the cached data for the life of the timer object, and a new SQL call will not need to be generated.

Note: Be aware of the following conditions:

- When this feature is enabled, your configuration will not be compliant with the EJB specification.
- This feature can lead to the potential for a timer to use stale data. Cached data for a timer service will become stale after the next expiration period for the timer has passed.

  For example, assume you have a timer that is configured to expire every hour. If you create and save the timer object, the data that the application server caches for that object will only be current for one hour. The cached data would be the same as the data that is stored in the database.

  If you call any of the timer methods within the first hour, the timer data is current. After that expiration period, however, the cached data for the timer becomes stale and might not reflect the data that is actually in the database. In this example, if you queried the EJB container for all timers after one and one half hours, the application would get back a new timer object that contains cached data that will be current for thirty minutes; This is because at hour two the timer will expire again, and any cached data stale will then be stale.

Procedure

1. In the application server's administrative console, select the server that you want to configure. Click **Servers** > **Application Servers** > ***server***.
2. In the Server Infrastructure area, select **Java and Process Management** > **Process Definition**.
3. In the Additional Properties area, select **Java Virtual Machine**.
4. In the Additional Properties area on the Java Virtual Machine panel, select **Custom Properties**.
5. Create or modify the com.ibm.websphere.ejbcontainer.allowCachedTimerDataFor custom property.
   - If the property does not exist, click **New** to create the property.
   - If the property already exists, select the property and click **Modify** to change the values.
6. Enter `com.ibm.websphere.ejbcontainer.allowCachedTimerDataForname` for the name of the custom property.
7. Determine the best value for your needs and environment. The value for this property allows you as much control over caching as you need. You can specify a wildcard or use specific timer names, and you can fine tune control over which methods are cached by assigning integer values based upon those methods.

   These integer values allow you to have precise control over which methods you allow to use cached data. Integers are assigned on a per bean basis or to all beans if you use an asterisk (*). The integer values and their corresponding methods are:

   1 Specifies the getHandle() method

   2 Specifies the getInfo() method

   4 Specifies the getNextTimeout() method

   8 Specifies the getTimeRemaining() method

   16 Specifies the getSchedule() method

   32 Specifies the isPersistent() method

   64 Specifies the isCalendarTimer() method

Note: You can apply this property to any individual methods listed above by using the assigned integer value, or you can apply it to a combination of these methods. For example:

- To apply this property to the getHandle method and the getTimeRemaining method, sum the integer value for the two methods, and use the value 9 (1+8).
- To apply the property to all seven methods, use the value 127 (1+2+4+8+16+32+64), or you could not specify an integer. The default behavior when this property is set is to apply caching to all methods.

When you make your decision, use a wildcard to specify all timers, or specify the JNDI names of the timer beans for which the application server will apply caching.

- You can enter an asterisk (*), which will configure all timers, optionally followed by an integer value - or summation of integer values - that indicate the applicable method on the timer interface. If you do not specify an integer value, the application server will apply caching to all methods.

  For example, the following value applies caching to methods for all timers:

  ```
  *
  ```

- You can enter the name of the EJB timer bean, optionally followed by an integer value - or summation of integer values - that indicate the applicable method on the timer interface. To enter more than one timer bean, separate each application name with a colon (:). If you do not specify an integer value, the application server will apply caching to all methods.

  For example, the following value applies caching to all methods for MyTimerBean1 and MyTimerBean2:

  ```
  MyApp1#MyEJBModule1#MyTimerBean1:MyApp2#MyEJBModule2#MyTimerBean2
  ```

8. Select **OK**.
9. Restart the application server.

Example

The following examples demonstrate different ways to implement the caching feature for timer services. Assume that you have two applications, and each application has timers. The timers use the following J2EE names:

- App1#EJBJar1.jar#EJBTimer1
- App2#EJBJar2.jar#EJBTimer2

The examples will show the value to use for the com.ibm.websphere.ejbcontainer.allowCachedTimerDataForname custom property.

Example 1

This example applies caching to all methods, for all timers, and for all applications.

Use one of the following values:

- Using the defaults:

  ```
  *
  ```

- Specifying an integer:

  ```
  *=127
  ```

Example 2

This example applies caching to the getInfo method on all timers for all applications.

Use the following value:

```
*=2
```

Example 3

This example applies caching to the getHandle and getNextTimeout methods on EJBTimer2.

Use the following value:

App2#EJBJar2.jar#EJBTimer2=5

Example 4

This example applies caching to:

- the getInfo method on EJBTimer1
- the getNextTimeout and getTimeRemaining methods on EJBTimer2

Use the following value:

App1#EJBJar1.jar#EJBTimer1=2:App2#EJBJar2.jar#EJBTimer2=12

Configuring the timer service using scripting

Use wsadmin scripting to configure the Enterprise JavaBeans (EJB) timer service.

Before you begin

You must have a working knowledge of Jacl or Jython and wsadmin scripting.

About this task

The behavior for EJB timers is configured using the EJBTimer configuration object in the server.xml file. If you have EJB timers, you must update the EJBTimer configuration object to obtain the optimal settings for your environment.

The EJBTimer configuration object exists at the server level. This means that each server in a multi-server environment has its own EJBTimer configuration object and must be configured individually.

Procedure

1. Launch the scripting tool using the Jython or scripting language.
2. Determine the attributes on the EJBTimer configuration object that must be updated. You can update the following attributes on the EJBTimer configuration object:
   - datasourceJNDIName
   - datasourceAlias
   - tablePrefix
   - pollInterval
   - numAlarmThreads
   - schedulerJNDIName
   - numNPTimerThreads
   - nonPersistentTimerRetryCount
   - nonPersistentTimerRetryInterval
   - uniqueTimerManagerForNP

   For a complete description of each attribute, see information about EJB timer service settings.

   Four types of EJB timers exist:

   - Persistent timers, supported by a default internal scheduler instance.
   - Persistent timers, supported by a custom scheduler instance.
   - Non-persistent timers, sharing a thread pool with persistent timers.
   - Non-persistent timers, not sharing a thread pool with persistent timers.

   The server is always configured to use one of the two types of persistent timers, and one of the two types of non-persistent timers.

   The EJBTimer configuration object contains the configuration data for all four types of EJB timers. Each of the four types of timer uses a subset of the configuration attributes on the EJBTimer configuration object. All the attributes on the EJBTimer configuration object are used to configure at

least one of the timer types, and none of the attributes are used to configure all the timer types. Thus, you must understand which type of timer you are configured to use, and which configuration attributes apply to that type of timer.

Table 42. Timer types and configuration attributes. Indicates the EJBTimer attributes that are used to configure each type of timer.

Attribute	Persistent, default scheduler	Persistent, custom scheduler	Non-persistent, shared thread pool	Non-persistent, unique thread pool
datasourceJNDIName	Yes	No, specified on custom scheduler configuration instead	No	No
datasourceAlias	Yes	No, specified on custom scheduler configuration instead	No	No
tablePrefix	Yes	No, specified on custom scheduler configuration instead	No	No
pollInterval	Yes	No, specified on custom scheduler configuration instead	No	No
numAlarmThreads	Yes	No	Yes	No
schedulerJNDIName	No	Yes	No	No
numNPTimerThreads	No	No	No	Yes
nonPersistentTimerRetryCount	No	No	Yes	Yes
nonPersistentTimerRetryInterval	No	No	Yes	Yes
uniqueTimerManagerForNP	No	No	Yes	Yes

The presence of a value for the schedulerJNDIName attribute determines which type of persistent timer is used. If the schedulerJNDIName attribute has a value, then a custom scheduler instance is used. If the schedulerJNDIName does not have a value, then the default internal scheduler instance is used.

The numAlarmThreads attribute maps to the Number of timer threads option in the Persistent EJB timer configuration section of the administrative console. The numNPTimerThreads attribute maps to the Number of timer threads option in the Non-persistent EJB timer configuration section of the administrative console.

The uniqueTimerManagerForNP attribute maps to the Share thread pool configured for persistent timers and Create a separate thread pool for non-persistent timers options in the administrative console.

The uniqueTimerManagerForNP attribute determines if the thread pool is shared between persistent and non-persistent timers. It also determines if the numAlarmThreads or numNPTimerThreads configuration attribute is used.

Table 43. The uniqueTimerManagerForNP attribute impacts. The uniqueTimerManagerForNP attribute affects both thread pool sharing and thread configuration.

uniqueTimerManagerForNP attribute	Persistent and non-persistent timers share a thread pool	Thread configuration attribute that is used	Thread configuration attribute that is ignored
true	No	numNPTimerThreads	numAlarmThreads
false	Yes	numAlarmThreads	numNPTimerThreads

3. Obtain a reference to the correct EJBTimer configuration object and store it in a variable.

   Using Jacl:

   ```
   set timer [$AdminConfig list EJBTimer]
   ```

   Using Jython:

   ```
   timer = AdminConfig.list('EJBTimer')
   ```

   If you have a multi-server environment, then multiple EJBTimer configuration objects are returned. Programmatically loop over the list and select the EJBTimer configuration object that corresponds to the server you must update.

In a multi-server environment, as an alternative to programmatically looping over the list of EJBTimer objects, you can manually select the correct EJBTimer object and copy and paste it into your variable.

For example, if the output of your `AdminConfig list` command is:

```
(cells/myCell01/nodes/myCellManager01/servers/dmgr|server.xml#EJBTimer_1)(cells/myCell01/
nodes/myNode02/servers/server1|server.xml#EJBTimer_1246050925244)
```

Copy and paste the reference for the needed EJBTimer object into your variable.

Using Jacl:

```
set timer "(cells/myCell01/nodes/myNode02/servers/server1|server.xml#EJBTimer_1246050925244)"
```

Using Jython:

```
timer = "(cells/myCell01/nodes/myNode02/servers/server1|server.xml#EJBTimer_1246050925244)"
```

4. Update attributes on the EJBTimer configuration object.

   Update attributes on the EJBTimer configuration object using the `AdminConfig modify` command. The first argument to the command is the EJBTimer reference that you obtained in the previous step. The second argument to the command is a list of name-value pairs.

   To set a retry count of 10 attempts, and a retry interval of 15 seconds between each attempt:

   Using Jacl:

   ```
   set update "{nonPersistentTimerRetryCount 10} {nonPersistentTimerRetryInterval 15}"
   $AdminConfig modify $timer $update
   ```

   Using Jython:

   ```
   AdminConfig.modify(timer, '[[nonPersistentTimerRetryCount "10"] [nonPersistentTimerRetryInterval "15"]]')
   ```

5. Save the configuration changes.

   Using Jython:

   ```
   AdminConfig.save()
   ```

   Using Jacl:

   ```
   $AdminConfig save
   ```

6. In a network deployment environment only, synchronize the node.

   Using Jacl:

   ```
   set sync1 [$AdminControl completeObjectName type=NodeSync,node=<your node>,*]
   $AdminControl invoke $sync1 sync
   ```

   Using Jython:

   ```
   sync1 = AdminControl.completeObjectName('type=NodeSync,node=<your node>,*')
   AdminControl.invoke(sync1, 'sync')
   ```

   The node synchronization in these examples must be executed while connected to the server.

Results

As a result of your updates, the EJBTimer configuration object now reflects the attribute values you specified. Restart your server so that the changes are updated on the server.

EJB timer service settings

Use this page to configure and manage the Enterprise JavaBeans (EJB) timer service for a specific EJB container.

To view this administrative console page, click **Servers** > **Server types** > **WebSphere application servers** > ***server name*** > **EJB Container Settings** > **EJB timer service settings**.

Both persistent and non-persistent timers can exist simultaneously, and the persistent and non-persistent configurations are not mutually exclusive. Your application might use both persistent and non-persistent timers.

Use persistent timers when the timer must persist through server shutdowns and restarts. Otherwise, use non-persistent timers when a server shutdown must cancel the timer.

When a persistent timer does not fire because the server is unavailable, then the missed attempt is recovered when the server restarts. When a non-persistent timer does not fire because the server is unavailable, the missed attempt is not recovered, because the server shutdown cancels the non-persistent timer.

Persistent EJB timer configuration

Use internal EJB timer service scheduler instance

The product provides an internal scheduler instance for use by the EJB timer service. The internal scheduler instance is pre-configured for basic EJB timer functionality, and provides limited configuration settings for an EJB timer service.

You can specify that you want to use the internal scheduler instance to manage your persistent timer tasks. They are persisted to a Cloudscape database associated with the server process. Selecting this choice precludes the Use Custom Scheduler Instance option.

The internal scheduler instance is the default. Alternatively, a custom scheduler instance might be used.

Use custom scheduler instance

You can perform a more advanced configuration for the EJB timer service by defining a custom scheduler instance.

A custom Scheduler instance provides more configuration options than the internal EJB timer service pre-configured scheduler instance. You might want to define a custom scheduler instance when running in a clustered environment, allowing all cluster members to run with a single scheduler instance. This definition enables persistent EJB Timers created on one cluster member to run on other cluster members. Providing a custom scheduler instance also enables persistent EJB Timers to be maintained in the same database as other scheduled tasks. Selecting this choice precludes the Use Internal EJB Timer Service Scheduler Instance option.

You might want to define a custom scheduler instance to isolate threads used by the scheduler service from those threads used by the EJB timer service. EJB timer service threads from a custom scheduler instance might be shared for use with non-persistent timers, or you might configure a separate thread pool for non-persistent timers. Even with a thread pool dedicated to EJB timers, timer expirations might fall behind if there are not enough available threads. You must evaluate the number of timers and their expiration frequencies to establish the number of threads.

Data source JNDI name

Specifies the Java Naming and Directory Interface (JNDI) name of the data source where persistent EJB Timers are stored for this EJB container. Any data source available in the name space can be used for EJB Timers.

Multiple EJB containers can share a single data source while using different tables by specifying a table prefix.

Data type String
Default *jdbc/DefaultEJBTimerDataSource*

Data source alias

Specifies an authentication alias to a user name and password used to access the data source.

Data type String

Table prefix

A string prepended to the EJB timer service table names (TASK, TREG, LMGRand LMPR). These tables are created during server start if they do not exist. See the scheduler service for information about manually creating these tables. Multiple independent EJB timer services can share the same database if each instance specifies a different prefix string. If the removeAutomaticEJBTimers command is used to remove timers from a specified scheduler, that scheduler must have a unique table prefix. Otherwise, more timers than expected could be removed.

Data type	String
Default	*EJBTIMER_*

Poll interval

Specifies the interval at which the EJB timer service daemon polls the database. Each poll operation can be expensive. If the interval is small and there are multiple scheduled tasks, polling can use a large portion of system resources. New timers set to expire sooner than this interval might not run until the interval ends. If this value is too large, a potentially large number of timer events might be loaded into memory because all the timer events occurring in the next poll interval are loaded each time.

Data type	Integer
Units	seconds
Default	300
Range	3 to 1800

Number of timer threads

The number of threads used to run concurrent EJB Timer tasks. Setting the number of timer threads to zero disables the EJB timer service.

Data type	Integer
Default	1
Range	0 to 500

Scheduler JNDI name

Specifies the JNDI name of a custom Scheduler instance to use for managing and persisting EJB Timers. This field is only used when you select **Use Custom Scheduler Instance**. Internal EJB timer service scheduler instance configuration information is not applied to the specified scheduler instance.

Data type	String

Non-persistent EJB timer configuration

Maximum number of retries

Specifies the maximum number of times that a failing timeout might be retried. If a timeout is successful upon retry, the server stops attempting to run it. If a retry fails, the server continues to attempt retries until the timeout succeeds, or the timeout limit is reached. Once the retry limit is reached, the server does not attempt to execute the timeout, even if the timeout has not succeeded. The default value of -1 indicates unlimited retries. A value of 0 indicates no retries, and is not specification-compliant. A value of 1 or greater indicates that specific number of retries are allowed.

Data type	Integer
Default	-1
Range	-1 or greater

Time interval between retries

Specifies the interval between retry attempts for a failed timeout. The first retry always occurs immediately, regardless of the interval configured here. All additional retries wait for the interval specified here. A value of 0 indicates that all retries are immediate. A value of 1 or higher indicates that retries must wait for that specific number of seconds.

Data type	Integer
Default	300 seconds
Range	0 or greater

Share thread pool configured for persistent timers

Specifies that non-persistent timers share a thread pool with persistent timers. If persistent timers are using the default internal scheduler instance, the shared thread pool is configured using the configuration settings specified in the Persistent EJB timer configuration section. If the persistent timers are using a custom defined scheduler, the thread pool configuration was specified as part of the configuration for that custom scheduler.

Create a separate thread pool for non-persistent timers

Specifies that non-persistent timers do not share a thread pool with persistent timers. Rather, a unique thread pool is created for non-persistent timers only.

Number of timer threads

Specifies the number of threads available in the unique thread pool used for non-persistent timers. This configuration option is only available when non-persistent timers are not sharing a thread pool with persistent timers. This configuration option is different from the Number of timer threads configuration option in the Persistent EJB timers configuration section because that option applies only to persistent timers using the default internal scheduler instance.

Data type	Integer
Default	1
Range	0 to 500

Managing message-driven beans

You can manage the Java EE Connector Architecture (JCA) Version 1.5-compliant message-driven beans that you deploy as message endpoints, and you can manage the message listener resources for non-JCA message-driven beans that you deploy against listener ports.

Before you begin

For WebSphere Application Server Version 7 and later, listener ports are stabilized. For more information, read the article on stabilized features. You should plan to migrate your WebSphere MQ message-driven bean deployment configurations from using listener ports to using activation specifications. However, you should not begin this migration until you are sure the application does not have to work on application servers earlier than WebSphere Application Server Version 7. For example, if you have an application server cluster with some members at Version 6.1 and some at Version 7, you should not migrate applications on that cluster to use activation specifications until after you migrate all the application servers in the cluster to Version 7.

If you want to use message-driven beans with a messaging provider that does not have a JCA 1.5 resource adapter, you cannot use activation specifications and therefore you must configure your beans against a listener port. There are also a few scenarios in which, although you could use activation specifications, you might still choose to use listener ports. For example, for compatability with existing message-driven bean applications.

For more information about when to use listener ports rather than activation specifications, see Message-driven beans, activation specifications, and listener ports.

About this task

You can manage the following resources for message-driven beans:

- JCA 1.5-compliant message-driven beans that you deploy as message endpoints, and the associated activation specifications.
- The message listener service, listener ports, and listeners for non-JCA message-driven beans that you deploy against listener ports.

Procedure

- Manage JCA 1.5-compliant message-driven beans that are used as message endpoints.

  JCA 1.5-compliant message-driven beans, deployed by using activation specifications, can be used as message endpoints. You can start and stop specific endpoints within your applications to ensure that messages are delivered only to listening message-driven beans that are interacting with healthy resources.
- Manage message listener resources for message-driven beans.

  The message listener service supports message-driven beans that are used with a non-JCA messaging provider. A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. When you deploy a message-driven bean, you associate the bean with a listener port. When a message arrives on the destination, the listener passes the message to a new instance of a message-driven bean for processing. You can manage the resources used by the message listener service, including being able to start and stop specific listener ports manually.

Managing messages with message endpoints

Manage message delivery for message-driven beans (MDB) that are deployed as message endpoints. The message endpoints are managed beans (MBeans) for inbound resource adapters that are compliant with Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) Version 1.5.

About this task

The application server provides message endpoint MBeans to assist you in managing the delivery of a message to your message-driven beans that are acting as listeners on specific endpoints, which are destinations, and in managing the enterprise information system (EIS) resources that are utilized by these message-driven beans. Message-driven beans that are deployed as message endpoints are not the same as message-driven beans that are configured against a listener port. Message-driven beans that are used as message endpoints must be deployed using an ActivationSpecification that is defined within a resource adapter configuration for JCA Version 1.5.

With message endpoint MBeans, you can activate and deactivate specific endpoints within your applications to ensure that messages are delivered only to listening message-driven beans that are interacting with healthy EIS resources. This capability allows you to optimize the performance of your JMS applications in situations where an EIS resource is not behaving as expected. Message delivery to an endpoint typically fails when the message driven bean that is listening invokes an operation against a resource that is not healthy. For example, a messaging provider, which is an inbound resource adapter that is JCA Version 1.5 compliant, might fail to deliver messages to an endpoint when its underlying message-driven bean attempts to commit transactions against a database server that is not responding.

Note: Design your message-driven beans to delegate business processing to other enterprise beans. Do not access the EIS resources directly in the message-driven bean, but do so indirectly through a delegate bean.

Message endpoint MBeans alleviate two problems that are inherent to applications that provide message endpoints that access resources:

- Failed messages require additional processing, such as delivering them to the listening endpoint again or redirecting them to alternate destinations that process failed messages. In addition, a resource adapter might redeliver a message to an endpoint an infinite number of times.
- Message redirection requires the implementation of specialized destinations (queues and listeners) to process failed messages, as well as the logic to detect message failures. Message redirection is potentially error prone and computationally expensive due to its complexity.

The capability to deactivate (pause) and reactivate (resume) a specific message endpoint alleviates these problems by enabling the administrator to deactivate the endpoint from processing messages that are destined to fail. When the message endpoint is deactivated, you can repair the resource that is causing the problems and reactivate the endpoint to resume handling message requests. In the course of troubleshooting, you will not affect the resource adapter or the application that is hosting the endpoint.

If you are connecting to WebSphere MQ, you can also use the WAS_EndpointInitialState custom property in the activation specification to make the message endpoint start out in a deactivated state. When you set this property to Inactive, the message-driven bean connects with the destination, but does not start receiving messages. Use this setting to automatically deactivate a message endpoint when you know that certain tasks must be completed, services must be started, or checks must be carried out, before message handling begins. You activate the message endpoint in the same way as you would reactivate a message endpoint that you paused during its operation.

Procedure

1. Using the administrative console, navigate to the Message Endpoints panel for the application that is hosting the message endpoint.
   a. Select the **Applications** > **Application Types** > **Websphere enterprise applications** > ***application_name***.
   b. Select the **Runtime** panel.
   c. Select **Message Endpoints**. The panel lists the set of message endpoints that are hosted by the application.
2. Optional: Temporarily disable a message endpoint from handling messages and troubleshoot the problem.
   a. Deactivate the message endpoint by selecting the appropriate endpoint and clicking **Pause**.
   b. When the message endpoint is inactive, diagnose and repair the underlying cause of the delivery failures.
   c. Reactivate the message endpoint by selecting the appropriate endpoint and clicking **Resume**.
3. Optional: Activate a message endpoint that started out in a deactivated state. Select the appropriate endpoint and click **Resume**.

Results

The behavior you will observe when you deactivate (pause) a message endpoint using the message endpoint MBean is dependent upon a variety of factors, including the resource adapter that manages the message endpoint, the configuration of the message endpoint and the application server topology. Some specific examples of interest are as follows:

- **MDB listening on a non-durable topic (dependent on configuration):** The behavior that is implied by the deactivation (pause) of a message endpoint is often dependent upon the function that it is fulfilling. For example, if you have configured a message-driven bean to listen on a non-durable topic on the service integration bus, deactivating the message endpoint is analogous to stopping the application and will cause the subscription to be closed. This means that any messages that are published during the time that the message endpoint is paused will not be received by the message-driven bean.

- **Clustered message-driven bean (dependent on topology):** In this scenario a message-driven bean application has been deployed to a cluster of servers. A given message endpoint MBean controls only the behavior of the MDB in one server from the cluster, so will cause only one server to stop processing messages. Depending upon the messaging configuration and the specific resource adapter in use the messages that would have been consumed by the paused message endpoint may be consumed by the active message endpoints in the cluster, or they may remain unconsumed until the paused message endpoint is resumed.
- **Clustered message-driven bean, a non-clustered queue:** In this scenario, you have a cluster of servers with the same message-driven bean deployed to them. This is similar to the case, in which you have different message-driven beans with the same message selection criteria, except that in this case the message-driven beans are logically the same message-driven bean. Pausing the endpoint will cause only one of the servers to stop receiving messages, and the other message-driven beans will receive all the messages; none of the messages will be orphaned. To stop all of the endpoints, you must direct each server in the cluster to stop the local message endpoint.
- **Clustered message-driven bean, clustered queue:** In this scenario, each message-driven bean is pulling messages from a different partition of the queue. Messaging through WebSphere MQ and the Service Integration Bus have similar, but different, capabilities. If you are using WebSphere MQ, then pausing one endpoint will not allow the other instances of the message-driven bean to receive the messages. In the Service Integration Bus, messages from a paused endpoint will be redirected to the other message-driven beans.

Managing message listener resources for message-driven beans

Manage the resources used by the message listener service to support message-driven beans, typically for use with a messaging provider that does not have a Java EE Connector Architecture (JCA) 1.5 resource adapter.

Before you begin

For WebSphere Application Server Version 7 and later, listener ports are stabilized. For more information, read the article on stabilized features. You should plan to migrate your WebSphere MQ message-driven bean deployment configurations from using listener ports to using activation specifications. However, you should not begin this migration until you are sure the application does not have to work on application servers earlier than WebSphere Application Server Version 7. For example, if you have an application server cluster with some members at Version 6.1 and some at Version 7, you should not migrate applications on that cluster to use activation specifications until after you migrate all the application servers in the cluster to Version 7.

If you want to use message-driven beans with a messaging provider that does not have a JCA 1.5 resource adapter, you cannot use activation specifications and therefore you must configure your beans against a listener port. There are also a few scenarios in which, although you could use activation specifications, you might still choose to use listener ports. For example, for compatability with existing message-driven bean applications.

If you have existing message-driven beans that use the WebSphere MQ messaging provider (or a compliant third-party JMS provider) with listener ports, and instead you want to use EJB 3 message-driven beans with listener ports, these new beans can continue to use the same messaging provider.

For more information about when to use listener ports rather than activation specifications, see Message-driven beans, activation specifications, and listener ports.

About this task

The message listener service is an extension to the JMS functions of the JMS provider and provides a listener manager, which controls and monitors one or more JMS listeners. Each listener monitors either a JMS queue destination (for point-to-point messaging) or a JMS topic destination (for publish/subscribe

messaging). A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. When you deploy a message-driven bean, you associate the bean with a listener port. When a message arrives on the destination, the listener passes the message to a new instance of a message-driven bean for processing. For more information, see Message-driven beans - listener port components.

Procedure

1. Configure the message listener service.
2. Administer listener ports.

   You can complete any of the following administrative tasks:
   - Create or configure a listener port.
   - Start or stop a listener port.
   - Delete a listener port.
3. Configure security for message-driven beans that use listener ports.

Results

You have configured the resources needed by the message listener service to support message-driven beans.

Configuring the message listener service

To support message-driven beans deployed against listener ports, you configure the properties of the message listener service for an application server.

Before you begin

If you want to use message-driven beans with a messaging provider that does not have a JCA 1.5 resource adapter, you cannot use activation specifications and therefore you must configure your beans against a listener port. There are also a few scenarios in which, although you could use activation specifications, you might still choose to use listener ports. For example, for compatability with existing message-driven bean applications.

If you have existing message-driven beans that use the WebSphere MQ messaging provider (or a compliant third-party JMS provider) with listener ports, and instead you want to use EJB 3 message-driven beans with listener ports, these new beans can continue to use the same messaging provider.

For more information about when to use listener ports rather than activation specifications, see Message-driven beans, activation specifications, and listener ports.

About this task

The message listener service is an extension to the JMS functions of the JMS provider and provides a listener manager, which controls and monitors one or more JMS listeners. Each listener monitors either a JMS queue destination (for point-to-point messaging) or a JMS topic destination (for publish/subscribe messaging). For more information, see Message-driven beans - listener port components.

When you deploy an enterprise application to use message-driven beans with listener ports, you can browse or change the configuration of the message listener service for a given application server.

| If your messaging system is running in non-ASF mode, to avoid unwanted transaction timeouts, you must
| make sure that the time that you specify for the **NON.ASF.RECEIVE.TIMEOUT** message listener service
| custom property is smaller than the sum of the maximum amount of time that the `onMessage()` method of
| the message-driven bean (MDB) takes to process the message, plus the time you specify for the **Total
| transaction lifetime timeout** transaction service property.

Procedure

1. Display the listener service settings page:
   a. In the navigation pane, select **Servers** > **Server Types** > **WebSphere application servers**.
   b. In the content pane, click the name of the application server.
   c. Under Communications, click **Messaging** > **Message Listener Service**.
2. Optional: Browse or change the value of properties for the message-driven bean thread pool.
   a. Click **Thread Pool**.
   b. Change the following properties, as required:

      Minimum size
      The minimum number of threads to allow in the pool.

      Maximum size
      The maximum number of threads to allow in the pool.

      Thread inactivity timeout
      The number of milliseconds of inactivity that should elapse before a thread is reclaimed. A value of 0 indicates not to wait and a negative value (less than 0) means to wait forever.

      Note: The administrative console does not allow you to set the inactivity timeout to a negative number. To do this you must modify the value directly in the config.xml file.

      Allow thread allocation beyond maximum thread size
      Select this check box to enable the number of threads to increase beyond the maximum size configured for the thread pool.
   c. Click **OK**.
3. Optional: Specify any message listener service custom properties that you need, as **Custom properties** of the message listener service.
   a. Click **Custom properties**
   b. For each custom property, specify the name and value you require.
      If you have not specified a property before:
      1) Click **New**.
      2) Type the name of the property.
      3) Type the value of the property.
      4) Click **OK**.

   For more information about these custom properties, see “Message listener service custom properties” on page 419.
4. Save your changes to the master configuration.
5. To activate the changed configuration, stop then restart the application server.

Results

You have configured the properties of the message listener service for a given application server.

Avoiding transaction timeouts in non-ASF mode:

If your messaging system runs in non-Application Server Facilities (non-ASF) mode, you must configure the **Total transaction lifetime timeout** transaction service property and the **NON.ASF.RECEIVE.TIMEOUT** message listener service custom property correctly, to avoid unwanted transaction timeouts.

Before you begin

To carry out the steps in this task, your messaging system must be running in non-ASF mode. To change from ASF mode to non-ASF mode, add the **NON.ASF.RECEIVE.TIMEOUT** custom property to the message listener service as described in “Configuring the message listener service” on page 415.

About this task

For WebSphere Application Server Version 7 and later, listener ports are stabilized. For more information, read the article on stabilized features. You should plan to migrate your WebSphere MQ message-driven bean deployment configurations from using listener ports to using activation specifications. However, you should not begin this migration until you are sure the application does not have to work on application servers earlier than WebSphere Application Server Version 7. For example, if you have an application server cluster with some members at Version 6.1 and some at Version 7, you should not migrate applications on that cluster to use activation specifications until after you migrate all the application servers in the cluster to Version 7.

If your messaging system is running in non-ASF mode, to avoid unwanted transaction timeouts, you must make sure that the time that you specify for the **NON.ASF.RECEIVE.TIMEOUT** message listener service custom property is smaller than the sum of the maximum amount of time that the `onMessage()` method of the message-driven bean (MDB) takes to process the message, plus the time you specify for the **Total transaction lifetime timeout** transaction service property.

Procedure

1. To configure the **Total transaction lifetime timeout** transaction service property, complete step 8 in “Configuring transaction properties for an application server” on page 2491.
2. To configure the **NON.ASF.RECEIVE.TIMEOUT** message listener service custom property, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Communications] Messaging** > **Message Listener Service** > **Custom Properties**.
3. Click **NON.ASF.RECEIVE.TIMEOUT**. The General Properties page is displayed.
4. Modify the **Value** field. The value for **NON.ASF.RECEIVE.TIMEOUT** must be specified in milliseconds. Make sure that the value you specify, when converted into seconds (by dividing by 1000) , is less than the value you have specified for **Total transaction lifetime timeout** combined with the maximum number of seconds the onMessage() method of your MDB takes to process a message.
5. Click **OK**.
6. Stop and restart the application server.

Example

If **Total transaction lifetime timeout** and **NON.ASF.RECEIVE.TIMEOUT** are not correctly configured, transactions can time out before they are completed. This is because the thread begins calling the `receive()` method as soon as the transaction is created. In the following example, **NON.ASF.RECEIVE.TIMEOUT** is set to `110000` milliseconds (110 seconds), **Total transaction lifetime timeout** is set to `120` seconds and the onMessage () method of the MDB takes 15 seconds to process a message. The example supposes that a message does not appear at the destination until the `receive()` method has almost timed out:

1. The listener port starts and allocates a thread from the thread pool and creates a transaction on the thread.
2. The thread calls the `receive()` method to listen for messages.
3. After 110 seconds a message appears at the destination.
4. The thread removes the message from the destination and calls the `onMessage()` method of the MDB to begin processing the message.

5. Ten seconds later, the transaction timeout is reached. The application server marks the transaction for rollback.
6. Five seconds later, the `onMessage()` method finishes processing the message and tries to commit the transaction.
7. The total amount of time that has elapsed since the transaction was started is 125 seconds (110 seconds waiting for a message, plus 15 seconds to process the message). As this time is longer than the transaction timeout, the application server prevents the transaction from being committed, and it is rolled back.

Message listener service:

The message listener service is an extension to the JMS functions of the JMS provider. It provides a listener manager that controls and monitors one or more JMS listeners, which each monitor a JMS destination on behalf of a deployed message-driven bean.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Communications] Messaging** > **Message Listener Service**

Custom Properties

You can use the Custom properties page to define the following properties for use by the message listener service.

- "DYNAMIC.CONFIGURATION.ENABLED" on page 419
- "MAX.RECOVERY.RETRIES" on page 419
- "MQJMS.POOLING.THRESHOLD" on page 419
- "MQJMS.POOLING.TIMEOUT" on page 420
- "NON.ASF.RECEIVE.TIMEOUT" on page 420
- "NON.ASF.BMT.ROLLBACK.ENABLED" on page 421
- "RECOVERY.RETRY.INTERVAL" on page 421
- "SERVER.SESSION.POOL.REAP.TIME" on page 421
- "SERVER.SESSION.POOL.UNUSED.TIMEOUT" on page 422
- "SERVER.SESSION.POOL.UNUSED.TIMEOUT.*lpname*" on page 422

Listener Ports

You can use the Listener Ports page to create and modify listener ports by specifying the following properties:

- Name
- Initial State
- Description
- Connection factory JNDI name
- Destination JNDI name
- Maximum sessions
- Maximum retries
- Maximum messages

Thread pool

You can use the Thread pool page to change the following properties for the message-driven bean thread pool:

- Minimum size

- Maximum size
- Thread inactivity timeout

Message listener service custom properties:

Use this panel to view or change custom properties of the message listener service.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Communications] Messaging** > **Message Listener Service** > **Custom Properties**.

You can use the Custom properties page to define the following properties for use by the message listener service.

- "DYNAMIC.CONFIGURATION.ENABLED"
- "MAX.RECOVERY.RETRIES"
- "MQJMS.POOLING.THRESHOLD"
- "MQJMS.POOLING.TIMEOUT" on page 420
- "NON.ASF.RECEIVE.TIMEOUT" on page 420
- "NON.ASF.BMT.ROLLBACK.ENABLED" on page 421
- "RECOVERY.RETRY.INTERVAL" on page 421
- "SERVER.SESSION.POOL.REAP.TIME" on page 421
- "SERVER.SESSION.POOL.UNUSED.TIMEOUT" on page 422
- "SERVER.SESSION.POOL.UNUSED.TIMEOUT.*lpname*" on page 422

DYNAMIC.CONFIGURATION.ENABLED:

This property controls whether the application server on which a listener port is created requires to be restarted. Set this property to true to enable dynamic configuration.

Data type	Boolean
Default	False (not selected)

MAX.RECOVERY.RETRIES:

The maximum number of times that a listener port managed by this service tries to recover from a failure before giving up and stopping. When stopped the associated listener port is changed to the stop state. The interval between retry attempts is defined by the **RECOVERY.RETRY.INTERVAL** property.

A failure can be caused by either of the following conditions:

- An unexpected error has occurred when a listener port tries to get a message from the JMS provider.
- The connection between the application server and the JMS provider has been lost, usually due to a network error.

Data type	Integer
Units	Retry attempts
Default	5
Range	0 (no retries) through 2147483647

MQJMS.POOLING.THRESHOLD:

The maximum number of unused connections in the pool.

An MQSimpleConnectionManager allocates connections on a most-recently-used basis, and destroys connections on a least-recently-used basis. By default, a connection is destroyed if there are more than ten unused connections in the pool.

Data type	Integer
Units	Number of connections
Default	10

MQJMS.POOLING.TIMEOUT:

The number of milliseconds after which a connection in the pool is destroyed if it has not been used.

An MQSimpleConnectionManager allocates connections on a most-recently-used basis, and destroys connections on a least-recently-used basis. By default, a connection is destroyed if it has not been used for five minutes.

Data type	Integer
Units	Milliseconds
Default	5 minutes

NON.ASF.RECEIVE.TIMEOUT:

The timeout in milliseconds for synchronous message receives performed by message-driven bean listener sessions in the non-ASF mode of operation.

Note: The message listener service has two modes of operation, Application Server Facilities (ASF) and non-Application Server Facilities (non-ASF):

- ASF mode provides concurrency and transactional support for applications. For publish/subscribe message-drive beans, ASF mode provides better throughput and concurrency, because in the non-ASF mode the listener is single-threaded.
- Non-ASF mode is mainly for use with third-party messaging providers that do not support JMS ASF, which is an optional extension to the JMS specification. Non-ASF mode is also transactional but, because the path length is shorter than for ASF mode, usually provides improved performance.

To enable the non-ASF mode of operation for all message-driven bean listeners on the application server, set this property to a non-zero value.

If your messaging system is running in non-ASF mode, to avoid unwanted transaction timeouts, you must make sure that the time that you specify for the **NON.ASF.RECEIVE.TIMEOUT** message listener service custom property is smaller than the sum of the maximum amount of time that the `onMessage()` method of the message-driven bean (MDB) takes to process the message, plus the time you specify for the **Total transaction lifetime timeout** transaction service property.

Data type	Integer
Units	Milliseconds
Default	ASF mode (custom property not created)
Range	0 or greater milliseconds

0 Non-ASF mode is disabled

1 or more
The timeout in milliseconds for non-ASF message-driven bean listener synchronous session receives

Recommended	If a transaction timeout occurs, the message must recycle causing extra work. If you want to use the non-ASF mode, set this property to less than the transaction timeout, but greater than or equal to the maximum duration of your message-driven bean onMessage() method. For example, if your message-driven bean onMessage() method typically takes a maximum of 10 seconds, and the transaction timeout is set to 120 seconds, you might set the **NON.ASF.RECEIVE.TIMEOUT** property to no more than 110000 milliseconds (that is, 110 seconds).

NON.ASF.BMT.ROLLBACK.ENABLED:

When the non-Application Server Facilities (non-ASF) mode of operation is in use (because you have set the **NON.ASF.RECEIVE.TIMEOUT** property to a non-zero value), and a message-driven bean that uses bean-managed transactions generates a runtime exception, the **NON.ASF.BMT.ROLLBACK.ENABLED** property determines whether messages are returned to the destination.

Note: The message listener service has two modes of operation, Application Server Facilities (ASF) and non-Application Server Facilities (non-ASF):

- ASF mode provides concurrency and transactional support for applications. For publish/subscribe message-drive beans, ASF mode provides better throughput and concurrency, because in the non-ASF mode the listener is single-threaded.
- Non-ASF mode is mainly for use with third-party messaging providers that do not support JMS ASF, which is an optional extension to the JMS specification. Non-ASF mode is also transactional but, because the path length is shorter than for ASF mode, usually provides improved performance.

When this property is set to false (default), the message is automatically acknowledged before it is passed to the message-driven bean.

When this property is set to true, the message listener service sends a message acknowledgement to the client after the message is successfully processed by the message-driven bean, and the message listener service requests recovery of any message for which the bean generates an exception.

Data type	Boolean
Default	False

RECOVERY.RETRY.INTERVAL:

The time in seconds between retry attempts by a listener port to recover from a failure. The maximum number of retry attempts is defined by the **MAX.RECOVERY.RETRIES** property.

A failure can be caused by either of the following conditions:

- An unexpected error has occurred when a listener port tries to get a message from the JMS provider.
- The connection between the application server and the JMS provider has been lost, usually due to a network error.

Data type	Integer
Units	Seconds
Default	60
Range	1 through 2147483647

SERVER.SESSION.POOL.REAP.TIME:

The time in seconds between checks on server session pools. To enable server session pool monitoring, set this property to a non-negative value.

The **SERVER.SESSION.POOL.REAP.TIME** custom property is not applicable if your messaging system is running in non-ASF mode.

Data type	Integer
Units	Seconds
Default	-1 (disabled)
Range	-2147483648 through 2147483647

SERVER.SESSION.POOL.UNUSED.TIMEOUT:

The default server session pool timeout in seconds.

When this property is set to a non-negative value, it is compared to the time that has elapsed since a server session was used. If the timeout value is less than the elapsed time, the server session is removed from the server session pool and its JMS session is returned to the JMS session pool. For example, if the timeout value is one second and the time that has elapsed since a particular server session was used is two seconds, that server session is removed from the server session pool and its JMS session is returned to the JMS session pool.

The **SERVER.SESSION.POOL.UNUSED.TIMEOUT** custom property is not applicable if your messaging system is running in non-ASF mode.

Data type	Integer
Units	Seconds
Default	-1 (disabled)
Range	-2147483648 through 2147483647

SERVER.SESSION.POOL.UNUSED.TIMEOUT.lpname:

This property overrides the default **SERVER.SESSION.POOL.UNUSED.TIMEOUT** value for the listener port with the name defined for *lpname*. This value applies to all message-driven beans that use the specified listener port.

If this override is set to a non-negative value, it overrides the **SERVER.SESSION.POOL.UNUSED.TIMEOUT** property, even if the **SERVER.SESSION.POOL.UNUSED.TIMEOUT** property has a negative value.

If this override is set to a negative value, it disables server session pool monitoring for the specified listener port.

The **SERVER.SESSION.POOL.UNUSED.TIMEOUT.lpname** custom property is not applicable if your messaging system is running in non-ASF mode.

Data type	Integer
Units	Seconds
Default	Not set
Range	-2147483648 through 2147483647

Administering listener ports

You can use the WebSphere Application Server administrative console to administer listener ports, which each define the association between a connection factory, a destination, and a message-driven bean.

Before you begin

If you want to use message-driven beans with a messaging provider that does not have a JCA 1.5 resource adapter, you cannot use activation specifications and therefore you must configure your beans against a listener port. There are also a few scenarios in which, although you could use activation specifications, you might still choose to use listener ports. For example, for compatability with existing message-driven bean applications.

If you have existing message-driven beans that use the WebSphere MQ messaging provider (or a compliant third-party JMS provider) with listener ports, and instead you want to use EJB 3 message-driven beans with listener ports, these new beans can continue to use the same messaging provider.

For more information about when to use listener ports rather than activation specifications, see Message-driven beans, activation specifications, and listener ports.

About this task

A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. If you set the initial state of a listener port to Started, the listener port is started automatically when a message-driven bean associated with that port is installed.

Listener ports can be manually started and stopped. If a message-driven bean fails to process a message several times, the listener port is automatically stopped by the application server. When a listener port is stopped, the listener manager stops the listeners for all message-driven beans associated with the port. Consequently, the associated message-driven beans can no longer process messages.

Note: You do not usually need to start or stop a listener port manually.

Procedure

- Create a new listener port.

  Create a new listener port, to specify a new association between a connection factory, a destination, and a message-driven bean. This association enables deployed message-driven beans associated with the port to retrieve messages from the destination.
- Configure a listener port.

  Browse or change the configuration properties of a listener port.
- Start a listener port.
- Stop a listener port.
- Delete a listener port.

Creating a new listener port:

You create a new listener port for the message listener service to define the association between a connection factory, a destination, and a deployed message-driven bean. This association enables the message-driven bean to retrieve messages from the associated destination.

Before you begin

If you want to use message-driven beans with a messaging provider that does not have a JCA 1.5 resource adapter, you cannot use activation specifications and therefore you must configure your beans against a listener port. There are also a few scenarios in which, although you could use activation specifications, you might still choose to use listener ports. For example, for compatability with existing message-driven bean applications.

If you have existing message-driven beans that use the WebSphere MQ messaging provider (or a compliant third-party JMS provider) with listener ports, and instead you want to use EJB 3 message-driven beans with listener ports, these new beans can continue to use the same messaging provider.

For more information about when to use listener ports rather than activation specifications, see Message-driven beans, activation specifications, and listener ports.

About this task

A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. This association enables deployed message-driven beans associated with the port to retrieve messages from the destination. For more information, see Message-driven beans - listener port components.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Servers** > **Server Types** > **WebSphere application servers->*server_name*** > **[Communications] Messaging** > **Message listener service** > **[Additional Properties] Listener Ports**. The “Message listener port collection” on page 425 panel is displayed.
3. Click **New**.
4. Specify the following required properties:

   Name The name by which the listener port is known for administrative purposes.

   Connection factory JNDI name
   The JNDI name for the JMS connection factory to be used by the listener port; for example, `jms/connFactory1`.

   Destination JNDI name
   The JNDI name for the destination to be used by the listener port; for example, `jms/destn1`.
5. Optional: Change other properties for the listener port, as required.
6. Click **OK**.
7. Save your changes to the master configuration.
8. To have the changed configuration take effect, stop then restart the application server.

Results

If you set the initial state of a listener port to Started, the listener port is started automatically when a message-driven bean associated with that port is installed.

Configuring a listener port:

Use this task to browse or change the properties of an existing listener port, which is used by message-driven beans associated with the port to retrieve messages.

Before you begin

If you want to use message-driven beans with a messaging provider that does not have a JCA 1.5 resource adapter, you cannot use activation specifications and therefore you must configure your beans against a listener port. There are also a few scenarios in which, although you could use activation specifications, you might still choose to use listener ports. For example, for compatability with existing message-driven bean applications. For more information about when to use listener ports rather than activation specifications, see Message-driven beans, activation specifications, and listener ports.

About this task

A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. This association enables deployed message-driven beans associated with the port to retrieve messages from the destination. For more information, see Message-driven beans - listener port components.

When you deploy an enterprise application to use message-driven beans with listener ports, you can browse or change the configuration of a listener port.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Servers** > **Server Types** > **WebSphere application servers->*server_name*** > **[Communications] Messaging** > **Message listener service** > **[Additional Properties] Listener Ports**

   The “Message listener port collection” panel is displayed.
3. Select the name of the listener port that you want to work with. This displays the properties of the listener port in the content pane.
4. Optional: Change properties for the listener port, according to your needs.
5. Click **OK**.
6. Save your changes to the master configuration.
7. To have a changed configuration take effect, stop then restart the application server.

Message listener port collection:

The message listener ports configured in the administrative domain

A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. This association enables deployed message-driven beans associated with the port to retrieve messages from the destination.

This panel displays a list of the message listener ports configured in the administrative domain. You can use this panel to add new listener ports or to change the properties of existing listener ports.

To view this administrative console panel, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Messaging] Message Listener Service** > **Listener Ports**

To manage a listener port, select the check box beside the listener port name in the list and click a button:

Button	Resulting action
Convert to activation specification	Opens a wizard that helps you convert the selected listener port to an activation specification.
New	Accesses the panel to configure a new listener port.
Delete	Deletes the selected listener port or ports.
Start	Starts the selected listener port or ports.
Stop	Stops the selected listener port or ports.

Listener port settings:

A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. This association enables deployed message-driven beans associated with the port to retrieve messages from the destination.

Use this panel to view or change the configuration properties of the selected listener port.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Communications] Messaging** > **Message Listener Service** > **Listener Ports** > ***listener_port***.

Name:

The name by which the listener port is known for administrative purposes.

Data type String
Default Null

Initial state:

The state that you want the listener port to have when the application server is next restarted

Data type Enum
Units Not applicable
Default Started
Range

Started
When the application server is next started, the listener port is started automatically.

Stopped
When the application server is next started, the listener port is not started automatically. If message-driven beans are to use this listener port on the application server, the system administrator must start the port manually or select the Started value of this property then restart the application server.

Description:

A description of the listener port, for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

Connection factory JNDI name:

The JNDI name for the JMS connection factory to be used by the listener port; for example, jms/connFactory1.

Data type String
Default Null

Destination JNDI name:

The JNDI name for the destination to be used by the listener port; for example, jms/destn1.

You cannot use a temporary destination for late responses.

Data type String
Default Null

Maximum sessions:

The maximum number of concurrent sessions that a listener can have with the JMS server to process messages.

Each session corresponds to a separate listener thread and therefore controls the number of concurrently processed messages. Adjust this parameter when the server does not fully use the available capacity of the machine.

Data type	Integer
Units	Sessions
Default	1
Range	1 through 2147483647
Recommended	• For message concurrency, that is to process multiple messages simultaneously, set this property to a value greater than 1. Keep this value as low as possible to prevent overloading client applications. A good starting point for a 100% JMS workload with short transaction times is 2 to 4 sessions per processor. If longer running transactions exist, you might need more sessions, which should be determined by experimentation. The total number of sessions specified in the Maximum Sessions property of all configured listener ports must be less than or equal to the number of threads specified for the Maximum Size property of the message listener service thread pool.

Maximum retries:

The maximum number of times that the listener tries to deliver a message to a message-driven bean instance before the listener is stopped, in the range 0 through 2147483647.

Note: A WebSphere MQ queue has a similar property called the **BackoutThreshold** property. If your listener port is reading from a WebSphere MQ queue, then the retry limit and the behavior when the limit is reached is determined by whichever of these two properties is set to the lower limit:

- If you exceed the WebSphere MQ queue **BackoutThreshold** limit, the message that cannot be delivered is moved to somewhere else by WebSphere MQ (for example, to the WebSphere MQ backout requeue queue or the WebSphere MQ dead letter queue) and the listener port services the next message on the queue. In this case, WebSphere Application Server might not know that the message has not been delivered successfully.
- If you exceed the listener port **maximum retries** limit, the listener port stops. You then manually intervene to investigate the problem, possibly to remove the message from the WebSphere MQ queue then restart the listener port.

Data type	Integer
Units	Retry attempts
Default	0 (no retries)
Range	0 (no retries) through 2147483647

Maximum messages:

The maximum number of messages that the listener can process in one transaction.

If the queue is empty, the listener processes each message when it arrives. Each message is processed within a separate transaction.

For the WebSphere V5 default messaging provider or WebSphere MQ as the JMS provider, if messages start accumulating on the queue then the listener can start processing messages in batches. For third-party messaging providers, this property value is passed to the JMS provider but the effect depends on the JMS provider.

Data type	Integer
Units	Number of messages
Default	1
Range	1 through 2147483647
Recommended	For the WebSphere default messaging providers or WebSphere MQ as the JMS provider, to process multiple messages in a single transaction, set this value to more than 1. If messages start accumulating on the queue, a value greater than 1 enables multiple messages to be batch-processed into a single transaction, and eliminates much of the transaction processing costs for JMS messages. **CAUTION:** • If one message in the batch fails processing with an exception, the entire batch of messages is put back on the queue for processing. • Any resource lock held by any of the interactions for the individual messages are held for the duration of the entire batch. • Depending on the amount of processing that messages need, and if XA transactions are being used, setting a value greater than 1 can cause the transaction to time out. If an XA transaction does time out routinely because processing multiple messages exceeds the transaction timeout, reduce this property to 1 (to limit processing to one message per transaction) or increase your transaction timeout.

Starting a listener port:

Use this task to start a listener port on an application server, to enable the listeners for message-driven beans associated with the port to retrieve messages.

About this task

A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. For more information, see Message-driven beans - listener port components.

A listener is active, that is able to receive messages from a destination, if the deployed message-driven bean, listener port, and message listener service are all started. Although you can start these components in any order, they must all be in a started state before the listener can retrieve messages.

If you set the initial state of a listener port to Started, the listener port is started automatically when a message-driven bean associated with that port is installed. You can also start a listener port manually.

When a listener port is started, the listener manager tries to start the listeners for each message-driven bean associated with the port. If a message-driven bean is stopped, the port is started but the listener is not started, and remains stopped. If you start a message-driven bean, the related listener is started.

Procedure

1. Start the administrative console.
2. If you want the listener for a deployed message-driven bean to be able to receive messages at the port, check that the message-driven bean has been started.
3. In the navigation pane, click **Servers** > **Server Types** > **WebSphere application servers->*server_name*** > **[Communications] Messaging** > **Message listener service** > **[Additional Properties] Listener Ports**

   The “Message listener port collection” on page 425 panel is displayed.
4. Select the check box for the listener port that you want to start.
5. Click **Start**.
6. Save your changes to the master configuration.

Stopping a listener port:

Use this task to stop a listener port on an application server, to prevent the listeners for message-driven beans associated with the port from retrieving messages.

About this task

A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. For more information, see Message-driven beans - listener port components.

If a message-driven bean fails to process a message several times, the listener port is automatically stopped by the application server. You can also stop a listener port manually. When a listener port is stopped, the listener manager stops the listeners for all message-driven beans associated with the port. Consequently, the associated message-driven beans can no longer process messages.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Servers** > **Server Types** > **WebSphere application servers->*server_name*** > **[Communications] Messaging** > **Message listener service** > **[Additional Properties] Listener Ports**

   The “Message listener port collection” on page 425 panel is displayed.
3. Select the check box for the listener port that you want to stop.
4. Click **Stop**.
5. Save your changes to the master configuration.
6. To have the changed configuration take effect, stop then restart the application server.

Deleting a listener port:

Use this task to delete a listener port from the message listener service, to prevent message-driven beans associated with the port from retrieving messages.

About this task

A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. For more information, see Message-driven beans - listener port components.

To delete a listener port, use the administrative console to complete the following steps:

Procedure

1. Start the administrative console.

2. In the navigation pane, click **Servers** > **Server Types** > **WebSphere application servers->*server_name*** > **[Communications] Messaging** > **Message listener service** > **[Additional Properties] Listener Ports**

   The “Message listener port collection” on page 425 panel is displayed.
3. Select the check box for the listener port that you want to delete.
4. Click **Delete**.

   This action stops the port (needed to allow the port to be deleted) then deletes the port.
5. Save your changes to the master configuration.
6. To have the changed configuration take effect, stop then restart the application server.

Monitoring server session pools for listener ports:

You can minimize the number of resources that server sessions use by enabling server session pool monitoring and defining the timeout value to be applied to a server session.

About this task

Each listener port uses one or more server sessions, which are held in a server session pool. Each server session is associated with a JMS session, which is taken from the JMS session pool that is associated with the JMS connection factory that the listener port is configured to use.

By default, server session pool monitoring is disabled. When a listener port uses a server session the listener port does not release the server session from the server session pool until the listener port is shut down. This means that the associated JMS session is not released into the JMS session pool until the listener port is shut down, even if the listener port is not processing any messages. Consequently the resources that the JMS session uses, for example TCP/IP connections, can be held for a long time, and this can cause problems for resource-constrained systems.

To minimize the number of resources that server sessions use, you must monitor the server session pools. When you enable server session pool monitoring each server session in each server session pool that a listener port uses is monitored to determine how much time has elapsed since the server session was last used. If the elapsed time is greater than the timeout value that you have configured, the server session is removed from the server session pool and its associated JMS session is returned to the JMS session pool. The returned JMS session can be either reused by another application or closed, depending on your JMS session pool settings. You can also configure additional pooling mechanisms, depending on your JMS provider.

Note: Server session pool monitoring cannot be used if the message listener service is operating in non-Application Server Facilities (non-ASF) mode, that is if the NON.ASF.RECEIVE.TIMEOUT message listener service custom property is set to a non-zero value.

Procedure

To enable server session pool monitoring, configure the following message listener service custom properties on each application server as required.

SERVER.SESSION.POOL.REAP.TIME
: To enable server session pool monitoring, set this property to the time in seconds between checks on server session pools (this must be a non-negative value).

SERVER.SESSION.POOL.UNUSED.TIMEOUT
: To specify the default server session pool timeout, set this property to the required number of seconds for the timeout. When this property is set to a non-negative value, it is compared with the time that has elapsed since a server session was used. If the timeout value is less than the elapsed time, the server session is removed from the server session pool and its JMS session is returned to the JMS session pool. For example, if the timeout value is one second and the time

that has elapsed since a particular server session was used is two seconds, that server session is removed from the server session pool and its JMS session is returned to the JMS session pool.

SERVER.SESSION.POOL.UNUSED.TIMEOUT.*lpname*
To override the default SERVER.SESSION.POOL.UNUSED.TIMEOUT value for the listener port with the name *lpname*, set this property to the appropriate value:

- To override the SERVER.SESSION.POOL.UNUSED.TIMEOUT for the specified listener port, set this property to a non-negative value defining the required number of seconds for the server session timeout for this listener port.
- To disable server session pool monitoring for the specified listener port, set this property to a negative value.

The value that you set for this property applies to all message-driven beans that are using the specified listener port.

Example

For example, consider an application server that is configured with listener ports lp1, and lp2.

The following rules apply:

No properties set
If none of the properties are set, server session pool monitoring is disabled and JMS sessions used by server sessions are not returned to the JMS session pool until the listener port (lp1 or lp2), or its associated message-driven bean, is shut down.

SERVER.SESSION.POOL.REAP.TIME and SERVER.SESSION.POOL.UNUSED.TIMEOUT set
Consider, for example, the following settings:

SERVER.SESSION.POOL.REAP.TIME=60

SERVER.SESSION.POOL.UNUSED.TIMEOUT=120

The server session pool of both listener ports (lp1 and lp2) is checked for inactive server sessions every 60 seconds. If a server session is detected as being inactive for more than 120 seconds, it is removed from the server session pool and its JMS session is returned to the JMS session pool. Taking into account the SERVER.SESSION.POOL.REAP.TIME value, the server session pool could be removed from the session pool between two and three minutes after the server session was last used.

SERVER.SESSION.POOL.REAP.TIME and SERVER.SESSION.POOL.UNUSED.TIMEOUT set, and overrides set for SERVER.SESSION.POOL.UNUSED.TIMEOUT.*lpname*
Consider, for example, the following settings:

SERVER.SESSION.POOL.REAP.TIME=60

SERVER.SESSION.POOL.UNUSED.TIMEOUT=120

SERVER.SESSION.POOL.UNUSED.TIMEOUT.lp2=-1

SERVER.SESSION.POOL.UNUSED.TIMEOUT.lp1=60

The server session pool for listener port lp2 is not checked because it has a negative timeout value. In the server session pool for listener port lp1, any server sessions that are inactive for more than 60 seconds are removed from the server session pool.

Administering applications that use the Java Persistence API

Configure JPA to work in your environment

You have developed your applications to work with Java Persistence API (JPA) and now you must configure your JPA applications to work in your environment.

About this task

You must specify options for your database as a part of configuring JPA applications. The application server manages access to data sources. You can configure the data sources, connection pooling, and Java Transaction API (JTA) service in the administrative console. If you have a specific data source for your application, configure the data source before you install your JPA application.

Procedure

1. Configure your data sources through the administrative console. See the topic, Configuring a JDBC provider and data source.
2. Specify the Java Naming and Directory Interface (JNDI) names for the `<jta-data-source>` and `<non-jta-data-source>` elements. For example to use JNDI lookup:

   ```
   <jta-data-source>jdbc/myJTADataSource</jta-data-source>
   <non-jta-data-source>jdbc/myNonJTADataSource</non-jta-data-source>
   ```

   If you use the component name space method (for example, java:comp/env) for data source retrieval, ensure that your application defines these resource references so that you can use these JNDI names to access the data source. This component name space configuration provides more flexibility if you must alter the configuration for the data source. Otherwise, the standard, direct JNDI is used as the data source name. For more information about using the JNDI interface, see the topic, Developing applications that use JNDI. For example, the `persistence.xml` file would have an entry like the following:

   ```
   <jta-data-source>java:comp/env/jdbc/DataSourceJNDI</jta-data-source>
   ```

   OR

   ```
   <jta-data-source>jdbc/DataSourceJNDI</jta-data-source>
   ```
3. Configure persistence provider support in the application server.
   a. “Configuring the JPA default persistence provider” on page 437.
   b. Optional: “Using third-party persistence providers” on page 440.

What to do next

For more information about the commands, classes or other OpenJPA information, refer to the Apache OpenJPA User Guide.

Configuring a JDBC provider and data source

For access to relational databases, applications use the Java Database Connectivity (JDBC) drivers and data sources that you configure for the application server.

Before you begin

Each vendor database requires different JDBC driver implementation classes for JDBC connectivity. A JDBC provider encapsulates those vendor-specific driver files. Through the data source that you associate with the JDBC provider, an application server obtains and manages the physical connections for transactions between applications and the database.

Attention: If you are accessing a DB2 database, IBM Optim pureQuery Runtime is an alternative to JDBC. For more information on pureQuery, see the topic, Task overview: IBM Optim pureQuery Runtime, in the related links section.

Before starting this task, determine the version of data source that you need according to the API specification of your applications.

- *Data sources (WebSphere Application Server Version 4)* are for use with the Enterprise JavaBeans (EJB) 1.0 specification and the Java Servlet 2.2 specification.

- Data sources of the latest standard version are for use with applications that implement the more advanced releases of these specifications.

Procedure

1. Verify that all of the necessary JDBC driver files are installed on your application server. Consult the article, Data source minimum required settings, by vendor for that information. If you opt to configure a user-defined JDBC provider, check your database documentation for information about the driver files.
2. Create a JDBC provider.

   When you create a JDBC provider from the administrative console, see the topic, Configuring a JDBC provider using the administrative console.

   OR

   Using the wsadmin scripting client, see the topic, Configuring a JDBC provider using the scripting.

   OR

   Using the Java Management Extensions (JMX) API, see the topic, Creating a JDBC provider and data source using the JavaManagement Extensions API.
3. Create a data source.

   From the administrative console, see the topic, Creating a data source using the administrative console.

   OR

   Using the wsadmin scripting client, see the topic, Configuring new data sources using scripting. For V4 data sources, see the topic, Configuring new WAS40 data sources using scripting.

   OR

   Using the JMX API, see the topic, Creating a JDBC provider and data source using the JavaManagement Extensions API.

   Required properties: Different database vendors require different properties for implementations of their JDBC drivers. Set these properties on the WebSphere Application Server data source. Because Application Server contains templates for many vendor JDBC implementations, the administrative console surfaces the required properties and prompts you for them as you create a data source. However, if you script your data access configurations, you must consult the article Data source minimum required settings, by vendor, for the required properties and settings options.
4. Optional: Configure custom properties. Like the required properties, custom properties for specific vendor JDBC drivers must be set on the Application Server data source. Consult your database documentation for information about available custom properties. To configure a custom class to facilitate the handling of database properties that are not recognized natively by the Application Server, refer to the topic, Developing a custom DataStoreHelper class.

   You can also learn about optional data source properties in the Application Programming Guide and Reference for Java for your version of DB2 for z/OS if you use the DB2 Universal JDBC Driver provider.
5. Bind resource references to the data source. See the article, Data source lookups for enterprise beans and web modules.
6. Test the connection (for non-container-managed persistence usage). See the topic, Test connection service.

Results

If you use the DB2 JDBC Universal Driver, you might experience data source failures that the application server JVM log does not document. Check the DB2 database log or the WebSphere Application Server JDBC trace log (if JDBC trace was active). You might find that a bad authentication credential is the cause

of failure. Currently the DB2 JDBC Universal Driver does not identify or surface the errors that are produced by non-valid authentication credentials in a proper or consistent way.

Even if you receive information about a bad credential, check the database and JDBC trace logs. These logs provide more reliable, detailed error data on authentication failures.

Note: The JDBC trace log exists only if the JDBC trace service is active during server start up. Activate the service in the administrative console. For more information, see the topic, Enabling trace at server startup. Specify **WAS.database** as the trace group and select **com.ibm.ws.db2.logwriter** as the trace string.

Configuring data source JDBC providers to use pureQuery in a Java SE environment:

Use this task to configure the application data source Java Database Connectivity (JDBC) provider to use pureQuery to access DB2 in a Java Standard Edition (Java SE) environment.

Before you begin

If you need to use multiple DB2 package collections, see the information center topic, Configure pureQuery to use multiple package collections, before continuing with this task.

About this task

IBM Optim PureQuery Runtime makes use of DB2 packages. These packages include information for one or more Structured Query Language (SQL) statements and are stored in the DB2 catalog. You must first run the wsdbgen command on a Java Persistence API (JPA) application to create the packages. The wsdbgen command creates an XML file containing SQL statement information. This XML file must be included into the application Java archive (JAR) file. The DB2 bind command uses this file as input to create the DB2 package.

Important:

- JPA sets the IBM Optim PureQuery Runtime property `pdq.executionMode` to the value `STATIC`.
- The class path must include the installation location for the IBM Optim PureQuery Runtime. See the information center topic on installing IBM Optim PureQuery Runtime for more information.
- The JPA provider implementation must be JPA for the application server (`com.ibm.websphere.persistence.PersistenceProviderImpl`). The OpenJPA persistence provider does not provide support for pureQuery.
- The wsdbgen command requires the URL of a database. The wsdbgen command forces a synchronize mapping function that creates or alters the required tables. For DB2 zOS, V8 unique indexes and LOB tables must be manually created prior to executing the wsdbgen command.

IBM Optim PureQuery Runtime properties are specified in a `pdq.properties` file in the META-INF directory of the application JAR file. The `pdq.ExecutionMode` property is defaulted to STATIC for JPA applications. You can use the pdqProperties property to use pureQuery in DYNAMIC mode. See the information center topic, Using pureQuery in dynamic mode, for more information. PDQ properties, if specified, pass on to the IBM Optim PureQuery Runtime. See the IBM Optim PureQuery Runtime documentation for list of properties and valid values.

- **wsjpa.jdbc.CollectionId**: String value specifying the collection ID to use. This parameter overrides any collection ID that is used during wsdbgen.

Attention: Read more about the DB2 JAR level compliance for IBM Optim PureQuery Runtime at the IBM Support website: System requirements for IBM Optim PureQuery Runtime for Linux, UNIX, and Windows.

Procedure

1. Update the application data source JDBC provider configuration to include the IBM Optim PureQuery Runtime JAR files. Include the `pdq.jar` and `pdqmgmt.jar` files on the class path in addition to the JDBC driver jar files. Either define a new JDBC provider or modify an existing provider to include the JAR files. The class path must include the installation location for the IBM Optim PureQuery Runtime. See the information center topics on JDBC provider settings and installing IBM Optim PureQuery Runtime for more information.
2. Using the DB2 bind command provided by IBM Optim PureQuery Runtime, bind the XML file to the database. This creates the DB2 packages. Refer to the information center topic on the pureQuery Bind utility for more information.

What to do next

If you want to reconfigure the data source for JDBC, remove the `pdq.jar` and `pdqmgmt.jar` from the class path.

Configuring the default JTA and non-JTA data source JNDI names

The Java Transaction API (JTA) and non-JTA data sources to be used for an application can be specified through the <jta-data-source> and <non-jta-data-source> elements of the `persistence.xml` file within an Enterprise JavaBeans (EJB) module.

About this task

If these elements are not configured in the persistence.xml file, then the default JTA and non-JTA data sources configured for the server are used. These values are null by default. However, the default JTA and non-JTA data source Java Naming and Directory Interface (JNDI) names to be used by applications running on this server can be defined using the administrative console.

Procedure

1. Open the administrative console.
2. Select **Servers** > **Application server** > ***server*** > **Container Services**.
3. Click **Default Java Persistence API settings**.
4. Select the **Default JTA data source JNDI name** or the **Default non-JTA data source JNDI name** field.
5. Click **Apply** to save the configuration.

Associating persistence providers and data sources

Java Persistence API (JPA) applications specify the underlying data source that is used by the persistence provider to access the database.

About this task

The application server provides three methods for defining the data sources in the `persistence.xml` file.

Procedure

- Explicitly specify the Java Naming and Directory Interface (JNDI) name in the `persistence.xml` file, and the application directly references the data source. Switching to another data source requires an update to the `persistence.xml` file.

  JPA has two transactional patterns for accessing a data source:

  – The Java Transaction API (JTA) resource pattern depends on global transactions. The JTA resource pattern is typically used within the scope of an Enterprise JavaBeans (EJB) session facade. This supports the session bean to control transaction and security contexts while JPA handles the persistence mappings. In this case, the application does not use the EntityTransaction interface but relies on the EntityManager enlisted with the global transaction when it is accessed.

– The non-JTA resource pattern is used when dealing with a single resource in the absence of global transactions. The non-JTA resource pattern is typically used within the scope of a web application or an application client. The application controls the transaction with the data source with the EntityTransaction interface.

  Within the application server, the use of the <non-jta-data-source> element requires a special configuration for a non-transactional data source. Data sources that are configured for the application server do not function as a <non-jta-data-source>, because all data sources that are configured by the application server are automatically enlisted with the current transactional context. To prevent this automatic enlistment, add an additional data source custom property `nonTransactionalDataSource=true`:

  1. Select **Resources** > **JDBC** > **Data sources**
  2. Select the name of the data source that you want to configure.
  3. Select **WebSphere Application Server data source properties** from the **Additional Properties** heading.
  4. Select **Non-transactional data source**.
  5. Click **OK**.

Note: The JPA specification assumes that connections are obtained with an isolation level that does not hold long-term locks in the database, such as `READ_COMMITTED`. This might not match the WebSphere Application Server default isolation level, which is `REPEATABLE_READ` for most databases. You can find the level that is used for your database by reading the topic, Requirements for setting isolation level.

If the default for your database is not `READ_COMMITTED`, you can change the default by adding an additional data source custom property webSphereDefaultIsolationLevel.

Table 44. Isolation level values. This table shows valid isolation level values.

Value	Isolation Level
1	READ_UNCOMMITTED
2	READ_COMMITTED (JPA default)
4	REPEATABLE_READ (WebSphere Application Server default)
8	SERIALIZABLE

If the isolation level is set to a value that holds long-term read locks, configure the JPA provider to use Pessimistic Locking instead of the default Optimistic Locking. For the JPA provider included with WebSphere Application Server, you can do this by adding the following properties to `persistence.xml` file:

```
<property name="openjpa.Optimistic"="false"/>
<property name="openjpa.LockManager"=pessimistic"/>
```

The JPA specification mandates that the data sources that are defined in `<jta-data-source>` and `<non-jta-data-source>` elements of a persistence unit register in the JNDI name space. For example, the `persistence.xml` file should contain an entry like the following:

```
<jta-data-source>jdbc/DataSourceJNDI</jta-data-source>
```

- The JPA for WebSphere Application Server solution extends the JNDI data-source implementation to allow you to reference data sources in the component name space. In the EJB or web module deployment descriptor file, this is the <resource-ref> element. You can prefix the data source with java:`comp/env/` so the application indirectly references the data source by using the local JNDI name. In this association, the application does not require updates, you change <resource-ref> to use another data source. See the following example:

  ```
  <jta-data-source>java:comp/env/jdbc/DataSourceJNDI</jta-data-source>
  ```

  Note: The JPA specification does not require implementations to include data sources referenced in local JNDI names, so this method of reference might not be portable to other implementations of JPA.

- You can declare openjpa.Connection* properties in the persistence unit as follows:

```
<property name="openjpa.ConnectionDriverName" value="org.apache.derby.jdbc.EmbeddedDriver" />
<property name="openjpa.ConnectionURL" value="jdbc:derby:target/database/jpa-test-database;create=true"/>
```

OR

You can use alternative standard JPA properties that are equivalent to the OpenJPA properties, such as:

Table 45. Standard JPA 2.0 property equivalents. Standard JPA 2.0 properties and the OpenJPA equivalents.

Standard JPA 2.0	OpenJPA Equivalent
javax.persistence.jdbc.driver	openjpa.ConnectionDriverName
javax.persistence.jdbc.url	openjpa.ConnectionURL

What to do next

For information about configuring data sources, see the topic on creating and configuring a data source.

For information about data sources and JPA, see the section on persistence in the Apache OpenJPA User Guide.

Configuring persistence provider support in the application server

Persistence providers are implementations of the Java Persistence API (JPA) specification and can be deployed in the Java EE compliant application server that supports JPA persistence.

About this task

The Enterprise JavaBeans (EJB) 3.0 and later specifications require that an application server container that supports the EJB 3.0 and later programming model must provide a JPA implementation. This is also referred to as a persistence provider. There are two built-in JPA persistence providers: the JPA persistence provider for the application server and the OpenJPA persistence provider. If an explicit provider element is not specified in the persistence unit definitions, the application server will use the default persistence provider, which is the JPA persistence provider for the application server.

The application server provides both the default persistence provider and the Apache OpenJPA persistence provider to support the open source implementation of JPA and allow for easy migration of existing OpenJPA applications to the application server's solution for JPA.

Procedure

- **Configuring a default persistence provider**

  Use the default persistence provider, or specify a persistence provider for your application. With the application server's JPA persistence provider, you can take advantage of the stability and application extensions that are provided with the application server's implementation of JPA. You can decide which persistence implementation best fits your needs. If an application relies on a specific persistence provider for certain functions and settings, you should specify the provider in the persistence unit definition to avoid any incompatibilities.
- **Using third-party persistence providers**

  Use third-party persistence providers in the application server environment.

Configuring the JPA default persistence provider:

Two persistence providers are included in the product: *JPA for WebSphere Application Server persistence provider* and *Apache OpenJPA persistence provider*. The Java Persistence API (JPA) for WebSphere Application Server persistence provider is the default provider for the product. You can use one of these two providers, or a third-party persistence provider, as the default provider.

About this task

Attention: If you have a default persistence provider, default Java Transaction API (JTA) data source Java Naming and Directory Interface (JNDI) name, and default non-JTA data source JNDI name values that were set in the product before V7.0, through the Java virtual machine (JVM) properties, any change to these values through the administrative console override values that were set with the JVM properties.

These properties include, com.ibm.websphere.jpa.default.provider, com.ibm.websphere.jpa.default.jta.datasource, and com.ibm.websphere.jpa.default.nonjta.datasource. Support for these properties has been deprecated. Any values that were set through these properties are displayed as default values on this panel. These values that are set through the administrative console panel overrides any values set through the JVM properties.

JPA for WebSphere persistence provider

While built from the Apache OpenJPA persistence provider, the JPA for WebSphere Application Server persistence provider contains the following enhancements and differences:

- Static SQL support using the DB2 pureQuery feature
- Access intent support
- Enhanced tracing support
- Version ID generation
- WebSphere product-specific commands and scripts
- Translated message files
- The following table shows how the default values for the JPA for WebSphere Application Server persistence provider configuration properties are different from the Apache OpenJPA provider:

Table 46. Comparison. JPA for WebSphere Application Server persistence provider and Apache OpenJPA provider comparison

Property	Apache OpenJPA default value	JPA for WebSphere Application Server persistence provider default value
openjpa.Compatibility	StrictIdentityValues=false	StrictIdentityValues=true
openjpa.RuntimeUnenhancedClasses	supported	warn
openjpa.DynamicEnhancementAgent	true	false
open.jdbc.DriverDataSource	auto	simple

In addition to the above property overrides, the use of the default JPA for WebSphere Application Server persistence provider also implies the use of the following JPA for WebSphere Application Server classes which override the corresponding classes in Apache OpenJPA:

```
com.ibm.ws.persistence.jdbc.kernel.ConstraintUpdateManager;
com.ibm.ws.persistence.jdbc.kernel.WsJpaJDBCBrokerFactory;
com.ibm.ws.persistence.jdbc.sql.DB2Dictionary;
com.ibm.ws.persistence.jdbc.sql.OracleDictionary;
com.ibm.ws.persistence.jdbc.sql.SQLFactoryImpl;
com.ibm.ws.persistence.jdbc.sql.SQLServerDictionary;
com.ibm.ws.persistence.kernel.WsJpaBrokerImpl;
com.ibm.ws.persistence.kernel.WsJpaFinalizingBrokerImpl;
```

If no JPA provider is configured in the <provider> element of the `persistence.xml` file within an Enterprise JavaBeans (EJB) module, the default JPA provider that is currently configured for this server is used. The product is packaged with the JPA for WebSphere Application Server persistence provider defined as the default provider. However, it is possible to override this default and specify a different default through the administrative console.

You can set your default persistence provider in one of two ways. Use one of the following procedures.

Procedure

1. Select the default JPA provider from a list of providers included with the product.
   a. Open the administrative console.
   b. Click **Servers** > **Application Servers**
   c. Select a *server*.
   d. Click **Container Services** > **Default Java Persistence API Settings**
   e. Select **Select a default persistence provider that is included with WebSphere Application Server**.
   f. Click the slider and select from the list.
   g. Click **Apply** and save the configuration.
2. Specify an alternative default persistence provider through the administrative console
   a. Open the administrative console.
   b. Click **Servers** > **Application Servers**
   c. Select a *server*.
   d. Click **Container Services** > **Default Java Persistence API Settings**
   e. Select **Specify an alternative default persistence provider**.
   f. Enter the fully qualified JPA implementation class name of a JPA persistence provider in the box.
   g. Click **Apply** and save the configuration.

Default Java Persistence API settings:

The Java Persistence API (JPA) specification requires a default provider to be defined. If you have applications that use JPA, it is recommended you use this page to provide default values. To increase the portability of your applications, you can use this page to configure the default JPA settings for applications running on this server instead of defining the <provider> element in each persistence unit in your applications. The JPA settings defined here are used for the persistence unit of an application only when the application does not define the JPA settings for that persistence unit.

Note: Application JPA settings always override the settings on this page.

To view this administrative console page, click **Servers** > **Server types** > **WebSphere application servers** > **server** > **Container Services** > **Default Java Persistence API settings**.

Default persistence provider:

Specify the default persistence provider for the application server container. The default persistence provider can be selected either from a list of providers that are included with the product or a user-specified alternate persistence provider.

Select a persistence provider from the product list or specify a fully package qualified JPA implementation class name of an alternate persistence provider.

Default
com.ibm.websphere.persistence.PersistenceProviderImpl

Note: If an alternate persistence provider is specified as the default, make sure the alternate persistence provider is created in the server. See the information center topic on using a third-party persistence provider.

Default Java Transaction API (JTA) data source Java Naming and Directory Interface (JNDI) name:

Specify the default JTA data source used by persistence units for the application server container.

Select the JNDI name for the data source from the drop down box. The JTA data sources that are currently configured and visible to the application server are available in the drop down box selection.

Default
None

Note: If a default JTA data source is not specified, ensure an appropriate JTA data source is specified in the <jta-data-source> or connection properties field in the <properties> element in the persistence unit.

Default non-JTA data source JNDI name:

Specify the default non-JTA data source used by persistence units for the application server container.

Select the JNDI name for the data source from the drop down box. The data sources that are currently configured, visible to the application server, and are set to "non-transactional" are available in the drop down box selection.

Default
None

Note: Some JPA entity features will require a non-JTA data source to be specified. An example of this is automatic entity identity generation. Ensure a non-JTA data source is configured to match your application needs. For information on configuring a non-JTA data source, see the information center topic on associating persistence units and data sources.

Using third-party persistence providers:

Java Persistence API (JPA) for WebSphere Application Server supports third-party persistence providers in their application server environment.

About this task

Java EE applications that use JPA functions can employ third-party persistence providers other than the providers that are included with the application server. Applications can also specify an Apache OpenJPA provider that is a different version than what is included with the application server, as long as the same version of the JPA specification is supported.

There are two basic means to incorporate third-party providers into an application:
- Embedding the persistence provider inside an application
- Using shared libraries

Depending on your requirements, you can embed a persistence provider inside an application, or place the persistence provider into a shared library.

Procedure
- **Embedding a third-party persistence provider within an application** Sometimes an application design must rely on the implementation of a specific persistence provider. The JPA specification permits embedding of a specific JPA provider within a persistence archive. When building the application, you can assemble a specific version of a provider implementation in the application enterprise archive (EAR) file or in a web application (WAR) file. To embed a third-party persistence provider into an application, you must inspect the application design and all dependent prerequisites. Use the following steps to embed a persistence provider inside an application:
  1. Modify the <provider> element to specify explicitly which persistence provider to use to access the persistence entity.

2. Build the specific version of the third-party persistence provider into the application. To manage the persistence correctly, verify that the EntityManagerFactory and the EntityManager are calling the correct provider. Many providers write startup and version information to standard output, which gets included in the SystemOut.log of the application server. This information can be helpful to determine if a third-party provider is being used by your application.

   Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.
3. To use a third-party JPA provider that was not bundled with the application server, configure the class loader order for your application to load the classes with the application class loader first. This is also required if the third-party JPA provider is defined in a shared library that is assigned to a user-defined class loader on the server. If the class loader is not configured properly, the third-party JPA provider that is included with the application server is not loaded and used by your application.
4. Depending on how you packaged the provider, perform one of the following steps:
   – If you packaged the provider in an EAR file, specify the third-party persistence provider binaries in the Manifest.mf class path in those application modules that needs JPA access.
   – If the provider was bundled in a WAR file, include the necessary provider binaries in the `WEB-INF/lib` directory of the web application.
5. Install your application normally.

This configuration localizes the availability of the provider and limiting it to the application alone. While sometimes necessary, embedding persistence providers increases the application memory footprint accordingly.

- **Using shared libraries to implement a third-party persistence provider** Persistence providers accessed by applications in a global environment can be installed as a shared library for the application server. Depending on your requirements, you can share the library to the server and application. Use the following steps to implement a third-party persistence provider using shared libraries:
  1. Modify the <provider> element to specify explicitly which persistence provider to use to access the persistence entity.
  2. Define the persistence provider in a shared library. See the topic on creating shared libraries for more information.
  3. Associate the shared library with the application class loader, or associate the shared library with the server class loader if the library is accessed by many applications.
  4. Configure the class loader order for your application to load the classes with the application class loader first. This is required if the third-party JPA provider is included in the application or if it is defined in a shared library. If the class loader is not configured properly, the JPA provider that is included with the application server is used by your application instead of the third-party JPA provider.

  When the application starts, the specified persistence provider is resolved. From this point on, all persistence requests are handled by this provider.
- A shared library persistence provider can override an existing persistence provider that is the same type and exists in your application class loader hierarchy. If a shared library persistence provider overrides the persistence provider that is shipped with the product, it is recommended that you use an isolated class loader for the shared library. See the topic, Creating shared libraries, for more information.

Task overview: IBM Optim pureQuery Runtime

IBM Optim pureQuery Runtime provides Java Persistence API (JPA) with an alternative way to access a database. PureQuery supports static Structured Query Language (SQL).

About this task

JPA in the Java EE and Java SE environments provides optional support for the pureQuery runtime environment. PureQuery is a high performance Java data access platform that helps manage applications that access data. PureQuery provides an alternate set of APIs that can be used instead of Java Database Connectivity (JDBC) to access the DB2 and Informix database.

To use this feature on the application server, you must install Data Studio pureQuery runtime version 1.2 or later. If you plan to perform the DB2 bind command from the administrative console, or with the wsadmin tool, you must have pureQuery v1.2 or later. Refer to the IBM Optim pureQuery Runtime information center topic on installing pureQuery Runtime for more information.

You can use pureQuery dynamically. The `pdqxml` file location is specified by the pdqProperties property on the data source or connection URL. For more information, see the topic, Using pureQuery in dynamic mode.

PureQuery uses DB2 packages. These packages consist of information for one or more SQL statements and are stored in the DB2 catalog. To create the packages, the user must first run the wsdbgen command on a JPA application. The wsdbgen command creates a *persistence_unit_name*`.pdqxml` file. This file contains pre-generated SQL statements for Create, Update, Delete, and Retrieve, NamedQueries, and NamedNativeQueries of JPA entities. The *persistence_unit_name*`.pdqxml` file must be bound against database. Associated DB2 packages are generated and the SQL statement is started statically at run time. This *persistence_unit_name*`.pdqxml` file must be included into the application Java archive (JAR) file.

The application server offers support for static SQL for Enterprise JavaBeans (EJB) 2.x and later entity beans with the ejbdeploy SQLj option. With JPA, this feature is offered through pureQuery.

There are several benefits to using pureQuery instead of JDBC and SQLJ. Static SQL offers greater security and control over access to data because applications are only granted authority to execute known SQL. Static SQL offers better resource utilization on the DB2 server because it avoids runtime parsing and optimizing of the SQL statements.

When doing the bind process and when you define your JDBC provider, the following four Java archive (JAR) files must be in the class path:

- `db2jcc_license_cisuz.jar`
- `db2jcc_license_cu.jar`
- `pdq.jar`
- `pdqmgmt.jar`

Attention: Read more about the DB2 JAR level compliance for pureQuery at the IBM Support website: System requirements for IBM Optim pureQuery Runtime for Linux, UNIX, and Windows.

WebSphere Application Server support for pureQuery

Restriction:

- There is no support for the QueryTimeout property specified either through the FetchPlan API or through the property plug-in string for wsjpa.ConnectionFactoryProperties. The QueryTimeout value is ignored if specified.
- There is no support for the QueryTimeout property specified through the FetchPlan API. The QueryTimeout value is ignored if specified.
- OpenJPA large result processing uses JDBC APIs for scrollable cursors.

Important:

- JPA sets the pureQuery property, pdq.executionMode, to the value `STATIC`.

- In addition to the JDBC driver JAR file, the JDBC provider configuration must include the JAR file for the pureQuery runtime environment.
- OpenJPA provides support for application programs to programmatically access and alter the FetchPlan at run time. Altering the fetch plan might result in an SQL that has not been generated by the wsdbgen command at application build time. If this occurs, the SQL is executed dynamically rather than using static SQL from the database package.
- If the user changes the application queries, entity mapping or persistence properties, run the wsdbgen command and bind again. This process generates and binds the updated database packages.
- Input parameter values in JPA queries (with both EJB SQL queries and native SQL queries) cannot be `NULL` values except in the case of update statements `SET` expression values. To search for `NULL` values in a WHERE clause of SELECT, UPDATE or DELETE, then enter the `is null` predicate instead.

Procedure

- Learn how to **"Configuring JDBC providers to use pureQuery to access DB2"**.
- Learn how to **"Configuring JDBC providers to use pureQuery to access Informix" on page 444**.
- Learn how to **"Configuring data source JDBC providers to use pureQuery in a Java SE environment" on page 434**.
- Learn how to **"Using pureQuery in dynamic versus static mode for DB2 and Informix" on page 445**.

Configuring JDBC providers to use pureQuery to access DB2:

Use this task to configure the application data source Java Database Connectivity (JDBC) provider to use pureQuery to access DB2 in a Java EE environment.

Before you begin

If you must use multiple DB2 package collections, see the information center topic configure pureQuery to use multiple package collections before continuing with this task.

About this task

PureQuery uses DB2 packages. These packages consist of information for one or more SQL statements and are stored in the DB2 catalog. You must first run the wsdbgen command on a JPA application to create the packages. The wsdbgen command creates an XML file containing SQL statement information. This XML file must be included into the application Java archive (JAR) file. The DB2 bind command uses this file as input to create the DB2 package .

Important:

- JPA sets the pureQuery property pdq.executionMode to the value `STATIC`.
- The JDBC provider configuration must include the JAR file for the pureQuery runtime environment. This JAR file is in addition to the JDBC driver JAR file. See the information center topic on installing pureQuery run time for more information.
- If this is an XA data source, define a new custom property on the data source where *property_name* = `downgradeHoldCursorsUnderXa` and boolean value = `true`.

Procedure

1. Update the application data source JDBC provider configuration to include the pureQuery runtime JAR file. Either define a new JDBC provider or modify an existing provider to include the following JAR files. See information center topics on JDBC provider settings and installing IBM Optim pureQuery Run time for more information.

- pdq.jar
- pdqmgmt.jar

2. Using the DB2 bind command, bind the XML file to the database. This creates the DB2 packages. There are three ways to do this:
   - Use the wsadmin command. Refer to the information center topic on application management command group for the AdminTask object for more information.
   - Using the administrative console. Refer to the information center topic on SQLj profiles and pureQuery bind files settings for more information.
   - Using the DB2 bind command provided by IBM Optim pureQuery Run time. Refer to the information center topic on the pureQuery Bind utility for more information.

What to do next

If you want to reconfigure the data source for JDBC, remove the pdq.jar and pdqmgmt.jar from the class path.

Configuring JDBC providers to use pureQuery to access Informix:

Use this task to configure the application data source Java Database Connectivity (JDBC) provider to use pureQuery to access Informix in a Java EE environment.

About this task

PureQuery provides heterogeneous batching which performs better than homogeneous batching in JDBC. Applications benefit from heterogeneous batching if updates in a transaction involve many entity types and those entities do not have DB-generated keys. To use pureQuery the JDBC driver must specify the db2jcc.jar file (pureQuery does not work with the Informix legacy JDBC driver, ifxjdbc.jar file) and when using JPA, in the persistence.xml file that is included in the application Java archive (JAR) file must specify the following:

```
<property name="pdqProperties" value="dynamic"/>
```

Important:

- The JDBC provider configuration must include the JAR file for the pureQuery runtime environment. This JAR file is in addition to the JDBC driver JAR file. See the information center topic on installing IBM Optim pureQuery Runtime for more information.
- If this is an XA data source, define a new custom property on the data source where *property_name* = downgradeHoldCursorsUnderXa and boolean value = true.

Procedure

1. Update the application data source JDBC provider configuration to include the pureQuery runtime JAR file. Either define a new JDBC provider or modify an existing provider to include the following JAR files. See information center topics on JDBC provider settings and installing IBM Optim pureQuery Runtime for more information.
   - pdq.jar
   - pdqmgmt.jar
   - db2jcc.jar
2. Ensure that the persistence.xml file included in the application JAR file defines the following property:

   ```
   <property name="pdqProperties" value="dynamic"/>
   ```

   See the topic, Using pureQuery in dynamic mode, for more information.

What to do next

If you want to reconfigure the data source for JDBC, remove the `pdq.jar`, `pdqmgmt.jar`, and `db2jcc.jar` files from the class path and replace these files with the JDBC driver, `ifxjdbc.jar` file.

Using pureQuery in dynamic versus static mode for DB2 and Informix:

Using IBM Optim PureQuery Runtime is another way for Java Persistence API (JPA) to access a DB2 and Informix databases. IBM Optim PureQuery Runtime supports static Structured Query Language (SQL).

Before you begin

Important: BatchLimit is a configurable property. The default value for DB2 is `100` and for Informix the default value is `0`. If you set batchLimit to `0`, batching does not occur. For an application to get heterogenous batching for the Informix database backend, batchLimit is configured in the `persistence.xml` file. An example of how to set batchLimit to `100` is as follows:

```
<property name="openjpa.jdbc.DBDictionary" value="batchLimit=100"/>
```

About this task

The Feature Pack for OSGi Applications and Java Persistence API (JPA) 2.0 introduced support for IBM Optim PureQuery Runtime 2.2.0.2 and later. The new feature added for IBM Optim PureQuery Runtime 2.2.0.3, supports Informix, and DB2 applications to use pureQuery in DYNAMIC mode.

This is achieved by setting up pdqProperties on the data source in the Java Enterprise Edition (Java EE) environment. Or, setting pdqProperties on the connection URL in the Java Standard Edition (Java SE) environment.

If pdqProperties is not defined, pureQuery runs in `compatible` mode, which means that the `pdqxml` file is packaged in the application Java archive (JAR) files.

There are several topics that reference pdqProperties in the IBM Integrated Data Management information center.

Procedure

1. When defining a data source In a Java EE environment, add a custom property pdqProperties and set a string value to valid IBM Optim PureQuery Runtime properties. In the following table, an example of executionMode(DYNAMIC) is shown to use pureQuery dynamic mode. Any valid IBM Optim PureQuery Runtime property can be specified to get dynamic execution. When the pdqProperties contains the pureQuery Xml(*pdqxml-file-location*) property, the IBM Optim PureQuery Runtime uses the SQL in STATIC mode that is found in the pdqxml file. This pureQueryXML property contains the pdqxml file location.

   Attention: It is assumed that the pdqxml file is previously bound against the database.

Table 47. pdqProperties settings for DB2 and Informix examples. pdqProperties settings for DB2 and Informix examples

pdqProperties=	DB2 backend	Informix
executionMode(DYNAMIC)	dynamic execution	dynamic execution

Table 47. pdqProperties settings for DB2 and Informix examples (continued). pdqProperties settings for DB2 and Informix examples

pdqProperties=	DB2 backend	Informix
executionMode(STATIC), pureQueryXML(c:/temp/ItemEJB.pdqxml) **Attention:** executionMODE(DYNAMIC) and executionMode(STATIC) are required for dynamic and static executions. For static execution mode, the pdqxml file specification follows the IBM Optim PureQuery Runtime documentation. pureQueryXML(*pdqxml-file-location*) is one of many ways to specify the pdqxml-file-location.The location of the pdqxml file is the path of the pdqxml file. For example, c:/temp/ItemEJB.pdqxml.	static execution	NA (ignored)

2. In a Java SE environment, pdqProperties can be set on the connectionURL. There are two ways to specify the pdqProperties on the connectionURL:
   a. Use openjpa.connectionProperties For example:

```
<property name="openjpa.ConnectionProperties"
          value="DriverClassName=com.ibm.db2.jcc.DB2Driver,
                                Url='jdbc:db2://localhost:50000/demodb:pdqProperties=
                                    pureQueryXml(C:/wsjpa1/fvt/resources/demo.pdqxml);',
          Username=myid, Password=secret" />
```

   b. Use openjpa.ConnectionURL. For example:

```
<property name="javax.persistence.jdbc.driver" value="com.ibm.db2.jcc.DB2Driver"/>
<property name="javax.persistence.jdbc.url"
          value="jdbc:db2:fvt2:pdqProperties=pureQueryXml(C:/wsjpa1/fvt/resources/demo.pdqxml);"/>
<property name="javax.persistence.jdbc.user" value="myid"/>
<property name="javax.persistence.jdbc.password" value="secret"/>
```

   Attention: The pureQueryXml file location must grant read-write permissions for the IBM Optim PureQuery Runtime to update the file.

   Attention: The data source that is defined to run IBM Optim PureQuery Runtime should not be shared with applications that run SQL in JDBC.
   When pdqProperties is set on the data source of a connection URL, even if the pdqxml file is packaged within the application JAR file, the pdqxml file is ignored. However, if the pdqProperties is not set, the pdqxml file that is in the application JAR file is searched by the runtime (this is the `compatible` mode). If the pdqxml file is found, then the setting is STATIC execution mode. Otherwise, all SQLs are run in JDBC.

Configuring pureQuery to use multiple DB2 package collections:

Set up a pureQuery Java Persistence API (JPA) application to use multiple DB2 package collections.

About this task

It is possible for multiple copies of a database schema to exist. This situation might happen in a partitioned database schema where there is one database for east coast employee data and another database for west coast employee data. In this case, the two databases have the same schema. There might be two databases with two database catalogs. Or there might be only one database, in which case, the high-level qualifier of the table names (the schema name) must be different. Since the schemas are the same, there can be a single set of JPA entities that are used to access both sets of data. There are several ways to configure JPA to handle these situations.

Important: When there are multiple persistence units, either with separate databases or a single database, you must run the wsdbgen command once for each persistence unit.

The following three scenarios exist that require the use of multiple DB2 package collections. If you need more information, read about configuring an application to use IBM Optim PureQuery Runtime.

1. When there are two persistence units with different data source names, using static SQL, two sets of DB2 packages exist: one DB2 package in each database. Since two persistence units exist, two *persistence_unit_name*.pdqxml files for the JPA runtime environment exist.
2. If the tables are in a single database, then two persistence units can also be used. In this case, the data source is the same in both persistence units. However, the schema name property, wsjpa.jdbc.Schema must be different. There are two sets of DB2 packages. Each DB2 package must have a different package name or a different package collection name. Both the wsdb2gen and the DB2 bind command have options to specify the package collection and package names.
3. You can create a single persistence unit, which will eliminate the need to maintain two persistence unit configurations and run the wsdbgen command multiple times. This configuration requires a common package name. Thus the package collection names must be different. Use the createEntityManager(Map map) method, where the map contains the values for the wsjpa.jdbc.Schema and wsjpa.jdbc.CollectionId properties to specify the package collection name and schema name.

Configuring OpenJPA caching to improve performance

The OpenJPA implementation gives you the option of storing frequently used data in the memory to improve performance. OpenJPA provides concurrent data and concurrent query caches that support applications to save persistent object data and query results in memory to share among threads and for use in future queries.

About this task

OpenJPA data cache functionality

The OpenJPA data cache is a cache of persistent object data that operates at the EntityManagerFactory level. This optional-use cache is designed to increase performance while remaining in full compliance with the Java Persistence API (JPA) standard. This means that enabling the caching option can increase the performance of your application, with no changes to your code. The OpenJPA data cache is designed to provide significant performance increases over cacheless operations and ensures that behavior is identical in both cache-enabled and cacheless operations.

When enabled, the cache is examined before accessing the data store. The cache stores data when objects are committed and when persistent objects are loaded from the data store. If operating in a single Java virtual machine (JVM) environment, the JVM maintains and shares a data cache across all EntityManager instances obtained from a particular EntityManagerFactory. The OpenJPA data cache cannot do this in a distributed environment because caches in different JVMs, created from different EntityManagerFactory objects are not synchronized.

Using the OpenJPA cache in a multi-JVM environment can be done by configuring the OpenJPA second level (L2) cache provider plug-in. See the topic, Dynamic cache provider for the JPA 2.0 second level cache, and the section "Using the dynamic cache L2 Cache Provider in a clustered environment", for more information. Configuring the DynaCache plug-in allows for the Data and Query cache content to be replicated and consistent across JVMs. Other alternatives include setting up an event notification framework or using a third-party distributed cache such as IBM WebSphere eXtreme Scale.

Enabling and configuring the OpenJPA data cache

You can enable the OpenJPA data cache for a single or a multiple JVM environment, set its default element size, including soft references, and specify **timeout** values.

To set up and configure the OpenJPA data cache, do the following:

1. To enable the cache for a single JVM, set the openjpa.DataCache property to `true`, and set the openjpa.RemoteCommitProvider property to `sjvm`:

   ```
   <property name="openjpa.DataCache" value="true"/>
   <property name="openjpa.RemoteCommitProvider" value="sjvm"/>
   ```

   To enable the data cache in a distributed environment, the openjpa.RemoteCommitProvider must be configured specifically for the environment, or a third-party cache management utility can be used.
2. The maximum cache size can be adjusted by setting the CacheSize property:

   ```
   <property name="openjpa.DataCache" value="true(CacheSize=5000...
   ```

   By default, the OpenJPA data cache holds 1000 elements. Objects that are pinned into the cache are not counted when determining if the cache size exceeds its maximum size. If the cache overflows, it evicts random elements. You can preserve evicted elements longer with the SoftReferenceSize property. By default, soft references are unlimited. If you must, you can limit the number of soft references or set to 0 to disable soft references completely:

   ```
   <property name="openjpa.DataCache" value="true(CacheSize=5000 SoftReferenceSize=0 ...
   ```
3. You can specify that a cache is cleared at certain times. The EvictionSchedule property of the OpenJPA cache implementation accepts a cron style eviction schedule. The cron format specifies the minute, hour of day, day of month, day of month, and day of the week beginning with 1 for Sunday; the * symbol (asterisk), indicates match all. To schedule a cache to evict at 45 minutes past 3 PM on Sunday every month you would add this property:

   ```
   <property name="openjpa.DataCache" value="true(CacheSize=5000 SoftReferenceSize=0 EvictionSchedule='15,45 * * 1'")/>
   ```
4. You also can specify a cache timeout value for a single class by setting the timeout metadata extension to the amount of time in milliseconds that the data of the class is valid; for example:

   ```
   @Entity
   @DataCache(timeout=10000)
   public class Employee {
       ...
   }
   ```

   Refer to the org.apache.openjpa.persistence.DataCache Javadoc for more information.

After configuring your data cache, you can use it after you restart your application.

Refresh with active DataCache

Refreshing an entity may lead to different behavior with or without a DataCache when a separate process or part of the same application are updated or even deleted the corresponding record in the database. By default, entities are refreshed from the database even when DataCache is active. Therefore, with the default configuration the refresh behaves identically with or without a DataCache. However, a persistence unit can be configured to refresh entities from DataCache with the property openjpa.RefreshFromDataCache for improved performance. Under this configuration, any out-of-band changes that occur in the database record do not appear in the refreshed state of the entity.

Note: Regardless of the **openjpa.RefreshFromDataCache** setting, the DataCache is always bypassed for refresh when locks are active, such as for a pessimistic transaction, in a persistence context. An application may activate **openjpa.RefreshFromDataCache** but can still bypass the DataCache while refreshing an entity by explicitly evicting the entity from DataCache before refresh.

Query Caching functions

OpenJPA provides a concurrent query cache that supports applications to save persistent object data and query results in memory to share among threads and for use in future queries. The query cache stores the object IDs returned by query executions. When you run a query, OpenJPA assembles a key based on the query properties and the parameters used at execution time, and checks for a cached query result. If one

is found, the object IDs in the cached result are looked up, and the resultant persistence-capable objects are returned. Otherwise, the query is executed against the database, and the object IDs loaded by the query are put into the cache.

Configuring or disabling the query cache

You can configure the query cache settings in a similar way to the data cache. The interface provided to the query cache is the org.apache.openjpa.persistence.QueryResultCache class. You can access this class through the OpenJPAEntityManagerFactory.

The default query cache implementation caches 100 query executions in a *least-recently-used* cache. This can be changed by setting the cache size in the CacheSize plug-in property. Like the data cache, the query cache also has a backing soft reference map that can be changed using the SoftReferenceSize property. To keep queries in the cache at all times, you can pin them to a cache. To change the query cache properties do the following:

1. Modify the CacheSize property of the openjpa.QueryCache:
   ```
   <property name="openjpa.QueryCache" value="true("CacheSize=1000, ...
   ```
2. Change the SoftReferenceSize property to enable and control the size of this map:
   ```
   <property name="openjpa.QueryCache" value="true(CacheSize=1000, SoftReferenceSize=100")/>
   ```

   The SoftReferenceSize table is disabled by default. Setting the size enables it.
3. Pin or unpin queries in the cache through the QueryResultCache with this syntax:
   ```
   public void pin(Query q);
   public void unpin(Query q);
   ```

Modifying these properties allows you to make better use of the query cache.

Extending a cache

OpenJPA provides classes that may be extended for further functionality.

- As previously mentioned, if you want to implement a distributed cache that uses an unsupported method for communications, create an implementation of org.apache.openjpa.event.RemoteCommitProvider.
- If you are adding new behavior, extend org.apache.openjpa.datacache.DataCacheImpl.
- To use your own storage mechanism, extend org.apache.openjpa.datacache.AbstractDataCache.
- To add query functionality, you can extend the default org.apache.openjpa.datacache.QueryCacheImpl.
- Implement your own storage mechanism for query results by extending org.apache.openjpa.datacache.AbstractQueryCache

OpenJPA query SQL cache

OpenJPA provides a cache that provides caching of SQL strings used by find operations performed on the entity manager and some queries to manage eagerly fetched relationships. When this cache is enabled, SQL queries used by these operations are generated one time per entity manager factory and can be reused. This cache is enabled by default but can also be configured through the openjpa.jdbc.QuerySQLCache configuration property.

Configuring or disabling the SQL query cache

The query SQL cache can be configured or disabled through the openjpa.jdbc.QuerySQLCache property. By default, this property is set to `true`. When the property is set to `true`, the cache is enabled and uses the org.apache.openjpa.util.CacheMap class for its cache store. The CacheMap is a managed cache, meaning that it limits the number of cache entries and has a cache eviction scheme to manage memory usage. If the cache is set to all the org.apache.openjpa.lib.util.ConcurrentHashMap class is used as a

cache store. The ConcurrentHashMap is not a managed cache so entries remain in the cache for the lifetime of an entity manager factory. This caching mechanism can provide better performance at the expense of increased memory usage. A custom cache store class can also be specified if it implements the java.util.Map interface. To disable the cache, specify the value `false`. See the following examples on how to configure or disable the SQL query cache:

- To use an unmanaged cache:

  ```
  <property name="openjpa.jdbc.QuerySQLCache" value="all"/>
  ```

- To specify a custom cache class:

  ```
  <property name="openjpa.jdbc.QuerySQLCache" value="com.mycompany.MyCustomCache"/>
  ```

- To use an unmanaged cache:

  ```
  <property name="openjpa.jdbc.QuerySQLCache" value="false"/>
  ```

What to do next

You can read more about Caching in the OpenJPA for all caching extensions in the Apache OpenJPA User Guide.

Chapter 10. Administering Internationalization service

This page provides a starting point for finding information about globalization and the internationalization service, a WebSphere extension for improving developer productivity.

With the internationalization service, you can automatically recognize the time zone and location information of the calling client so that your application can act appropriately. The technology enables you to deliver each user, around the world, the right date and time information, the appropriate currencies and languages, and the correct date and decimal formats.

This documentation also includes information about internationalizing interface strings using the localizable-text application programming interface. More introduction...

Task overview: Globalizing applications

An application that can present information to users according to regional cultural conventions is said to be *globalized*: The application can be configured to interact with users from different localities in culturally appropriate ways. In a globalized application, a user in one region sees error messages, output, and interface elements in the requested language. Date and time formats, as well as currencies, are presented appropriately for users in the specified region. A user in another region sees output in the conventional language or format for that region. Globalization consists of two phases: *internationalization* (enabling an application component for multicultural support) and *localization* (translating and implementing a specific regional convention). This product supports globalization through the use of its localizable-text API and internationalization service.

Procedure

- Make sure the server runtime environment is properly configured.

  For more information about supported locales and character encodings, see “Working with locales and character encodings” on page 453.
- Implement message catalogs in your application by using the localizable-text API.

  This product supports the maintenance and deployment of centralized message catalogs for the output of properly formatted, language-specific (*localized*) interface strings.

  For more information about the localizable-text API, see “Task overview: Internationalizing interface strings (localizable-text API)” on page 455.
- Implement more extensive locale support by using the internationalization service.

  With the internationalization service, you can manage the distribution of the internationalization information, or *internationalization context*, that is necessary to support globalized Java Platform, Enterprise Edition (Java EE) application components. Supported application components also include web service client environments and web service-enabled enterprise beans.

  For more information about the internationalization service, see “Task overview: Internationalizing application components (internationalization service)” on page 467.

Globalization

An application that can present information to users according to regional cultural conventions is said to be *globalized*: The application can be configured to interact with users from different localities in culturally appropriate ways. In a globalized application, a user in one region sees error messages, output, and interface elements in the requested language. Date and time formats, as well as currencies, are presented appropriately for users in the specified region. A user in another region sees output in the conventional language or format for that region. Globalization consists of two phases: *internationalization* (enabling an application component for multicultural support) and *localization* (translating and implementing a specific regional convention).

Historically, the creation of globalized applications has been restricted to large corporations writing complex systems. However, given the rise in distributed computing and in the use of the World Wide Web, application developers are pressured to globalize a much wider variety of applications. This trend requires making globalization techniques much more accessible to application developers.

Internationalization of an application is driven by two variables, the time zone and the locale. The *time zone* indicates how to compute the local time as an offset from a standard time like Greenwich Mean Time. The *locale* is a collection of information about language, currency, and the conventions for presenting information like dates. A time zone can cover many locales, and a single locale can span time zones. With both time zone and locale, the date, time, currency, and language for users in a specific region can be determined.

By convention, a given locale is specified with a pair of codes (for language and region) that are governed by different standards. The ISO-639 standard governs the language code; the ISO-3166 standard governs the regional code. In notation, the two codes are typically joined by an underscore (_) character, for example, en_US for English in the United States. In Java code, locales are set and retrieved by means of the java.util.Locale class.

A first step: Localization of interface strings

In an application that is not globalized, the user interface is unalterably written into the application code. Internationalizing a user interface adds a layer of abstraction into the design of an application. The additional layer of abstraction enables you to localize the application for each locale that must be supported by the application.

In a localized application, the locale determines the message catalog from which the application retrieves message strings. Instead of printing an error message, the application represents the error message with some language-neutral information; in the simplest case, each error condition corresponds to a key. To print a usable error message, the application looks up the key in a *message catalog*. Each message catalog is a list of keys with associated strings. Different message catalogs provide strings for the different languages that are supported. The application looks up the key in the appropriate catalog, retrieves the corresponding error message in the requested language, and prints the string for the user.

Localization of text can be used for far more than translating error messages. For example, by using keys to represent each element in a graphical user interface (GUI) and by providing the appropriate message catalogs, the GUI (buttons, menus, and so on) can support multiple languages. Extending support to additional languages requires that you provide message catalogs for those languages; in many cases, the application needs no further modification.

The localizable-text package is a set of Java classes and interfaces that can be used to localize the strings in distributed applications easily. Language-specific string catalogs can be stored centrally so that they can be maintained efficiently.

Globalization challenges in distributed applications

With the advent of Internet-based business computational models, applications increasingly consist of clients and servers that operate in different geographical regions. These differences introduce the following challenges to the task of designing a solid client-server infrastructure:

Clients and servers can run on computers that have different endian architectures or code sets

Clients and servers can reside in computers that have different endian architectures: A client can reside in a little-endian CPU, while the server code runs in a big-endian one. A client might want to call a business method on a server running in a code set different from that of the client.

A client-server infrastructure must define precise endian and code-set tracking and conversion rules. The Java platform has nearly eliminated these problems in a unique way by relying on its

Java virtual machine (JVM), which encodes all of the string data in UCS-2 format and externalizes everything in big-endian format. The JVM uses a set of platform-specific programs for interfacing with the native platform. These programs perform any necessary code set conversions between UCS-2 and the native code set of a platform.

Clients and servers can run on computers with different locale settings

Client and server processes can use different locale settings. For example, a Spanish client might call a business method upon an object that resides on an American English server. Some business methods are locale-sensitive in nature; for example, given a business method that returns a sorted list of strings, the Spanish client expects that list to be sorted according to the Spanish collating sequence, not in the English collating sequence of the server. Because data retrieval and sorting procedures run on the server, the locale of the client must be available to perform a legitimate sort.

A similar consideration applies in instances where the server has to return strings containing date, time, currency, exception messages, and so on, that are formatted according to the cultural expectations of the client.

Clients and servers can reside in different time zones

Client and server processes can run in different time zones. To date, all internationalization literature and resources concentrate mainly on code set and locale-related issues. They have generally ignored the time zone issue, even though business methods can be sensitive to time zone as well as to locale.

For example, suppose that a vendor makes the claim that orders received before 2:00 PM are processed by 5:00 PM the same day. The times given, of course, are in the time zone of the server that is processing the order. It is important to know the time zone of the client to give customers in other time zones the correct times for same-day processing.

Other time zone-sensitive operations include time stamping messages logged to a server, and accessing file or database resources. The concept of Daylight Savings Time further complicates the time zone issue.

Java Platform, Enterprise Edition (Java EE) provides support for application components that run on computers with differing endian architecture and code sets. It does not provide dedicated support for application components that run on computers with different locales or time zones.

The conventional method for solving locale and time zone mismatches across remote application components is to pass one or more extra parameters on all business methods needed to convey the client-side locale or time zone to the server. Although simple, this technique has the following limitations when used in Enterprise JavaBeans (EJB) applications:

- It is intrusive because it requires that one or more parameters be added to all bean methods in the call chain to locale-sensitive or time zone-sensitive methods.
- It is inherently error-prone.
- It is impracticable within applications that do not support modification, such as legacy applications.

The internationalization service addresses the challenges posed by locale and time zone mismatch without incurring the limitations of conventional techniques. The service systematically manages the distribution of internationalization contexts across the various components of EJB applications, including client applications, enterprise beans, and servlets. For more information, see “Task overview: Internationalizing application components (internationalization service)” on page 467.

Working with locales and character encodings

Internationalization support for this product relies on that provided by the Java Platform, Standard Edition (JSE). Support varies by platform.

Procedure

- Verify that the operating system on which the application server is installed supports the locales and encodings that you plan to use.

  Java internationalization support might use underlying services of the operating system. For example, if user IDs for your server are expected to contain non-English characters, make sure that the operating system is configured to process those characters.
- Plan for encoding changes as necessary.

  Consider differences in encoding support among operating system subcomponents. Although this product and the Java platform are based on Unicode encoding, it is not always possible to run applications in a purely Unicode environment.
- Set the console.encoding property as necessary.

Results

If your application produces an UnsupportedEncodingException exception, check your operating system documentation to determine if the target operating system supports the required encoding and adjust the runtime environment as needed. Use the converter.properties file as appropriate to map an unsupported character set to a supported character set. A typical converter.properties file appears below:

```
Shift_JIS=CP943C
EUC-JP=Cp33722C
EUC-JP=Cp33722C
EUC-KR=Cp970
EUC-TW=Cp964
Big5=Co950
GB2312=Cp1386
ISO-2022–KR=ISO2022KR
```

The converter.properties file implements a method for specifying a content type header field that browsers would understand (such as, SHIFT_JIS) and a writer that can output characters correctly (such as, Cp943c).

Language versions offered by this product

This product is offered in several languages, as enabled by the operating platform on which the product is installed.

WebSphere Application Server offers translations for the following languages.

- Brazilian Portuguese
- Chinese (Simplified)
- Chinese (Traditional)
- Czech
- English
- French
- German
- Hungarian
- Italian
- Japanese
- Korean
- Polish
- Romanian
- Russian
- Spanish

Task overview: Internationalizing interface strings (localizable-text API)

This topic summarizes the steps involved in implementing message catalogs through the localizable-text API.

About this task

This product supports the maintenance and deployment of centralized message catalogs for the output of properly formatted, language-specific (*localized*) interface strings.

Procedure

1. Identify localizable text in your application.
2. Create the message catalogs that are necessary for the locales to be supported by your application.
3. In your application code, compose the language-specific strings for output.
4. Using an assembly tool, assemble your application code as one or more application components.
5. Prepare the localizable-text package for deployment with your localized application. In this step, you create a deployment Java archive (JAR) file.

6. Assemble the application modules and the deployment JAR file into a Java Platform, Enterprise Edition (Java EE) application.
7. Deploy and manage the application.

Results

Your application is deployed with localized text.

Identifying localizable text

The first step in localizing strings in an application component is identifying the best candidates for translation.

Procedure

1. Determine which elements of the application need translating. Good candidates for localization include the following:
   - Graphical user interfaces: window titles, menus and menu items, buttons, on-screen instructions
   - Prompts in command-line interfaces
   - Application output: messages and logs
2. Assign a unique key to each element for use in message catalogs for the application. The key provides a language-neutral link between the application and language-specific strings in the message catalogs. Establishing a naming convention for keys before creating the catalogs can make writing code with these keys much more intuitive for interface programmers.

Example

Suppose you are localizing the GUI for a banking system, and the first window contains a pull-down list to use for selecting a type of account.

The labels for the list and the account types in the list are good choices for localization. Three elements require keys: the list and two items in the list.

What to do next

Create message catalogs for the language-specific strings.

Creating message catalogs

Perform this task to begin the localization of strings in an application component.

Before you begin

Identify strings that need to be localized.

About this task

You can create a catalog as either a java.util.ResourceBundle subclass or a Java properties file. The properties-file approach is more common, because properties files can be prepared by people without programming experience and swapped without modifying the application code.

Procedure

1. For each string that is identified for localization, add a line to the message catalog that lists the string key and value in the current language. In a properties file, each line has the following structure:

   ```
   key = string associated with the key
   ```

2. Save the catalog, giving it a locale-specific name. To enable resolution to a specific properties file, the Java API specifies naming conventions for the properties files in a resource bundle as *bundleName_localeID*.properties. Give the set of message catalogs a collective name, for example, BankingResources. For information about locale IDs that are recognized by the Java APIs, see "Resources for learning."

Example

The following English catalog (BankingResources_en.properties) supports the labels for the list and its two list items:

```
accountString = Accounts
savingsString = Savings
checkingString = Checking
```

Do not create compound strings by concatenation (for example, combining the values of savingsString and accountString to form `Savings Accounts` in English. Success depends upon the grammar of the original language (in this case, English) and is not likely to extend to other languages.

The corresponding German catalog (BankingResources_de.properties) supports the labels as follows:

```
accountString = Konten
savingsString = Sparkonto
checkingString = Girokonto
```

What to do next

Write code to compose the language-specific strings.

Composing language-specific strings

Perform this task to complete the localization of strings in an application component.

Before you begin

Create message catalogs for the language-specific strings.

Procedure

1. In application code, create a LocalizableTextFormatter instance, passing in required localization values.
2. Set other localization values as needed for more complex situations.
3. Generate a properly formatted, language-specific string.

What to do next

When the application is finished, deploy your application. For more information, see “Preparing the localizable-text package for deployment” on page 465.

Localization API support

The com.ibm.websphere.i18n.localizabletext package contains classes and interfaces for localizing text.

This package makes extensive use of the internationalization features of the standard Java APIs from Sun Microsystems, including the following classes:

- java.util.Locale

- java.util.TimeZone
- java.util.ResourceBundle
- java.text.MessageFormat

For more information about the standard Java APIs, see “Globalization: Resources for learning” on page 455.

The localizable-text package wraps the Java support and extends it for efficient and simple use in a distributed environment. The primary class used by application programmers is LocalizableTextFormatter. Instances of this class are usually created in server programs, but client programs can also create them. Formatter instances are created for specific resource-bundle names and keys. Client programs that receive a LocalizableTextFormatter instance call its format method. This method uses the locale of the client application to retrieve the appropriate resource bundle and compose a locale-specific message based on the key.

For example, suppose that a distributed application supports both French and English locales; the server is using an English locale and the client, a French locale. The server creates two resource bundles, one each for English and French. When the client makes a request that triggers a message, the server creates a LocalizableTextFormatter instance that contains the name of the resource bundle and the key for the message and passes the instance back to the client.

When the client receives the LocalizableTextFormatter instance, it calls the format method of the object. By using the locale and name of the resource bundle, the format method determines the name of the resource bundle that supports the French locale and retrieves the message that corresponds to the key from the French resource bundle. Formatting of the message is transparent to the client.

In this simple example, the resource bundles reside centrally with the server. They do not have to exist with the client. Part of what the localizable-text package provides is the infrastructure to support centralized catalogs. This implementation uses an enterprise bean (a stateless session bean provided with the localizable-text package) to access the message catalogs. When the client calls the format method on the LocalizableTextFormatter instance, the following events occur:

1. The client application sets the time-zone and locale values in the LocalizableTextFormatter instance, either by passing them explicitly or through default values.
2. A LocalizableTextFormatterEJBFinder call is made to retrieve a reference to the formatter bean.
3. Information from the LocalizableTextFormatter instance, including the time zone and locale of the client, is sent to the formatting bean.
4. The formatting bean uses the name of the resource bundle, the message key, the time zone, and the locale to compose a language-specific message.
5. The formatter bean returns the formatted message to the client.
6. The formatted message is inserted into the LocalizableTextFormatter instance and returned by the format method.

A call to the format method requires at most one remote call, to contact the formatter bean. As an alternative, the LocalizableTextFormatter instance can cache formatted messages, eliminating the remote call for subsequent uses. In addition, you can set a fallback string so that the application can return a readable string even if it cannot access the appropriate message catalog.

The resource bundles can be stored locally. The localizable-text package provides a static variable that indicates whether the bundles are stored locally (LocalizableConfiguration.LOCAL) or remotely (LocalizableConfiguration.REMOTE). However, the setting of this variable applies to all applications running within the same Java virtual machine.

LocalizableTextFormatter class

The LocalizableTextFormatter class, found in the com.ibm.websphere.i18n.localizabletext package, is the primary programming interface for using the localizable-text package. Instances of this class contain the information needed to create language-specific strings from keys and resource bundles.

The LocalizableTextFormatter class extends the java.lang.Object class and implements the following interfaces:

- java.io.Serializable
- com.ibm.websphere.i18n.localizabletext.LocalizableText
- com.ibm.websphere.i18n.localizabletext.LocalizableTextL
- com.ibm.websphere.i18n.localizabletext.LocalizableTextTZ
- com.ibm.websphere.i18n.localizabletext.LocalizableTextLTZ

Creation and initialization of class instances

The LocalizableTextFormatter class supports the following constructors:

- LocalizableTextFormatter()
- LocalizableTextFormatter(String resourceBundleName, String patternKey, String appName)
- LocalizableTextFormatter(String resourceBundleName, String patternKey, String appName, Object[] args)

The LocalizableTextFormatter instance must have certain values, such as a resource-bundle name, a key, and the name of the formatting application. If you do not pass these values in by using the second constructor listed previously, you can set them separately by making the following calls:

- setResourceBundleName(String resourceBundleName)
- setPatternKey(String patternKey)
- setApplicationName(String appName)

You can use a fourth method, setArguments(Object[] args), to set optional localization values after construction. See “Processing of application-specific values” on page 460 at the end of this topic. For a usage example, see “Composing complex strings” on page 462.

API for formatting text

The formatting methods in the LocalizableTextFormatter class generate a string from a set of message keys and resource bundles, based on some combination of locale and time-zone values. Each method corresponds to one of the four localizable-text interfaces implemented. The following list indicates the interface in which each formatting method is defined:

- LocalizableText.format()
- LocalizableTextL.format(java.util.Locale locale)
- LocalizableTextTZ.format(java.util.TimeZone timeZone)
- LocalizableTextLTZ.format(java.util.Locale locale, java.util.TimeZone timeZone)

The format method with no arguments uses the locale and time-zone values set as defaults for the Java virtual machine. All four methods issue LocalizableException objects as needed.

Location of message catalogs and the appName value

Applications written with the localizable-text package can access message catalogs locally or remotely. In a distributed environment, the use of remote, centrally located message catalogs is appropriate. All clients can use the same catalogs, and maintenance of the catalogs is simplified. Local formatting is useful in test situations and appropriate under some circumstances. To support either local or remote formatting, a LocalizableTextFormatter instance must indicate the name of the formatting application.

For example, when an application formats a message by using remote catalogs, the message is actually formatted by an enterprise bean on the server. Although the localizable-text package contains the code to

automate the lookup of the formatter bean and to issue a call to it, the application needs to know the name of the formatter bean. Several methods in the LocalizableTextFormatter class use a value described as *appName*, which refers to the name of the formatting application. It is not necessarily the name of the application in which the value is set.

Caching of messages

LocalizableTextFormatter instances can optionally cache formatted messages so that they do not require reformatting when needed again. By default, caching is not enabled, but you can use a `LocalizableTextFormatter.setCacheSetting(true)` call to enable caching. When caching is enabled and the format method is called, the method determines whether the message is already formatted. If so, the cached message is returned. If the message is not found in the cache, the message is formatted and returned to the caller, and a copy of the message is cached for future use.

If caching is disabled after messages are cached, those messages remain in the cache until the cache is cleared by a call to the LocalizableTextformatter.clearCache method. You can clear the cache at any time; the cache is automatically cleared when any of the following methods is called:
- setResourceBundleName(String resourceBundleName)
- setPatternKey(String patternKey)
- setApplicationName(String appName)
- setArguments(Object[] args)

API for providing fallback information

Under some circumstances, it can be impossible to format a message. The localizable-text package implements a fallback strategy, making it possible to get some information even if a message cannot be formatted correctly into the requested language. The LocalizableTextFormatter instance can optionally store fallback values for a message string, the time zone, and the locale. These values can be ignored unless the LocalizableTextFormatter instance issues an exception. To set fallback values, call the following methods as appropriate:
- setFallBackString(String message)
- setFallBackLocale(Locale locale)
- setFallBackTimeZone(TimeZone timeZone)

For a usage example, see “Generating localized text” on page 464.

Processing of application-specific values

The localizable-text package provides native support for localization based on time zone and locale, but you can construct messages on the basis of other values as well. If you need to consider variables other than locale and time zone in formatting localized text, write your own formatter class.

Your formatter class can extend the LocalizableTextFormatter class or independently implement some or all of the same localizable-text interfaces. As a minimum, your class must implement the java.io.Serializable interface and at least one of the localizable-text interfaces and its corresponding format method. If your class implements more than one localizable-text interface and format method, the order of evaluation of the interfaces is as follows:
1. LocalizableTextLTZ
2. LocalizableTextL
3. LocalizableTextTZ
4. LocalizableText

As an example, the localizable-text package provides a class that reports the time and date (LocalizableTextDateTimeArgument). In that class, date and time formatting is localized in accordance with three values: locale, time zone, and style.

Creating a formatter instance

Perform this task to set localization values for strings in an application component.

About this task

Server programs typically create LocalizableTextFormatter instances that are sent to clients as the result of some operation; clients format the objects at the appropriate time. Less typically, client programs create LocalizableTextFormatter objects locally.

Procedure

1. If needed for your application, write your own formatter class. For more information about implementation, see “LocalizableTextFormatter class” on page 459.
2. In application code, call the appropriate constructor for the formatter class and set required localization values. Some localization values, such as resource bundle name, key and formatting application, must be set, either through a constructor or soon after construction. Other localization values can be set only as needed. For more information about the API, see the related reference.

Example

The following code creates a LocalizableTextFormatter instance by using the default constructor and then sets the required localization values:

```
import com.ibm.websphere.i18n.localizabletext.LocalizableException;
import com.ibm.websphere.i18n.localizabletext.LocalizableTextFormatter;
import java.util.Locale;

public void drawAccountNumberGUI(String accountType) {
   ...
   LocalizableTextFormatter ltf = new LocalizableTextFormatter();
   ltf.setPatternKey("accountNumber");
   ltf.setResourceBundleName("BankingSample.BankingResources");
   ltf.setApplicationName("BankingSample");
   ...
}
```

The line of code in boldface exploits default behavior of the Java platform. By default, the Java platform looks first for a subclass of java.util.ResourceBundle called BankingResources. When none is found, the Java platform looks for a valid properties file of the same name. In this continuing example, a properties file is found.

The application that is requesting a localized message can specify the locale and time zone for message formatting, or the application can use the default values set for the Java virtual machine.

For example, a GUI can enable users to select the language in which to display the interface. A default value must be set initially so that the GUI can be created properly when the application first starts, but users can then change the locale for the GUI to suit their needs. The following code shows how to change the locale used by an application based on the selection of a menu item:

```
import java.awt.event.ActionListener;
import java.awt.event.ActionEvent;
...
import java.util.Locale;

public void actionPerformed(ActionEvent event) {
   String action = event.getActionCommand();
   ...
   if (action.equals("en_us")) {
      applicationLocale = new Locale("en", "US");
      ...
   }
   if (action.equals("de_de")) {
```

```
      applicationLocale = new Locale("de", "DE");
      ...
   }
   if (action.equals("fr_fr")) {
      applicationLocale = new Locale("fr", "FR");
      ...
   }
   ...
}
```

For more information, see "Generating localized text."

What to do next

Set optional localization values.

Setting optional localization values

In addition to setting localization values that are required by the LocalizableTextFormatter interface, you can set a number of optional values in application code, either through the constructor or by calling any of several methods for that purpose.

About this task

With optional values, you can do the following actions:
- Compose complex strings from variable substrings
- Customize the formatting of strings, considering variables other than time zone and locale

Procedure

1. In application code, add the optional values into an array of type Object.
   ```
   Object[] arg = {new String(getAccountNumber())};
   ```
2. Pass the array into a LocalizableTextFormatter instance. You can pass the array through the appropriate constructor or call the setArguments(Object[]) method. For a usage example, see “Composing complex strings.”

   Because the array is passed by value rather than by reference, any updates to the array variable after this point are not reflected in the LocalizableTextFormatter instance unless it is reset by calling the setArguments(Object[]) method.

What to do next

Write code to generate the localized text.

Composing complex strings:

Perform this task to insert variable substrings into a localized string.

Before you begin

Identify strings that need to be localized.

About this task

The localized-text package supports the substitution of variable substrings into a localized string that is retrieved from the message catalog by key.

Procedure

1. In the message catalog, specify the location of the substitution in the string to be retrieved. Variable components are designated by braces (for example, {0}).
2. In application code, create a LocalizableTextFormatter instance, passing in an array that contains the variable value. If the variable substring must be localized, you can create a nested LocalizableTextFormatter instance and pass the instance in instead of a value.
3. Generate a localized string. When a format method is called on a formatter instance, the formatter takes each element of the array passed in the previous step and substitutes it for the placeholder with the matching index in the string that is retrieved from the message catalog. For example, the value at index 0 in the array replaces the {0} variable in the retrieved string.

Example

The following line from an English message catalog shows a string with a single substitution:

```
successfulTransaction = The operation on account {0} was successful.
```

The same key in message catalogs for other languages has a translation of this string with the variable at the appropriate location for each language.

The following code shows the creation of a single-element argument array and the creation and use of a LocalizableTextFormatter instance:

```
public void updateAccount(String transactionType) {
   ...
   Object[] arg = {new String(this.accountNumber)};
   ...
   LocalizableTextFormatter successLTF =
      new LocalizableTextFormatter ("BankingResources",
                                    "successfulTransaction",
                                    "BankingSample",
                                    arg);
   ...
   successLTF.format(this.applicationLocale);
   ...
}
```

Nesting formatter instances for localized substrings:

The ability to substitute variable substrings into the strings retrieved from message catalogs adds a level of flexibility to the localizable-text package, but this capability is of limited use unless the variable value can be localized. You can localize this value by nesting LocalizableTextFormatter instances.

Before you begin

Identify strings that need to be localized.

Procedure

1. In the message catalog, add entries that correspond to potential values for the variable substring.
2. In application code, create a LocalizableTextFormatter instance for the variable substring, setting required localization values.
3. Create a LocalizableTextFormatter instance for the primary string, passing in an array that contains the formatter instance for the variable substring.

Example

The following line from an English message catalog shows a string entry with two substitutions and entries to support the localizable variable at index 0 (the second variable in the string, the account number, does not need to be localized):

```
successfulTransaction = The {0} operation on account {1} was successful.
depositOpString = deposit
withdrawOpString = withdrawal
```

The following code shows the creation of the nested formatter instance and its insertion (with the account number variable) into the primary formatter instance:

```
public void updateAccount(String transactionType) {
   ...
   // Successful deposit
   LocalizableTextFormatter opLTF =
      new LocalizableTextFormatter("BankingResources",
                                   "depositOpString",
                "BankingSample");
   Object[] args = {opLTF, new String(this.accountNumber)};
   ...
   LocalizableTextFormatter successLTF =
      new LocalizableTextFormatter ("BankingResources",
                                    "successfulTransaction",
                                    "BankingSample",
                                    args);
   ...
   successLTF.format(this.applicationLocale);
   ...
}
```

Generating localized text

Perform this task to specify the runtime formatting of localized text in an application component.

Before you begin

Create a formatter instance and set the localization values as needed.

Procedure

1. If needed, customize the formatting behavior.
2. In application code, call the appropriate format method.

Example

You can provide fallback behavior for use if the appropriate message catalog is not available at formatting time.

The following code generates a localized string. If the formatting fails, the application retrieves and uses a fallback string instead of the localized string:

```
import com.ibm.websphere.i18n.localizabletext.LocalizableException;
import com.ibm.websphere.i18n.localizabletext.LocalizableTextFormatter;
import java.util.Locale;

public void drawAccountNumberGUI(String accountType){
   ...
   LocalizableTextFormatter ltf = new LocalizableTextFormatter();
   ...
   ltf.setFallBackString("Enter account number: ");
   try {
      msg = new Label(ltf.format(this.applicationLocale), Label.CENTER);
   }
```

```
   catch (LocalizableException le) {
      msg = new Label(ltf.getFallBackString(), Label.CENTER);
   }
   ...
}
```

What to do next

When the application is finished, deploy your application. For more information, see “Preparing the localizable-text package for deployment.”

Customizing the behavior of a formatting method:

Perform this task to change the runtime formatting of localized strings in an application component.

About this task

You can customize formatting behavior by passing your own formatter classes into a LocalizableTextFormatter instance through an array of optional values. This action enables you to consider variables other than locale and time zone when formatting localized text.

Procedure

1. Write your own formatter class. For more information about implementation, see "LocalizableTextFormatter class."
2. In application code, create an instance of your formatter class as appropriate and pass it with any other optional localization values into an instance of LocalizableTextFormatter. When the LocalizableTextFormatter instance reads the instance that has been passed in, it attempts to call the format() method on the passed-in instance. The string returned is then processed with any other elements in the array.

Example

The localizable-text package provides an example of a user-defined class, called LocalizableTextDateTimeArgument. This class enables date and time information to be selectively formatted according to the style values defined in the java.text.DateFormat interface as well as the constants that are defined within the LocalizableTextDateTimeArgument class.

Preparing the localizable-text package for deployment

The LocalizableTextEJBDeploy tool is used to create a deployment Java Archive (JAR) file for the localizable text service. You must deploy the enterprise bean in each enterprise application that requires support for localized text.

Before you begin

Write code to compose the language-specific strings.

Procedure

1. Make sure that the LocalizableTextEJBDeploy tool is included in the class path.

   transition: In versions 6.0.x and earlier, the LocalizableTextEJBDeploy tool used to reside in the file *app_server_root*/lib/ltext.jar. It now resides in the file *app_server_root*/plugins/com.ibm.ws.runtime_1.0.0.jar.
2. Set up a working directory for the LocalizableTextEJBDeploy tool to use. You need to pass this location to the tool through a command-line interface.

3. Run the LocalizableTextEJBDeploy tool. You might be asked if you want to regenerate deployment code for the LocalizableText bean. Do not redeploy the bean; if you do, an incorrect Java Naming and Directory Interface (JNDI) name will be generated.

   To deploy the bean on multiple hosts and servers, run the tool for each host and server combination. This action generates a unique JNDI name for each deployment. After the tool is run, a deployment JAR file is located in the working directory that you specified.

What to do next

Using an assembly tool, assemble the deployment JAR file in an enterprise application with other application components.

As part of preparing for deployment, perform the following:
- Add the resource bundles for your application to the Enterprise Archive (EAR) file as files.
- Add the location of the EAR file to the server class path for the server so that the resource bundles can be located on the virtual host and server.

The same deployment JAR file can be included in several enterprise applications.

LocalizableTextEJBDeploy command

This topic describes the command-line syntax for the LocalizableTextEJBDeploy tool.

transition: In versions 6.0.x and earlier, the LocalizableTextEJBDeploy tool used to reside in the file *app_server_root*/lib/ltext.jar. It now resides in the file *app_server_root*/plugins/com.ibm.ws.runtime_1.0.0.jar.

```
LocalizableTextEJBDeploy
   -a applicationName
   -h virtualHostName
   -i installationDirectory
   -s serverName
   -w workingDirectory
```

Parameters

The required parameters, which can be specified in any order, follow:

applicationName
The name of the formatting session bean. This name is used in LocalizableTextFormatter instances to specify where the actual formatting occurs. If the name cannot be resolved at run time, the format method issues an exception.

virtualHostName
The name of the virtual host on which the formatting session bean is deployed. This value is case-sensitive on all operating platforms.

installationDirectory
The location at which the application server product is installed.

serverName
The name of the application server. If this argument is not specified, the default server name for the product is used.

workingDirectory
A location for the tool to use temporarily.

Task overview: Internationalizing application components (internationalization service)

This topic summarizes the steps involved in using the internationalization service.

About this task

With the internationalization service, you can manage the distribution of the internationalization information, or *internationalization context*, that is necessary to support globalized Java Platform, Enterprise Edition (Java EE) application components. Supported application components also include web service client environments and web service-enabled enterprise beans.

Procedure

1. Use the internationalization context API within application components to obtain or manage internationalization context.

   Servlet and enterprise bean business methods can use internationalization context to perform locale- and time zone-sensitive localizations. Enterprise JavaBeans (EJB) client applications, and server components that are configured to manage internationalization context must use the internationalization context API to set the context elements scoped to their invocations.

   You use the internationalization context API within Web service-enabled Java EE client programs and stateless session beans in the same manner that you would use conventional Java EE application components, with one exception. Internationalization context propagated over Web service requests contains a time zone ID, whereas conventional Remote Method Invocation/ Internet Inter-ORB Protocol (RMI/IIOP) requests propagate complete time zone information, including the raw offset, Daylight Savings Time information, and so on.

2. Assemble internationalized applications.

   The internationalization type specifies the internationalization policy that applies to a servlet or an enterprise bean and, in particular, indicates whether the application component or its hosting Java EE container manages internationalization context. Container internationalization attributes can be specified for container-managed servlet and enterprise bean business methods. These attributes tailor a policy by indicating which context the container scopes to an invocation. Configuring internationalization policies declaratively prescribes, by means of the application deployment descriptor, the distribution and management of context throughout an application.

   As you edit the deployment descriptor for assembly, you can also set the internationalization type and configure any container internationalization attributes for the servlets and enterprise beans in your application.

   You configure internationalization type and container internationalization attributes for Web service-enabled stateless session beans in the same manner as you do for conventional beans.

3. Manage the internationalization service.

   Use the administrative console to enable the service on all application servers.

   By default, the service is enabled within Java EE client environments but is disabled on application servers. You must enable the service on all application servers hosting your servlets and enterprise beans to use internationalization context.

4. Troubleshoot the internationalization service as needed.

   Use the administrative console to enable the trace service to log internationalization service messages when debugging your applications.

   The trace strings for the internationalization service follow; use both:

   ```
   com.ibm.ws.i18n.context.*=all=enabled:com.ibm.websphere.i18n.context.*=all=enabled
   ```

Internationalization service

In a distributed client-server environment, application processes can run on different machines, configured for different locales, corresponding to different cultural conventions; they can also be located across geographical boundaries. The internationalization service can help manage your application in a globally distributed environment.

For an understanding of how differences in locale impact application development, read “Globalization” on page 451.

Java Platform, Enterprise Edition (Java EE) provides support for application components that run on computers with differing endian architecture and code sets. It does not provide dedicated support for application components that run on computers with different locales or time zones.

The internationalization service addresses the challenges posed by locale and time zone mismatch without incurring the limitations of conventional techniques. The service systematically manages the distribution of internationalization contexts across the various components of EJB applications, including client applications, enterprise beans, and servlets.

The service works by associating an internationalization context with every service request within an application. When a client-side component calls a business method, the internationalization service interposes by obtaining the internationalization context associated with the current client-side process and by attaching that context to the outgoing request. On the server side, the internationalization service again interposes by detaching the context from the incoming request and associating it with the server-side process on which the business method will run, effectively scoping the context to the business method. For HTTP requests, the caller context is constructed from the HTTP attributes and default values. The service propagates internationalization context on subsequent business method invocations in the same manner, which distributes the context of the originating request over the entire chain of business method invocations.

This basic operation of scoping and propagation is defined precisely by *internationalization context management policies*. Internationalization policies specify whether an application component or its hosting Java EE container are to manage internationalization context. For container-managed components, the policy indicates which internationalization context the container scopes to invocations on that component. Server components configured to manage internationalization context, as well as EJB clients, must use the internationalization context API to manage the internationalization context elements scoped to their invocations.

Every application component has a default policy, which can be overridden and tailored for servlets and enterprise beans at assembly time.

At run time, application components can use the internationalization context API to get any element of the internationalization contexts scoped to an invocation. To programmatically access context elements, application components first resolve an internationalization context API reference, then call the appropriate API method to access the various context elements, such as the caller locale or the invocation time zone. These elements can be used in calls to Java SDK internationalization API methods; for example, to perform localizations such as formatting messages, configuring dates, or comparing strings.

Assembling internationalized applications

Perform this task to configure application components for deployment with the internationalization service.

About this task

Use an assembly tool to configure internationalization in the deployment descriptors for servlets and enterprise beans.

Procedure

1. Set the **internationalization type**.

   All servlets and enterprise beans have an internationalization type setting that specifies whether internationalization context is managed by the application component or by its hosting Java Platform, Enterprise Edition (Java EE) container during invocations of their respective life cycle and business methods. The internationalization type can be configured for all server application components except entity beans, which are container-managed only.

   By default, all server components use container-managed internationalization (CMI). The default setting suffices in most cases; when it does not, modify the internationalization type setting by completing the steps that are described in one of the following topics:
   - "Setting the internationalization type for servlets"
   - "Setting the internationalization type for enterprise beans" on page 471

2. Set the **container internationalization attribute**.

   You can associate CMI servlets, and business methods of CMI enterprise beans, with a container internationalization attribute. That attribute specifies which of three internationalization contexts (**Caller**, **Server**, or **Specified**) the container is to scope to an invocation. When running as specified, the container internationalization attribute also specifies the custom internationalization context elements.

   Named container internationalization attributes can be associated with sets of servlets or with sets of Enterprise JavaBeans (EJB) business methods. Initially, CMI servlets and business methods implicitly run as caller and do not associate with a container internationalization attribute. When the implicit behavior or an associated attribute setting is unsuitable, configure an attribute by completing the steps that are described in one of the following topics:
   - "Configuring container internationalization for servlets" on page 470
   - "Configuring container internationalization for enterprise beans" on page 471

Setting the internationalization type for servlets

This task sets the internationalization type for a servlet within a Web module.

Before you begin

This topic assumes that you have an assembly tool such as Rational Application Developer.

For information about assembly, refer to the documentation for your assembly tool. The steps in this topic refer to Rational Application Developer.

This topic assumes that you have started the assembly tool, configured the assembly tool for work on Java Platform, Enterprise Edition (Java EE) modules, and created or imported a dynamic Web project.

Procedure

1. In the Java EE perspective, open the Web project for which you want to set the internationalization type.
   a. Double-click **Dynamic Web Projects**.
   b. Double-click the name of the Web project to see its contents.
   c. Double-click the deployment descriptor object.

   The Web Deployment Descriptor panel is displayed.
2. In the Web Deployment Descriptor panel, click the Servlets tab.
3. Scroll down to **WebSphere Programming Model Extensions** and then **Internationalization**.
4. From the **Servlets and JSPs** list of the Servlets panel, select the servlet for which you want to set the internationalization type.
5. Under **Internationalization**, select a value from the **Internationalization type** list. Valid values are `Application` or `Container`.
6. From the menu bar, click **File > Save**.

Results

The internationalization type setting is assigned to the servlet.

What to do next

If you selected container-managed internationalization, you can then set container-managed internationalization attributes for methods within the servlet. For more information, see "Configuring container internationalization for servlets."

Configuring container internationalization for servlets

This task configures container internationalization for a servlet within a Web module.

Before you begin

This topic assumes that you have an assembly tool such as Rational Application Developer.

For information about assembly, refer to the documentation for your assembly tool. The steps in this topic refer to Rational Application Developer.

This topic assumes that you have started the assembly tool, configured the assembly tool for work on Java Platform, Enterprise Edition (Java EE) modules, and created or imported a dynamic Web project.

You must also have set the internationalization type of one or more servlets in a Web project to `Container`.

About this task

This procedure relates one or more servlets to a container-managed internationalization attribute.

Procedure

1. In the Java EE perspective, open the Web project for which you want to configure container internationalization.
   a. Double-click **Dynamic Web Projects**.
   b. Double-click the name of the Web project to see its contents.
   c. Double-click the deployment descriptor object.

   The Web Deployment Descriptor panel is displayed.
2. In the Web Deployment Descriptor panel, click the Servlets tab.
3. Scroll down to **WebSphere Programming Model Extensions** and then **Internationalization**.
4. Following **Container-managed Internationalization Attribute**, set the **Run As** field by selecting `Caller`, `Server`, or `Specified`.
5. If the servlet is to be run as Specified, select an internationalization policy from the **Specified** list or define a new policy.
   a. To define an internationalization policy, click **New**. The New Specified Initialization wizard is displayed.
   b. In the **Description** field, give the policy a name.
   c. If needed, set a time zone ID and add a time zone description. If you do not find the appropriate time zone in the ID list, click **Customize** to define one relative to Greenwich Mean Time (GMT).
   d. Create at least one locale for the policy. To create a locale, click **Add**; select a language and (optional) geographic region; specify a variant as needed. Add a locale description and click **OK** to finish. The new locale is added to the **Locales** list.
   e. If more than one locale is defined for the policy, select a locale from the **Locales** list and click **Finish**. Otherwise, just click **Finish**

6. From the menu bar, click **File > Save**.

Results

Selected servlets are now configured to run under the associated internationalization settings.

Setting the internationalization type for enterprise beans

This task sets the internationalization type for an enterprise bean within an Enterprise JavaBeans (EJB) module.

Before you begin

This topic assumes that you have an assembly tool such as Rational Application Developer.

For information about assembly, refer to the documentation for your assembly tool. The steps in this topic refer to Rational Application Developer.

This topic assumes that you have started the assembly tool, configured the assembly tool for work on Java Platform, Enterprise Edition (Java EE) modules, and created or imported an EJB project.

About this task

Container-managed internationalization (CMI) is the default type; entity beans cannot be set to application-managed internationalization (AMI). Use CMI also for stateless session beans that are enabled for Web services.

Procedure

1. In the Java EE perspective, open the EJB project for which you want to set the internationalization type.
   a. Double-click **EJB Projects**.
   b. Double-click the name of the EJB project to see its contents.
   c. Double-click the deployment descriptor object.

   The EJB Deployment Descriptor panel is displayed.
2. In the EJB Deployment Descriptor panel, click the Internationalization tab. Any enterprise beans that are already configured for AMI are displayed in the **Internationalization type** list.
3. To set the internationalization type for any other enterprise beans to AMI, click **Add** following the **Internationalization type** list. The Internationalization Type wizard opens. Only message-driven or session beans can be selected.
4. Select the beans that you want to set and click **Finish** to exit the wizard.
5. From the menu bar, click **File > Save**.

Results

The internationalization type is assigned to the bean.

What to do next

For beans that use container-managed internationalization, you can then set container-managed internationalization attributes. For more information, see "Configuring container internationalization for enterprise beans."

Configuring container internationalization for enterprise beans

This task configures container internationalization for enterprise bean business methods.

Before you begin

This topic assumes that you have an assembly tool such as Rational Application Developer.

For information about assembly, refer to the documentation for your assembly tool. The steps in this topic refer to Rational Application Developer.

This topic assumes that you have started the assembly tool, configured the assembly tool for work on Java Platform, Enterprise Edition (Java EE) modules, and created or imported an EJB project.

You must also have one or more enterprise beans set to container-managed internationalization (CMI) by default.

About this task

This procedure relates one or more business methods to one or more container-managed internationalization (CMI) attributes. Use this procedure also for stateless session beans that are enabled for Web services.

Procedure

1. In the Java EE perspective, open the EJB project for which you want to configure container internationalization.
   a. Double-click **EJB Projects**.
   b. Double-click the name of the EJB project to see its contents.
   c. Double-click the deployment descriptor object.

   The EJB Deployment Descriptor panel is displayed.
2. In the EJB Deployment Descriptor panel, click the Internationalization tab. Any business methods that are already configured are displayed in the **Internationalization attributes** list.
3. To configure a CMI business method, click **Add** following the **Internationalization attributes** list. The Internationalization Attributes wizard opens.
4. Set the **Run As** field by selecting `Caller`, `Server`, or `Specified`. Add a meaningful description. As a group, the CMI attribute settings comprise an internationalization policy.
   - The description appears as `Internationalization` *`description`* (*`runAsSetting`*) in the **Internationalization attributes** list when you are finished.
   - If you do not provide a description, the policy name appears as `Internationalization` (*`runAsSetting`*).

   If the bean is to be run as Specified, complete the following steps to specify the context elements that the container scopes to bean method invocations.
   a. Set a time zone ID and add a time zone description as needed. If you do not find the appropriate time zone in the ID list, click **Custom** to define one relative to Greenwich Mean Time (GMT).
   b. Set a locale. Select a language and (optional) geographic region; specify a variant as needed. Add a locale description as needed and click **OK** to finish.
5. Click **Next**.
6. Select the beans for which you want to configure method-level internationalization attributes and click **Next**.
7. Select the methods that you want to configure and click **Next**. A check box is displayed next to each method name that you select.
   - Click **Apply to All** to place a check box next to the displayed bean name.
   - Click **Select Beans** to select more beans with CMI.
8. Click **Finish** to exit the wizard.
9. From the menu bar, click **File > Save**.

Results

The bean methods are now configured to run under the associated internationalization settings.

Using the internationalization context API

Enterprise JavaBeans (EJB) client applications, servlets, and enterprise beans can programmatically obtain and manage internationalization context using the internationalization context API. For Web service client applications, you use the API to obtain and manage internationalization context in the same manner as for EJB clients.

Before you begin

The java.util and com.ibm.websphere.i18n.context packages contain all of the classes necessary to use the internationalization service within an EJB application.

Procedure

1. Gain access to the internationalization context API.

   Resolve internationalization context API references once over the life cycle of an application component, within the initialization method of that component (for example, within the init method of servlets, or within the SetXxxContext method of enterprise beans). For Web service client programs, resolve a reference to the internationalization context API during initialization. For stateless session beans enabled for Web services, resolve the reference in the setSessionContext method.
2. Access caller locales and time zones.

   Every remote invocation of an application component has an associated caller internationalization context associated with the thread that is running that invocation. A caller context is propagated by the internationalization service and middleware to the target of a request, such as an Enterprise JavaBeans (EJB) business method or servlet service method. This task also applies to Web service client programs.
3. Access invocation locales and time zones.

   Every remote invocation of a servlet service or Enterprise JavaBeans (EJB) business method has an invocation internationalization context associated with the thread that is running that invocation. Invocation context is the internationalization context under which servlet and business method implementations run; it is propagated on subsequent invocations by the internationalization service and middleware. This task also applies to Web service client programs.

Results

The resulting components are said to use *application-managed internationalization* (AMI). For more information about AMI, see “Internationalization context: Management policies” on page 488.

Example

Each supported application component uses the internationalization context API differently. Code examples are provided that illustrate how to use the API within each component type. Differences in API usage, as well as other coding tips, are noted in comments that precede the relevant statement blocks.

- Managing internationalization context in an EJB client program
- Managing internationalization context in a servlet
- Managing internationalization context in a session bean
- Representing internationalization context in a SOAP header

Managing internationalization context in an EJB client program: The following code example illustrates how to use the internationalization context API within a contained EJB client program or Web service client program.

```
//----------------------------------------
// Basic Example: J2EE EJB client.
//----------------------------------------
package examples.basic;

//----------------------------------------
// INTERNATIONALIZATION SERVICE: Imports.
//----------------------------------------
import com.ibm.websphere.i18n.context.UserInternationalization;
import com.ibm.websphere.i18n.context.Internationalization;
import com.ibm.websphere.i18n.context.InvocationInternationalization;

import javax.naming.InitialContext;
import javax.naming.Context;
import javax.naming.NamingException;
import java.util.Locale;
import java.util.SimpleTimeZone;

public class EjbClient {

  public static void main(String args[]) {

    //------------------------------------------------
    // INTERNATIONALIZATION SERVICE: API references.
    //------------------------------------------------
    UserInternationalization userI18n = null;
    Internationalization callerI18n = null;
    InvocationInternationalization invocationI18n = null;

    //------------------------------------------------
    // INTERNATIONALIZATION SERVICE: JNDI name.
    //------------------------------------------------
    final String UserI18NUrl =
        "java:comp/websphere/UserInternationalization";

    //------------------------------------------------
    // INTERNATIONALIZATION SERVICE: Resolve the API.
    //------------------------------------------------
    try {
     Context initialContext = new InitialContext();
     userI18n = (UserInternationalization)initialContext.lookup(
         UserI18NUrl);
     callerI18n = userI18n.getCallerInternationalization();
     invI18n = userI18n.getInvocationInternationalization ();
    } catch (NamingException ne) {
      log("Error: Cannot resolve UserInternationalization: Exception: " + ne);
    } catch (IllegalStateException ise) {
      log("Error: UserInternationalization is not available: " + ise);
    }
    ...

    //--------------------------------------------------------------------
    // INTERNATIONALIZATION SERVICE: Set invocation context.
    //
    // Under Application-managed Internationalization (AMI), contained EJB
    // client programs may set invocation context elements. The following
    // statements associate the supplied invocation locale and time zone
    // with the current thread. Subsequent remote bean method calls will
    // propagate these context elements.
    //--------------------------------------------------------------------
    try {
      invocationI18n.setLocale(new Locale("fr", "FR", ""));
      invocationI18n.setTimeZone("ECT");
    } catch (IllegalStateException ise) {
      log("An anomaly occurred accessing Invocation context: " + ise );
    }
    ...
```

```
    //---------------------------------------------------------------
    // INTERNATIONALIZATION SERVICE: Get locale and time zone.
    //
    // Under AMI, contained EJB client programs can get caller and
    // invocation context elements associated with the current thread.
    // The next four statements return the invocation locale and time zone
    // associated above, and the caller locale and time zone associated
    // internally by the service. Getting a caller context element within
    // a contained client results in the default element of the JVM.
    //---------------------------------------------------------------
    Locale invocationLocale = null;
    SimpleTimeZone invocationTimeZone = null;
    Locale callerLocale = null;
    SimpleTimeZone callerTimeZone = null;
    try {
      invocationLocale = invocationI18n.getLocale();
      invocationTimeZone =
          (SimpleTimeZone)invocationI18n.getTimeZone();
      callerLocale = callerI18n.getLocale();
      callerTimeZone = SimpleTimeZone)callerI18n.getTimeZone();
    } catch (IllegalStateException ise) {
      log("An anomaly occurred accessing I18n context: " + ise );
    }

    ...
  } // main

  ...
  void log(String s) {
    System.out.println (((s == null) ? "null" : s));
  }
} // EjbClient
```

Managing internationalization context in a servlet: The following code example illustrates how to use the internationalization context API within a servlet. Note comments in the init and doPost methods.

```
...
//---------------------------------------------------------------
// INTERNATIONALIZATION SERVICE: Imports.
//---------------------------------------------------------------

```

Representing internationalization context in a SOAP header: This code example illustrates how internationalization context is represented within the SOAP header of a Web service request.

```
<InternationalizationContext>
   <Locales>
      <Locale>
         <LanguageCode>ja</LanguageCode>
         <CountryCode>JP</CountryCode>
         <VariantCode>Nihonbushi</VariantCode>
      </Locale>
      <Locale>
         <LanguageCode>fr</LanguageCode>
         <CountryCode>FR</CountryCode>
      </Locale>
      <Locale>
         <LanguageCode>en</LanguageCode>
         <CountryCode>US</CountryCode>
      </Locale>
   </Locales>
   <TimeZoneID>JST</TimeZoneID>
</InternationalizationContext>
```

This representation is valid against the following schema:

```
<?xml version="1.0" encoding="UTF-8"?>
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema">
    <xsd:element name="InternationalizationContext"
                 type="InternationalizationContextType">
    </xsd:element>

    <xsd:complexType name="InternationalizationContextType">
        <xsd:sequence>
            <xsd:element name="Locales"
                         type="LocalesType">
            </xsd:element>
            <xsd:element name="TimeZoneID"
                         type="xsd:string">

        </xsd:sequence>
    </xsd:complexType>

</xsd:schema>
```

Gaining access to the internationalization context API

Perform this task to access the internationalization service by resolving a reference to the internationalization context API.

About this task

Resolve internationalization context API references once over the life cycle of an application component, within the initialization method of that component (for example, within the init method of servlets, or within the SetXxxContext method of enterprise beans). For Web service client programs, resolve a reference to the internationalization context API during initialization. For stateless session beans enabled for Web services, resolve the reference in the setSessionContext method.

Procedure

1. Resolve a reference to the UserInternationalization interface by performing a lookup on the Java Naming and Directory Interface (JNDI) name `java:comp/websphere/UserInternationalization`. For example:

```
//--------------------------------------------------------------------
// Internationalization context imports.
//--------------------------------------------------------------------
import com.ibm.websphere.i18n.context.*;
import javax.naming.*;
...

public class MyApplication {
  ...

  //--------------------------------------------------------------------
  // Resolve a reference to the UserInternationalization interface.
  //--------------------------------------------------------------------
  InitialContext initCtx = null;
  UserInternationalization userI18n = null;
  final String UserI18nUrl = "java:comp/websphere/UserInternationalization";
  try {
    initCtx = new InitialContext();
    userI18n = (UserInternationalization)initCtx.lookup(UserI18nUrl);
  }
  catch (NamingException ne) {
    // UserInternationalization URL is unavailable.
  }
```

   If the UserInternationalization object is unavailable because of an anomaly or a restriction, the JNDI lookup invocation issues a javax.naming.NameNotFoundException exception that contains the java.lang.IllegalStateException instance.

2. Use the UserInternationalization reference to create references to the CallerInternationalization or InvocationInternationalization objects, which provide access to elements of the Caller or Invocation internationalization contexts, respectively. The CallerInternationalization reference can be bound to the Internationalization interface only; the InvocationInternationalization reference can be bound to either the Internationalization or the InvocationInternationalization interfaces, depending on whether the application requires read-only or read-write access to the invocation context. For example:

```
  ...
  //--------------------------------------------------------------------
  // Resolve references to the Internationalization and
  // InvocationInternationalization interfaces.
  //--------------------------------------------------------------------
  Internationalization callerI18n = null;
  InvocationInternationalization invocationI18n = null;
```

```
try {
  callerI18n = userI18n.getCallerInternationalization();
  invocationI18n = userI18n.getInvocationInternationalization();
}
catch (IllegalStateException ise) {
  // An Internationalization interface(s) is unavailable.
}
```

Accessing caller locales and time zones

Perform this task to access elements of the caller internationalization context.

Before you begin

An application component must first resolve a reference to the CallerInternationalization object and then bind it to the Internationalization interface.

About this task

Every remote invocation of an application component has an associated caller internationalization context associated with the thread that is running that invocation. A caller context is propagated by the internationalization service and middleware to the target of a request, such as an Enterprise JavaBeans (EJB) business method or servlet service method. This task also applies to Web service client programs.

Procedure

1. Obtain the desired caller context elements.

   ```
   java.util.Locale [] myLocales  = null;
   try {
     myLocales  = callerI18n.getLocales();
   }
   catch (IllegalStateException ise) {
     // The Caller context is unavailable;
     // is the service started and enabled?
   }
   ...
   ```

   The Internationalization interface contains the following methods to get caller internationalization context elements:
   - **Locale [] getLocales()** Returns the list of caller locales that are associated with the current thread.
   - **Locale getLocale()** Returns the first in the list of caller locales that are associated with the current thread.
   - **TimeZone getTimeZone()** Returns the SimpleTimeZone caller that is associated with the current thread.

   The Internationalization interface supports read-only access to internationalization context within application components. Methods of the Internationalization interface are available to all EJB application components and are used in the same manner for each, but the method semantics vary according to the component type. For instance, when obtaining the caller locale within an EJB client application, the interface returns the default locale of the host Java virtual machine (JVM); in contrast, when obtaining caller context within a servlet service method (for example, doPost or doGet methods), the interface returns the first locale (accept-language) propagated within the corresponding HTML request. See Internationalization context for a discussion of how the service propagates internationalization context throughout an application.
2. Use the caller context elements to localize computations under a locale or time zone of the calling process.

   ```
   DateFormat df = DateFormat.getDateInstance(myLocale);
   String localizedDate = df.getDateInstance().format(aDateInstance);
   ...
   ```

Accessing invocation locales and time zones

Perform this task to access elements of the invocation internationalization context.

Before you begin

An application component must first resolve a reference to the InvocationInternationalization object and then bind it to the InvocationInternationalization interface of the internationalization context API.

About this task

Every remote invocation of a servlet service or Enterprise JavaBeans (EJB) business method has an invocation internationalization context associated with the thread that is running that invocation. Invocation context is the internationalization context under which servlet and business method implementations run; it is propagated on subsequent invocations by the internationalization service and middleware. This task also applies to Web service client programs.

Procedure

1. Obtain the desired invocation context elements.

   ```
   java.util.Locale myLocale;
   try {
     myLocale = invocationI18n.getLocale();
   }
   catch (IllegalStateException ise) {
     // The invocation context is unavailable;
     // is the service started and enabled?
   }
   ...
   ```

   The InvocationInternationalization interface contains the following methods to both get and set invocation internationalization context elements:
   - **Locale [] getLocales()**. Returns the list of invocation locales that is associated with the current thread.
   - **Locale getLocale()**. Returns the first in the list of invocation locales that is associated with the current thread.
   - **TimeZone getTimeZone()**. Returns the SimpleTimeZone invocation that is associated with the current thread.
   - **setLocales(Locale [])**. Sets the list of invocation locales that are associated with the current thread to the supplied list.
   - **setLocale(Locale)**. Sets the list of invocation locales that are associated with the current thread to a list that contains the supplied locale.
   - **setTimeZone(TimeZone)**. Sets the invocation time zone that is associated with the current thread to the supplied SimpleTimeZone.
   - **setTimeZone(String)**. Sets the invocation time zone that is associated with the current thread to a SimpleTimeZone that has the supplied ID.

   The InvocationInternationalization interface supports read and write access to invocation internationalization context within application components. However, according to internationalization context management policies, only components configured to manage internationalization context (application-managed internationalization, or AMI, components) have write access to invocation internationalization context elements. Calls to set invocation context elements within container-managed internationalization (CMI) application components result in a java.lang.IllegalStateException exception. Any differences in how application components can use InvocationInternationalization methods are explained in Internationalization context.
2. Use the invocation context elements to localize a computation under a locale or time zone of the calling process.

   ```
   DateFormat df = DateFormat.getDateInstance(myLocale);
     String localizedDate = df.getDateInstance().format(aDateInstance);
     ...
   ```

Example

In the following code example, locale (en,GB) and simple time zone (GMT) transparently propagate on the call to the myBusinessMethod method. Server-side application components, such as `myEjb`, can use the InvocationInternationalization interface to obtain these context elements.

```
...
//--------------------------------------------------------------------
// Set the invocation context under which the business method or
// servlet will run and propagate on subsequent remote business
// method invocations.
//--------------------------------------------------------------------
try {
  invocationI18n.setLocale(new Locale("en", "GB"));
  invocationI18n.setTimeZone(SimpleTimeZone.getTimeZone("GMT"));
}
catch (IllegalStateException ise) {
  // Is the component CMI; is the service started and enabled?
}
myEjb.myBusinessMethod();
```

Within CMI application components, the Internationalization and InvocationInternationalization interfaces are semantically equivalent. You can use either of these interfaces to obtain the context associated with the thread on which that component is running. For instance, both interfaces can be used to obtain the list of locales propagated to the servlet doPost service method.

Internationalization context API: Programming reference

Application components programmatically manage internationalization context through the UserInternationalization, Internationalization, and InvocationInternationalization interfaces in the com.ibm.websphere.i18n.context package.

The following code example introduces the internationalization context API:

```
public interface UserInternationalization {
  public Internationalization getCallerInternationalization();
  public InvocationInternationalization
  getInvocationInternationalization();
}

public interface Internationalization {
  public java.util.Locale[] getLocales();
  public java.util.Locale getLocale();
  public java.util.TimeZone getTimeZone();
}

public interface InvocationInternationalization
    extends Internationalization {
  public void setLocales(java.util.Locale[] locales);
  public void setLocale(java.util.Locale jmLocale);
  public void setTimeZone(java.util.TimeZonetimeZone);
  public void setTimeZone(String timeZoneId);
}
```

UserInternationalization interface

The UserInternationalization interface provides factory methods for obtaining references to the CallerInternationalization and InvocationInternationalization context objects. Use these references to access elements of the caller and invocation contexts correlated to the current thread.

Methods of the UserInternationalization interface:

Internationalization getCallerInternationalization()

Returns a reference implementing the Internationalization interface that supports access to

elements of the caller internationalization context correlated to the current thread. If the service is disabled, this method issues an IllegalStateException exception.

InvocationInternationalization getInvocationInternationalization()
Returns a reference implementing the InvocationInternationalization interface. If the service is disabled, this method issues an IllegalStateException exception.

Internationalization interface

The Internationalization interface declares methods that provide read-only access to internationalization context. Given a caller or invocation internationalization context object created with the UserInternationalization interface, bind the object to the Internationalization interface to get elements of that context type. Observe that caller internationalization context can be accessed only through this interface.

Methods of the Internationalization interface:

Locale[] getLocales()
Returns the chain of locales within the internationalization context (object) that is bound to the interface, provided the chain is not null; otherwise this method returns a chain of length(1) containing the default locale of the Java virtual machine (JVM).

Locale getLocale()
Returns the first in the chain of locales within the internationalization context (object) that is bound to the interface, provided the chain is not null; otherwise this method returns the default locale of the JVM.

TimeZone getTimeZone()
Returns the caller time zone (that is, the SimpleTimeZone instance) that is associated with the current thread, provided the time zone is non-null; otherwise this method returns the process time zone.

InvocationInternationalization interface

The InvocationInternationalization interface declares methods that provide read and write access to InvocationInternationalization context. Given an invocation internationalization context object created with the UserInternationalization interface, bind the object to the InvocationInternationalization interface to get and set elements of the invocation context.

According to the container-managed internationalization (CMI) policy, all set methods, setXxx(), issue an IllegalStateException exception when called within a CMI servlet or enterprise bean.

Methods of the InvocationInternationalization interface:

void setLocales(java.util.Locale[] locales)
Sets the chain of locales to the supplied chain, *locales*, within the invocation internationalization context. The supplied chain can be null or have length(>= 0). When the supplied chain is null or has length(0), the service sets the chain of invocation locales to an array of length(1) containing the default locale of the JVM. Null entries can exist within the supplied locale list, for which the service substitutes the default locale of the JVM on remote invocations.

void setLocale(java.util.Locale locale)
Sets the chain of locales within the invocation internationalization context to an array of length(1) containing the supplied locale, *locale*. The supplied locale can be null, in which case the service instead sets the chain to an array of length(1) containing the default locale of the JVM.

void setTimeZone(java.util.TimeZone timeZone)
Sets the time zone within the invocation internationalization context to the supplied time zone, *time zone*. If the supplied time zone is not an exact instance of java.util.SimpleTimeZone or is null, the service sets the invocation time zone to the default time zone of the JVM instead.

void setTimeZone(String timeZoneId)
Sets the time zone within the invocation internationalization context to the java.util.SimpleTimeZone having the supplied ID, *timeZoneId*. If the supplied time zone ID is null or

invalid (that is, the ID is not displayed in the list of IDs returned by the java.util.TimeZone.getAvailableIds method) the service sets the invocation time zone to the simple time zone having an ID of GMT, an offset of 00:00, and otherwise invalid fields.

Internationalization context:

An *internationalization context* is a distributable collection of internationalization information containing an ordered list, or chain, of locales and a single time zone, where the locales and time zone are instances of the java.util.Locale and java.util.TimeZone Java SDK types, respectively. A locale chain is ordered according to the user's preference.

The internationalization service manages and makes available two varieties of internationalization context: the *caller context*, which represents the caller's localization environment, and the *invocation context*, which represents the localization environment under which a business method runs. Server application components use elements of the caller and invocation internationalization contexts to appropriately tailor locale-sensitive and time zone-sensitive computations.

The internationalization service does not support time zone types other than the java.util.SimpleTimeZone type that is found in the Java SDK. Unsupported time zone types silently map to the default time zone of the JVM when supplied to internationalization context API methods. For a complete description of the java.util.Locale, java.util.TimeZone and java.util.SimpleTimeZone types, refer the Java SDK API documentation.

Caller context

Caller internationalization context contains the locale chain and time zone received on incoming EJB business method and servlet service method invocations; it is the internationalization context propagated from the calling process. Use caller context elements within server application components to localize computations to the calling component. Caller context is read-only and can be accessed by all application components by using the Internationalization interface of the internationalization context API.

Caller context is computed in the following manner: On an EJB business method or servlet service method invocation, the internationalization service extracts the internationalization context from the incoming request and scopes this context to the method as the caller context. For any missing or null context element, the service inserts the corresponding default element of the JVM (for example, java.util.Locale.getDefault() or java.util.TimeZone.getDefault().) The service performs a similar insertion whenever missing or null Caller context elements are encountered on invocations of stateless session beans that are enabled for Web services.

Formally, caller context is the invocation context of the calling business method or application component.

Invocation context

Invocation internationalization context contains the locale chain and time zone under which EJB business methods and servlet service methods run. It is managed by either the hosting container or the application component, depending on the applicable internationalization policy. On outgoing business method requests, it is the context that propagates to the target process. Use invocation context elements to localize computations under the specified settings of the current application component.

Invocation context is computed in the following manner: On an incoming business method or servlet service method invocation, the internationalization service queries the associated context management policy. If the policy is container-managed internationalization (CMI), the container scopes the context designated by the policy to the invocation; otherwise the policy is application-managed internationalization (AMI), and the container scopes an empty context to the invocation that can be altered by the method implementation.

Application components can access invocation context elements through both the Internationalization and InvocationInternationalization interfaces of the internationalization context API. Invocation context elements can be set (overwritten) under the application-managed internationalization policy only.

On an outgoing business method request, the service obtains the currently scoped invocation context and attaches it to the request. This outgoing exported context becomes the caller context of the target invocation. When supplying invocation context elements, either for export on outgoing requests or through the API, the internationalization service always provides the most recent element set using the API; the service also supplies the corresponding default element of the JVM for any null invocation context element.

Because the internationalization context that is propagated over Web services (SOAP) requests contains a time zone ID rather than the entire state of a java.lang.SimpleTimeZone object, time zone information might be lost when a Web service-enabled client program or session bean becomes involved in remote business computation.

Internationalization context: Propagation and scope:

The scope of internationalization context is implicit. Every Enterprise JavaBeans (EJB) client application, servlet service method, and EJB business method call has two internationalization contexts under which it runs.

For each application component call, the container enters the caller context and the call context, as indicated by the pertinent internationalization policy, into scope before the container delegates to the actual implementation. When the implementation returns, the service removes these contexts from scope. The internationalization service supplies no programmatic mechanism for components to explicitly manage the scope of internationalization context.

The service scopes internationalization context differently with respect to application component type:
- "EJB client programs (contained)"
- "Servlets" on page 487
- "Enterprise beans" on page 487
- "Web service client programs (contained)" on page 487
- "Stateless session beans that are enabled for Web services" on page 488

Internationalization context observes by-value semantics over remote method requests. Changes to internationalization context elements that are scoped to a call do not affect the corresponding elements of the internationalization context that is scoped to the remote calling process. Also, modifications to context elements obtained using the internationalization context API do not affect the corresponding elements that are scoped to the invocation.

EJB client programs (contained)

Before it calls the main method of a client program, the Java EE client container introduces into scope invocation and caller internationalization some contexts that contain null elements. These contexts remain in scope throughout the life of the program. EJB client programs are the base in a chain of remote business method invocations and, technically, do not have a logical caller context. Accessing a caller context element yields the corresponding default element of the client JVM. On outgoing EJB business method requests, the internationalization service propagates the invocation context to the target process. Any unset (null) invocation context elements are replaced with the default of the JVM when exported by the internationalization context API or by outgoing requests.

Tip:

To propagate values other than the JVM defaults to remote business methods, EJB client programs, as well as AMI servlets or enterprise beans, must set (override) elements of the invocation context. To learn how to set invocation context elements, see “Accessing invocation locales and time zones” on page 481.

Servlets

On every servlet service method (doGet or doPost) invocation, the Java EE Web container introduces caller and invocation internationalization contexts into scope before delegating to the service method implementation. The caller context contains the accept-languages propagated in the HTTP servlet request, typically from a Web browser. The invocation context contains whichever context is indicated by the container internationalization attribute of the internationalization policy that is associated with the servlet. Any unset (null) invocation context elements are replaced with the default of the server JVM when exported by the internationalization context API or by outgoing requests. The caller and invocation contexts remain effective until immediately after the implementation returns, at which time the container removes them from scope.

Enterprise beans

On every EJB business method invocation, the Java EE EJB container introduces caller and invocation internationalization contexts into scope before delegating to the business method implementation. The caller context contains the internationalization context elements imported from the incoming IIOP request; if the incoming request lacks a particular internationalization context element, the container scopes a null element. The invocation context contains whichever context is indicated by the container internationalization attribute of the internationalization policy that is associated with the business method.

On outgoing EJB business method requests, the service propagates the invocation context to the target process. Any unset (null) invocation context elements are replaced with the default of the server JVM when exported by the internationalization context API or by outgoing requests. The caller and invocation contexts remain effective until immediately after the implementation returns, when the container removes them from scope.

Consider a simple EJB application with a Java client that calls the remote myBeanMethod bean method. On the client side, the application can use the Internationalization Service API to set invocation context elements. When the client calls myBeanMethod(), the service exports the client invocation context to the outgoing request. On the server side, the service detaches the imported context from the incoming request and scopes it to the method as its caller context; the service also scopes the invocation context to the method as indicated by the associated internationalization context management policy. The EJB container then calls the myBeanMethod method, which can use the internationalization context API to access elements of either the caller or invocation contexts. When the myBeanMethod method returns, the EJB container removes these contexts from scope.

Web service client programs (contained)

Before it calls the main method of a Web service client program, the client container introduces into scope both invocation and caller internationalization contexts that contain null elements. These contexts remain in scope throughout the duration of the program. Web service client programs are the base in a chain of remote business method invocations and, technically, do not have a logical caller context. Accessing a Caller context element yields the corresponding default element of the client virtual machine.

On outgoing Web service requests, the internationalization service transparently creates a SOAP header block that contains the invocation context that is associated with the current thread; the SOAP representation of invocation context is propagated through the request to the target process. Any unset (that is, null) invocation context elements are replaced with the default element of the JVM when exported by the internationalization context API or by outgoing requests. Also, because the header contains only a

time zone ID, the additional state of the time zone object (java.lang.SimpleTimeZone) of the invocation context might be lost, because it does not get propagated through the request.

Tip:

To propagate values other than the JVM defaults to remote business methods, Web service client programs, as well as AMI servlets or enterprise beans, must set (override) elements of the invocation context. For more information, see “Accessing invocation locales and time zones” on page 481.

Stateless session beans that are enabled for Web services

On every method invocation of a Web service-enabled bean, the EJB container introduces caller and invocation internationalization contexts into scope before delegating control to the business method implementation. The caller context contains the internationalization context elements that are imported from the SOAP header block of the incoming request. If the incoming request lacks a particular internationalization context element, the container introduces a null element into scope. The invocation context contains whichever context is indicated by the container internationalization attribute of the internationalization policy that is associated with the business method.

On outgoing EJB business method requests, the service propagates the invocation context to the target process. Any unset (that is, null) invocation context elements are replaced with the default element of the server JVM when exported by the internationalization context API or by outgoing requests. The caller and invocation contexts remain effective until immediately after control returns from the business method implementation, at which time the container removes them from scope.

On outgoing Web service requests, the internationalization service transparently creates a SOAP header block that contains the invocation context associated with the current thread. The SOAP representation of the invocation context is propagated through the request to the target process. Any unset (that is, null) invocation context elements are replaced with the default element of the JVM when exported by the internationalization context API or by outgoing requests.

Thread association considerations

The Web and EJB containers scope internationalization contexts to a method by associating the method with the thread that run the method implementation. Similarly, methods of the internationalization context API either associate context with, or obtain context associated with, the thread on which these methods run.

In cases where new threads are spawned within an application component (for instance, a user-generated thread inside the service method of a servlet, or a system-generated event handling thread in an AWT client) the internationalization contexts associated with the parent thread does not automatically transfer to the newly-spawned thread. In such instances, the service exports the default locale and time zone of the JVM on any remote business method request and on any API calls that run on the new thread.

If the default context is inappropriate, the desired invocation context elements must be explicitly associated to the new thread by using the setXxx methods of the InvocationInternationalization interface. Currently, internationalization context management policies enable invocation context to be set within EJB client programs, as well as within servlets, session beans, and message-driven beans that use application-managed internationalization.

Internationalization context: Management policies:

Internationalization policies prescribe how Java EE application components or their hosting containers manage internationalization context on component invocations. Two internationalization context management policies apply to all component types: Application-managed internationalization (AMI) and Container-managed internationalization (CMI).

These policies are represented in two parts:
- Internationalization type
- Container internationalization attribute

The service defines a default, or implicit, internationalization policy for every application component type. At development time, assemblers can override the default policy for server component types by explicitly configuring their internationalization type, and optional container internationalization attributes. Policies configured during assembly are preserved in the deployment descriptor for the application.

All components have an internationalization type that indicates whether it is AMI or CMI; that is, whether a component is to deploy under the application-managed or the container-managed internationalization policy. Application assemblers can set the internationalization type for servlets, session beans, and message-driven beans. Entity beans are implicitly CMI and EJB clients are implicitly AMI; neither can be configured otherwise.

For CMI servlets and enterprise beans, optional container internationalization attributes can be specified to indicate which invocation internationalization context the container is to scope to service or business methods. A CMI service or business method invocation can run under the context of the caller's process, under the default context of the server JVM, or under a custom context specified in the attribute. Assemblers can specify one container internationalization attribute per disjoint set of CMI servlets within a Web module, or one Attribute per disjoint set of business methods of CMI beans within an EJB module. A container internationalization attribute can be associated with more than one method, but a method cannot be associated with more than one attribute.

When an application server launches an application, the internationalization service collects policy information from the deployment descriptor, then uses this information to construct and associate an internationalization policy to every component invocation. A policy is denoted as:

```
[<Internationalization Type>,<Container Internationalization Attribute>]
```

Several cases exist in which the deployment descriptor seems to lack policy information, for example: EJB client applications have no configurable internationalization policy settings; AMI components do not have container internationalization attributes; and you are not required to specify container internationalization attributes for CMI components. When the service cannot obtain the explicit internationalization type and container attribute settings from a well-formed deployment descriptor, it implicitly inserts the appropriate setting into the policy.

The service observes the following conventions when applying policies to invocations:
- Servlets (service) and EJB business methods lacking all internationalization policy information in the deployment descriptor implicitly run under policy `[CMI,RunAsCaller]`.
- CMI servlets and business methods lacking a container internationalization attribute in the deployment descriptor implicitly run under policy `[CMI,RunAsCaller]`.
- AMI servlets and business methods always lack container internationalization attributes in the deployment descriptor, but implicitly run under the logical policy `[AMI,RunAsServer]`.
- EJB clients always lack internationalization policy information in the deployment descriptor. By definition, EJB clients are implicitly AMI types and run under the invocation context of the JVM; they run under the logical policy `[AMI,RunAsServer]`.

For conditions other than these cited examples, such as a malformed deployment descriptor, refer to Internationalization service errors.

Internationalization policies for EJB clients and HTTP clients cannot be configured; HTTP clients do, however, run under the language priority settings of the hosting Web browser. These settings are configurable under the options dialog of most Web browsers. Refer to your Web browser documentation for details.

Internationalization type:

Every server application component has an *internationalization type* setting that indicates whether the invocation internationalization context is managed by the component or by the hosting Java EE container.

Server application components can be deployed to use one of two types of internationalization context management:
- Application-managed internationalization (AMI)
- Container-managed internationalization (CMI)

A server component can be deployed as AMI or CMI, but not both; CMI is the default. The setting applies to the entire component on every invocation. Entity beans use CMI only. Enterprise JavaBeans (EJB) client applications do not have an internationalization type setting; they implicitly use AMI.

Application-managed internationalization

Under the AMI deployment policy, component developers assume complete control over the invocation internationalization context. AMI components can use the internationalization context API to programmatically set invocation context elements.

AMI components are expected to manage invocation context. Invocations of AMI components implicitly run under the default locale and time zone of the hosting JVM. Invocation context elements not set using the API default to the corresponding elements of the JVM when accessed through the API or when exported on business methods. To export context elements other than the JVM defaults, AMI servlets, AMI enterprise beans, and EJB client applications must set (overwrite) invocation elements using the internationalization context API. Moreover, the container logically suspends the caller context that is imported on the AMI servlet lifecycle method and AMI EJB business method invocations. To continue propagating the context of the calling process, AMI servlets and enterprise beans must use the API to transfer caller context elements to the invocation context.

Specify AMI for server components that have internationalization context management requirements that are not supported by container-managed internationalization (CMI).

Container-managed internationalization

CMI is the preferred internationalization context management policy for server application components; it is also the default policy. Under CMI, the internationalization service collaborates with the Web and EJB containers to set the invocation internationalization context for servlets and enterprise beans. The service sets invocation context according to the container internationalization attribute of the policy that is associated with a servlet (service method) or an EJB business method.

A CMI policy has a container internationalization attribute that indicates which internationalization context the container is to scope to an invocation. For details, see Container internationalization attributes. By default, invocations of CMI components run under the caller's internationalization context; or rather, they adhere to the implicit policy `[CMI,RunasCaller]` whenever the servlet or business is not associated with an attribute in the deployment descriptor. For complete details, see Internationalization context: Management policies.

Methods within CMI components can obtain elements of the invocation context using the internationalization context API, but cannot set them. Any attempt to set invocation context elements within CMI components results in a java.lang.IllegalStateException exception.

Specify container-managed internationalization for server application components that require standard internationalization context management. Then specify the container internationalization attributes for CMI servlets and for business methods of CMI enterprise beans that you do not want to run under the caller's internationalization context.

Container internationalization attributes:

The internationalization policy of every CMI servlet and EJB business method has a *container internationalization attribute* that specifies which internationalization context the container is to scope to its invocation.

The container internationalization attribute has three main fields:
- Run as
- Locales
- Time zone ID

As a convenience, you can create named container internationalization attributes and associate them to the following subsets:
- CMI servlets within a Web module
- Business methods of CMI enterprise beans within an Enterprise JavaBeans (EJB) module
- Business methods of Web service-enabled session beans. In the following descriptions, the term *supported enterprise bean* refers to both CMI enterprise beans and Web service-enabled session beans.

Run-as field

The **Run-as** field specifies one of three types of invocation context that a container can scope to a method. For servlet service and EJB business methods, the container constructs the invocation internationalization context according to the **Run as** field setting and associates this context to the current thread before delegating to the method implementation.

By default, invocations of servlet service methods and EJB business methods implicitly run as caller (`RunAsCaller`) unless the **Run as** field of a policy attribute specifies otherwise. EJB client applications and AMI server components always run as server (`RunAsServer`).

You can specify the following invocation context types with the **Run as** field are:

Caller The container calls the method under the internationalization context of the calling process. For any missing context element, the container supplies the corresponding default context element of the Java virtual machine (JVM). Select run as caller when you want the invocation to run under the invocation context of the calling process.

Server
The container calls the method under the default locale and time zone of the JVM. Select run as server when you want the invocation to run under the invocation context of the JVM.

Specified
The container calls the method under the internationalization context specified in the attribute. Select run as specified when you want the invocation to run under the custom invocation context that is specified in the policy; then provide the custom context elements by completing the Locales and Time zone ID fields.

Remember: Java Message Service (JMS) messages do not contain internationalization context. Although container-managed message-driven beans can be configured to run as caller, the container associates the default elements of the server process when calling the onMessage method of any message-driven bean that is configured as `[CMI, RunAsCaller]`. You can also configure the **Run as** field for Web service business methods.

Locales field

The **Locales** field specifies an ordered list of locales that the container scopes to an invocation. A locale represents a specific geographical, cultural, or political region and contains three fields:
- **Language code**. Ideally, language code is one of the lower-case, two-character codes that are defined by the ISO 639 standard; however, language code is not restricted to ISO codes and is not a required field. A valid locale must specify a language code if it does not specify a country code.

- **Country code**. Ideally, country code is one of the upper-case, two-character codes that are defined by the ISO 3166 standard; however, country code is not restricted to ISO codes and is not a required field. A valid locale must specify a country code if it does not specify a language code.
- **Variant**. Variant is a vendor-specific code. Variant is not a required field and serves only to supplement the language and country code fields according to application- or platform-specific requirements.

A valid locale must specify at least a language code or a country code; the variant is always optional. The first locale of the list is returned when accessing invocation context using the getLocale method of the internationalization context API.

Time zone ID field

The **Time zone ID** field specifies an abbreviated identifier for a time zone that the container scopes to an invocation. You can also configure the **Time zone ID** field for Web service business methods.

A time zone represents a temporal offset and computes daylight savings information. A valid ID indicates any time zone supported by the java.util.TimeZone type. Specifically, a valid ID is any of the IDs that appear in the list of time zone IDs returned by method java.util.TimeZone.getAvailableIds(), or a custom ID having the form `GMT[+|-]hh[[:]mm]`; for example, `America/Los_Angeles`, `GMT-08:00` are valid time zone IDs.

Administering the internationalization service

To use internationalization context in an Enterprise JavaBeans (EJB) application, the internationalization service must be enabled in the runtime environments for all server-side components (servlets and enterprise beans, including session beans enabled for Web service usage) as well as all client-side components (EJB client applications and Web service clients).

About this task

If you do not require the internationalization service, do not enable it. Leaving the service disabled prevents any possible performance degradation incurred by the implicit distribution of internationalization resources.

The internationalization service cannot be enabled for HTTP clients, because support for internationalization in that case is provided by the browser, not by the application server.

Procedure

- Enable or disable the internationalization service for servlets and enterprise beans. By default, the service is disabled for server-side components within the application server. You enable the service by using either the administrative console or the wsadmin tool.
- Enable or disable the internationalization service for EJB clients. By default, the service is disabled within the client container. You enable the service by using the launchClient tool.

Enabling the internationalization service for servlets and enterprise beans

Perform this task to enable the internationalization service in the application server runtime environment.

About this task

Any servlet or enterprise bean can use internationalization context if the internationalization service is enabled within the hosting application server instance.

Procedure

1. Start the administrative console.
2. Click **Servers** > **Application servers** > ***server_name*** > **Container services** > **Internationalization service**.

3. Enable the internationalization service.
   a. If not already selected, select the **Enable service at server startup** check box.
   b. Click **OK**.

Results

When you select the **Enable service at server startup** setting, the application server automatically initializes and starts the internationalization service whenever the server starts. If you change this setting, be sure to restart the application server for the new setting to take effect.

To disable the service, clear the **Enable service at server startup** check box. In this case, the internationalization service is initialized but not started when the application server starts.

Example

Alternatively, the internationalization service can be enabled from the command line by using the wsadmin tool. Start the wsadmin tool and enter the following commands:

```
set x [$AdminConfig list I18NService]
$AdminConfig modify $x { { enable true } }
$AdminConfig save
exit
```

What to do next

If you enable or disable the internationalization service, be sure to stop and then restart the application server for the new setting to take effect.

Enabling the internationalization service for EJB clients

By default, the internationalization service is disabled for use within Enterprise JavaBeans (EJB) and Web-service enabled client applications. You must enable the service for client applications as well as for all server instances in the runtime environment.

Procedure

Enable the service.
When calling the launchClient tool, include the argument `-CCDI18NService.enable=true` or `-CCDI18NService.enable=yes`.

Internationalization service settings

Use this page to enable or disable the internationalization service. The internationalization service manages the implicit propagation and scoping of locale and time zone information, called *internationalization context*, within application components. When the service is enabled, application components can use the internationalization context API to programmatically manage locale and time zone information. In turn, components can use that locale and time zone information with the Java Platform, Standard Edition (JSE) Internationalization API to perform localizations. If internationalization support is not required on the server, disabling the service can improve performance.

To view this administrative console page, click **Servers > Server Types > WebSphere application servers >** *server_name*. Then, under Container Settings, click **Container Services > Internationalization Service**.

Enable service at server startup:

Specifies whether the server attempts to start the internationalization service.

Default Cleared

Range Valid values are Selected or Cleared

More information about valid values follows:

Selected
When the application server starts, it attempts to start the internationalization service automatically.

Cleared
The server does not try to start the internationalization service.

To enable the internationalization service for applications on this server, the system administrator must select this property and then restart the server.

Internationalization service errors

Certain conditions might cause the internationalization service not to start, to issue java.lang.IllegalStateException exceptions while an application is running, or to exercise default behaviors.

The java.lang.IllegalStateException exception indicates one of the following things:

- An application component attempted an operation that is not supported by the internationalization programming model.

  The IllegalStateException exception is issued whenever a server application component whose internationalization type is set to container-managed internationalization (CMI) attempts to set invocation context. This behavior is a violation of the CMI policy, under which servlets and enterprise beans cannot modify their invocation internationalization context.
- An anomaly occurred that disabled the service.

  For instance, if the internationalization service is not properly initialized, the Java Naming and Directory Interface (JNDI) lookup on the UserInternationalization URL attribute issues a javax.naming.NameNotFoundException exception that contains an IllegalStateException instance.

The following conditions can occur while your internationalized application is running. These conditions might cause the internationalization service not to start, to issue IllegalStateException exceptions, or to exercise default behaviors:

- "The service is disabled "
- "The service is not started" on page 495
- "Invalid context element" on page 496
- "Missing context element" on page 496
- "Invalid policy" on page 496
- "Missing policy" on page 496

If you encounter unexpected or exceptional behavior, the problem is likely related to one of these conditions. You need to examine the trace log to investigate these conditions, which requires that you configure the diagnostic trace service to generate messages about internationalization service function.

The trace strings for the internationalization service follow; use both:

```
com.ibm.ws.i18n.context.*=all=enabled:com.ibm.websphere.i18n.context.*=all=enabled
```

The service is disabled

The internationalization service is not initialized when the startup setting is cleared. The service generates a message that indicates whether it is enabled or disabled. Applications cannot access the internationalization API when the service is disabled. If an application attempts a JNDI lookup to obtain the UserInternationalization reference, the lookup fails with a NamingException exception, indicating that the reference cannot be found. In addition, the service does not scope (propagate) internationalization context on incoming (outgoing) business method calls.

The service is not started

The internationalization service is operational whenever it is in the STARTED state. For example, if an application attempts to access internationalization context and the service is not started, the API issues an IllegalStateException exception. In addition, the service does not provide runtime support for servlets and enterprise beans.

As an application server progresses through its life cycle, it initializes, starts, stops, and terminates (destroys) the internationalization service. If an anomaly occurs during initialization, the service does not start. After the service is started, its state can change to BLOCKED in the event that a serious error occurs. The service generates a message for every state change.

If a trace message indicates that the service is not STARTED, examine previous messages to determine the problem. For instance, the internationalization service does not start if the activity service is unavailable and a message is displayed to that effect during initialization of the internationalization service.

During startup, the following messages indicate potential configuration or runtime problems:

No ORB support
: The service cannot obtain an instance of the object request broker (ORB). This condition is a fatal error. Examine the `SystemErr.log` and `SystemOut.log` files for information.

No TCM support
: The service cannot obtain an instance of its thread context manager (TCM). This condition is a fatal error. Examine the `SystemErr.log` and `SystemOut.log` files for information.

No IIOP (activity service) support
: The service cannot register with the activity service. This condition is a fatal error. The internationalization service cannot propagate or receive context on Internet Inter-ORB Protocol (IIOP) requests without activity service support. Examine the `SystemErr.log` and `SystemOut.log` files for information.

No AsynchBeans support
: The service cannot register into the asynchronous beans environment. This warning indicates that the asynchronous beans environment cannot support internationalization context.

No EJB container support
: The service cannot register with the Enterprise JavaBeans (EJB) container. This warning indicates that the internationalization service cannot support enterprise beans. Without EJB container support, internationalization contexts do not scope properly to EJB business methods. Review the trace log for any EJB container-related error conditions.

No Web container support
: The service cannot register with the Web container. This warning indicates that the internationalization service cannot support servlets and JavaServer Page (JSP) files. Without Web container support, internationalization contexts do not scope properly to servlet service methods. Review the trace log for any Web container-related error conditions.

No Metadata support
: The service cannot register with the metadata service. This warning indicates that the internationalization service cannot process the internationalization policies within application deployment descriptors. Without metadata support, the service associates the default internationalization context management policy, [CMI, RunAsCaller], to every servlet lifecycle method and enterprise bean business method invocation. Review the trace log for any metadata service-related error conditions.

No JNDI (Naming service) support
: The service cannot bind the UserInternationalization object into the namespace. This condition is a fatal error. Application components are unable to access internationalization context API references, and are therefore unable to access internationalization context elements. Review the trace log for any Naming (JNDI) service-related error conditions.

No API support
: The service cannot obtain an instance of an internationalization context API object. This condition

is a fatal error. Application components are unable to access internationalization context API references, and are therefore unable to access internationalization context elements.

Invalid context element

The service detected an invalid internationalization context element. For example, the internationalization service does not support TimeZone instances of a type other than java.util.SimpleTimeZone. If the service encounters an unusable element, it logs a message and substitutes the corresponding default element of the JVM.

Missing context element

The service detected a missing internationalization context element. Incoming requests (for example, from application servers that do not support the internationalization service) lack internationalization context. When the service attempts to access a caller internationalization context element (which does not exist in this case), the service logs a message and substitutes the corresponding default element of the Java virtual machine (JVM).

Whenever possible, enable the internationalization service within all clients and hosting application servers that comprise an internationalized enterprise application. Read more information about Administering the internationalization service in the *Administering applications and their environment* PDF book.

Invalid policy

The internationalization service detected a malformed internationalization policy in the application deployment descriptor. The service replaces the malformed attribute with the appropriate default. For instance, if the internationalization type for an entity bean is set to `Application` during the run of a servlet or EJB business method call, the service logs the inconsistency and enforces the `Container` setting instead.

Also, AMI application components do have an implicit container internationalization attribute. By default they run as server. The service silently enforces the implicit policy, `[AMI, RunAsServer]`, and logs messages to this effect.

Invalid container internationalization attributes are likely to occur when specifying the Locales and Time zone ID fields. When encountering invalid locales and time zone IDs within attributes, the service replaces each value with the corresponding default element of the JVM. Be sure to follow the guidelines provided in the *Developing and deploying applications* PDF book.

Missing policy

The service detected a missing internationalization policy. The service replaces the missing policy with the appropriate default. For instance, if the internationalization type is missing for a servlet or enterprise bean, the service sets the attribute to Container.

Container internationalization attributes are not mandatory for CMI application components. In the event that a CMI servlet or EJB business method lacks a container internationalization attribute, the service silently enforces the implicit policy `[CMI, RunAsCaller]`.

When an application lacks internationalization policies in its deployment descriptor, or metadata support is unavailable, the service logs a message and applies the policy `[CMI, RunAsCaller]` on every servlet service method and EJB business method invocation.

Read the information in the *Developing and deploying applications* PDF book:
- Assembling internationalized applications
- Container internationalization attributes

- Internationalization type

Chapter 11. Administering Mail, URLs, and other Java EE resources

This page provides a starting point for finding information about resources that are used by applications that are deployed on a Java Enterprise Edition (Java EE)-compliant application server. They include:

- JavaMail support for applications to send Internet mail
- URLs, for describing logical locations
- Resource environment entries, for mapping logical names to physical names
- Java DataBase Connectivity (JDBC) resources and other technology for data access (discussed elsewhere)
- Java Message Service (JMS) resources and other messaging system support (discussed elsewhere)

Configuring mail providers and sessions

Configure your own mail providers and sessions to customize how mail is handled in the application server. A mail provider encapsulates a collection of protocol providers, like SMTP, IMAP and POP3, and others. Mail sessions authenticate users and control access to messaging systems.

About this task

The application server includes a default mail provider that is called the built-in provider. If you use the default mail provider, you only have to configure the mail session.

To use a customized mail provider, you must create the mail session and provider.

Procedure

- Create the mail session.
  1. In the administrative console, click **Resources** > **Mail** > **Mail sessions**.
  2. Select the scope for the new mail session.
  3. Click **New**.
  4. Type the mail session name in the Name field.
  5. Type the JNDI name in the JNDI Name field.
  6. Optional: Enable strict Internet address parsing. This option specifies whether the recipient addresses must be parsed in strict compliance with RFC 822, which is a specifications document that is issued by the Internet Architecture Board. This setting is not generally used for most mail applications, and by default this setting is not enabled.

     RFC 822 syntax for parsing addresses effectively enforces a strict definition of a valid email address. If you select this setting, your mail component adheres to RFC 822 syntax and rejects recipient addresses that do not parse into valid email addresses as defined by the specification. If you do not select this setting, your mail component does not adhere to RFC 822 syntax and accepts recipient addresses that do not comply with the specification. You can view the RFC 822 specification at the website for the World Wide Web Consortium.
  7. Optional: Enable debug mode. Select this option to print interaction between the mail application and the mail servers and the properties of this mail session to the SystemOut.log file.

     Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer

command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

8. Provide information for the incoming mail service, outgoing service, or both. Enter the following information in the fields that are provided:
   - Server
   - Protocol
   - User
   - Password
   - Return email address. This field is available for outgoing mail properties.
9. Click **Apply** or **OK**.

- Create the mail provider, and optionally define one or more protocol providers. In the administrative console, click **Resources** > **Mail** > **Mail Providers**.
  1. Select the scope for the new mail provider.
  2. Click **New**.
  3. Type the name of the mail provider in the name field.
  4. Optional: Isolate the mail provider.

     You can isolate a mail provider to allow different versions of the same provider to be loaded in the same Java Virtual Machine (JVM). For example, you might want to deploy multiple applications on a single server, but each application requires different versions or implementations of the mail provider. You can isolate each version or implementation of the provider, and the provider is loaded in its own class loader and does not interfere with other implementations. There are some general considerations for isolating any type of resource provider; refer to the topic on considerations for isolated resource providers for more information.
     a. Select **Isolate this mail provider**.
     b. Give the mail provider a unique class path that is appropriate for that version or implementation.
  5. Click **Apply** or **OK**.
  6. Define one or more protocol providers for the mail provider.
     a. Click *mail_provider*.
     b. Click **Protocol Providers**.
     c. Click **New**.
     d. Type the protocol name in the **Protocol** field.
     e. Type the class name in the **Class name** field.
     f. Select the type of mail server that this protocol provider supports. Select TRANSPORT or STORE. TRANSPORT corresponds to outgoing mail services, and STORE corresponds to incoming mail services.
     g. Click **Apply** or **OK**.

     Ensure that every mail session is defined under a parent mail provider. Select a mail provider first and then create your mail session.
- Optional: Configure the mail session.
  1. Click *mail_provider*.
  2. Click **Mail Sessions**.
  3. Click *mail_session*.
  4. Make changes to appropriate fields.
  5. Click **Apply** or **OK**.

What to do next

If your application has a client, you can configure mail providers and sessions using the Application Client Resource Configuration Tool.

Mail provider collection

Use this page to view available JavaMail service providers, also known as *mail providers*. The mail provider encapsulates a collection of protocol providers, which implement the protocols for communication between your mail application and mail servers.

To view this administrative console page, click **Resources** > **Mail** > **Mail Providers**.

The **built-in mail provider** made available by WebSphere Application Server encompasses three protocol providers: Simple Mail Transfer Protocol (SMTP), Internet Message Access Protocol (IMAP) and Post Office Protocol (POP3). Select the built-in provider if these protocols provide the right support for your mail system. If you have installed or plan to install different protocol providers, you must assign them a mail provider; select the scope at which you want the new mail provider to implement the protocols, then select **New**.

Name
Specifies the name of the JavaMail resource provider.

Scope
Specifies the scope in which the mail provider supports installed mail applications.

Description
Specifies the resource provider description.

Mail provider settings

Use this page to edit mail provider properties or configure a new mail provider. The mail provider encapsulates a collection of protocol providers, which implement the protocols for communication between your mail application and mail servers.

To view this administrative console page, click **Resources** > **Mail** > **Mail Providers** > ***mail_provider***, or create a new mail provider by clicking **Resources** > **Mail** > **Mail Providers** > **New**.

Scope
Specifies the scope in which the mail provider supports installed mail applications.

Name
Specifies the name of the mail provider.

Description
Specifies the resource provider description.

Isolate this mail provider
Specifies that this mail provider will be loaded in its own class loader. This allows the application server to load different versions or implementations of the same mail provider in the same Java Virtual Machine. Give each version or implementation of the mail provider a unique class path that is appropriate for that version or implementation.

Class path
Specifies the class path to a Java archive (JAR) file that contains the implementation classes for this mail provider. If more than one JAR file provides the complete implementation, add an entry for each JAR file that the mail provider requires. Enter one class path per line; do not use class path separator information.

Protocol providers collection

Use this page to select or add a protocol provider that supports interaction between your mail application and mail servers. For example, your application might require the Simple Mail Transfer Protocol (SMTP), which is a popular transport protocol for sending mail. Selecting that protocol provider allows your mail application to connect and send mail through the server.

To view this administrative console page, click **Resources** > **Mail** > **Mail Providers** > ***mail_provider*** > **Protocol Providers**.

Protocol

Specifies the configuration of the protocol provider for a given protocol.

Class name

Specifies the implementation class for the specific protocol provider, which is also known as the mail service provider.

Type

Specifies the type of protocol provider. Valid options are **STORE** or **TRANSPORT**.

Protocol providers settings

Use this page to set properties of a protocol provider, including SMTP, IMAP and POP3, which provides the implementation class for a specific protocol to support communication between your mail application and mail servers.

Built-in providers: The application server contains protocol providers for various types of protocols, including SMTP, IMAP and POP3. If you require custom providers for protocols that are not provided by the application server, install them in your application serving environment before configuring the providers. See the JavaMail API design specification for guidelines. After configuring your protocol providers, return to the mail provider page to find the link for configuring mail sessions.

To view this administrative console page, click **Resources** > **Mail** > **Mail Providers** > ***mail_provider*** > **Protocol Providers** > ***protocol_provider***.

Scope

Specifies the scope at which this protocol provider was created. Only applications that are installed within this scope can use a protocol that is configured according to the settings of this protocol provider.

Protocol

Specifies the configuration of the protocol provider for a given protocol.

Class name

Specifies the implementation class of this protocol provider.

Type

Specifies the type of protocol provider. Valid options are **STORE** or **TRANSPORT**.

Mail session collection

Use this page to view mail sessions that are defined under the parent mail provider.

You can access this administrative console page in one of two ways:

- **Resources** > **Mail** > **Mail Sessions**
- **Resources** > **Mail** > **Mail Providers** > *mail_provider* > **Mail Sessions**

Name
Specifies the administrative name of the JavaMail session object.

Scope
Specifies the scope at which the mail session was created. Only JavaMail applications that are installed in this scope can use this mail session.

Provider
Specifies the mail provider that WebSphere Application Server uses for this mail session.

JNDI Name
Specifies the Java Naming and Directory Interface (JNDI) name for the resource, including any naming subcontexts.

This name provides the link between the platform binding information for resources defined in the client application deployment descriptor and the actual resources bound into JNDI by the platform.

Description
Specifies an optional description for your administrative records.

Category
Specifies an optional collection for classifying or grouping sessions.

Mail session configuration settings
Use this page to configure mail sessions.

You can access this administrative console page in one of two ways:

- **Resources** > **Mail** > **Mail sessions** > ***mail_session***
- **Resources** > **Mail** > **Mail Providers** > ***mail_provider*** > **Mail sessions** > ***mail_session***

Scope
Specifies the scope of the mail provider that implements the JavaMail API for this mail session. Only applications that you installed within this scope can use this mail session.

Provider
Specifies the mail provider that the application server uses for this mail session.

When you create a mail session, if you previously defined one or more mail providers at the relevant scope, you will see a list from which you can select an existing mail provider for the new mail session.

Create New Provider
Provides the option of configuring a new mail provider for the new mail session.

Create New Provider is displayed only when you click **Resources** > **Mail** > **Mail sessions** > **New** to create a new mail session.

Clicking **Create New Provider** triggers the console to display the mail provider configuration page, where you create a new provider. After you click **OK** to save your settings, you see the mail session collection page. Click **New** to define a new mail session for use with the new provider; the console now displays a configuration page that lists the new mail provider as the mail session Provider.

Note: After you create a mail session, you cannot change the provider of that mail session.

Name
Specifies the administrative name of the JavaMail session object.

JNDI name
Specifies the Java Naming and Directory Interface (JNDI) name for the resource, including any naming subcontexts.

This name provides the link between the platform binding information for resources that are defined in the client application deployment descriptor and the actual resources bound into JNDI by the platform.

Important: Adhere to the following requirements for JNDI names:

- Do not assign duplicate JNDI names across different resource types (such as mail sessions versus data sources).
- Do not assign duplicate JNDI names for multiple resources of the same type in the same scope.

Description
Specifies an optional description for your administrative records.

Category
Specifies an optional collection for classifying or grouping sessions.

Enable debug mode
Toggles debug mode on and off for this mail session.

Enable strict Internet address parsing
Specifies whether the recipient addresses must be parsed in strict compliance with RFC 822, which is a specifications document issued by the Internet Architecture Board.

This setting is not generally used for most mail applications. RFC 822 syntax for parsing addresses effectively enforces a strict definition of a valid email address. If you select this setting, your mail component adheres to RFC 822 syntax and rejects recipient addresses that do not parse into valid email addresses (as defined by the specification). If you do not select this setting, the mail component does not adhere to RFC 822 syntax and accepts recipient addresses that do not comply with the specification. By default, this setting is not selected. You can view the RFC 822 specification at the World Wide Web Consortium website.

Outgoing Mail Properties

Server:

Specifies the server that is accessed when sending mail.

Protocol:

Specifies the protocol to use when sending mail. Actual protocol values are defined in the protocol providers that you configured for the current mail provider.

User:

Specifies the user of the mail account when the outgoing mail server requires authentication.

This setting is not generally used for most mail servers. Leave this field blank unless you use a mail server that requires a user ID and password.

Password:

Specifies the password to use when the outgoing mail server requires authentication.

This setting is not generally used for most mail servers. Leave this field blank unless you use a mail server that requires a user ID and password.

Verify Password:

Verify the password.

Return email address:

Specifies the Internet email address that is displayed in messages as the mail originator.

This value represents the Internet email address that, by default, displays in the received message in the **From** or the **Reply-To** address. The recipient's reply will come to this address.

Incoming Mail Properties

Server:

Specifies the server that is accessed when receiving mail.

Protocol:

Specifies the protocol to use when receiving mail. Actual protocol values are defined in the protocol providers that you configured for the current mail provider.

User:

Specifies the user of the mail account when the incoming mail server requires authentication.

This setting is not generally used for most mail servers. Leave this field blank unless you use a mail server that requires a user ID and password.

Password:

Specifies the password to use when the incoming mail server requires authentication.

This setting is not generally used for most mail servers. Leave this field blank unless you use a mail server that requires a user ID and password.

Verify Password:

Verify the password.

Administering URLs

URL provider collection

Use this page to view existing URL providers, which supply the implementation classes that are necessary for WebSphere Application Server to access a URL through a specific protocol. The default URL provider provides connectivity through protocols that are supported by the IBM Developer Kit for the Java™ Platform, compatible with the Java 2 Standard Edition Platform 1.3.1. These protocols include HyperText Transfer Protocol (HTTP) and File Transfer Protocol (FTP), which work for must URLs.

To view this administrative console page, click **Resources** > **URL** > **URL Providers**.

Name

Specifies the administrative name for the URL provider.

Scope
Specifies the scope of this URL provider, which can support multiple URL configurations. All of the URL configurations that are supported by this provider inherit this scope.

Description
Describes the URL provider for your administrative records.

URL provider settings
Use this page to configure URL providers, which support WebSphere Application Server connections to a URL over a specific protocol.

To view this administrative console page, click **Resources** > **URL** > **URL Providers** > *URL_provider*.

Scope
Specifies the scope of this URL provider, which can support multiple URL configurations. All of the URL configurations that are supported by this provider inherit this scope.

Name
Specifies the administrative name for the URL provider.

Description
Describes the URL provider, for your administrative records.

Class path
Specifies paths or JAR file names which together form the location for the resource provider classes.

Stream handler class name
Specifies fully qualified name of a user-defined Java class that extends the `java.net.URLStreamHandler` class for a particular URL protocol, such as FTP.

Protocol
Specifies the protocol supported by this stream handler. For example, NNTP, SMTP, FTP.

URL configurations collection
Use this page to view existing Uniform Resource Locator (URL) configurations, which are sets of properties that define WebSphere Application Server connections to URLs. URLs are location names that represent electronically accessible resources, such as a directory file on a machine in a network or a document stored in a database.

You can access this administrative console page in one of two ways:

- **Resources** > **URL Providers** > *URL_provider* > **URLs**
- **Resources** > **URL** > **URLs**

Name
Specifies the display name for the resource.

JNDI Name
Specifies the JNDI name.

Scope
Specifies the scope of the URL provider that supports this URL configuration. Only applications that are installed within this scope can use this URL configuration to access URL resources.

Provider
Specifies the URL provider that supplies the implementation classes for using a specific protocol to access this URL.

Description
Specifies the description of the resource.

Category
Specifies the category string, which you can use to classify or group the resource.

URL configuration settings
Use this page to define connections to Uniform Resource Locators (URLs), which are location names that represent electronically accessible resources. A collection of URL connection properties is often called a URL configuration in the WebSphere Application Server environment. The targeted resources are remote to your Application Server installation.

You can access this administrative console page in one of two ways:

- **Resources** > **URL** > **URLs** > *URL*
- **Resources** > **URL** > **URL Providers** > *URL_provider* > **URLs** > *URL*

Scope
Specifies the scope of the URL provider that supports this URL configuration. Only applications that are installed within this scope can use this URL configuration to access URL resources.

Provider
Specifies the URL provider that WebSphere Application Server uses for this URL configuration.

To create a new URL configuration: If you previously defined one or more URL providers at the relevant scope, you see a list from which you can select an existing URL provider for your new URL configuration.

Create New Provider
Provides the option of configuring a new URL provider for the new URL configuration.

Create New Provider is displayed only when you create a new URL from the **Resources** > **URL** > **URLs** path. In this flow, you can create a new URL provider if needed. The URL provider can not be changed during an edit.

Clicking **Create New Provider** triggers the console to display the URL provider configuration page, where you create a new provider. After you click **OK** to save your settings, you see the URL collection page. Click **New** to define a new URL configuration for use with the new provider; the console now displays a configuration page that lists the new provider as the URL configuration Provider.

Name
Specifies the display name for the resource.

JNDI Name
Specifies the JNDI name.

Important: Adhere to the following requirements for JNDI names:

- Do not assign duplicate JNDI names across different resource types (such as mail sessions versus URL configurations).
- Do not assign duplicate JNDI names for multiple resources of the same type in the same scope.

Description
Specifies the description of the resource.

Category
Specifies the category string, which you can use to classify or group the resource.

Specification
Specifies the string from which to form a URL.

Administering resource environment entries

Configuring new resource environment entries to map logical environment resource names to physical names

This topic provides instructions on configuring *new* resource environment entries, which define environment resources that are the binding targets for resource-environment-references in an application's deployment descriptor.

Procedure

1. Configure a resource environment provider, which is a library that provides the implementation for an environment resource factory. In the administration console, begin by clicking **Resources > Resource Environment > Resource Environment Providers > New**. See the topic New Resource Environment Provider for more information.
2. After saving your resource environment provider, go to the Additional Properties heading and click **Resource environment entries**. Click **New** to define a new resource environment entry. Refer to the topic Resource environment entry settings for descriptions of the required fields.
3. You also might need to create a referenceable, which specifies the factory class name that converts information in the name space into a class instance for your resource. To view the appropriate administrative console page for referenceables, click **Resources > Resource Environment > Resource Environment Providers >** *your_resource_environment_provider* > **Referenceables**. Click **New** to begin the configuration process. See the topic Referenceable settings for descriptions of the required fields.

Resource environment providers and resource environment entries

A resource environment reference maps a logical name used by the client application to the physical name of an object.

Not all objects bound into the server JNDI namespace are intended for use by an application client. For example, the WebSphere Application Server client run time does not support the use of Java 2 Connector (J2C) objects on the client. The object needs to be remotable, and the client-side implementations must be made available on the application client run-time classpath.

Resource environment references are different than resource references. Resource environment references allow your application client to use a logical name to look up a resource bound into the server JNDI namespace. A resource reference allows your application to use a logical name to look up a local J2EE resource. The J2EE specification does not specify a particular implementation of a resource.

Resource environment provider collection

Use this page to view resource environment providers, which encapsulate the referenceables that convert resource environment entry data into resource objects.

To view this administrative console page, click **Resources > Resource Environment > Resource Environment Providers**.

Name:

Specifies a text identifier for the resource environment provider.

Data type String

Scope:

Specifies the scope of this resource environment provider, which automatically becomes the scope of the resource environment entries that you define with this provider.

Description:

Specifies a text string describing the resource environment provider.

Data type String

Resource environment provider settings:

Use this page to create settings for a resource environment provider.

To view this administrative console page, click **Resources** > **Resource environment** > **Resource environment providers** > *resource environment provider*.

Scope:

Specifies the scope of this resource environment provider, which automatically becomes the scope of the resource environment entries that you define with this provider.

Name:

Specifies the name of the resource provider.

Data type String

Description:

Specifies a text description for the resource provider.

Data type String

New Resource environment provider:

Use this page to define the configuration for a library that provides the implementation for a environment resource factory.

To view this administrative console page, click **Resources > Resource Environment > Resource Environment Providers > New**.

Scope:

Specifies the scope of this resource environment provider, which automatically becomes the scope of the resource environment entries that you define with this provider.

Name:

Specifies a text identifier for the resource environment provider.

Data type String

Description:

Specifies a text string describing the resource environment provider.

Data type String

Resource environment entries collection

Use this page to view configured resource environment entries. Within an application server name space, the data contained in a resource environment entry is converted into an object that represents a physical resource. This resource is frequently called an *environment resource*.

An environment resource can be of any arbitrary type. See the latest EJB specification for more information about resource environment references and environment resources.

You can access this administrative console page in one of two ways:

- **Resources** > **Resource Environment** > **Resource environment entries**
- **Resources** >**Resource Environment** > **Resource Environment Providers** > *resource_environment_provider* > **Resource Environment Entries**

Name:

Specifies a text identifier that helps distinguish this resource environment entry from others.

For example, you can use *My Resource* for the name.

Data type String

JNDI Name:

Specifies the string to be used when looking up this environment resource using JNDI.

This is the string to which you bind resource environment reference deployment descriptors.

Data type String

Scope:

Specifies the resource environment entry scope, which is inherited from the resource environment provider.

Provider:

Specifies the resource environment provider for this entry. The provider encapsulates the classes that, when implemented, convert resource environment entry data into resource objects.

Description:

Specifies text for information to help further identify and distinguish this resource

Data type String

Category:

Specifies a category you can use to group environment resources according to some common feature.

It is strictly an organizational property and has no effect on the function of the environment resource.

Data type String

Resource environment entry settings:

Use this page to configure resource environment entries. Within an application server name space, the data contained in a resource environment entry is converted into an object that represents a physical resource. Rather than represent a connection factory, which provides connections to a resource, this object *directly* represents a resource. This design can make the resource available to application modules that do not run entirely on the application server. Examples include some application clients and web modules.

You can access this administrative console page in one of two ways:

- **Resources** > **Resource Environment** > **Resource environment entries** > *resource_environment_entry*
- **Resources** >**Resource Environment** > **Resource Environment Providers** > *resource_environment_provider* > **Resource Environment Entries** > *resource_environment_entry*

Scope:

Specifies the scope of the resource environment provider, which is a library that supplies the implementation class for a resource environment factory. Within a JNDI name space, WebSphere Application Server uses the factory to transform your resource environment entry into an object that directly represents a physical resource.

Provider:

Specifies the resource environment provider.

Provider shows all of the existing resource environment providers that are defined at the relevant scope. Select one from the list if you want to use an existing resource environment provider as Provider.

Name:

Specifies a display name for the resource.

Data type String

JNDI name:

Specifies the JNDI name for the resource, including any naming subcontexts.

This name is used as the linkage between the platform's binding information for resources defined by a module's deployment descriptor and actual resources bound into JNDI by the platform.

Data type String

Important: Adhere to the following requirements for JNDI names:

- Do not assign duplicate JNDI names across different resource types (such as resource environment entries versus J2C connection factories).
- Do not assign duplicate JNDI names for multiple resources of the same type in the same scope.

Description:

Specifies a text description for the resource.

Data type String

Category:

Specifies a category string that you can use to classify or group the resource.

Data type String

Referenceables:

Specifies the referenceable, which encapsulates the class name of the factory that converts resource environment entry data into a class instance for a physical resource.

Data type Drop-down menu

Referenceables collection

Use this page to view configured referenceables, which encapsulate the class name of the factory that converts information in the name space into a class instance for a physical resource.

To view this administrative console page, click **Resources** > **Resource environment** > **Resource Environment Providers** > *resource_environment_provider* > **Referenceables**.

Factory Class name:

Specifies a javax.naming.spi.ObjectFactory implementation name

Data type String

Class name:

Specifies the package name of the referenceable, for example: `javax.naming.Referenceable`

Data type String

Referenceables settings:

Use this page to set the class name of the factory that converts information in the name space into a class instance of a physical resource.

To view this administrative console page, click **Resources > Resource Environment > Resource Environment Providers >** *resource_environment_provider* **> Referenceables >** *referenceable*.

Factory class name:

Specifies a javax.naming.ObjectFactory implementation class name

Data type String

Class name:

Specifies the Java type to which a Referenceable provides access, for binding validation and to create the reference.

Data type String

Resource environment references

Use this page to designate how the resource environment references of application modules map to remote resources, which are represented in the product as resource environment entries.

To view this administrative console page, click **Applications** > **Application Types** > **WebSphere enterprise applications** > ***application_name*** > **Resource environment references**.

Each row of the table depicts a resource environment reference within a specific module of your application. If you bound any references to resource environment entries during application assembly, you see the JNDI names of those resource environment entries in the applicable rows.

To set the mapping relationships between your resource environment references and resource environment entries:

1. Select a row. Be aware that if you check multiple rows on this page, the resource mapping target that you select in step 2 applies to all of those references.
2. Click **Browse** to select a resource environment entry from the new page that is displayed, the Available Resources page. The Available Resources page shows all resource environment entries that are available mapping targets for your application references.
3. Click **Apply**. The console displays the Resource environment references page again. In the rows that you previously selected, you now see the JNDI name of the new resource mapping target.
4. Repeat the previous steps as necessary.
5. Click **OK**. You now return to the general configuration page for your enterprise application.

Table column heading descriptions:

Select:

Select the check boxes of the rows that you want to edit.

Module:

The name of a module in the application.

EJB:

The name of an enterprise bean that is accessed by the module.

URI:

Specifies location of the module relative to the root of the application EAR file.

Reference binding:

The name of a resource environment reference that is declared in the deployment descriptor of the application module. The reference corresponds to a resource that is bound as a resource environment entry into the JNDI name space of the application server.

JNDI name:

The Java Naming and Directory Interface (JNDI) name of the resource environment entry that is the mapping target of the resource environment reference.

Data type String

Chapter 12. Administering Messaging resources

This page provides a starting point for finding information about the use of asynchronous messaging resources for enterprise applications with WebSphere Application Server.

WebSphere Application Server supports asynchronous messaging based on the Java Message Service (JMS) and the Java EE Connector Architecture (JCA) specifications, which provide a common way for Java programs (clients and Java EE applications) to create, send, receive, and read asynchronous requests, as messages.

JMS support enables applications to exchange messages asynchronously with other JMS clients by using JMS destinations (queues or topics). Some messaging providers also allow WebSphere Application Server applications to use JMS support to exchange messages asynchronously with non-JMS applications; for example, WebSphere Application Server applications often need to exchange messages with WebSphere MQ applications. Applications can explicitly poll for messages from JMS destinations, or they can use message-driven beans to automatically retrieve messages from JMS destinations without explicitly polling for messages.

WebSphere Application Server supports the following messaging providers:

- The WebSphere Application Server default messaging provider (which uses service integration as the provider).
- The WebSphere MQ messaging provider (which uses your WebSphere MQ system as the provider).
- Third-party messaging providers that implement either a JCA Version 1.5 resource adapter or the ASF component of the JMS Version 1.0.2 specification.

Managing messaging with the default messaging provider

The default messaging provider is installed and runs as part of WebSphere Application Server, and is based on service integration technologies. For messaging between application servers, perhaps with some interaction with a WebSphere MQ system, you can configure your messaging applications to use messaging resources provided by the default messaging provider.

Before you begin

For messaging between application servers, perhaps with some interaction with a WebSphere MQ system, you can use the default messaging provider as described in this topic. To integrate WebSphere Application Server messaging into a predominantly WebSphere MQ network, you can use the WebSphere MQ messaging provider. You can also use a third-party messaging provider. To choose the provider that is best suited to your needs, see Choosing a messaging provider.

About this task

The default messaging provider supports JMS 1.1 domain-independent interfaces (sometimes referred to as “unified” or “common” interfaces). This enables applications to use common interfaces for both point-to-point and publish/subscribe messaging. This also enables both point-to-point and publish/subscribe messaging within the same transaction. With JMS 1.1, this approach is recommended for new applications. The domain-specific interfaces are supported for backwards compatibility for applications developed to use domain-specific queue interfaces, as described in section 1.5 of the JMS 1.1 specification.

You can use the WebSphere Application Server administrative console to configure JMS resources for applications, and can manage messages and subscriptions associated with JMS destinations.

WebSphere Application Server Version 5.1 Java EE applications can use messaging resources of the default messaging provider in later versions. This JMS interoperation from WebSphere Application Server Version 5.1 to later versions is enabled and managed by a WebSphere MQ client link created on the node in the later version. This JMS interoperation is only intended as an aid to the migration from the embedded messaging in WebSphere Application Server Version 5.1 to the default messaging provider in the later version.

Note: Java EE applications running under the later version can use messaging resources of Version 5 embedded messaging without any need for a WebSphere MQ client link.

For more information about using the default messaging provider of WebSphere Application Server, see the following topics:

Procedure

- Default messaging
- "Configuring resources for the default messaging provider"
- "Interoperating with a WebSphere MQ network" on page 545
- Migrating from WebSphere Application Server Version 5 embedded messaging
- "Enabling WebSphere Application Server Version 5.1 JMS usage of messaging resources in later versions of the product" on page 583
- "Configuring the messaging engine selection process for JMS applications" on page 593
- "Managing messages and subscriptions for default messaging JMS destinations" on page 595
- "Using JMS from stand-alone clients to interoperate with service integration resources" on page 596
- "Using JMS from a third party application server to interoperate with service integration resources" on page 605

Configuring resources for the default messaging provider

Use the following tasks to configure JMS connection factories, activation specifications, and destinations for the default messaging provider.

About this task

Use these tasks to configure administrative JMS resources provided by the default messaging provider.

These administrative JMS resources are in addition to any temporary JMS destinations created by applications.

- List JMS resources.
- Configure a unified connection factory.
- Configure a queue connection factory.
- Configure a topic connection factory.
- Configure a queue.
- Configure a topic.
- Configure an activation specification.

Listing JMS resources for the default messaging provider

Use the WebSphere Application Server administrative console to list JMS resources for the default messaging provider, for administrative purposes.

About this task

You use the WebSphere Application Server administrative console to list JMS resources, if you want to view, modify or delete any of the following resources:

- Activation specifications

- Unified connection factories
- Queue connection factories
- Topic connection factories
- Queues
- Topics

When you use the administrative console to locate these resources, two different navigation pathways are available:

- **Provider-centric navigation** lets you view all providers, or just those for a specified scope, then navigate to a specific resource for a specific provider. This is the traditional way of navigating to a resource when you know which provider supports it. Any navigation that starts with **Resources -> JMS -> JMS providers** is provider-centric.
- **Resource-centric navigation** lets you view all resources of a specified type, then navigate to a resource. This is useful if you want to find a resource, but you do not know which provider supports it (you can list all resources of a given type across all scopes, for all providers, in a single panel). Any navigation that follows the pattern **Resources -> JMS -> *resource_type*** is resource-centric, where *resource_type* is one of the resource types previously listed.

You can use either of these navigation pathways to locate JMS resources of any type.

Procedure

- Use provider-centric navigation, for example to navigate to a specified queue connection factory.
  1. Start the administrative console.
  2. In the navigation pane, click **Resources -> JMS -> JMS providers**.

     The JMS providers collection panel is displayed. This lists all currently configured messaging providers across all scopes (you can modify the scope if required).
  3. Select the required JMS provider.

     The settings panel for this provider is displayed. The configuration tab contains a set of links to all the JMS resources owned by this provider.
  4. Click the link for a JMS resource type. For example, click **Queue connection factories**.

     The queue connection factories collection panel is displayed. This panel lists all the queue connection factories for this provider.
  5. Select the required queue connection factory.
- Use resource-centric navigation, for example to navigate to a specified queue connection factory.
  1. Start the administrative console.
  2. In the navigation pane, click **Resources -> JMS -> Queue connection factories**.

     The queue connection factories collection panel is displayed. This panel lists all the queue connection factories across all messaging providers.
  3. Select the required queue connection factory.

Results

You can now view and work with the resource properties.

Configuring JMS resources for point-to-point messaging

Configure connection factories, queues and service integration bus destinations for point-to-point messaging.

About this task

For an application to use point-to-point messaging with JMS queues, you configure the following JMS resources. These JMS resources depend on the corresponding configuration of service integration

resources, including a service integration bus and a queue. For more information about defining these resources, see the related tasks.

Procedure

- Configure a connection factory.

  Use the connection factory type that matches the JMS level and domain pattern in which an application is developed. For example, use a domain-independent JMS connection factory for a JMS application developed to use JMS 1.1 domain-independent interfaces, and use a JMS queue connection factory for a JMS application developed to use domain-specific queue interfaces.
- Configure a queue.

  A *JMS queue* is an administrative object that encapsulates the name of a queue destination on a service integration bus. Applications find the JMS queue by looking up its name in the JNDI namespace.
- Configure a queue destination.

  For each JMS queue, define a bus destination of type queue on the appropriate service integration bus.

Configuring JMS resources for publish/subscribe messaging

Use this task to configure a JMS resources for publish/subscribe messaging.

About this task

For an application to use publish/subscribe messaging with JMS topics, you configure the following JMS resources. These JMS resources depend on the corresponding configuration of service integration resources, including a service integration bus and topicspace. For more information about defining these resources, see the related tasks.

Procedure

- A JMS connection factory

  You should use the connection factory type that matches the JMS level and domain pattern in which an application is developed. For example, use a domain-independent JMS connection factory for a JMS application developed to use JMS 1.1 domain-independent interfaces, and use a JMS topic connection factory for a JMS application developed to use domain-specific topic interfaces.

  If durable subscriptions are to be used by the application, set the durable subscription properties on the connection factory.
- A JMS topic

  A *JMS topic* is an administrative object that encapsulates the name of a topic and a topic space on a service integration bus. Applications can obtain the JMS topic by looking its name up in the JNDI namespace.
- Service integration resources For each JMS topic, define a bus destination as a topic space on a service integration bus, and assign the JMS topic to a topic name within that topic space.

Configuring a unified connection factory for the default messaging provider

Use this task to configure a unified JMS connection factory for applications that use the JMS 1.1 domain-independent (unified) interfaces.

About this task

The term “unified” refers to the support of both queues and topics by the same connection factory. This is similar to the JMS 1.1 domain-independent interfaces (referred to as the “common interfaces” in the JMS specification). A unified JMS connection factory can be used for both point-to-point and publish/subscribe JMS messaging. With JMS 1.1, this approach is preferred to the domain-specific queue connection factory and topic connection factory.

This task contains an optional step for you to create a new connection factory if you have not already created the connection factory that you want to configure.

Procedure

1. Display the default messaging provider. In the navigation pane, click **Resources -> JMS -> JMS providers**.
2. Select the default provider for which you want to configure a unified connection factory.
3. Optional: Change the **Scope** check box to set the level at which the connection factory is to be visible.
4. In the content pane, under the Additional properties heading, click **Connection factories**. This displays any existing connection factories in the content pane.
5. If the connection factory is for use by client applications, display the properties of the JMS connection factory. If you want to display an existing JMS connection factory, click one of the names listed.

   Alternatively, if you want to create a new JMS connection factory, click **New**, then specify the following required properties:

   Name Type the name by which the connection factory is known for administrative purposes.

   JNDI name
   Type the JNDI name that is used to bind the connection factory into the namespace.

   Bus name
   Select the name of the service integration bus to which the connection factory is to create connections. This service integration bus hosts the destinations that the JMS queues and topics represent.
6. Review the other properties for the JMS connection factory, to check that the defaults are suitable.

   If the connection factory is for use by client applications running outside of an application server, specify suitable provider endpoints. For more information about configuring provider endpoints, see “Configuring a connection to a non-default bootstrap server” on page 531.

   By default, connections created by using the connection factory in the server containers (for example, from an enterprise bean) are pooled by using Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) connection pooling. You can modify the connection pool settings for the connection factory by selecting the Connection pool properties link in the Additional Properties section of the panel. For more information about changing the connection pool properties, see Changing connection pool settings with the wsadmin tool.
7. Click **OK**.
8. Save your changes to the master configuration.

Administrative properties for JMS connections to a bus:

You can configure properties to enable workload management of connections to a service integration bus for JMS applications. The same properties can also be used to control the client connection topology. For example, connection options can be specified such that client applications only connect to a set of client serving messaging engines and never to the set of destination serving messaging engines in a bus.

The properties for connecting JMS applications to a bus are used by the administrator. The JMS applications do not specify how to connect to the bus, beyond using a JMS connection factory or JMS activation specification (for message-driven beans).

The general aim of connecting to a bus is to connect to a suitable messaging engine that provides the message point for a JMS destination that the application is to use. Applications running inside an application server can locate a suitable messaging engine and connect directly to the selected messaging engine. Client applications running outside of an application server cannot locate a suitable messaging engine themselves, these clients must use a bootstrap server to locate a suitable messaging engine on behalf of the client application.

When an application connects to the bus, the bus chooses a suitable messaging engine based on administrative properties of the JMS connection factory or activation specification that the application uses. For maximum connection flexibility, you can leave most properties to default, the only required connection property is the name of the bus that the application is to connect to.

The bus uses the following general process to choose a suitable messaging engine, based on the value you select for the Connection proximity property. If you understand this process, you can better configure the properties that control how the bus chooses messaging engines.

- If a **Target group** is specified then the process checks the nearest messaging engine that supports the required **Remote transport chain** and is a member of the target group in the bus. If the messaging engine is within the specified **Connection proximity** it is chosen as a suitable messaging engine for the application to connect to.
- If a **Target group** is not specified then the process checks the nearest messaging engine that supports the required **Remote transport chain** in the bus. A messaging engine in the same server is nearer than a messaging engine in the same host, which is nearer than a messaging engine in another host. If the messaging engine is within the specified **Connection proximity** it is chosen as a suitable messaging engine for the application to connect to.
- If the selected messaging engine is not within the specified **Connection proximity**, then the **Target significance** is used. If the **Target significance** is set to Required, then no connection is possible and the connection request is rejected with no suitable messaging engine being available. If the **Target significance** is set to Preferred then the target group is ignored and the nearest messaging engine that supports the required **Remote transport chain** is used. If no messaging engine is found then the connection request is rejected with no suitable messaging engine being available.

The following rules are used to test the connection proximity for a selected messaging engine:

- If the Connection proximity value is Bus, then the selected messaging engine is used.
- If the Connection proximity value is Host, and the selected messaging engine is in the same host as the application (or bootstrap server), then the selected messaging engine is used. Otherwise, one of the following options is chosen.
  - If the selected messaging engine is not in the same host as the application (or the bootstrap server), and the **Target significance** is set to Required, then no connection is possible and the connection request is rejected with no suitable messaging engine being available.
  - If the **Target significance** is set to Preferred then the nearest messaging engine - in the same host - that supports the required **Remote transport chain** is used
  - If no suitable messaging engine is found, then the connection request is rejected.
- If the Connection proximity value is Server, and the selected messaging engine is in the same server as the application (or bootstrap server), then the selected messaging engine is used. Otherwise, one of the following options is chosen.
  - If the selected messaging engine is not in the same server as the application (or is in the bootstrap server), and the **Target significance** is set to Required, then no connection is possible and the connection request is rejected with no suitable messaging engine being available.
  - If the **Target significance** is set to Preferred then the nearest messaging engine - in the same server - that supports the required **Remote transport chain** is used
  - If no suitable messaging engine is found, then the connection request is rejected.

When a connection is made to a messaging engine in the same server as the application, the connection is made directly through memory, so the **Remote transport chain** is ignored.

Configuring a queue connection factory for the default messaging provider

Use this task to configure a JMS queue connection factory for point-to-point messaging with the default messaging provider. This is intended more for backwards compatibility, as described in section 1.5 of the JMS 1.1 specification.

About this task

To configure a JMS queue connection factory for the default messaging provider, use the administrative console to complete the following steps. This task contains an optional step for you to create a new queue connection factory.

Procedure

1. Display the default messaging provider. In the navigation pane, click **Resources -> JMS -> JMS providers**.
2. Select the default provider for which you want to configure a queue connection factory.
3. Optional: Change the **Scope** check box to set the level at which the connection factory is to be visible, according to your needs.
4. In the content pane, under the Additional properties heading, click **Queue connection factories**. This displays any existing JMS queue connection factories for the default messaging provider in the content pane.
5. Display the properties of the JMS connection factory. If you want to display an existing JMS connection factory, click one of the names listed.

   Alternatively, if you want to create a new JMS connection factory, click **New**, then specify the following required properties:

   Name Type the name by which the connection factory is known for administrative purposes.

   JNDI name
   Type the JNDI name that is used to bind the connection factory into the namespace.

   Bus name
   Type the name of the service integration bus that the connection factory is to create connections to. This service integration bus hosts the destinations that the JMS queues and topics represent.
6. Review the other “Default messaging provider queue connection factory [Settings]” on page 641, to check that the defaults are suitable.

   If the connection factory is for use by client applications running outside of an application server, specify suitable provider endpoints. For more information about configuring provider endpoints, see “Configuring a connection to a non-default bootstrap server” on page 531.

   By default connections created by using the connection factory in the server containers (for example, from an enterprise bean) are pooled by using Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) connection pooling. You can modify the connection pool settings for the connection factory by selecting the Connection pool properties link in the Additional Properties section of the panel. For more information about changing the connection pool properties, see Changing connection pool settings with the wsadmin tool.
7. Click **OK**.
8. Save your changes to the master configuration.

Configuring a topic connection factory for the default messaging provider

Use this task to configure a JMS topic connection factory for publish/subscribe messaging with the default messaging provider. This is intended more for backwards compatibility, as described in section 1.5 of the JMS 1.1 specification.

About this task

You configure JMS connection factories when you deploy JMS applications that use publish/subscribe messaging.

This task contains an optional step for you to create a new topic connection factory.

Procedure

1. Display the default messaging provider. In the navigation pane, click **Resources -> JMS -> JMS providers**.
2. Select the default provider for which you want to configure a topic connection factory.
3. Optional: Change the **Scope** check box to set the level at which the connection factory is to be visible, according to your needs.
4. In the content pane, under the Additional properties heading, click **Topic connection factories**. This displays any existing JMS topic connection factories for the default messaging provider in the content pane.
5. Optional: Display the properties of the JMS connection factory. If you want to display an existing JMS connection factory, click one of the names listed.

   Alternatively, if you want to create a new JMS connection factory, click **New**, then specify the following required properties:

   Name Type the name by which the connection factory is known for administrative purposes.

   JNDI name
   Type the JNDI name that is used to bind the connection factory into the namespace.

   Bus name
   Type the name of the service integration bus that the connection factory is to create connections to. This service integration bus hosts the destinations that the JMS queues and topics represent.
6. Review the other properties for the connection factory, to check that the defaults are suitable.

   If the connection factory is for use by client applications running outside of an application server, specify suitable provider endpoints. For more information about configuring provider endpoints, see "Configuring a connection to a non-default bootstrap server" on page 531.

   By default, connections created by using the connection factory in the server containers (for example, from an enterprise bean) are pooled by using Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) connection pooling. You can modify the connection pool settings for the connection factory by selecting the Connection pool properties link in the Additional Properties section of the panel. For more information about changing the connection pool properties, see Changing connection pool settings with the wsadmin tool.
7. Click **OK**.
8. Save your changes to the master configuration.

Configuring a queue for the default messaging provider

Use this task to configure a JMS queue for point-to-point messaging with the default messaging provider.

Before you begin

This task configures a JMS queue to use a queue destination on a service integration bus. The queue destination is the virtual location on the bus where messages are stored and processed for the JMS queue. If you have not created the required destination, use the task described in Configuring a destination for JMS queues.

About this task

To configure a JMS queue for the default messaging provider, use the administrative console to complete the following steps.

Procedure

1. Display the default messaging provider. In the navigation pane, click **Resources -> JMS -> JMS providers**.

2. Select the default provider for which you want to configure a queue.
3. Optional: Change the **Scope** check box to set the level at which the JMS queue is to be visible, according to your needs.
4. In the content pane, under the Additional properties heading, click **Queues**. This displays any existing JMS queues for the default messaging provider in the content pane.
5. Display the properties of the JMS queue. If you want to display an existing JMS queue, click one of the names listed.

   Alternatively, if you want to create a new JMS queue, click **New**, then specify the following required properties:

   Name Type the name by which the queue is known for administrative purposes.

   JNDI name
   Type the JNDI name that is used to bind the queue into the namespace.

   Queue name
   Select the name of the queue on a service integration bus that this JMS queue is to use.
6. Specify properties for the JMS queue, according to your needs.
7. Click **OK**.
8. Save your changes to the master configuration.

Configuring a topic for the default messaging provider

Use this task to configure a JMS topic for publish/subscribe messaging with the default messaging provider.

Before you begin

This task configures a JMS topic to use a topic space destination on a service integration bus. The topic space (a hierarchical collection of topics) is the virtual location on the bus where messages are stored and processed for the JMS topic. If you have not created the required destination, use the task described in Configuring a destination for publish/subscribe messaging.

About this task

To configure a JMS topic for the default messaging provider, use the administrative console to complete the following steps. This task contains an optional step for you to create a new JMS topic.

Procedure

1. Display the default messaging provider. In the navigation pane, expand **Resources -> JMS -> JMS providers**.
2. Select the default provider for which you want to configure a topic.
3. Optional: Change the **Scope** check box to set the level at which the topic is to be visible, according to your needs.
4. In the content pane, under the Additional properties heading, click **Topics**. This displays any existing JMS topics for the default messaging provider in the content pane.
5. Display the properties of the JMS topic. If you want to display an existing JMS topic, click one of the names listed.

   Alternatively, if you want to create a new JMS topic, click **New**, then specify the following required properties:

   Name Type the name by which the topic is known for administrative purposes.

   JNDI name
   Type the JNDI name that is used to bind the topic into the namespace.

Topic name
Type the name of the topic (as a qualifier in the topic space) that this JMS topic is to use.

Topic space
Type the name of the topic space that this JMS topic is to use.

6. Specify properties for the JMS topic, according to your needs.
7. Click **OK**.
8. Save your changes to the master configuration.

Configuring an activation specification for the default messaging provider

Configure a JMS activation specification to enable a message-driven bean to communicate with the default messaging provider.

About this task

You create a JMS activation specification if you want to use a message-driven bean to communicate with the default messaging provider through Java EE Connector Architecture (JCA) 1.5. JCA provides Java connectivity between application servers such as WebSphere Application Server, and enterprise information systems. It provides a standardized way of integrating JMS providers with Java EE application servers, and provides a framework for exchanging data with enterprise systems, where data is transferred in the form of messages.

One or more message-driven beans can share a single JMS activation specification.

Because a JMS activation specification is a group of messaging configuration properties not a component, it cannot be manually started and stopped. For this reason, to prevent a message-driven bean from processing messages you must complete the following tasks:

- Stop the application that contains the message-driven bean.
- Stop the messaging engine.

All the activation specification configuration properties apart from **Name**, **JNDI name**, **Destination JNDI name**, and **Authentication alias** are overridden by appropriately named activation-configuration properties in the deployment descriptor of an associated EJB 2.1 or later message-driven bean. For an EJB 2.0 message-driven bean, the **Destination type**, **Subscription durability**, **Acknowledge mode** and **Message selector** properties are overridden by the corresponding elements in the deployment descriptor. For either type of bean the **Destination JNDI name** property can be overridden by a value specified in the message-driven bean bindings.

Procedure

1. Start the administrative console.
2. Display the default messaging provider. In the navigation pane, expand **Resources -> JMS -> JMS providers**.
3. Select the default provider for which you want to configure an activation specification.
4. Optional: Change the **Scope** check box to the scope level at which the activation specification is to be visible to applications, according to your needs.
5. In the content pane, under the Additional properties heading, click **Activation specifications**. This lists any existing JMS activation specifications for the default messaging provider in the content pane.
6. Display the properties of the JMS activation specification. If you want to display an existing activation specification, click one of the names listed.

   Alternatively, if you want to create a new activation specification, click **New**, then specify the following required properties:

   "Name" on page 618
   Type the name by which the activation specification is known for administrative purposes.

"JNDI name" on page 618
Type the JNDI name that is used to bind the activation specification into the JNDI namespace.

"Destination type" on page 618
Whether the message-driven bean uses a queue or topic destination.

"Destination JNDI name" on page 618
Type the JNDI name that the message-driven bean uses to look up the JMS destination in the JNDI namespace.

Select the type of destination on the Destination type property.

"Bus name" on page 619
The name of the bus to connect to.

Specify the name of the service integration bus to which connections are made. This must be the name of the bus on which the bus destination identified by the "Destination JNDI name" on page 618 property is defined.

You can either select an existing bus or type the name of another bus. If you type the name of a bus that does not exist, you must create and configure that bus before the activation specification can be used.

7. Specify properties for the JMS activation specification, according to your needs.
8. Optional: Specify the JMS activation specification connection properties that influence how the default messaging provider chooses the messaging engine to which your message-driven bean application connects. By default, the environment automatically connects applications to an available messaging engine on the bus. However you can specify extra configuration details to influence the connection process; for example to identify special bootstrap servers, or to limit connection to a subgroup of available messaging engines, or to improve availability or performance, or to ensure sequential processing of messages received. For information about why and how to do this, see How JMS applications connect to a messaging engine on a bus.
9. Click **OK**.
10. Save your changes to the master configuration.

Deleting JMS resources for the default messaging provider

Use this task with the WebSphere Application Server administrative console to delete JMS resources.

About this task

To delete JMS resources, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Resources -> JMS -> JMS providers**.
2. Select the default provider for which you want to delete resources.
3. In the content pane, under the Additional properties heading, select the link for the type of JMS resource:
   - Connection factory
   - Queue connection factory
   - Topic connection factory
   - Queue
   - Topic
   - Activation specification

   This displays a list of the selected JMS resource type in the content pane.
4. Select the check box next to the JMS resource that you want to delete.

5. Click **Delete**
6. Save your changes to the master configuration.

Configuring JMS connection factory properties for durable subscriptions

Use this task to configure durable subscription properties of JMS connection factories for use by enterprise beans with the default messaging provider.

About this task

To enable applications to create durable subscriptions to JMS topics with the default messaging provider, you can set a number of properties on JMS connection factories.

If applications use message-driven beans to create durable subscriptions, you should set the properties on the JMS activation specification used by the message-driven beans, as described in Configuring JMS activation specifications for durable subscriptions, instead of as described in this topic.

This topic describes the setting of properties on a unified JMS connection factory. You can also set the same properties on a JMS topic connection factory instead.

To configure the durable subscription properties to a topic for use by enterprise beans with the default messaging provider, use the administrative console to complete the following steps:

Procedure

1. Display the default messaging provider. In the navigation pane, click **Resources -> JMS -> JMS providers**.
2. Select the default provider for which you want to configure connection factory properties.
3. Optional: Change the **Scope** check box to set the level at which the connection factory is to be visible, according to your needs.
4. In the content pane, under the Additional properties heading, click **Connection factories**. This displays any existing JMS connection factories for the default messaging provider in the content pane.
5. Click the name of the connection factory you want to configure. This displays the properties for the connection factory in the content pane.
6. Specify the following properties for the connection factory:

   Client identifier
   This is the JMS client identifier that applications use to identify durable topic subscriptions created on all connections that use this connection factory. For more information about client identifiers, see section 4.3.2 of the JMS 1.1 specification.

   Durable subscription home
   The name of the messaging engine used to store messages delivered to durable subscriptions for objects created from this JMS connection factory.

   This identifies the messaging engine where durable subscriptions are localized on the service integration bus. Administrators can manage the runtime state of durable subscriptions through publication points for that messaging engine.
7. Click **OK**.
8. Save your changes to the master configuration.

What to do next

When applications have created durable subscriptions, you can use the administrative console to manage the runtime state of those subscriptions, as described in “Administering durable subscriptions” on page 2002.

The JMS connection factory has some other advanced properties that you can configure to change the behavior for durable subscriptions. You should not usually need to change these properties from their default values.

Read ahead
This controls read ahead optimization during message delivery. This defines whether the provider can stream messages to durable subscribers ahead of their requests (to provide a performance enhancement).

Share durable subscriptions
This controls whether durable subscriptions can be accessed simultaneously by several subscribers.

If you want to control read ahead optimization during message delivery for individual topics, you can set the Read ahead property on the topics.

Configuring JMS activation specification properties for durable subscriptions

Use this task to configure durable subscription properties of JMS activation specifications for use by message-driven beans with the default messaging provider.

About this task

To enable a message-driven bean (MDB) application to create durable subscriptions on JMS topics with the default messaging provider, you set a number of properties on the JMS activation specification used by the application.

If applications use message-driven beans to create durable subscriptions, you should set the properties on the JMS activation specification used by the message-driven beans, as described in this topic. Otherwise, for enterprise beans to create durable subscriptions, you should set the properties on the JMS connection factory as described in “Configuring JMS connection factory properties for durable subscriptions” on page 526.

Note: The *server_name*-durableSubscriptions.ser file in the *WAS_HOME*/temp directory is used by the messaging service to keep track of durable subscriptions for message-driven beans. If you uninstall an application that contains a message-driven bean, this file is used to unsubscribe the durable subscription. If you have to delete the *WAS_HOME*/temp directory or other files in it, ensure that you preserve this file.

To configure the durable subscription properties to a topic for use by message-driven beans with the default messaging provider, use the administrative console to complete the following steps

Procedure

1. Display the default messaging provider. In the navigation pane, click **Resources -> JMS -> JMS providers**.
2. Select the default provider for which you want to configure activation specification properties.
3. Optional: Change the **Scope** check box to set the level at which the connection factory is to be visible, according to your needs.
4. In the content pane, under the Additional properties heading, click **Activation specifications**. This displays any existing JMS activation specifications for the default messaging provider in the content pane.
5. Click the name of the activation specification you want to configure. This displays the properties for the activation specification in the content pane.
6. Specify the following properties for the activation specification:

   Client identifier
   This is the JMS client identifier that applications use to identify durable topic subscriptions

created on all connections tht use this activation specification. For more information about client identifiers, see section 4.3.2 of the JMS 1.1 specification.

Durable subscription home
The name of the messaging engine used to store messages delivered to durable subscriptions for objects created from this JMS activation specification. This is a required field when using a durable topic subscription.

This identifies the messaging engine where durable subscriptions are localized on the service integration bus. Administrators can manage the runtime state of durable subscriptions through publication points for that messaging engine.

Subscription durability
To be able to create durable subscriptions, set this property to Durable.

Subscription name
The subscription name needed for durable topic subscriptions. Required field when using a durable topic subscription.

Each JMS durable subscription is identified by a subscription name (specified on this property). A JMS connection also has an associated client identifier (specified on the Client identifier property), which is used to associate a connection and its objects with the list of messages (on the durable subscription) that is maintained by the JMS provider for the client.

This subscription name must be unique within a given client identifier.

7. Specify the properties for the activation specification, according to your needs.
8. Click **OK**.
9. Save your changes to the master configuration.

What to do next

When applications have created durable subscriptions, you can use the administrative console to manage the runtime state of those subscriptions, as described in “Administering durable subscriptions” on page 2002.

Configuring shared durable subscriptions for an activation specification:

Use this task to configure the **Share durable subscriptions** option; an attribute of the JMS activation specifications that message-driven beans use with the default messaging provider.

About this task

The **Share durable subscriptions** option controls whether durable subscriptions are shared between subscribers in a cluster. To set this option, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click **Resources -> JMS -> JMS providers**.
2. Select the default provider for which you want to configure activation specification properties.
3. Optional: Change the **Scope** check box to set the level at which the connection factory is visible, according to your needs.
4. In the content pane, under Additional Properties, click **Activation specifications**.
5. Click the name of the activation specification you want to configure. The properties for the activation specification are displayed in the content pane.
6. Under General Properties, in the Advanced section, set the **Share durable subscriptions** property. Select one of the following options from the list:

In cluster
Clients that are connected to the bus in a cluster member can use the same client identifier and durable subscription name, and can retrieve messages from the durable subscription.

Always shared
All clients, regardless of where they are connected to the bus, can use the same client identifier and durable subscription name, and can retrieve messages from the durable subscription.

Never shared
Clients cannot use the same client identifier and durable subscription name as an existing session.

See the administrative console help for information about the other fields on this page.

7. Click **OK**.
8. Save your changes to the master configuration.

Enabling a provider to stream messages to cloned durable subscriptions

Use this task to enable a provider to stream messages to consumers ahead of their message requests. This is most often used by publish/subscribe consumers to provide a performance enhancement.

About this task

To indicate that a provider must stream messages to consumers, you can set the Read ahead property to Enabled. This property can be set on a connection factory to specify the behavior for all connections created using that connection factory. The property can also be set on JMS topics, to enable different behavior when sending messages to different JMS topics from the same connection.

You are recommended to leave this property set to Default, which enables the messaging provider to decide whether it should stream messages to consumers. The messaging provider makes this decision based on the environment in which the durable subscriber is running. You should only set this property to enable message streaming if you are sure that a durable subscription is used by only one consumer at a time.

- In a non-cloned environment, the default setting enables messaging streaming for durable subscribers.
- For cloned durable subscribers (that is, a durable subscriber that is part of an application cloned in a server cluster), the default setting prevents message streaming and the messages on the subscription are shared among the clones. If you are moving from a non-cloned environment, to cloned durable subscribers, you might see a drop in performance. If you are sure that a durable subscription is still used by only one consumer at a time, you can enable message streaming as described in this topic.

  Server clusters can be used as bus members only in WebSphere Application Server environments that support server clusters.

Messages that are streamed to the consumer but are not consumed before the consumer disconnects are unlocked when the consumer closes. Only then do those messages become available for consumption by other consumers.

To force the messaging provider to stream messages to cloned durable subscriptions, use the administrative console to complete the following steps to change the connection factory:

Procedure

1. Display the JMS connection factory; for example, as described in “Configuring a unified connection factory for the default messaging provider” on page 518. All clones of a durable subscriber use the same JMS connection factory.
2. Set the Read ahead property to Enabled.
3. Click **OK**.
4. Save your changes to the master configuration.

Enabling CMP entity beans and messaging engine data stores to share database connections

Use this task to enable container-managed persistence (CMP) entity beans to share the database connections used by the data store of a messaging engine. Performing this task has been estimated to provide a potential performance improvement of 15% for overall message throughput, but can only be used for entity beans connected to the application server that contains the messaging engine.

About this task

To enable CMP entity beans to share the database connections used by the data store of a messaging engine, complete the following steps.

Procedure

1. Configure the data store to use a data source that is not XA-capable. For more information about configuring a data store, see “Configuring a JDBC data source for a messaging engine” on page 1960.
2. Select the **Share data source with CMP** option. This option is provided on the JMS connection factory or JMS activation specification used to connect to the service integration bus that hosts the bus destination that is used to store and process messages for the CMP bean.

   For example, to select the option on a unified JMS connection factory, complete the following steps:

   a. Display the default messaging provider. In the navigation pane, click **Resources -> JMS -> JMS providers**.
   b. Select the default provider for which you want to configure a unified connection factory.
   c. Optional: Change the **Scope** check box to set the level at which the connection factory is to be visible, according to your needs.
   d. In the content pane, under Additional Properties, click **Connection factories**.
   e. Optional: To create a new unified JMS connection factory, click **New**.

      Specify the following properties for the connection factory:

      Name Type the name by which the connection factory is known for administrative purposes.

      JNDI name
      Type the JNDI name that is used to bind the connection factory into the namespace.

      Bus name
      Type the name of the service integration bus that the connection factory is to create connections to. This service integration bus hosts the destinations that the JMS queues and topics are assigned to.

   f. Optional: To change the properties of an existing connection factory, select its name from one of the connection factories displayed. The properties for the connection factory are displayed in the content pane.
   g. Select the check box for the **Share data source with CMP** field.
   h. Click **OK**.
   i. Save your changes to the master configuration.

   The JMS connection factory can only be used to connect to a “local” messaging engine that is in the application server on which the CMP beans are deployed.
3. Deploy the CMP beans onto the application server that contains the messaging engine, and specify the same data source as that used by the messaging engine. You can use the administrative console to complete the following steps:

   a. Optional: To determine the data source used by the messaging engine, click **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] Messaging engines -> *engine_name* -> [Additional Properties] Message store**.

      The **Data source name** field displays the name of the data source, which is by default:

      `jdbc/com.ibm.ws.sib/`*`engine_name`*

b. Click **Applications -> New Application -> New Enterprise Application**.
c. On the first Preparing for the application installation page, specify the full path name of the source application file (.ear file, otherwise known as an EAR file), then click **Next**.
d. On the second Preparing for the application installation page, complete the following steps:
   1) Select the check box for **Generate Default Bindings**. Data source bindings (for EJB 1.1 JAR files) are generated based on the JNDI name, data source, user name, and password options. This results in default data source settings for each EJB JAR file. No bean-level data source bindings are generated.
   2) Under Connection Factory Bindings, select the check box for **Default connection factory bindings:**, then type the JNDI name for the data source and optionally select a **Resource authorization** value.
   3) Click **Next** to display the Install New Application pages. The contents of the application that you are installing determines which pages are available.

4. If your application uses EJB modules that contain CMP beans that are based on the EJB 1.x specification, for **Map default data sources for modules containing 1.x entity beans**, specify a JNDI name for the default data source for the EJB modules. The default data source for the EJB modules is optional if data sources are specified for individual CMP beans.
5. If your application has CMP beans that are based on the EJB 1.x specification, for **Map data sources for all 1.x CMP**, specify a JNDI name for data sources to be used for each of the 1.x CMP beans. The data source attribute is optional for individual CMP beans if a default data source is specified for the EJB module that contains CMP beans.
6. Click **Finish**. If neither a default data source for the EJB module nor a data source for individual CMP beans are specified, a validation error displays and the installation is cancelled.
7. Complete other pages as needed.
8. On the Summary page, verify the cell, node, and server onto which the application modules will install.
   a. Beside **Cell/Node/Server**, click **Click here**.
   b. Verify the settings on the Map modules to servers page that is displayed. Ensure that the application server that is specified contains the messaging engine and its data store.
   c. Specify the web servers as targets that will serve as routers for requests to this application. This information is used to generate the plug-in configuration file (plugin-cfg.xml) for each web server.
   d. Return to the Summary page.
   e. Click **Finish**.

Results

For more information about installing applications, see Installing enterprise application files with the console.

Configuring a connection to a non-default bootstrap server

A bootstrap server is an application server running in the same cell, specifically the same core group, as the service integration bus.

About this task

Connection to a non-default bootstrap server is provided by a JMS connection factory or a JMS activation specification. The connection allows applications to use a bootstrap server with a non-default endpoint address. The provider endpoint syntax example described in this topic is also relevant to bootstrap endpoint configuration in other tasks, for example when configuring a service integration bus link.

To use JMS destinations of the default messaging provider, an application or message-driven bean connects to a messaging engine on the target service integration bus on which the destinations are assigned. For example, a JMS queue is assigned to a queue destination on a service integration bus.

Applications that are running in a server that is part of the same cell as the service integration bus can usually connect to a messaging engine on that bus without requiring provider endpoints to be configured. If the cell has been divided into two core groups, each defined with its own policies, client applications that are running in a client container and client applications that are running outside the WebSphere Application Server environment, cannot automatically locate the required service integration bus so that, unless a core group bridge has been configured between the core groups in the same cell, you must configure one or more provider endpoints. Similarly, unless a core group bridge has been established between the two cells, an application that is running on a server in one cell cannot connect to a bus in another cell without the configuration of provider endpoints.

In the scenarios where provider endpoints are required, the clients or the servers in another bus must complete a bootstrap process through a bootstrap server. The bootstrap server does not have to be a member of the service integration bus, and it does not have to contain any messaging engines. For the application to locate the required bootstrap server, you must configure the provider endpoint property of the JMS connection factory or JMS activation specification used by the client application. When the bootstrap server receives the client request, it selects a messaging engine that matches the criteria specified by the connection factory or activation specification, for example the target transport chain, target group, or connection proximity. It returns the location information for this messaging engine to the client, and the client creates a new connection to the target messaging engine, if necessary.

The following figure shows a client application running outside an application server.

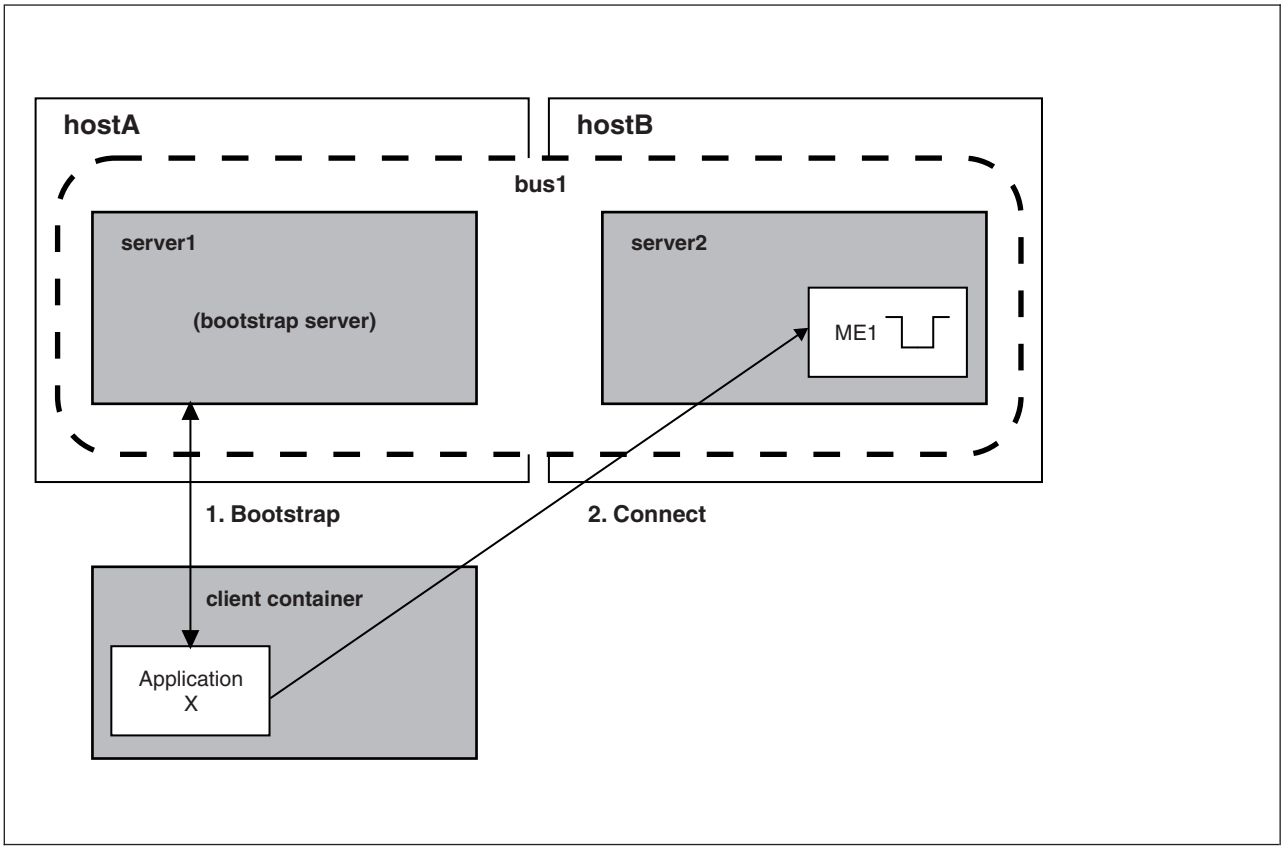

Figure 1. Connection to a messaging engine: Applications running outside an application server

To connect to a messaging engine, the application connects first to a bootstrap server. The bootstrap server selects a messaging engine then tells the client application to connect to that messaging engine.

The following figure shows a message-driven bean running in an application server that is in a different cell to the bus that the message-driven bean needs to be connected to in order to receive messages.

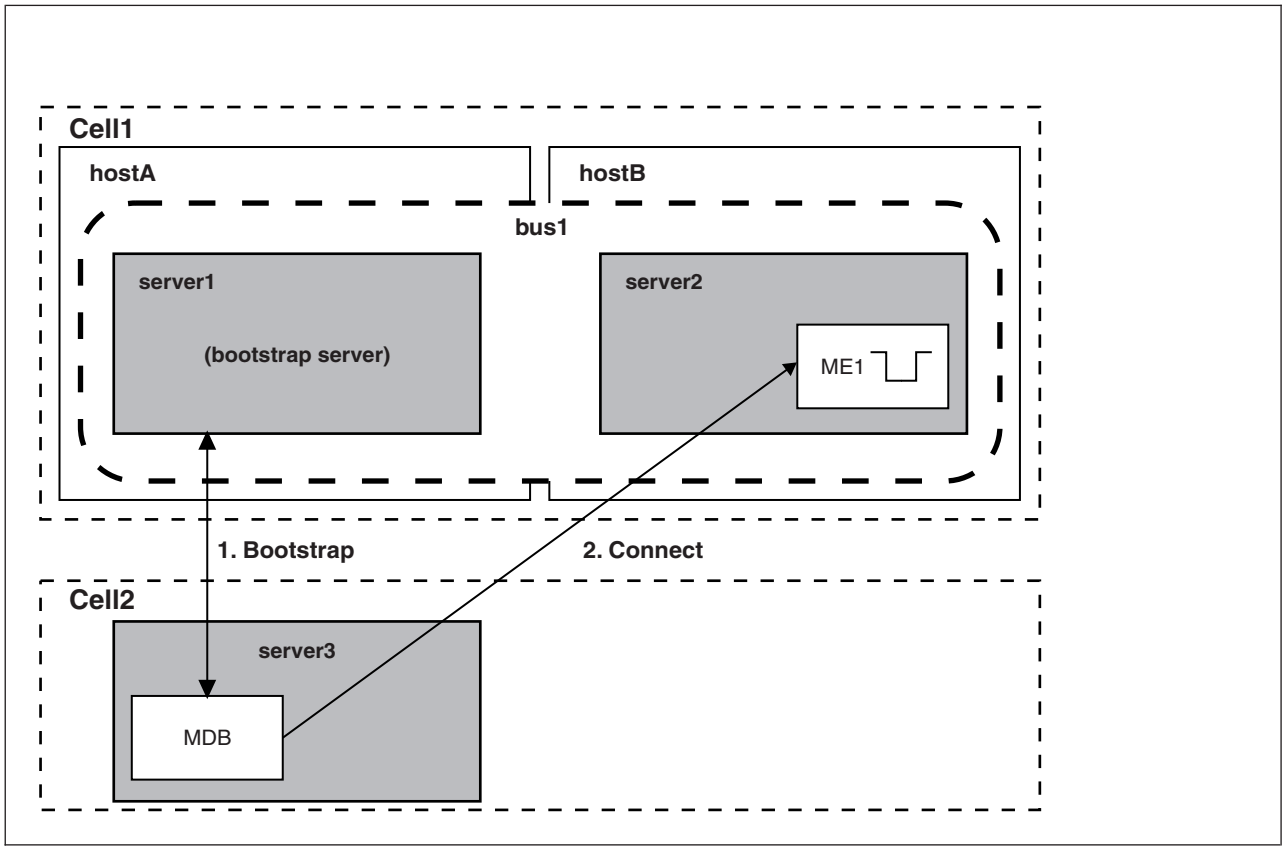

Figure 2. Connection to a messaging engine: message-driven bean application connecting to a destination in a different cell

To connect to a messaging engine, the message-driven bean connects first to a bootstrap server. The bootstrap server selects a messaging engine then tells the message-driven bean to connect to that messaging engine.

A bootstrap server listens on an endpoint that is defined by the combination of:

- The host name of the host on which the bootstrap server is running
- A specific port that is either SIB_END_POINT or, if security is enabled, SIB_ENDPOINT_SECURE_ADDRESS
- A bootstrap transport chain

JMS connection factory properties control how an application connects to a messaging engine, and which messaging engine is selected. If you deploy the application to an application server on which the service integration bus (SIB) service is enabled, the system uses the SIB service to locate a messaging engine that matches the connection factory criteria. The SIB service is aware of all the messaging engines running on servers in the core group of which the application server to which the application is deployed is a member.

If a suitable messaging engine is found, the application is connected to it, and does not use any provider endpoints specified on the connection factory.

Note: This means that you cannot deploy an application to one cell to connect to a bus with the same name in a different cell. Instead the application connects to the bus in the local cell.

The provider endpoints from the connection factory are used to connect to a remote bootstrap server if any of the following conditions are true:

- The application is running as a client application outside of an application server.
- No SIB service is running in the application server to which the application is deployed.
- The SIB service cannot find a suitable messaging engine for the application to connect to.

If you do not specify a value for the provider endpoints in the connection factory, the default value depends on whether the application has supplied a password.

- If the application does not supply a password, a default endpoint address of localhost:7276:BootstrapBasicMessaging is used. That is, by default, applications try to use a bootstrap server on the same host as the client, using port 7276 and the predefined bootstrap transport chain called BootstrapBasicMessaging.
- If the application does supply a password, the default secure port of 7286 and the transport chain BootstrapSecureMessaging is used to prevent the transmission of an unencrypted password to the server.

Note: For the IBM i platform, you must (at least) change the default host name from `localhost` to *your.server.name*.

If you want an application to use a bootstrap server with a different endpoint address, you must specify the required endpoint address on the **Provider endpoints** property of the JMS connection factories or JMS activation specifications that the client application or message-driven bean uses. You can specify one or more endpoint addresses of bootstrap servers by using a comma-separated list.

The endpoint addresses for bootstrap servers must be specified in every JMS connection factory that is used by applications outside of an application server. To avoid having to specify a long list of bootstrap servers, you can provide a few highly-available servers as dedicated bootstrap servers. Then you can specify a short list of bootstrap servers on each connection factory.

This task is based on an application that uses a unified JMS connection factory. You can use the same task to configure a JMS queue connection factory or JMS topic connection factory, but during the task you must select the appropriate type of connection factory instead of a JMS queue connection factory. You can also use this task to configure a JMS activation specification instead of a JMS connection factory.

When you configure a connection to a non-default bootstrap server, specify the required values and use colons as separators. The syntax is as follows:

```
[ [host_name] [ ":" [ port_number] [ ":" chain_name] ] ]
```

Specifying host_name : chain_name instead of host_name : : chain_name (with two colons) is incorrect. The default value applies if you do not specify a value, but you must separate the fields with ":"s.

For an application to use a bootstrap server with a non-default endpoint address, complete the following steps.

Procedure

1. Identify the endpoint address of the application server that you want to use as the bootstrap server. The endpoint address has the form *host_name*:*port_number*:*chain_name*.

   host_name
   The name of the host on which the server runs. It can be an IP address. For an IPv6 address, put square braces ([]) around *host_name*.The default is `localhost`.

   Note: You must (at least) change the default host name from `localhost` to *your.server.name*.

port_number
Where specified, one of the following addresses of the messaging engine hosting the remote end of the link:

- If security is not enabled: SIB_ENDPOINT_ADDRESS
- If security is enabled, for secure connections: SIB_ENDPOINT_SECURE_ADDRESS

This value is mandatory. The default is 7276 if the application has not specified a password, or 7286 if a password has been specified.

To find either of the *port_number* values by using the administrative console, click **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Communications] Ports**.

chain_name
The name of a predefined bootstrap transport chain used to connect to the bootstrap server. If not specified, the default is BootstrapBasicMessaging if a password has not been provided, or BootstrapSecureMessaging if a password has been provided.

The following predefined bootstrap transport chains are provided:

BootstrapBasicMessaging
The server transport chain InboundBasicMessaging (JFAP-TCP/IP).

BootstrapSecureMessaging
The server transport chain InboundSecureMessaging (JFAP-SSL-TCP/IP).

BootstrapTunneledMessaging
Before you can use this bootstrap transport chain, you must define a corresponding server transport chain on the bootstrap server. To do this, click **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] Messaging engine inbound transports**. This transport chain tunnels JFAP and uses HTTP wrappers.

BootstrapTunneledSecureMessaging
Before you can use this bootstrap transport chain, you must define a corresponding server transport chain on the bootstrap server. To do this, click **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] Messaging engine inbound transports**. This transport chain tunnels JFAP and uses HTTP wrappers.

If you want to provide more than one bootstrap server, identify all the required endpoint addresses. Separate each endpoint address with a comma. You should be able to specify the endpoint address for each bootstrap server; for example, for a server assigned non-secure port 7278, on host boothost1, and using the default transport chain BootstrapBasicMessaging:

```
boothost1:7278:BootstrapBasicMessaging
```

or

```
boothost1:7278
```

or, for a server assigned secure port 7289, on host boothost2, and using the predefined transport chain BootstrapTunneledSecureMessaging:

```
boothost2:7289:BootstrapTunneledSecureMessaging
```

2. Optional: Configure the endpoint address of the bootstrap server on the Provider endpoint property of the connection factory.

   If the client application uses a JMS connection factory in the client container, use the Application Client Resource Configuration tool (ACRCT).

   a. Start the tool and open the EAR file for which you want to configure the JMS connection factory. The EAR file contents are displayed in a tree view.
   b. From the tree, select the JAR file in which you want to configure the JMS connection factory.

c. Expand the JAR file to view its contents.
d. Expand **Messaging Providers > Default Provider > Connection Factories**.
e. Display the general properties of the connection factory.
   - To use an existing JMS connection factory, click the name of the connection factory.
   - To create a new JMS connection factory, click **New**.

   For more information about configuring a JMS connection factory in the JMS provider configuration for your application client, see "Configuring Java messaging client resources" on page 72.
f. On the **General** tab, ensure that the **Provider Endpoints** property includes the provider endpoint address for each bootstrap server. Type the value as a comma-separated list of endpoint addresses, for example:

   ```
   boothost1:7278,boothost2:7289:BootstrapTunneledSecureMessaging
   ```
g. Click **OK**.
h. Save your changes to the master configuration..

If the client application uses a JMS connection factory on the server, use the WebSphere Application Server administrative console.

a. Start the WebSphere Application Server administrative console.
b. To display the default messaging provider, click **Resources -> JMS -> JMS providers**.
c. Change the **Scope** check box to set the level at which the connection factory is to be visible, according to your needs.
d. In the content pane click **Default messaging provider** to display a table of properties for the default messaging provider, including links to the types of JMS resources that it provides.
e. In the content pane, under **Additional properties**, click **Connection factories** to display any existing connection factories in the content pane.
f. Display the general properties of the connection factory.
   - To use an existing JMS connection factory, click the name of the connection factory.
   - To create a new JMS connection factory, click **New**.

   For more information about configuring a JMS connection factory, see "Configuring a unified connection factory for the default messaging provider" on page 518.
g. Ensure that the **Provider Endpoints** property includes the provider endpoint address for each bootstrap server. Type the value as a comma-separated list of endpoint addresses; for example:

   ```
   boothost1:7278,boothost2:7289:BootstrapTunneledSecureMessaging
   ```
h. Click **OK**.
i. Save your changes to the master configuration.

3. Optional: Configure the endpoint address of the bootstrap server on the Provider endpoint property of the activation specification.

   If the client application uses a JMS activation specification on the server, use the WebSphere Application Server administrative console.

   a. Start the WebSphere Application Server administrative console.
   b. To display the default messaging provider, click **Resources -> JMS -> JMS providers**.
   c. Select the default provider for which you want to configure an activation specification.
   d. Optional: Change the **Scope** check box to the scope level at which the activation specification is visible to applications, according to your needs.
   e. In the content pane, under the **Additional properties** heading, click **Activation specifications** to list any existing JMS activation specifications for the default messaging provider in the content pane.
   f. Display the properties of the JMS activation specification.
      - To use an existing JMS activation specification, click one of the names listed.

- To create a new JMS activation specification, click **New**.

For more information about configuring a JMS activation specification, see “Configuring an activation specification for the default messaging provider” on page 524.

g. Ensure that the **Provider Endpoints** property includes the provider endpoint address for each bootstrap server. Type the value as a comma-separated list of endpoint addresses; for example:

```
boothost1:7278,boothost2:7289:BootstrapTunneledSecureMessaging
```

h. Click **OK**.

i. Save your changes to the master configuration.

Protecting an MDB application from system resource problems

You can configure the system so that if there is a problem with a dependent external system resource, the enterprise application is stopped before messages are moved unnecessarily to an exception destination. This configuration also handles occasional problems with messages without blocking the enterprise application.

Before you begin

This task assumes that you have deployed an enterprise application that contains a message-driven bean (MDB) that interacts with external system resources.

The destination to which the MDB listens must use an exception destination. This exception destination can be the system default, or one configured specifically for the destination.

To complete this task, you need the following information:

- The enterprise application that contains the MDB.
- The dependent external system resources.
- An acceptable value for the **Sequential failed message threshold**, that is, the maximum number of sequential failures of delivery of messages, after which the MDB is stopped. This property applies to sets of messages.
- An acceptable value for the **Delay between failing message retries**, that is, the time in milliseconds before a failing message is available to be delivered to the MDB. Other messages might be delivered during this period, unless the**Sequential failed message threshold** and the maximum concurrency is set to 1.
- An acceptable value for the **Maximum failed deliveries per message**, that is, the maximum number of failed attempts to process a message, after which the message is forwarded from its intended destination to the exception destination. This property applies to individual messages.

About this task

When an MDB fails to process a message, the message is rolled back and made available to the MDB again. Typically, the messaging system is configured in one of the following ways:

1. Failed messages are retried a finite number of times, and if they continue to fail, they are moved to an exception destination allowing subsequent messages to be processed.
2. Failed messages are retried indefinitely until the problem is rectified.

Configuration (1) protects the MDB from an occasional problem message that prevents subsequent messages from being processed. However, if there is a prolonged problem with a resource that the enterprise application depends on, for example a database, all messages that are sent to the destination might be moved to the exception destination.

Configuration (2) blocks the delivery of messages until the original failing message problem is resolved. This configuration prevents messages being moved unnecessarily to an exception destination, but it also blocks subsequent messages as soon as a single problem message fails to be processed.

You can configure the activation specification for an MDB so that the MDB endpoint is stopped automatically when a number of failures with sequential messages are detected. These failures indicate a problem with a dependent resource. When the problem is resolved, the MDB endpoint is restarted manually. This configuration tolerates occasional message failures, allowing individual problem messages to be moved to the exception destination without blocking the entire MDB.

Use the following steps to protect an enterprise application from dependent external system resource failures.

Procedure

1. Navigate to the deployed enterprise application that contains the MDB.
2. From the MDB, navigate to its JMS activation specification. Click **Resources -> JMS -> Activation specifications -> *activation_specification_name***.
3. Enter a value for the **Sequential failed message threshold** and the **Delay between failing message retries**.
4. Save the configuration.
5. Navigate to the destination to which the MDB is listening. Click one of the following, as appropriate:
   - **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *queue_name***
   - **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *topic_space_name***
6. Enter a value for the **Maximum failed deliveries per message**.
7. Save your changes to the master configuration.

Results

You have configured the enterprise application to protect itself from the sort of external resource problem that can occur at any time. This means that, in the event of a system resource problem, the MDB is stopped automatically when the Sequential failed message threshold is reached for any message.

What to do next

When the system resource that failed becomes available, you can restart the system resource and resume the MDB. The messages that failed during the system resource downtime are retried instead of being left on an exception destination.

Example 1: Handling a planned outage of an MDB application external resource:

You can configure the system so that, if there is a problem with a dependent external system resource, the enterprise application can continue.

Before you begin

During the time that the system resource is unavailable, there must be no exceptions in the enterprise application, or messages on the exception destination that must be resolved later.

About this task

Add a maintenance level to an external system resource that is used by the deployed message-driven bean (MDB) of one of the enterprise applications. The act of applying the maintenance level requires the system resource (for example, a database) to be unavailable for about five minutes.

Procedure

1. Navigate to the deployed enterprise application that contains the MDB.

2. From the MDB, navigate to its JMS activation specification. Click **Resources -> JMS -> Activation specifications -> *activation_specification_name*** and click **Pause** on the administrative panel for the MDB.
3. When you receive a JMX notification and a log entry indicating that the MDB is paused, stop the database and apply the maintenance level. While the MDB is paused, no messages are sent to the exception destination and no error messages appear in the console related to the stopped database.
4. Restart the database and test that it is working as expected.
5. Log on to the administrative console again, navigate to the same enterprise application and click **Resume** on the administrative panel for the MDB. You can also resume the MDB by using scripting and the JCA MBean. The initial JMX notification and log entry indicate which MBean to use to resume the MDB. The MDB begins to be driven with the messages that are on the destination.

Results

You have paused and resumed an application while an external resource that it uses is not available for a short time.

Example 2: Automatically stopping an MDB when a system resource becomes unavailable:

To prepare for a system resource becoming unavailable, configure the system to stop the message-driven bean (MDB) automatically after a small number of message failures, and to alert you to the problem.

Before you begin

This task assumes that you have deployed an enterprise application containing a message-driven bean (MDB) that interacts with external system resources.

The destination to which the MDB listens must use an exception destination. This exception destination can be the system default, or one configured specifically for the destination.

To complete this task you need the following information:

- The enterprise application that contains the MDB.
- The dependent external system resource.
- A value of `3` for the **Sequential failed message threshold**. This is the maximum number of sequential failures of delivery of messages, after which the MDB is stopped. This property applies to sets of messages.
- A value of `5000` for the **Delay between failing message retries**, that is, the time in milliseconds before a failing message is available to be delivered to the MDB. Other messages might be delivered during this period, unless the**Sequential failed message threshold** and the maximum concurrency is set to `1`.
- A value of `5` for the **Maximum failed deliveries per message**, that is, the maximum number of failed attempts to process a message, after which the message is forwarded from its intended destination to the exception destination. This property applies to individual messages.

About this task

In this scenario, the enterprise application is a continuously running system that uses a deployed MDB to access an external system resource.

If the external resource experiences a problem and becomes unavailable, the deployed MDB cannot access that resource, so the transaction that is associated with the MDB is rolled back and the message, msg1, is put back on the queue.

The message msg1 is hidden for a retry delay of five seconds, set in **Delay between failing message retries**, before it is made available to the MDB.

Meanwhile, the MDB processes the next message on the queue, msg2. The external resource is still unavailable, so the processing of this message also fails. The message transaction is rolled back and the message is hidden for five seconds. The next message on the queue, msg3, is processed, fails, and is also hidden.

When the number of hidden messages reaches the **Sequential failed message threshold**, the MDB will not process any further messages until one of the hidden messages becomes available again.

When the **Delay between failing message retries** for msg1 expires, msg1 is unhidden and reprocessed. Because the resource is still unavailable, the message is rehidden. The same thing happens to msg2 and msg3.

A message is considered a failed message when it is rolled back one less than the **Maximum failed deliveries per message** limit (five times in this scenario). So after msg1 is unhidden for the fourth time, rolled back and rehidden, the sequential failure count is incremented. At this point, msg2 becomes unhidden, rolled back and rehidden. Similarly, msg3 becomes unhidden, rolled back and rehidden. The sequential failure count reaches the **Sequential failed message threshold** and the MDB stops automatically. A JMX notification is emitted by the JCA MBean and a log entry alerts the system administrator that the MDB has stopped.

Note: In this scenario, the MDB is stopped automatically when the system resource has been unavailable for approximately 20 seconds. If the system resource is unavailable for a shorter time, and the sequential failure count does not reach the **Sequential failed message threshold**, messages are processed successfully on one of the retries. In effect, the system continues normally without manual intervention, and without sending any messages to the exception destination.

Procedure

1. Navigate to the deployed enterprise application that contains the MDB.
2. From the MDB, navigate to its JMS activation specification. Click **Resources -> JMS -> Activation specifications -> *activation_specification_name***.
3. Enter a value of `3` for the **Sequential failed message threshold**.
4. Enter a value of `5000` for the **Delay between failing message retries**.
5. Save the configuration.
6. Navigate to the destination to which the MDB is listening. Click one of the following paths, as appropriate:
   - **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *queue_name***
   - **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *topic_space_name***
7. Enter a value of `5` for the **Maximum failed deliveries per message**.
8. Save your changes to the master configuration.
9. When you receive a JMX notification and a log entry indicating that the MDB (or endpoint) has been paused, investigate the problem with the system resource that the MDB was using. While the MDB is paused, no messages are sent to the exception destination and no error messages appear in the console related to the stopped database.
10. When the system resource that failed becomes available, restart it.
11. Log on to the administrative console again, navigate to the same enterprise application and click **Resume** on the administrative panel for the MDB. You can also resume the MDB by using scripting and the JCA MBean. The initial JMX notification and log entry indicate which MBean to use to resume the MDB. The MDB begins to be driven with the messages that are on the destination.

Results

You have configured the system to protect itself from external resource failures.

What to do next

When the MDB is resumed, the JCA MBean emits a JMX notification to indicate that the MDB has resumed. Messages on the queue are consumed, messages that had failed are retried, and the transaction commits.

Example 3: The system experiences problems with a problem message:

To prepare for a problem message, configure the system to move that message to an exception destination and allow other messages to be processed successfully.

Before you begin

This task assumes that you have deployed an enterprise application containing a message-driven bean (MDB) that interacts with external system resources.

The destination to which the MDB listens must use an exception destination. This exception destination can be the system default, or one configured specifically for the destination.

To complete this task, you need the following information:

- The enterprise application that contains the MDB.
- The dependent external system resources.
- Set a value of `3` for the **Sequential failed message threshold**. This is the maximum number of sequential failures of delivery of messages, after which the MDB is stopped. This property applies to sets of messages.
- Set a value of `5000` for the **Delay between failing message retries**, that is, the time in milliseconds before a failing message is available to be delivered to the MDB. Other messages might be delivered during this period, unless the**Sequential failed message threshold** and the maximum concurrency is set to `1`.
- Set a value of `5` for the **Maximum failed deliveries per message**, that is, the maximum number of failed attempts to process a message, after which the message is forwarded from its intended destination to the exception destination. This property applies to individual messages.

About this task

In this scenario, the enterprise application is a continuously running system that uses a deployed MDB to access an external system resource.

When a problem message (msg1 in this scenario) is encountered, it is put back on the queue.

Instead of msg1 being made available to the MDB immediately, it is hidden for the **Delay between failing message retries** retry delay of five seconds.

The next message on the queue (msg2) is processed by the MDB. This message and subsequent messages succeeds.

When the **Delay between failing message retries** for msg1 expires, msg1 is unhidden and reprocessed. It is put back on the queue again.

The MDB continues to process subsequent messages normally but each time msg1 is processed, it is put back on the queue.

When the number of times msg1 has been unhidden, rolled back and rehidden reaches the **Maximum failed deliveries per message** limit (five times in this scenario), it is moved to the configured exception destination.

Procedure

1. Navigate to the deployed enterprise application that contains the MDB.
2. From the MDB, navigate to its JMS activation specification. Click **Resources -> JMS -> Activation specifications -> *activation_specification_name***.
3. Enter a value of `3` for the **Sequential failed message threshold**.
4. Enter a value of `5000` for the **Delay between failing message retries**.
5. Save the configuration.
6. Navigate to the destination to which the MDB is listening. Click one of the following paths, as appropriate:
   - **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *queue_name***
   - **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *topic_space_name***
7. Enter a value of `5` for the **Maximum failed deliveries per message**.
8. Save your changes to the master configuration..

Results

You have configured the system to protect itself from external resource failures and send problem messages to the exception destination.

Example 4: Automatically stopping an MDB when no exception destination is specified:

To prepare for a system resource becoming unavailable or a problem message, configure the system to stop the message-driven bean (MDB) automatically. To maintain message ordering, do not use an exception destination.

Before you begin

This task assumes that you have deployed an enterprise application containing a message-driven bean (MDB) that interacts with external system resources.

The destination to which the MDB listens must not use an exception destination, that is, the exception destination for the queue or topic space destination must be configured as none.

To complete this task, you need the following information:

- The enterprise application that contains the MDB.
- The dependent external system resources.
- A value of `1` for the **Sequential failed message threshold**. This is the maximum number of sequential failures of delivery of messages, after which the MDB is stopped. This property applies to sets of messages.

  Note: If this property is set to a value greater than 1, the system automatically resets it to 1 when an exception destination is configured as none.
- A value of `5000` for the **Delay between failing message retries**, that is, the time in milliseconds before a failing message is available to be delivered to the MDB. Other messages might be delivered during this period, unless the**Sequential failed message threshold** and the maximum concurrency is set to `1`.

- An acceptable value for the **Maximum failed deliveries per message**, that is, the maximum number of failed attempts to process a message. This property applies to individual messages.

About this task

In this scenario, the enterprise application is a continuously running system that uses a deployed MDB to access an external system resource.

When a problem message (msg1 in this scenario) is encountered, it is put back on the queue.

Instead of msg1 being made available to the MDB immediately, it is hidden for the **Delay between failing message retries** retry delay (5 seconds in this scenario).

When the number of hidden messages reaches the **Sequential failed message threshold**, the MDB will not process any further messages until one of the hidden messages becomes re-available. In this scenario, this threshold is reached as soon as msg1 is hidden.

When the **Delay between failing message retries** for msg1 expires, msg1 is unhidden and reprocessed.

This process is repeated until msg1 reaches its **Maximum failed deliveries per message** limit (five times in this scenario).

After msg1 is unhidden for the fourth time, rolled back and rehidden, the **Sequential failed message threshold** is reached and the MDB stops automatically. A JMX notification is emitted by the JCA MBean and a log entry alerts the system administrator that the MDB has stopped.

Procedure

1. Navigate to the deployed enterprise application that contains the MDB.
2. From the MDB, navigate to its JMS activation specification. Click **Resources -> JMS -> Activation specifications -> *activation_specification_name***.
3. Enter a value of `1` for the **Sequential failed message threshold**.
4. Enter a value of `5000` for the **Delay between failing message retries**.
5. Save the configuration.
6. Navigate to the destination to which the MDB is listening. Click one of the following paths, as appropriate:
   - **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *queue_name***
   - **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *topic_space_name***
7. Under **Exception destination**, select **None**.
8. Enter a value of `5` in **Maximum failed deliveries per message**.
9. Save your changes to the master configuration.
10. When you receive a JMX notification and a log entry indicating that the MDB (or endpoint) has been paused, investigate the problem with the system resource that the MDB was using. While the MDB is paused, because no exception destination is configured, msg1 remains on the queue. No other messages are processed.
11. If you resume the MDB but the problem with the failing message continues, the maximum failed deliveries limit is reached on the first retry of the message, but because no exception destination is configured, the message is not moved to another queue. Instead, the whole queue point is blocked to all consumers for the Delay between failing message retries retry delay interval (5 seconds in this scenario). After this time, consumers begin again. If the failing message is still there, and fails again, the queue point is blocked for another 5 seconds. This process continues until you remove the failing

message from the queue, either by deleting it manually or solving the problem with it, and in doing so allowing the consuming application to succeed in processing.

12. Log on to the administrative console again, navigate to the same enterprise application and click **Resume** on the administrative panel for the MDB. You can also resume the MDB by using scripting and the JCA MBean. The initial JMX notification and log entry indicate which MBean to use to resume the MDB. The MDB begins to be driven with the messages that are on the destination.

Results

You have configured the system to protect itself from external resource failures while maintaining message ordering.

What to do next

When the MDB is resumed, the JCA MBean emits a JMX notification to indicate that the MDB has resumed. Messages on the queue are consumed, messages that had failed are retried, and the transaction commits.

Sample JMS 1.1 application client

If you are new to JMS 1.1 application client programming, you can use this example code as a starting-point for developing your client application.

Example

Here is a typical example of JMS 1.1 application client code:

```
import java.util.Hashtable;
import javax.jms.JMSException;
import javax.naming.Context;
import javax.naming.*;
import javax.jms.*;

public class JMSppSampleClient
{
  public static void main(String[] args)
  throws JMSException, Exception

  {
    String  messageID                = null;
    String  outString                = null;
    String  cfName                   = "jms/blueconfactory";
    String  qnameIn                  = "java:comp/env/jms/Q1";
    String  qnameOut                 = "jms/bluequename";
    boolean verbose                  = false;

    Session               session    = null;
    Connection            connection = null;
    ConnectionFactory     cf         = null;
    MessageProducer       mp         = null;
    Destination           destination = null;

    try {

     Hashtable env = new Hashtable();
     env.put(Context.INITIAL_CONTEXT_FACTORY,
          "com.ibm.websphere.naming.WsnInitialContextFactory");
     env.put(Context.PROVIDER_URL, "iiop://localhost:2809");
     Context initialContext = new InitialContext(env);
  System.out.println("Getting Connection Factory");
```

```
cf= (ConnectionFactory)initialContext.lookup( cfName );

System.out.println("Getting Queue");
destination =(Destination)initialContext.lookup(qnameOut);

      System.out.println("Getting Connection for Queue");
connection = cf.createConnection();

      System.out.println("staring the connection");
connection.start();

      System.out.println("creating session");
session = connection.createSession(false, 1);

      System.out.println("creating messageProducer");
mp = session.createProducer(destination);

      System.out.println("creating TextMessage");
TextMessage outMessage = session.createTextMessage("this is test application");

      System.out.println("sending Message");
mp.send(outMessage);

mp.close();
session.close();
connection.close();
  }
  catch (Exception je)     {}
```

Interoperating with a WebSphere MQ network

The default messaging provider (service integration) can interoperate with a WebSphere MQ network by using a WebSphere MQ link or a WebSphere MQ server. Alternatively, you can use WebSphere MQ as your messaging provider. Each type of connectivity is designed for different situations, and provides different advantages. Choose the most appropriate interoperation method for each of your messaging applications.

About this task

WebSphere Application Server can interoperate with WebSphere MQ in the following ways:

- By configuring WebSphere MQ as an external JMS provider by using the WebSphere MQ messaging provider.
- By connecting a service integration bus to a WebSphere MQ network by using the default messaging provider and a WebSphere MQ link.
- By integrating WebSphere MQ queues into a bus by using the default messaging provider and a WebSphere MQ server.

A WebSphere MQ link provides a traditional WebSphere MQ -style solution to connecting resources. A WebSphere MQ server adds the ability to directly access WebSphere MQ queues from within a bus.

Table 48. The different ways of interoperating with WebSphere MQ. Table 1 has three columns. Each column contains a figure showing a different way of interoperating with WebSphere MQ. The left column describes interoperation using the WebSphere MQ messaging provider, with no bus. The middle column describes interoperation using a WebSphere MQ network as a foreign bus. The right column describes interoperation using a WebSphere MQ queue manager or queue-sharing group as a bus member.

WebSphere MQ messaging provider (no bus)	**WebSphere MQ network as a foreign bus (using a WebSphere MQ link)**	**WebSphere MQ queue manager or queue-sharing group as a bus member (using a WebSphere MQ server)**
		In this figure, a JMS application uses APIs to send a message to WebSphere MQ, for a topic or queue, via the WebSphere MQ messaging provider.	In this figure a JMS application uses the default messaging provider to pass a message to a local service integration bus. The local bus passes the message to a foreign bus, which forwards it across a WebSphere MQ link to a WebSphere MQ queue manager or queue sharing group that acts as the gateway to the WebSphere MQ network. Service integration views the WebSphere MQ network as if it were a foreign bus.	In this figure, a JMS application uses the default messaging provider to pass a message to a service integration bus. The bus passes the message through a WebSphere MQ server direct to a WebSphere MQ queue. Service integration views the WebSphere MQ server (a WebSphere MQ queue manager or queue-sharing group, and its associated queues) as a member of the local bus.

Table 48. The different ways of interoperating with WebSphere MQ (continued). Table 1 has three columns. Each column contains a figure showing a different way of interoperating with WebSphere MQ. The left column describes interoperation using the WebSphere MQ messaging provider, with no bus. The middle column describes interoperation using a WebSphere MQ network as a foreign bus. The right column describes interoperation using a WebSphere MQ queue manager or queue-sharing group as a bus member.

WebSphere MQ messaging provider (no bus)	WebSphere MQ network as a foreign bus (using a WebSphere MQ link)	WebSphere MQ queue manager or queue-sharing group as a bus member (using a WebSphere MQ server)
The WebSphere MQ messaging provider does not use service integration. It provides JMS messaging access to WebSphere MQ from WebSphere Application Server.	A WebSphere MQ link provides a server to server channel connection between a service integration bus and a WebSphere MQ queue manager or queue-sharing group, which acts as the gateway to the WebSphere MQ network.When you use a WebSphere MQ link, the messaging bus is seen by the WebSphere MQ network as a virtual queue manager, and the WebSphere MQ network is seen by service integration as a foreign bus. A WebSphere MQ link allows WebSphere Application Server applications to send point-to-point messages to WebSphere MQ queues (defined as destinations in the service integration bus), and allows WebSphere MQ applications to send point-to-point messages to destinations in the service integration bus (defined as remote queues in WebSphere MQ). The link also allows WebSphere Application Server applications to subscribe to messages published by WebSphere MQ applications, and WebSphere MQ applications to subscribe to messages published by WebSphere Application Server applications. The link ensures that messages are converted between the formats used by WebSphere Application Server and those used by WebSphere MQ.	A WebSphere MQ server represents a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. For interoperation with WebSphere Application Server Version 7.0 or later, the version of WebSphere MQ must be WebSphere MQ for z/OS Version 6 or later, or WebSphere MQ (distributed platforms) Version 7 or later. A WebSphere MQ server supports the high availability and optimum load-balancing characteristics provided by a WebSphere MQ for z/OS network. A WebSphere MQ server defines the connection and quality of service properties used for the connection, and also ensures that messages are converted between the formats used by WebSphere Application Server and those used by WebSphere MQ.

For more information about these approaches, see Interoperation with WebSphere MQ.

To interoperate with a WebSphere MQ network complete one or more of the following steps.

Procedure

- Choose the most appropriate interoperation method for each of your messaging applications. Complete this step if your existing or planned messaging environment involves both WebSphere MQ and WebSphere Application Server systems, and it is not clear to you whether you should use the default messaging provider, the WebSphere MQ messaging provider, or a mixture of the two.
- Configure the WebSphere MQ messaging provider.
- Use WebSphere MQ links to connect a bus to a WebSphere MQ network.
- Use WebSphere MQ server to integrate WebSphere MQ queues into a bus.

Using WebSphere MQ links to connect a bus to a WebSphere MQ network

If you operate within a WebSphere Application Server environment, sending messages across a service integration bus, you can also exchange point-to-point and publish/subscribe messages with applications in a WebSphere MQ network. To do this, you configure a foreign bus connection that links to a WebSphere MQ network through a WebSphere MQ link.

Before you begin

Decide which method to use to configure these resources. You can configure a WebSphere MQ link by using the administrative console as described in this task, or you can configure a WebSphere MQ link by using the wsadmin tool.

About this task

A WebSphere MQ link provides a server to server channel connection between a service integration bus and a WebSphere MQ queue manager or queue-sharing group, which acts as the gateway to the WebSphere MQ network. The link operates on a messaging engine in a service integration bus to provide functions that simplify and automate interoperation with WebSphere MQ.

Using the WebSphere MQ link panels of the WebSphere Application Server administration console, you can choose:

- The WebSphere MQ queue manager or queue-sharing group in the WebSphere MQ network through which your messages will flow
- Whether to enable WebSphere Application Server applications to publish and subscribe to a message broker in the WebSphere MQ network

Procedure

- Learn about interoperating with a WebSphere MQ network.
- Create a new WebSphere MQ link.
- Administer an existing WebSphere MQ link.
- Create applications that can interoperate with WebSphere MQ.

Creating a new WebSphere MQ link:

A WebSphere MQ link provides a server to server channel connection between a service integration bus and a WebSphere MQ queue manager or queue-sharing group, which acts as the gateway to the WebSphere MQ network. Use the foreign bus connection wizard to create a foreign bus and link it to the WebSphere MQ network through a WebSphere MQ link.

Before you begin

Decide which method to use to configure these resources. You can create a new WebSphere MQ link by using the administrative console as described in this task, or you can create a new WebSphere MQ link by using the wsadmin tool.

The following resources must be defined in WebSphere Application Server:

- A service integration bus that you want to connect from (known as the local bus) with at least one bus member.

The following resources must be defined in WebSphere MQ:

- A queue manager or queue-sharing group, which acts as the gateway to the WebSphere MQ network.
- A listener that is configured and running.
- (optionally) A sender channel to receive messages on the local bus, a receiver channel to send messages from the local bus, or both.
- (For publish-subscribe messaging) A topic and input queue for broker publish-subscribe flow.

About this task

You use the foreign bus connection wizard to connect a bus and a WebSphere MQ network. You can configure the connection for either point-to-point or publish-subscribe messaging.

Specifically, the wizard helps you configure the following resources:

- The bus and messaging engine on which the WebSphere MQ link is defined.
- The foreign bus that represents the WebSphere MQ network.
- The WebSphere MQ link.
- (Optionally) The sender and receiver channels and protocol. Using the wizard you can choose to define no channels (and add them afterward), or one channel if your WebSphere MQ link is to be one-way, or both channels.
- (Optionally) Security for messages flowing across the link.
- (Optionally) A publish/subscribe broker profile and associated topic mappings, to allow publication and subscription with a broker in the WebSphere MQ network.

The wizard does not ask you to set all possible properties of a WebSphere MQ link, and many of the properties are set to default values. You can fine tune these properties afterward if necessary, by modifying the WebSphere MQ link.

For a sample configuration showing a systems view of the setup for a WebSphere MQ link, see "WebSphere MQ link sample configuration" on page 550.

Procedure

1. Use the foreign bus connection wizard to connect a bus and a WebSphere MQ network to use point-to-point messaging or publish-subscribe messaging.

   A WebSphere MQ link is created and configured as part of the action of the wizard.

   Note: You can subsequently convert a point-to-point connection to a publish/subscribe connection, by adding a publish/subscribe broker on the WebSphere MQ link for the connection.
2. Optional: Modify the new WebSphere MQ link.

   When you create a new WebSphere MQ link, the following properties are set to default values:

   - Description
   - Adoptable
   - Exception destination
   - Initial state
   - Nonpersistent message speed

   You can fine tune these properties by modifying the link.
3. Optional: Add or modify the WebSphere MQ receiver channel.

   If you did not choose to **Enable Service integration bus to WebSphere MQ message flow** in the foreign bus connection wizard, you have not yet defined a WebSphere MQ receiver channel. If you did choose this option in the wizard, you have defined the receiver channel name, host name and communication port, and the wizard has used default values for the following properties:

   - Inbound nonpersistent message reliability
   - Inbound persistent message reliability
   - Prefer queue points local to this link's messaging engine
   - Initial state

   You can fine tune these properties by modifying the channel.
4. Optional: Add or modify the WebSphere MQ sender channel

If you did not choose to **Enable WebSphere MQ to Service integration bus message flow** in the foreign bus connection wizard, you have not yet defined a WebSphere MQ sender channel. If you did choose this option in the wizard, you have defined the sender channel name, host name, communication port and transport chain, and the wizard has used default values for the following properties:

- Disconnect interval
- Short retry count
- Short retry interval
- Long retry count
- Long retry interval
- Initial state

You can fine tune these properties by modifying the channel.

WebSphere MQ link sample configuration:

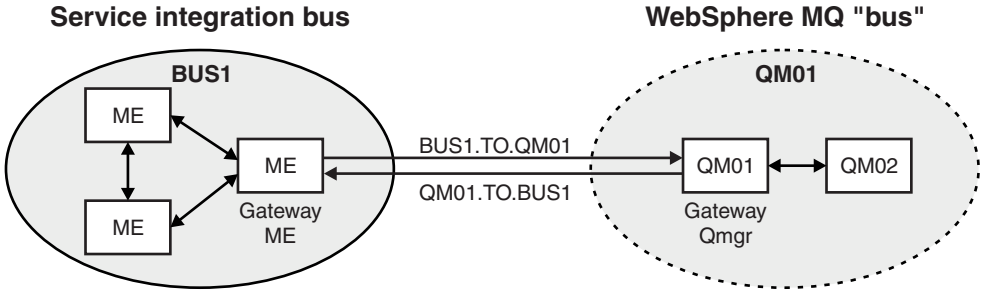
This sample configuration illustrates how you can use a WebSphere MQ link to connect WebSphere Application Server service integration messaging to WebSphere MQ messaging.

A WebSphere MQ link connects one service integration messaging engine, called the gateway messaging engine, to one WebSphere MQ queue manager or queue-sharing group, called the gateway queue manager. All messaging engines in the service integration bus use the gateway messaging engine to route messages to and from the WebSphere MQ network; all queue managers and queue-sharing groups in the WebSphere MQ network use the gateway queue manager to route messages to and from the service integration bus.

Typically, a WebSphere MQ link consists of two TCP/IP connections:

- The WebSphere MQ link sender channel, which carries messages from service integration to WebSphere MQ.
- The WebSphere MQ link receiver channel, which carries messages from WebSphere MQ to service integration.

WebSphere MQ calls these TCP/IP connections message channels, a receiver channel which connects to the WebSphere MQ link sender channel and a sender channel which connects to the WebSphere MQ link receiver channel. The following figure shows a configuration like the one just described, with a WebSphere MQ link sender channel called BUS1.TO.QM01 and a WebSphere MQ link receiver channel called QM01.TO.BUS1.



If you only require messages to flow in one direction, you need only define one TCP/IP connection. For example, a WebSphere MQ link sender channel in service integration that connects to a receiver channel in WebSphere MQ is enough to support message flow from service integration to WebSphere MQ. However, this sample builds a configuration that allows messages to flow in both directions.

Sample configuration context

The purpose of this sample is to connect a WebSphere Application Server configuration to a WebSphere MQ configuration so that asynchronous messages can flow in both directions between the two messaging systems. The sample assumes that you have already set up a WebSphere Application Server configuration like this:

- An application server called server1 located on a node called London. In a Network Deployment, server1 might be one of several servers in a cell and might be one of several servers in a cluster, but this sample is equally applicable to a base deployment containing just one application server.
- The IP host name for the server London is LONDON.
- A service integration bus called BUS1.
- server1 is a member of BUS1; the messaging engine it contains is called London.server1-BUS1.
- A queue-type bus destination called ServiceIntegrationQueue1, which is one of the destinations in BUS1.

The sample also assumes that you already have a WebSphere MQ configuration like this:

- Queue managers called QM01 and QM02 which are part of a network of interconnected WebSphere MQ queue managers and queue-sharing groups. If you have only one queue manager then you can ignore references to QM02 in this sample.
- The IP host name for the server where QM01 runs is PARIS.
- A queue called WMQ11 which is located on QM01 and a queue called WMQ21 which is located on QM02. There might be many other queues defined in the WebSphere MQ network but this sample is concerned only with the two WebSphere MQ queues that you are going to access from WebSphere Application Server.

You select London.server1-BUS1 to be the gateway messaging engine and QM01 to be the gateway queue manager.

Sample configuration for the connections

This section describes the settings that you or your WebSphere MQ administrator need to configure for the connections:

- The commands that your WebSphere MQ administrator uses to configure the WebSphere MQ components that correspond to the WebSphere MQ link:
  - The sender channel
  - The receiver channel
  - The transmission queue

  For JMS programs, the WebSphere MQ administrator also defines a JMS destination that identifies the queue in the service integration bus. Refer to the WebSphere MQ documentation for more details about these commands.
- The parameters that you need when you use the WebSphere Application Server administrative console to configure:
  - A foreign bus connection, which includes the foreign bus representing the network of WebSphere MQ queue managers and queue-sharing groups, and the WebSphere MQ link representing the connection to that network
  - JMS destinations that identify queues in the WebSphere MQ network

After you configure and activate these components your applications can exchange messages between WebSphere Application Server service integration messaging and WebSphere MQ messaging. Optionally you can configure additional administrative artifacts that allow you more detailed control over the queues and destinations, see “Sample configuration for the destinations” on page 553.

WebSphere MQ command to configure the sender channel

```
DEFINE    CHL(QM01.TO.BUS1) +
          CHLTYPE(SDR) +
          TRPTYPE(TCP) +
          CONNAME('LONDON(5558)') +
          XMITQ(BUS1)
```

Your WebSphere MQ administrator chooses the name for the sender channel, which in this sample is QM01.TO.BUS1.

The CONNAME parameter specifies the IP host and port of the gateway messaging engine.

The XMITQ parameter specifies the name of the transmission queue, which is normally the same as the virtual queue manager name of the service integration bus, which is preferably the same as the bus name.

WebSphere MQ command to configure the receiver channel

```
DEFINE    CHL(BUS1.TO.QM01) +
          CHLTYPE(RCVR) +
          TRPTYPE(TCP)
```

Your WebSphere MQ administrator chooses the name for the receiver channel, which in this sample is BUS1.TO.QM01.

WebSphere MQ command to configure the transmission queue

```
DEFINE   QL(BUS1) +
         USAGE(XMITQ)
```

Your WebSphere MQ administrator chooses the name for the transmission queue, but it is convenient to use the name of the service integration bus BUS1. If the service integration bus name is not a valid WebSphere MQ queue manager name then the WebSphere Application Server administrator must define a different virtual queue manager name for use here.

WebSphere MQ JMSAdmin command to configure the JMS destination

```
DEFINE   Q(ServiceIntegrationQueue1) +
         QMGR(BUS1) +
         QUEUE(ServiceIntegrationQueue1)
```

Your WebSphere MQ JMS applications can use this JMS destination to send messages to the service integration bus destination ServiceIntegrationQueue1 in BUS1.

WebSphere Application Server parameters for the foreign bus connection

You configure a foreign bus connection as part of the topology of the service integration bus. For this sample, the service integration bus is BUS1 and the foreign bus connection uses the following settings:

Bus connection type	Direct connection
Foreign bus type	WebSphere MQ
Messaging engine to host the connection	London.server1-BUS1
Virtual queue manager name	BUS1 (use the name of the local bus)
Foreign bus name	QM01 (use the name of the WebSphere MQ gateway queue manager)
MQ link name	TO.QM01
Enable Service integration bus to WebSphere MQ message flow	Checked (default)
WebSphere MQ receiver channel name	BUS1.TO.QM01
Host name	PARIS
Port	1414
Enable WebSphere MQ to Service integration bus message flow	Checked (default)
WebSphere MQ sender channel name	QM01.TO.BUS01

There are other options in the wizard relating to publish/subscribe messaging and security. Leave these settings to default.

WebSphere Application Server parameters for JMS destinations

You configure JMS destinations to allow service integration JMS applications to access queues in the WebSphere MQ network. This sample needs JMS destinations for queue WMQ11 on queue manager QM01, and for queue WMQ21 on queue manager QM02.

Note that these JMS destinations are WebSphere MQ queues but for the purposes of this sample you are accessing these queues from service integration JMS programs so you need to define JMS destinations for the default messaging provider (service integration) not for the WebSphere MQ JMS provider.

For WMQ11, configure the following parameters:

Name	WMQ11
JNDI name	jms/WMQ11
Bus name	QM01
Queue name	WMQ11

Leave all other settings to default.

For WMQ21, configure the following parameters:

Name	WMQ21
JNDI name	jms/WMQ21
Bus name	QM01
Queue name	WMQ21@QM02

Leave all other settings to default.

Sample configuration for the destinations

The sample JMS destinations in Sample configuration for the connections point directly to the corresponding WebSphere MQ queues and service integration destinations. If you prefer, you can configure additional components so that:

- The WebSphere MQ JMS destination points to a WebSphere MQ queue (actually a remote or alias queue) which points to the service integration destination.
- The service integration JMS destinations point to service integration destinations (actually foreign or alias destinations) which point to the WebSphere MQ queues.

Refer to the WebSphere MQ documentation for information about when and how to define remote and alias queues.

WebSphere Application Server parameters for foreign destinations

You configure foreign destinations for WebSphere MQ queues to allow control over how service integration applications access each queue. For example, you can configure foreign destinations for each of two queues and specify that service integration includes an MQRFH2 header in messages to one queue but not to the other.

You configure foreign destinations as destination resources of the service integration bus.

For WMQ11, configure the following parameters:

Identifier	WMQ11
Bus	QM01

Leave all other settings to default.

For WMQ21, configure the following parameters:

Identifier	WMQ21@QM02
Bus	QM01

Leave all other settings to default.

After you define these foreign destinations you can, for example, set the _MQRFHAllowed custom property for either destination or both, as required.

Administering an existing WebSphere MQ link:

The WebSphere MQ link enables the exchange of point-to-point and publish/subscribe messages with a WebSphere MQ network. After you have created a WebSphere MQ link you can undertake various administrative actions on the link.

About this task

The WebSphere MQ link connects a WebSphere Application Server and a WebSphere MQ network. Because these two systems are working together, their functions must be in step so that each is aware of the status of the other. Administrative actions on the WebSphere MQ link and its functions include the following:

Procedure

- Modify individual functions of the WebSphere MQ link .

  You can modify the link itself, add or modify the sender channel and receiver channel, or define a broker profile and associated topic mappings.
- Modify security for a WebSphere MQ link.
- View the status of a WebSphere MQ link and its components. You can view the status of a WebSphere MQ link and its sender and receiver channels, and you can view the status of subscriptions for a WebSphere MQ link publish/subscribe broker profile.
- Start a WebSphere MQ link.
- Stop a WebSphere MQ link.

  When you stop the link, all its functions are stopped too. For example, stopping a WebSphere MQ link with broker profiles on it might leave a message broker in the WebSphere MQ network with a backlog of messages. For more information, see “Stopping a WebSphere MQ link” on page 568, “Stopping the sender channel on a WebSphere MQ link” on page 570 and “Stopping the receiver channel on a WebSphere MQ link” on page 569.
- Delete a WebSphere MQ link or one of its components. When you remove a foreign bus connection between a service integration bus and a WebSphere MQ network, you also delete the associated WebSphere MQ link along with any publish/subscribe broker profiles and topic mappings. You can also delete a WebSphere MQ link publish/subscribe broker profile or delete a topic mapping from a WebSphere MQ link.

Modifying a WebSphere MQ link:

How and when to modify the properties of a WebSphere MQ link.

Before you begin

Decide which method to use to configure these resources. You can modify a WebSphere MQ link by using the administrative console as described in this task, or you can modify a WebSphere MQ link by using the wsadmin tool.

You have to know the name of the bus, and the messaging engine on the bus that contains the WebSphere MQ link you want to modify.

About this task

A WebSphere MQ link provides a server to server channel connection between a service integration bus and a WebSphere MQ queue manager or queue-sharing group, which acts as the gateway to the WebSphere MQ network. At any time after you create a new WebSphere MQ link, you can modify its properties.

When you use the foreign bus connection wizard to connect a bus and a WebSphere MQ queue manager or queue-sharing group (known as the "gateway queue manager") to use point-to-point messaging or publish-subscribe messaging, one or more WebSphere MQ links are created and configured as part of the task. However the wizard does not ask you to set all possible properties of a WebSphere MQ link, and some of the link properties are not set or are set to default values. You can fine tune these properties by modifying the link.

When you create a new WebSphere MQ link, you can also choose not to create sender or receiver channels. These channels can be added later by modifying the link.

When you use the foreign bus connection wizard to create a WebSphere MQ link for point-to-point messaging, you can later modify the link for publish-subscribe messaging by adding a publish/subscribe broker profile to the link.

Procedure

1. In the navigation pane, click, **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name***.
2. Modify the properties of the link.

   For information about all the properties that you can modify, see "WebSphere MQ link [Settings]" on page 2228.

   When you create a new WebSphere MQ link, the following properties are set to default values:

   Description
   An optional description for the WebSphere MQ link, for administrative purposes.

   Adoptable
   Whether or not a running instance of a WebSphere MQ link receiver channel (associated with this MQ link) should be adopted or not. In the event of a communications failure, it is possible for a running instance of a WebSphere MQ link receiver channel to be left waiting for messages. When communication is re-established, and the partner WebSphere MQ sender channel next attempts to establish a session with the WebSphere MQ link receiver channel, the request will fail as there is already a running instance of the WebSphere MQ link receiver channel that believes it is in session with the partner WebSphere MQ sender channel. You can overcome this problem by selecting this option, which causes the already running instance of the WebSphere MQ link receiver channel to be stopped and a new instance to be started. By default, this option is not selected.

   Exception destination
   The destination for an inbound message when the WebSphere MQ link cannot deliver the message to its target bus destination, or to the exception destination that is configured for that target destination, or when the target destination does not exist. By default, undeliverable messages are sent to the system default exception destination for the messaging engine that this link is assigned to. However, it can aid problem-solving if you separate these exceptions out from other system messages by configuring a specific exception destination for this link.

   Initial state
   Whether the WebSphere MQ link is started or stopped when the hosting messaging engine is first started. Until started, the WebSphere MQ link is unavailable. By default, the value is "Started".

Nonpersistent message speed
The class of service for nonpersistent messages on channels of this WebSphere MQ link. By default, the value is “Fast”.

3. Configure the additional properties. You can configure any of the following additional properties of this WebSphere MQ link:
   - Publish/subscribe broker profiles
   - Receiver channel
   - Sender channel
   - Sender channel transmitters
4. Configure the related items. You can configure any of the following related items of this WebSphere MQ link:
   - Foreign bus connection
   - Link transmitters
5. Save your changes to the master configuration.
6. If you have enabled dynamic configuration updates, the changes take effect immediately (or on channel restart if you also modified WebSphere MQ link sender or receiver channels), otherwise restart the application server.

Adding or modifying a publish/subscribe broker on the WebSphere MQ link:

A publish/subscribe broker profile, and associated topic mappings, allows publication and subscription with a broker in a WebSphere MQ network. You can use the administrative console to define a broker profile on a WebSphere MQ link, forming a publish/subscribe bridge with a WebSphere MQ network.

Before you begin

You have to know the name of the bus, messaging engine name, and the name of the WebSphere MQ link on which you intend to create or modify the broker profile. You also have to know the queue manager name for the message broker in the WebSphere MQ network where the input queues for the required publication message flows are located.

About this task

When you use the foreign bus connection wizard to connect a bus and a WebSphere MQ queue manager to use publish/subscribe messaging, you can define a publish/subscribe broker profile and associated topic mappings. Alternatively, you can use the foreign bus connection wizard to connect a bus and a WebSphere MQ queue manager to use point-to-point messaging, then later modify the WebSphere MQ link for publish/subscribe messaging by adding a publish/subscribe broker profile and associated topic mappings to the link.

After you have created the broker profile you must ensure that the service integration bus has sufficient authority on the message broker instance to send subscription requests.

Procedure

1. In the navigation pane, click one of the following paths:
   - **Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Related Items] WebSphere MQ links -> *link_name* -> [Additional Properties] Publish/subscribe broker profiles**
   - **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional Properties] Publish/subscribe broker profiles**
2. In the content pane, either click **New** to add a new broker profile, or click the name of a existing broker profile that you want to modify.

3. Add or modify the properties of the broker profile.

   For information about the broker profile properties (name, description, broker queue manager name), see “Publish/subscribe broker profiles [Settings]” on page 2139.

   For an existing broker profile you can only modify the description. Note that, for an existing broker profile created by using the foreign bus connection wizard, the broker profile name was generated automatically by adding “_broker_profile” to the end of the broker queue manager name.
4. Optional: Under Additional properties, configure the topic mappings for this broker profile. For more information, see “Adding or modifying topic mappings on the WebSphere MQ link publish/subscribe broker” on page 558.
5. Click **OK**.
6. Save your changes to the master configuration.

What to do next

After you have created the broker profile you must ensure that the service integration bus has sufficient authority on the message broker instance to send subscription requests. You can do this either by modifying the message broker configuration on the WebSphere MQ network, or by modifying the service integration bus configuration. See “Defining permissions for a WebSphere MQ link publish/subscribe broker to work with WebSphere MQ.”

Defining permissions for a WebSphere MQ link publish/subscribe broker to work with WebSphere MQ:

There are several ways to ensure that a service integration bus has authority with a message broker (in a WebSphere MQ network) to send subscription requests.

Before you begin

Before you start this task, you must have created a broker profile, part of a publish/subscribe bridge on a WebSphere MQ link.

About this task

When you have created a broker profile you must ensure that the service integration bus has sufficient authority on the message broker instance to send subscription requests. You can do this either by:

- Modifying the message broker configuration in the WebSphere MQ network if you are a WebSphere MQ administrator. Or
- Modifying the service integration bus configuration if you are a WebSphere Application Server administrator.

To ensure authority, complete one of the following steps:

Procedure

1. Modify the message broker configuration by granting WebSphere MQ permissions for the user "SIBServer", which is the user name under which the publish/subscribe bridge control messages will be published.
2. Modify the service integration bus by setting the OutboundUserID of the foreign bus that represents the WebSphere MQ network (which you defined as part of the WebSphere MQ link configuration). The OutboundUserID should be set to a user ID that already has the relevant WebSphere MQ permissions on the message broker installation image. By doing this you can be sure the publish/subscribe bridge control messages will arrive at the message broker in the WebSphere MQ network with the appropriate user ID set in them.

What to do next

You are now ready to define topic mappings on the publish/subscribe broker profile.

Adding or modifying topic mappings on the WebSphere MQ link publish/subscribe broker:

Define topic mappings on a publish/subscribe broker profile, part of the publish/subscribe bridge on a WebSphere MQ link. A topic mapping is a mapping between a topic on a service integration bus and a stream queue and subscription point provided by a WebSphere MQ broker.

Before you begin

You have to know the bus name, messaging engine name, WebSphere MQ link name and the name of the broker profile on which you intend to define the topic mappings.

About this task

Topic mappings are associated with a WebSphere MQ link publish/subscribe broker profile. Together, the profile and topic mappings enable publication and subscription with a broker in a WebSphere MQ network.

Note: Publication messages forwarded to a message broker in the WebSphere MQ network are republished on the same topic as they were originally published to in the service integration bus topic space, and vice versa.

To define topic mappings, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional Properties] Publish/subscribe broker profiles -> *profile_name* -> [Additional Properties] Topic mappings**
2. In the content pane, either click **New** to add a new topic mapping, or click the name of a existing topic mapping that you want to modify. The “Topic Mapping [Settings]” on page 2173 form is displayed.
3. Type the topic name.

   The name of the topic on the service integration bus. The name must be the same as the topic name on the message broker in a WebSphere MQ network.

   The topic name can contain wild cards that are in the service integration bus syntax. For more information, see Wild cards in topic mapping.
4. Select the name of the topic space that contains the topic. If you don't select a name the default is used.
5. Select the direction of publication flow. The direction of publication flow can be:

   Bi-directional
   Messages flow in both directions between the bus and WebSphere MQ.

   To WebSphere MQ
   Messages flow only from the bus to WebSphere MQ. That is, from WebSphere Application Server to a message broker in the WebSphere MQ network.

   From WebSphere MQ
   Messages flow only to the bus from WebSphere MQ. That is, from a message broker in the WebSphere MQ network to WebSphere Application Server.
6. Select the broker stream queue you want to use. If the queue you require is not on the list, click **other, please specify** then enter the name of the broker stream queue.

The broker stream queue in this instance is a queue on the WebSphere MQ queue manager to which the message broker is connected. This queue is being used as the input node for a message flow containing a publication node. Messages sent to this queue are processed by the message broker, then published to applications that have subscribed on the topic specified in the message.

Stream names are case sensitive.

After you type a new name, then save your changes, the name becomes available for selection in the drop-down list.

7. Select the WebSphere MQ message broker subscription point from which the service integration bus receives messages. If the subscription point you require is not on the list, click **other, please specify** then enter the name of the subscription point.

   The default subscription point is used if no value is specified.

   After you type a new name, then save your changes, the name becomes available for selection in the drop-down list.
8. Click **OK**.
9. Save your changes to the master configuration.
10. Optional: If you have enabled dynamic configuration updates, the changes take effect immediately. Otherwise, restart the application server.

Adding or modifying a WebSphere MQ link receiver channel:

How you can define the properties of the receiver channel on a WebSphere MQ link. This channel receives messages from the WebSphere MQ queue manager or queue-sharing group (known as the "gateway queue manager"). The receiver channel communicates with a WebSphere MQ sender channel on the gateway queue manager, and converts MQ format messages to service integration bus messages.

Before you begin

You have to know the name of the bus, and the messaging engine on the bus that contains the WebSphere MQ link with the receiver channel you intend to add or modify.

About this task

When you use the foreign bus connection wizard to connect a bus and a gateway queue manager to use point-to-point messaging or publish-subscribe messaging, the wizard does not ask you to set all possible properties of a WebSphere MQ link. If you did not choose to **Enable Service integration bus to WebSphere MQ message flow** in the foreign bus connection wizard, you have not yet defined a Websphere MQ receiver channel. If you did choose this option in the wizard, you have defined the receiver channel name, host name and port number, and the wizard has set the other properties to default values.

To add or modify a WebSphere MQ link receiver channel, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional Properties] Receiver channel**.
2. In the content pane, either click **New** to add a new receiver channel, or click the name of a existing receiver channel that you want to modify.
3. Add or modify the properties of the channel.

   For information about all the properties that you can modify, see "WebSphere MQ link receiver channel [Settings]" on page 2208.

If you used the foreign bus connection wizard to create the channel, the wizard has used default values for the following properties:

Inbound nonpersistent message reliability
The acceptable reliability of message delivery for nonpersistent message flows from WebSphere MQ through this WebSphere MQ link, from Best effort to Reliable, in order of increasing reliability. By default, the value is “Reliable”.

Inbound persistent message reliability
The acceptable reliability of message delivery for inbound persistent message flows from WebSphere MQ through this WebSphere MQ link, from Reliable to Assured, in order of increasing reliability. By default, the value is “Assured”.

Prefer queue points local to this link's messaging engine
When this check box is selected, the link prefers to send inbound messages to available queue points of target queue destinations that are located on the same messaging engine as the link. By default the check box is selected, which corresponds to the behavior in WebSphere Application Server Version 6 and can make it easier to handle links in a mixed-version cell. If you clear the check box, preference is not given to local queue points and inbound messages are workload balanced across all available queue points of target queue destinations. This option (not to give preference to local queue points) is available only on links running on WebSphere Application Server Version 7.0 or later.

Initial state
Whether the receiver channel is started or stopped when the associated WebSphere MQ link is first started. Until started, the channel is unavailable. By default, the value is “Started”.

4. Click **OK**.
5. Save your changes to the master configuration.
6. Restart the application server.

Adding or modifying a WebSphere MQ link sender channel:

The WebSphere MQ link sender channel sends messages to the WebSphere MQ queue manager or queue-sharing group (known as the “gateway queue manager”). The sender channel communicates with a WebSphere MQ receiver channel on the gateway queue manager, and converts service integration bus messages to MQ format messages. Use this task to add a sender channel if you have not already defined one, or to fine tune the properties of an existing sender channel.

Before you begin

To be able to complete this task, you must know the name of the bus, and the messaging engine on the bus that contains the WebSphere MQ link with the sender channel that you intend to add or modify.

About this task

This task allows you to define a WebSphere MQ sender channel if you have not already done so when using the foreign bus connection wizard to create a foreign bus and link it to the WebSphere MQ network through a WebSphere MQ link. If you did not choose the **Enable WebSphere MQ to Service integration bus message flow** option when using the foreign bus connection wizard, you have not yet defined the sender channel.

If you did choose the **Enable WebSphere MQ to Service integration bus message flow** option in the wizard, you will already have defined the sender channel name, host name, communication port and transport chain. However, the wizard will have set the other properties of the sender channel to default values, in which case you might need to fine tune these properties using this task.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional Properties] Sender channel**.
3. In the content pane, either click **New** to add a new sender channel, or click the name of a existing sender channel that you want to modify.
4. Add or modify the properties of the channel.

   For information about all the properties that you can modify, see “WebSphere MQ link sender channel [Settings]” on page 2214.

   If you used the foreign bus connection wizard to create the channel, the wizard has used default values for the following properties:

   Disconnect interval
   The time in seconds for which the sender channel waits for new messages to arrive on the transmission queue after sending a batch of messages. The channel disconnects after this interval, and must be restarted manually or by triggering. By default, the value is 900 seconds.

   Short retry count
   The maximum number of times that the sender channel tries to restart after a communication or partner failure. If the connection name list is provided, during each retry the connections are tried in the order in which they are specified in the connection list until a connection is successfully established. If the count of remaining retries reaches zero, and the channel has not restarted, then the long retry mechanism is invoked. By default, the value is 10.

   Short retry interval
   The number of seconds between attempts by the sender channel to restart after a communication or partner failure. By default, the value is 60 seconds.

   Long retry count
   The maximum number of times that the sender channel tries to restart after the short retry mechanism did not recover from a communication or partner failure. If the connection name list is provided, during each retry the connections are tried in the order in which they are specified in the connection list until a connection is successfully established. If the count of remaining retries reaches zero, and the channel has not restarted, then an error is logged and the channel is stopped. By default, the value is 999999999.

   Long retry interval
   The number of seconds between attempts by the sender channel to restart after the short retry mechanism did not recover from a communication or partner failure. By default, the value is 1200 seconds.

   Initial state
   Whether the sender channel is started or stopped when the associated WebSphere MQ link is first started. Until started, the channel is unavailable. By default, the value is “Started”.
5. Click **OK**.
6. Save your changes to the master configuration.
7. Restart the application server.

Modifying security for a WebSphere MQ link:

Securing access between a service integration bus and a WebSphere MQ Queue Manager.

About this task

When you create a new WebSphere MQ link, you can use the foreign bus connection wizard to enable security:

- If the WebSphere MQ queue manager requires a secure connection, you can set the WebSphere MQ receiver channel to accept only connections that have secure sockets layer (SSL) based encryption.
- If the local bus is secure, you can set the service integration bus inbound user ID to replace the user ID in messages from the WebSphere MQ queue manager, so that these messages are authorized to access their destinations.

  Inbound user ID

  If an inbound user ID is set, then all incoming messages will appear to have originated from that user ID. If the bus is security enabled then messages will appear authenticated as this user ID and have access to any resources that the user ID has access to.

  If an inbound user ID is not set, then messages will have the same user ID as in the WebSphere MQ message descriptor (MQMD) header of the WebSphere MQ message. These users will not be authenticated and therefore only have access to resources that require no authentication.

  Outbound user ID

  If an outbound user ID is set, then all outgoing messages will appear to have originated from that user ID (using the userid field of the MQMD)

  If an outbound user ID is not set, then messages will have the same user ID as in the original service integration bus message.

Use this task to secure the local and foreign bus that are part of a WebSphere MQ links configuration, and to secure an existing WebSphere MQ link that was not secured when it was first created.

For more general information about service integration bus security, see Securing service integration.

Procedure

1. Enable security on the service integration bus and the foreign bus representing the WebSphere MQ network. See Securing buses.
2. Secure the link between the buses - see Securing connections to a WebSphere MQ network.
3. Grant access to the local bus for users who will be sending messages to the foreign bus - see Securing buses.
4. Grant access to the foreign bus for users who will be sending messages to it - see Administering foreign bus roles.
5. Optional: Give users access to foreign or alias destinations that will forward messages to a foreign bus - see “Administering destination roles” on page 1991.

Viewing the status of a WebSphere MQ link and its sender and receiver channels:

You might want to view the status of a WebSphere MQ link or its components because you intend to stop the WebSphere MQ link and you want to see if there are any messages currently held on it, or you are about to delete the WebSphere MQ link and you have to verify there are no messages on it, or messages have not arrived at their expected destination and you want to check if they are being held, pending transmission over the WebSphere MQ link.

About this task

To view the status of a WebSphere MQ link, use the administrative console to complete the following steps.

Note: If you attempt to start a WebSphere MQ sender channel that is already in RUNNING state, the WebSphere Application Server administrative console might occasionally incorrectly report the channel status as INACTIVE. If this happens, you can ignore the error because the channel is still running. To return the channel status to RUNNING, stop and then restart the channel.

Procedure

1. In the navigation pane, click one of the following paths:
   - **Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Related Items] WebSphere MQ links**
   - **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links**
2. Click the WebSphere MQ link you want to view.
3. Click the **Runtime** tab. The content pane displays the status of the WebSphere MQ link.
4. Click the **Configuration** tab.
5. To view the status of the sender channel:
   a. Click **Sender channel**.
   b. Click the channel you want to view.
   c. Click the **Runtime** tab. The content pane displays status information for the sender channel. Some of the more important fields to check are:
      - The status of the channel.
      - Whether the message on the channel is in an indoubt state. If the message is in doubt, it has not been acknowledged by WebSphere MQ.
      - The number of messages in the current batch.
      - The number of batches that have been sent.
      - The time and date at which the channel was last started.
      - The time and date at which the last message was sent.
   d. Click **Saved batch status**. The content pane displays the saved status of message batches that have been saved for transmission to WebSphere MQ.
   e. If a batch is in an indoubt state, you can either commit or rollback the batch.
6. To view the status of the receiver channel:
   a. Return to the WebSphere MQ link page.
   b. Click **Receiver channel**.
   c. Click the **Runtime** tab. The content pane displays the status of the receiver channel.
   d. Click **Receiver channel connections**. The content pane displays the connections existing on the receiver channel, and their current status. You can stop connections if required, by selecting the check box next to the connection and clicking **Stop**.
   e. Return to the receiver channel page.
   f. Click **Saved batch status**. The content pane displays the saved status of message batches that have been received from WebSphere MQ.

What to do next

You can also view the status of subscriptions for a broker profile on the WebSphere MQ link: “Viewing the status of subscriptions for a WebSphere MQ link publish/subscribe broker profile.”

Viewing the status of subscriptions for a WebSphere MQ link publish/subscribe broker profile:

You can use the administrative console to view the status of subscriptions for a broker profile on a WebSphere MQ link.

Procedure

1. In the navigation pane, click one of the following paths:

- **Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Related Items] WebSphere MQ links -> *link_name* -> [Additional Properties] Publish/subscribe broker profiles**
- **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional Properties] Publish/subscribe broker profiles**

2. Click the broker profile containing the subscriptions you want to view.
3. Click the **Runtime** tab. The content pane displays the current number of subscriptions for the broker profile.
4. Click **Subscriptions**. The content pane displays the status of the subscriptions for the broker profile. Move the mouse pointer over a status icon to view hover help for that icon. You can remove the runtime subscriptions if required, by clicking **Unsubscribe**.

States of the WebSphere MQ link and its channels:

For each possible state of a WebSphere MQ link, this table lists the associated states of the link's sender and receiver channels.

State of WebSphere MQ link	WebSphere MQ link sender channel	WebSphere MQ link receiver channel
INACTIVE	Same as STOPPED for the WebSphere MQ link sender. If the administrator requests that the channel go into target state STOPPED it will transition into the STOPPED state. Similarly, an administrator starting the channel will cause it to transition into STANDBY state.	No network connection exists between the application server and the queue manager. If the attempts of a WebSphere MQ sender channel to establish a connection should succeed, it will become possible for messages to flow from the queue manager to the messaging engine. In this case the receiver channel will transition into RUNNING state.
STARTING	A transitional state. The channel should successfully pass through this into BINDING state with no intervention.	A transitional state. The channel should successfully pass through this into BINDING state with no intervention.
BINDING	A transitional state. The channel should successfully pass through this into RUNNING state with no intervention. The channel might transition into STOPPING state if a problem occurs.	A transitional state. The channel should successfully pass through this into RUNNING state with no intervention. The channel might transition into STOPPING state if a problem occurs.
INITIALIZING	A transitional state. The channel should successfully pass through this into STARTING state with no intervention.	A transitional state. The channel should successfully pass through this into STARTING state with no intervention.
RETRYING	A network connection to the queue manager has been lost. The channel attempts to reconnect. If the retry intervals are exhausted without successfully establishing the connection then the channel enters STOPPED state. If a connection is successfully reestablished, the channel enters INITIALIZING state.	Not applicable to receiver channel.

State of WebSphere MQ link	WebSphere MQ link sender channel	WebSphere MQ link receiver channel
STANDBY	When in this state, the sender channel is not network-connected to its WebSphere MQ counterpart receiver channel. It is waiting for a message to send before attempting to establish a connection. When a message arrives for transmission, the channel will transition into STARTING state and start the process of attempting to establish a network connection. The administrator may command the channel to transition into either INACTIVE or STOPPED state from this state.	Not applicable to receiver channel.
RUNNING	In this state a network connection has been established between application server and queue manager. Messages destined for the queue manager will be transmitted. Either attempting to stop the channel by using the administrative console, or the loss of the network connection will cause transition into the STOPPING state.	Network connection established between application server and queue manager. Messages destined for the messaging engine will be received. Attempting to stop the channel, or the loss of the network connection will cause a transition into STOPPING state.
STOPPING	A transitional state. The channel should transition into either RETRYING state or STOPPED state without intervention. If the channel has been placed in STOPPING state by the administrative request to become INACTIVE then it will transition into the STANDBY state. If the channel has been placed in this state by administrator request to stop, it will transition into the STOPPED state. If the channel has been placed in this state by a broken network connection it will transition into the RETRYING state, assuming that it has non-zero retry intervals or is otherwise STOPPED.	A transitional state. The channel will transition from this state into STOPPED without intervention.
STOPPED	No network connection exists between the application server and the queue manager. Messages destined for the queue manager will not be transmitted. To transition from this state requires the administrator to start the channel, this will place it in STANDBY state.	No network connection exists between the application server and the queue manager. Any attempt by a sender channel in the WebSphere MQ network to establish a connection will be rejected. Messages destined for the messaging engine will not be received. Administrator action is required to move the channel out of this state. Starting the channel will move it into INACTIVE state.

For information about the states of the channels in a WebSphere MQ network refer to the *Intercommunication* section of the WebSphere MQ information center, available from the WebSphere MQ library.

You can stop a WebSphere MQ link (and its sender and receiver channels) on a service integration bus, or you can stop individual sender or receiver channels. The following sections describe in more detail what happens when you transition between states.

Stopping a WebSphere MQ link

Stopping a WebSphere MQ link results in both the WebSphere MQ link sender and the WebSphere MQ link receiver channels being stopped:

- If a currently RUNNING WebSphere MQ link is stopped in state STOPPED with mode QUIESCE, the overall state of the WebSphere MQ link goes to STOPPED state. The WebSphere MQ link sender channel goes to STOPPED state. The WebSphere MQ link receiver channel goes to STOPPED state.
- If a currently RUNNING WebSphere MQ link is stopped in state INACTIVE with mode QUIESCE, the overall state of the WebSphere MQ link remains set to RUNNING. The WebSphere MQ link sender channel goes to STANDBY state. The WebSphere MQ link receiver channel goes to INACTIVE state. The WebSphere MQ sender channel will stop when convenient, as described below.
- If a currently RUNNING WebSphere MQ link is stopped in state STOPPED with mode FORCE, the overall state of the WebSphere MQ link goes to STOPPED state. The WebSphere MQ link sender channel goes to STOPPED state. The WebSphere MQ link receiver channel goes to STOPPED state.
- If a currently RUNNING WebSphere MQ link is stopped in state INACTIVE with mode FORCE, the overall state of the WebSphere MQ link remains set to RUNNING. The WebSphere MQ link sender goes to STANDBY state. The WebSphere MQ link receiver channel goes to INACTIVE state.

Stopping a WebSphere MQ link sender channel

Stopping a WebSphere MQ link sender stops only the WebSphere MQ link sender channel. (However, when the WebSphere MQ link sender channel is stopped, it communicates with the receiver channel in the WebSphere MQ network to say it is stopping, with the result that the receiver channel on WebSphere MQ stops and goes into inactive state.)

If a currently RUNNING WebSphere MQ link sender channel is stopped in state STOPPED, it goes to STOPPED state.

If a currently RUNNING WebSphere MQ link sender channel is stopped in state INACTIVE, it goes to STANDBY state.

Stopping a WebSphere MQ link receiver channel

Stopping a WebSphere MQ link receiver stops all receiver channel connections for that receiver.

If a currently RUNNING WebSphere MQ link receiver channel is stopped in state STOPPED, it goes to STOPPED state. The sender channel in the WebSphere MQ network will notice, either when it tries to next send some data, or when its heartbeat interval is reached and it tries to send a heartbeat flow, or when its disconnect interval expires and it attempts to close the session, that the WebSphere MQ link receiver in the service integration bus is in STOPPING state and itself stop and then enter a state of RETRYING. The WebSphere MQ link receiver will then go to STOPPED state, so preventing a sender channel in the WebSphere MQ network from establishing a session.

If a sender channel in the WebSphere MQ network is started while a WebSphere MQ link receiver channel in a service integration bus is in STOPPED state, the request fails with an error indicating that the WebSphere MQ link receiver channel is not available.

If a currently RUNNING WebSphere MQ link receiver channel is stopped in state INACTIVE, it goes to STOPPING state. The sender channel in the WebSphere MQ network will notice, either when it tries to next send some data, or when its heartbeat interval is reached and it tries to send a heartbeat flow, or when its disconnect interval expires and it attempts to close the session, that the WebSphere MQ link

receiver is in STOPPING state and itself stop and then enter a state of RETRYING. The WebSphere MQ link receiver will then go to INACTIVE state. The RETRYING sender channel in the WebSphere MQ network will then establish a session with the WebSphere MQ link receiver channel, at which point both channels will go to RUNNING state.

WebSphere MQ link receiver channel connection

Stopping a WebSphere MQ link receiver channel connection stops only that connection. Individual connections can only be stopped in target state INACTIVE.

Modes of a stopped WebSphere MQ link

When an active WebSphere MQ link receiver channel connection is stopped, the connection goes to a state of STOPPING. The sender channel in the WebSphere MQ network will notice, either when it tries to next send some data, or when its heartbeat interval is reached and it tries to send a heartbeat flow, or when its disconnect interval expires and it attempts to close the session, that the WebSphere MQ link receiver is in STOPPING state and itself stop and then enter a state of RETRYING.

The MODE has an effect on the stopping of channels.

1. QUIESCE, the channel stops when it is convenient for it to do so.

   For a WebSphere MQ link sender channel, the link sender goes to STANDBY or STOPPED state (depending on the stop state specified), this can occur either when it reaches the end of the current batch, or when it reaches a heartbeat interval.

   In the case of a WebSphere MQ link receiver, the link receiver goes to STOPPING state and then to INACTIVE or STOPPED state (depending on the stop state specified) when the sender in the WebSphere MQ network next attempts to communicate with it. Though, if a WebSphere MQ link receiver channel goes INACTIVE and the sender channel in the WebSphere MQ network goes to RETRYING, then as soon as a session is reestablished, both ends will go to RUNNING state.
2. FORCE, the channel stops immediately.

   For a WebSphere MQ link sender channel, the WebSphere MQ link sender goes to STANDBY or STOPPED state (depending on the stop state specified).

   For a WebSphere MQ link receiver, the WebSphere MQ link receiver goes to INACTIVE or STOPPED state (depending on the stop state specified). When the sender channel in the WebSphere MQ network next tries to communicate with the WebSphere MQ link receiver, it will either enter a state of RETRYING and reestablish a session with the WebSphere MQ link receiver, or go to a STOPPED state.

WebSphere MQ link sender channels can go to INDOUBT state (as can sender channels in a WebSphere MQ network). WebSphere MQ link receiver channels do not go to INDOUBT state.

While sending a batch of persistent messages, a WebSphere MQ link sender channel goes to a state of INDOUBT. When it commits the batch, it sends a commit request to the partner and waits for confirmation. When the partner sends a confirmation, the batch is finally committed and the sender channel is no longer in INDOUBT state. If the partner fails to send a confirmation flow, then the sender channel will remain in INDOUBT state.

INDOUBT batches can be COMMITTED or ROLLED back from the Saved Status panel for WebSphere MQ link sender channels.

Starting a WebSphere MQ link:

Change the state of a WebSphere MQ link from stopped to started.

Before you begin

You might want to tell the WebSphere MQ administrator that you are about to start this WebSphere MQ link.

About this task

To start a WebSphere MQ link, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click one of the following paths:
   - **Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Related Items] WebSphere MQ links**
   - **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links**
2. In the content pane, select the check box next to the WebSphere MQ link you want to start.
3. Click **Start**.

Results

If the WebSphere MQ link starts successfully, the status icon changes to indicate that the WebSphere MQ link is running.

Stopping a WebSphere MQ link:

You can change the state of a WebSphere MQ link from "Started" or "Running" to "Stopped". When you stop a WebSphere MQ link, all communication with the target WebSphere MQ network is stopped for both point-to-point and publication and subscription. Messages waiting for transmission are held on the service integration bus, and the MQ sender channel cannot start. If there is a publish/subscribe bridge on the WebSphere MQ link, its operations are stopped.

Before you begin

Inform the WebSphere MQ administrator that you are about to stop this WebSphere MQ link.

About this task

To stop a WebSphere MQ link, use the administrative console to complete the following steps. You can also stop either the sender or receiver channel on the WebSphere MQ link, while leaving the link itself running. See “Stopping the sender channel on a WebSphere MQ link” on page 570, and “Stopping the receiver channel on a WebSphere MQ link” on page 569.

Procedure

1. In the navigation pane, click one of the following paths:
   - **Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Related Items] WebSphere MQ links**
   - **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links**
2. In the content pane, select the check box next to the WebSphere MQ link that you want to stop.
3. In the **Stop mode** list, select "Quiesce" or "Force".
4. In the **Target state** list select "Inactive" or "Stopped".
5. Click **Stop**.

Results

The resultant state of the WebSphere MQ link, its sender and receiver channels, and the WebSphere MQ sender channel that is connected to the WebSphere MQ link receiver channel, depends on the options you chose:

- Stopping the WebSphere MQ link to target state INACTIVE causes the sender channel to go into state STANDBY and the receiver channel to go into state INACTIVE. The overall WebSphere MQ link status will be RUNNING.
- Stopping the WebSphere MQ link to target state STOP causes the sender channel to go into state STOPPED and the receiver channel to go into state STOPPED. The overall WebSphere MQ link status will be STOPPED.

These are the final states that the sender, receiver and WebSphere MQ link transition into. If you specify a mode of QUIESCE for either of the two final states, the channels and link might not transition into their final states immediately. Instead they temporarily transition through other states that are required to reach their final state.

For more details about stopped states of the WebSphere MQ link, see “States of the WebSphere MQ link and its channels” on page 564.

What to do next

You can restart the WebSphere MQ link by selecting the link again and clicking **Start**.

If the WebSphere MQ link is started and the sender channel is in the stop state, it goes into the standby state. The sender channel goes into negotiation with the partner receiver channel if it is started from the standby state. The sender channel then moves into the running state if the negotiation successful, or into the retry state if the negotiation fails. If messages are present when the WebSphere MQ link is started, the sender channel automatically goes into negotiation with its partner receiver channel and then moves to the running or retry state.

When the WebSphere MQ link is stopped, and not in doubt, you can delete the WebSphere MQ link and any associated publish/subscribe broker profiles and topic mappings as described in “Removing a foreign bus connection from a bus” on page 1917.

Stopping the receiver channel on a WebSphere MQ link:

You can stop the receiver channel on a WebSphere MQ link while leaving the link itself running.

Before you begin

Note: If you stop the receiver channel on a WebSphere MQ link, communication with the target WebSphere MQ network on that channel will cease for both point-to-point messaging and publishing and subscribing. Messages will be held at their transmission locations.

You might want to warn the administrator of the WebSphere MQ network that you are about to stop the channel.

About this task

If you stop a receiver channel, messages sent to the WebSphere MQ link engine are not received.

If a WebSphere MQ sender channel is started while an MQ link receiver channel is stopped, the request fails with an error indicating that the receiver channel is not available.

For more information about stopped states of the WebSphere MQ link and its channels, see “States of the WebSphere MQ link and its channels” on page 564.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional Properties] Receiver channel**.
3. Select the check box next to the channel you want to stop.
4. In the **Stop mode** list, select Quiesce or Force.
5. In the **Target state** list, select Inactive or Stopped.
6. Click **Stop**.

Results

Stopping a receiver channel stops all the receiver channel connections for that receiver. The resultant state of the receiver channel, and the sender channel in the WebSphere MQ network with which it is communicating, depends on the options you choose:

Table 49. Stop modes. The table contains information about the target states and the corresponding stop modes for stopping the receiver channel on a WebSphere MQ link. There are two target states such as inactive and stopped, and there are two stop modes such as quiesce and force. The rows in the table represent the two target states, and the two stop modes are described in the two columns for each of the target state.

		Stop mode	
		Quiesce	Force
Target state	Inactive	The receiver channel moves to the stopping state and the data flow to the WebSphere MQ sender channel stops. When the WebSphere MQ sender channel next tries to communicate with the receiver channel the WebSphere MQ sender channel enters a state of retrying. The receiver channel then becomes inactive. The retrying WebSphere MQ sender channel then reestablishes a session with the receiver channel, and both channels become running.	The receiver channel immediately becomes inactive. When the WebSphere MQ sender channel next tries to communicate with the receiver channel, the WebSphere MQ sender channel enters a state of retrying. The retrying WebSphere MQ sender channel then reestablishes a session with the receiver channel, and both channels become running.
	Stopped	The receiver channel moves to the stopping state and the data flow to the WebSphere MQ sender channel stops. When the WebSphere MQ sender channel next tries to communicate with the receiver channel the WebSphere MQ sender channel enters a state of retrying. The receiver channel then becomes stopped, so preventing the WebSphere MQ sender channel from reestablishing a session. The WebSphere MQ sender channel itself then becomes stopped.	The receiver channel immediately becomes stopped. When the WebSphere MQ sender channel next tries to communicate with the receiver channel, the WebSphere MQ sender channel enters a state of retrying, and then becomes stopped itself.

Stopping the sender channel on a WebSphere MQ link:

You can stop the sender channel on a WebSphere MQ link while leaving the link itself running.

Before you begin

You might want to tell the WebSphere MQ network administrator that you are about to stop a channel.

About this task

When you stop the sender channel on a WebSphere MQ link, communication with the target WebSphere MQ network on that channel is stopped for both point-to-point messaging and publishing and subscribing. Messages are held at their transmission locations.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional Properties] Sender channel**.
3. Select the check box next to the channel you want to stop.
4. In the **Stop mode** list, select Quiesce or Force.
5. In the **Target state** list, select Inactive or Stopped.
6. Click **Stop**.

Results

Only the sender channel is affected by this procedure. The resultant state of the sender channel depends on the options you chose:

Table 50. Stop modes. The table contains information about the target states and the corresponding stop modes for stopping the sender channel on a WebSphere MQ link. There are two target states such as inactive and stopped, and there are two stop modes such as quiesce and force. The rows in the table represent the two target states, and the two stop modes are described in the two columns for each of the target state.

		Stop mode	
		Quiesce	Force
Target state	Inactive	The sender channel becomes inactive either when it has finished processing its current batch, or when it reaches a heartbeat interval.	The sender channel immediately becomes inactive.
	Stopped	The sender channel becomes stopped either when it has finished processing its current batch, or when it reaches a heartbeat interval.	The sender channel immediately becomes stopped.

For more information about stopped states of the WebSphere MQ link and its channels, see “States of the WebSphere MQ link and its channels” on page 564.

Deleting a WebSphere MQ link publish/subscribe broker profile:

This describes how you delete a broker profile and all topic mappings on a WebSphere MQ link, which forms a publish/subscribe bridge between WebSphere Application Server and a WebSphere MQ network.

Before you begin

Before you start you have to know the names of the bus, messaging engine, and WebSphere MQ link that has the broker profile that you intend to delete. You should also consider informing the WebSphere MQ administrator that you are about to delete the connection to the message broker in the WebSphere MQ network.

If you also intend to delete the associated WebSphere MQ link, you need not complete this task. Refer instead to “Removing a foreign bus connection from a bus” on page 1917.

About this task

Deleting a broker profile is a three-stage operation to ensure both the application server and the WebSphere MQ network and its message brokers are synchronized after the deletion:

- Remove the subscriptions by unsubscribing the topic mappings on the broker profile.
- When the Runtime view is empty, delete the broker profile.
- If you have enabled dynamic configuration updates, the changes take effect immediately, otherwise restart the application server.

Note: If you remove the subscriptions but do not delete the broker profile, then the subscriptions are recreated when the server is restarted (because they are still present in the static configuration information for the WebSphere MQ link). These subscriptions are unrelated to the original subscriptions so this can lead to some messages in a publication flow being missing for subscribers on the target side of the bridge. For example, any messages published on an unsubscribed topic between the time the unsubscribe took place and the application server was restarted are not republished to the target side of the WebSphere MQ link.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional Properties] Publish/subscribe broker profiles -> *profile_name***.
3. Remove the subscriptions:
   a. Click the **Runtime** tab.
   b. Click **Subscriptions**.
   c. Click **Unsubscribe** to remove all the subscriptions listed. When an unsubscribe command is sent to the message broker in the WebSphere MQ network, the relevant topic mapping is put into an indoubt state until the unsubscribe is confirmed when the topic mapping is deleted. After the unsubscribe is confirmed the topic mapping is no longer shown in the runtime view. You might have to refresh the runtime view for all subscriptions to be shown as removed.
4. Delete the broker profile:
   a. Return to the **Publish/subscribe broker profiles** page.
   b. Select the check box next to the broker profile you want to delete.
   c. Click **Delete**.
5. Save your changes to the master configuration.
6. If you have enabled dynamic configuration updates, the changes take effect immediately. Otherwise, restart the application server.

Deleting a topic mapping on a WebSphere MQ link publish/subscribe broker profile:

This describes how you delete a topic mapping on a broker profile on a WebSphere MQ link, which forms part of a publish/subscribe bridge between WebSphere Application Server and WebSphere MQ.

Before you begin

Before you start you have to know the bus name, messaging engine name, WebSphere MQ link name and broker profile name on which you intend to delete the topic mapping.

Note:

- If you intend to delete *all* topic mappings before deleting the broker profile or the WebSphere MQ link, you can avoid restarting the application server more than once by following the steps given in “Deleting a WebSphere MQ link publish/subscribe broker profile” on page 571.

- Deleting a topic mapping is a two-stage operation to ensure both the WebSphere Application Server (base) and the message brokers in the WebSphere MQ network are synchronized once the deletions have taken place:
  1. Delete the topic mapping (see below).
  2. When you have deleted the topic mappings, the changes take effect immediately if you have enabled dynamic configuration updates, otherwise restart the application server.

About this task

To delete a topic mapping, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional Properties] Publish/subscribe broker profiles -> *profile_name* -> [Additional Properties] Topic mappings**
2. Select the check box next to the topic mapping you want to delete.
3. Click **Delete**.
4. Save your changes to the master configuration.

What to do next

Any topic mappings that you have deleted are automatically cleaned up by the publish/subscribe bridge when the application server is restarted.

Using a WebSphere MQ server to integrate WebSphere MQ queues into a bus

A WebSphere MQ server represents a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. For interoperation with WebSphere Application Server Version 7.0 or later, the version of WebSphere MQ must be WebSphere MQ for z/OS Version 6 or later, or WebSphere MQ (distributed platforms) Version 7 or later.

Before you begin

WebSphere Application Server can interoperate with WebSphere MQ in any of the following ways:

- Using the WebSphere MQ messaging provider
- Using a WebSphere MQ link
- Using a WebSphere MQ server

Each type of interoperation is designed for different situations, and provides different advantages. For information about the differences between these approaches, see “Interoperating with a WebSphere MQ network” on page 545.

Decide which method to use to configure these resources. You can configure WebSphere MQ server resources by using the administrative console as described in this task, or by using the “SIBAdminCommands: WebSphere MQ server administrative commands for the AdminTask object” on page 2352.

About this task

To set up and use a WebSphere MQ server, you configure the server properties, add the server to a service integration bus as a bus member, and create a WebSphere MQ queue-type destination. Destinations that are assigned to a WebSphere MQ server bus member can also be mediated.

You add the WebSphere MQ server as a bus member so that messaging engines on the bus can access queues on the target WebSphere MQ system. If your WebSphere MQ server is connected to a queue-sharing group, your bus applications can access shared queues on the target installation.

Notes:

- You can configure a WebSphere MQ server to connect to a WebSphere MQ queue manager by using either a bindings mode or a client mode connection. To use client mode with WebSphere MQ for z/OS, you need an additional product called the Client Attach Facility.
- You should configure the queues on the WebSphere MQ network as "shareable". This allows multiple server instances to get messages from the queues.

Procedure

1. Create a WebSphere MQ server definition and configure the server properties.
2. Add the new WebSphere MQ server as a member of a bus so that messaging engines on the bus can access queues on the target WebSphere MQ installation.
3. Create a WebSphere MQ queue type destination for the new bus member and assign it to a WebSphere MQ queue.
4. Optional: Mediate the new destination by using the WebSphere MQ queue as the mediation point.

Creating a WebSphere MQ server definition:

A WebSphere MQ server represents a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. To create a WebSphere MQ server definition, you use the administrative console to define the server connection and quality of service properties.

Before you begin

Decide which method to use to configure these resources. You can create a new WebSphere MQ server definition by using the administrative console as described in this task, or by using the "createSIBWMQServer command" on page 2352.

About this task

A WebSphere MQ server definition defines the connection to an underlying WebSphere MQ queue manager or queue-sharing group and the associated queues.

When you subsequently add the server as a member of a service integration bus, you can optionally override the server connection settings with the bus connection settings. This means that you can create a WebSphere MQ server definition that is specific to a bus, yet reusable in a multiple bus topology.

Procedure

1. Start the administrative console.
2. Complete either of the following sub-steps:
   a. Navigate to **Servers -> New server**, choose a server type of "WebSphere MQ server", then click **Next**.
   b. Navigate to **Servers -> Server Types -> WebSphere MQ servers**, then click **New**.

   The "WebSphere MQ server [Settings]" on page 2254 form is displayed.
3. Complete the fields as required.

   For more information, refer to the "WebSphere MQ server [Settings]" on page 2254 form and the following notes:

   Name
   The name that you use for this WebSphere MQ server definition must be unique.

UUID
This identifier is assigned automatically when you create a new WebSphere MQ server definition.

Use bindings transport mode if available
To connect to a WebSphere MQ queue manager or queue-sharing group in bindings mode, WebSphere Application Server needs to know where to load native libraries from. This information is stored in the **Native library path** property of the WebSphere MQ messaging provider. If you want to use a direct binding to WebSphere MQ, rather than a TCP/IP network connection, select this option and configure the **Native library path** property as described in "Configuring the WebSphere MQ messaging provider with native libraries information" on page 723.

If you are using Resource Access Control Facility (RACF®) as the security manager on your WebSphere MQ for z/OS system, and using bindings transport mode, you must specify in uppercase characters the user names and passwords for authentication aliases. If you are using RACF and client transport mode, you can specify the user names and passwords in either upper or lowercase characters.

Test connection
After you have configured the Connection properties, click this button to test the connection to WebSphere MQ.

Trust user identifiers received in messages
Select this option if you do not want the user IDs in messages to be overwritten with the administrative name of the WebSphere MQ server.

JAAS - J2C authentication data
This item is not available until after the WebSphere MQ server definition has been created.

4. Click **OK** to confirm.
5. Save your changes to the master configuration.
6. Restart the application server.

What to do next

You are now ready to add the new WebSphere MQ server as a member of a bus.

Modifying a WebSphere MQ server definition:

A WebSphere MQ server represents a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. This topic describes how to modify a WebSphere MQ server connection and quality of service properties.

Before you begin

Decide which method to use to configure these resources. You can modify a WebSphere MQ server by using the administrative console as described in this task, or by using the "modifySIBWMQServer command" on page 2355.

About this task

A WebSphere MQ server definition defines the connection to an underlying WebSphere MQ queue manager or queue-sharing group and the associated queues.

When you modify a WebSphere MQ server definition, you do not change any configuration values previously inherited from this WebSphere MQ server by existing bus members. For example, suppose you create a WebSphere MQ server with the port number 1234, then add the server to a bus and specify that server port number. If you subsequently modify the WebSphere MQ server port number to 2345, the bus member you previously created is not affected and still has the port number 1234.

Procedure

1. Start the administrative console.
2. Navigate to **Servers -> Server Types -> WebSphere MQ servers -> *server_name***. The “WebSphere MQ server [Settings]” on page 2254 form is displayed.
3. Make modifications as required.

   For more information, refer to the “WebSphere MQ server [Settings]” on page 2254 form and the following notes:

   UUID
   This identifier is assigned automatically when you create a new WebSphere MQ server definition.

   Use bindings transport mode if available
   To connect to a WebSphere MQ queue manager or queue-sharing group in bindings mode, WebSphere Application Server needs to know where to load native libraries from. This information is stored in the **Native library path** property of the WebSphere MQ messaging provider. If you want to use a direct binding to WebSphere MQ, rather than a TCP/IP network connection, select this option and configure the **Native library path** property as described in “Configuring the WebSphere MQ messaging provider with native libraries information” on page 723.

   If you are using Resource Access Control Facility (RACF) as the security manager on your WebSphere MQ for z/OS system, and using bindings transport mode, you must specify in uppercase characters the user names and passwords for authentication aliases. If you are using RACF and client transport mode, you can specify the user names and passwords in either upper or lowercase characters.

   Test connection
   After you have configured the Connection properties, click this button to test the connection to WebSphere MQ.

   Trust user identifiers received in messages
   Select this option if you do not want the user IDs in messages to be overwritten with the administrative name of the WebSphere MQ server.
4. Click **OK** to confirm.
5. Save your changes to the master configuration.
6. Restart the application server.

Deleting a WebSphere MQ server definition:

A WebSphere MQ server represents a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. This topic describes how to delete a WebSphere MQ server definition.

Before you begin

Decide which method to use to configure these resources. You can delete a WebSphere MQ server by using the administrative console as described in this task, or by using the “deleteSIBWMQServer command” on page 2360.

Ensure that no application is putting messages to the bus members located on the WebSphere MQ server.

Inform the WebSphere MQ administrator that the WebSphere MQ server is about to be deleted and therefore will no longer interoperate with its WebSphere MQ queue manager or queue-sharing group in the WebSphere MQ network.

About this task

When you delete a WebSphere MQ server definition, the deletion process also modifies the following associated resources:

- It deletes all WebSphere MQ server bus members that were created when the server was added to service integration buses.
- It unmediates all destinations that were assigned to those bus members.
- It removes all queue points that were assigned to those bus members.

Deleting a WebSphere MQ server definition does not affect the associated queue managers, queue-sharing groups, queues or messages on your WebSphere MQ network.

Procedure

1. Start the administrative console.
2. Navigate to **Servers -> Server Types -> WebSphere MQ servers**. The "WebSphere MQ servers [Collection]" on page 2253 form is displayed.
3. Select the check box next to the WebSphere MQ server you want to delete.
4. Click **Delete**. If the processing completes successfully, the list of WebSphere MQ servers is updated. Otherwise, an error message is displayed.
5. Save your changes to the master configuration.
6. Restart the application server.

Adding a WebSphere MQ server as a member of a bus:

A WebSphere MQ server represents a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. A WebSphere MQ server bus member is used as a bus member for assigning queue points and mediation points to WebSphere MQ queues.

Before you begin

Get details of the client connection from your WebSphere MQ administrator.

Ensure that the WebSphere MQ server has been configured, that the bus has been defined and that the server is not already a member of the bus.

Decide which method to use to configure these resources. You can add the WebSphere MQ server as a bus member by using the administrative console as described in this task, or by using the "addSIBusMember command" on page 2268.

About this task

When you add a WebSphere MQ server to one or more buses, messaging engines on these buses can access queues on the target WebSphere MQ installation. When you make the server a bus member, you can override the server connection settings with settings that are specific to the new bus member. This can be useful in a multiple bus topology.

Procedure

1. Start the administrative console.
2. Navigate to the list of bus members for the bus to which you are adding the WebSphere MQ server. Click **Service integration -> Buses -> *bus_name* -> [Topology] Bus members**.
3. Click **Add**. The "Add a new bus member" wizard is displayed.
4. Select the WebSphere MQ server to add to the bus:
   a. Select **WebSphere MQ server**.
   b. From the drop-down list, select the server to add.
   c. Click **Next**.
5. Specify the virtual queue manager name.

When sending messages to WebSphere MQ, the WebSphere MQ gateway queue manager sees the bus as a remote queue manager. The virtual queue manager name is the name that is passed to WebSphere MQ as the name of this remote queue manager. The default value is the name of the bus. If this value is not a valid name for a WebSphere MQ queue manager, or if another WebSphere MQ queue manager already exists that has the same name, then replace the default value with another value that is a valid and unique name for a WebSphere MQ queue manager. To be valid, the name must meet the following criteria:

- It must contain between 1 and 48 characters.
- It must conform to the WebSphere MQ queue naming rules (see the *Rules for naming WebSphere MQ objects* topic in the WebSphere MQ information center).

6. Optional: To override the server connection settings, select the **Override WebSphere MQ server connection properties** check box.

   When you select this option, the connection properties for the server are made available so that you can change them to settings that are specific to this bus member. For more information about these connection properties, see “WebSphere MQ server bus member [Settings]” on page 2250.
7. Optional: If you have changed the server connection settings, you can click **Test connection** to test the connection to the associated WebSphere MQ network.
8. Click **Next**.
9. Click **Finish** to confirm.
10. Save your changes to the master configuration.

What to do next

You are now ready to create a WebSphere MQ queue-type destination for the new bus member.

Modifying a WebSphere MQ server bus member definition:

A WebSphere MQ server bus member is used for assigning queue points and mediation points to WebSphere MQ queues. This topic describes how to modify the attributes of a WebSphere MQ server bus member.

Before you begin

Decide which method to use to configure these resources. You can modify a WebSphere MQ server bus member by using the administrative console as described in this task, or by using the “modifySIBWMQServerBusMember command” on page 2361.

About this task

A WebSphere MQ server provides a direct client connection between a service integration bus and queues on a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. This command modifies the attributes of a WebSphere MQ server bus member.

Procedure

1. Start the administrative console.
2. Navigate to **Service integration -> Buses -> *bus_name* -> [Topology] Bus members -> *member_name***. The “WebSphere MQ server bus member [Settings]” on page 2250 form is displayed.
3. Make modifications as required. For more information, refer to the “WebSphere MQ server bus member [Settings]” on page 2250 form.
4. After you have configured the **Connection settings**, click **Test connection** to test the connection toWebSphere MQ.
5. When you have made all the changes that you require, click **OK** to confirm.
6. Save your changes to the master configuration.

7. Restart the application server.

Deleting a WebSphere MQ server bus member definition:

A WebSphere MQ server represents a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. You cannot delete a WebSphere MQ server bus definition directly. Instead, when you delete a specified WebSphere MQ server, you remove any associated WebSphere MQ server bus members, as well as assigned queue points and mediation points.

Before you begin

Decide which method to use to configure these resources. You can delete a WebSphere MQ server by using the administrative console as described in “Deleting a WebSphere MQ server definition” on page 576, or by using the “deleteSIBWMQServer command” on page 2360.

About this task

When you delete a WebSphere MQ server definition, the deletion process also modifies the following associated resources:

- It deletes all WebSphere MQ server bus members that were created when the server was added to service integration buses.
- It un-mediates all destinations that were assigned to those bus members.
- It removes all queue points that were assigned to those bus members.

Deleting a WebSphere MQ server definition does not affect the associated queue managers, queue-sharing groups, queues or messages on your WebSphere MQ network.

Creating a queue-type destination and assigning it to a WebSphere MQ queue:

You can use the administrative console to create a queue-type destination and assign it to a WebSphere MQ queue. Select the WebSphere MQ server to host the queue, then specify the WebSphere MQ queue to be hosted.

Before you begin

Get the name of the WebSphere MQ queue from your administrator, and ensure that the following configuration is established:

- The WebSphere MQ server is added as a member of a bus
- The WebSphere MQ queue for the queue point exists
- The WebSphere MQ administrator has set the queue attributes to “shareable”

Note: A shareable queue can be accessed by more than one service integration application.

Decide which method to use to configure these resources. You can create a bus destination by using the administrative console as described in this task, or by using the “createSIBDestinations command” on page 2325.

About this task

After you have added a WebSphere MQ server as a bus member, you can create a queue-type destination on the bus member that uses a WebSphere MQ queue as a queue point. This configuration enables service integration applications to send messages to and receive messages from that queue.

Procedure

1. Start the administrative console.
2. Navigate to the list of destinations for the appropriate bus.

   Click **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations**.

   The "Destinations [Collection]" on page 2053 form is displayed.
3. Click **New**. The "Create a new destination" panel is displayed.
4. Select **Queue** as the destination type, then click **Next**. The "create a new queue" wizard is displayed.
5. Set the queue attributes. Enter the name that you want WebSphere Application Server to use to refer to the associated WebSphere MQ queue, and (optionally) a description of the queue.
6. Assign the queue to the bus member that is to store and process the messages for the queue.

   Select a WebSphere MQ server bus member from the list of available bus members.
7. Set the WebSphere MQ queue point attributes:
   a. Specify a value in the **WebSphere MQ queue name filter** field, then click **Go**.

      The wizard automatically discovers available WebSphere MQ queues. However, some WebSphere MQ topologies have many thousands of queues defined to a queue manager. Use this filter to limit the number of queues that are listed.

      The default filter value is an asterisk (*). If this value (or no value) is set then all queues, or all queues of a specific type (based on any queue type custom property that is set), are listed. Any other value that you specify must meet the following criteria:

      - It must contain between 1 and 48 characters.
      - It must conform to the WebSphere MQ queue naming rules (see the *Rules for naming WebSphere MQ objects* topic in the WebSphere MQ information center).

      You can also use the wildcard character (*) with other text. For example, if you enter a value of PAYROLL*, then all available queues with names that start with PAYROLL are displayed.

   b. Specify a WebSphere MQ queue name.

      Select a queue name from the filtered list. If the list does not include the queue that you want, select the last entry in the list labeled **other, please specify**. A text entry box is displayed next to the drop-down list. Type the queue name into the text entry box.

      If the queue is found on the remote WebSphere MQ system, the properties of the queue as defined within WebSphere MQ are displayed as read-only fields. This should help you to confirm that you have found the queue that you want, and that it is configured as you intend. If the queue is not found, these read-only fields are removed from view.

   c. Specify the reliability levels that you require when inbound nonpersistent and inbound persistent WebSphere MQ messages are converted to service integration format messages.

      Applications receive messages direct from the specified WebSphere MQ queue, so in general the reliability level for a message is of no interest to the receiver because the message has already been delivered successfully. However, the message is converted to a service integration format message (and typically to a JMS format service integration message) as it is received, and this option specifies the reliability level for the service integration format message. For information about the available reliability levels, see "WebSphere MQ queue points [Settings]" on page 2241.

   d. Specify whether you want WebSphere MQ to include an MQRFH2 message header when sending messages to the queue.

      The MQRFH2 header stores service integration messaging information that does not have a corresponding WebSphere MQ message header field. When a message is sent to the destination, service integration instructs WebSphere MQ to write the message to the queue. This option specifies whether service integration instructs WebSphere MQ to write the message with an MQRFH2 header.

      If the consumer of the message is a JMS application running in WebSphere MQ or service integration, or a WebSphere MQ XMS application, or a WebSphere MQ MQI application that

expects an MQRFH2 header, select this option. If the consumer is a WebSphere MQ MQI application that does not expect an MQRFH2 header, do not select this option.

8. Click **Next**.
9. Click **Finish** to confirm queue creation.

Results

You have created a queue-type destination with a WebSphere MQ queue point.

What to do next

You are now ready to (optionally) mediate the new destination by using the WebSphere MQ queue as the mediation point.

Mediating a destination by using a WebSphere MQ queue as the mediation point:

Mediate a destination by using the administrative console to specify a WebSphere MQ server bus member where the mediation point is to be assigned, and a WebSphere MQ queue to use as the mediation point where messages are stored. To mediate the destination using a service integration mediation, you must also specify a second bus member (not a WebSphere MQ server) to use as the mediation execution point and process the messages.

Before you begin

Decide which method to use to configure these resources. You can mediate a destination by using the administrative console as described in this task, or by using the “mediateSIBDestination command” on page 2335.

Before performing this task, ensure that the following resources exist:

- The mediation that you want to apply to the destination.
- The WebSphere MQ server bus member where the mediation point is to be assigned.
- The WebSphere MQ queue to use as the mediation point, with the queue attributes set to `shareable`.
- For a service integration mediation, a second bus member (not a WebSphere MQ server bus member) to use as the mediation execution point where the mediation code runs.

Note: The queue manager on the WebSphere MQ network does not have to be available when you complete this task, but the destination is not usable until the queue manager becomes available.

About this task

You can mediate a destination with a WebSphere MQ mediation point. This ensures that messages arriving at the designated WebSphere MQ queue are mediated. In this scenario, the mediated messages are delivered to the queue point, or to another destination that is determined by the default forward routing path destination, or by the mediation code. The mediation can be hosted by service integration, or hosted by WebSphere MQ.

Procedure

1. Start the administrative console.
2. Navigate to the list of destinations for the appropriate bus. Click **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations**.
3. Select the check box beside the destination to mediate, then click **Mediate**. The Mediation wizard is displayed.
4. Step 1: Select mediation.

To mediate the destination by using a mediation hosted by service integration:

a. Select **The mediation to apply to this destination**.

b. From the drop-down list, select the mediation.

c. Click **Next**.

To mediate the destination by using a WebSphere MQ program (for example, a WebSphere MQ flow):

a. Select **Externally mediated**.

b. Click **Next**.

5. Step 2: Assign the mediation to a bus member.

   When a mediation is assigned to a WebSphere MQ server bus member, you need a separate bus member that is not a WebSphere MQ server to act as the mediation execution point and process the messages.

   a. From the drop-down list, select the WebSphere MQ server bus member where the mediation point is to be assigned.

   b. Optional: If you are using a service integration mediation, select the bus member where the mediation is to run.

      For a mediation hosted by service integration, select a bus member from the list box that is labeled **Select a bus member where the mediation will run**. If you are using an external mediation, by definition it does not run in a bus member.

   c. Click **Next**.

6. Optional: If the mediation point is a WebSphere MQ queue, set the WebSphere MQ mediation point attributes.

   Note: This step is only displayed if you assigned the mediation point to a WebSphere MQ queue in the previous step.

   a. Specify a value in the **WebSphere MQ queue name filter** field, then click **Go**.

      The wizard automatically discovers available WebSphere MQ queues. However, some WebSphere MQ topologies have many thousands of queues defined to a queue manager. Use this filter to limit the number of queues that are listed.

      The default filter value is an asterisk (*). If this value (or no value) is set then all queues, or all queues of a specific type (based on any queue type custom property that is set), are listed. Any other value that you specify must meet the following criteria:

      - It must contain between 1 and 48 characters.
      - It must conform to the WebSphere MQ queue naming rules (see the *Rules for naming WebSphere MQ objects* topic in the WebSphere MQ information center).

      You can also use the wildcard character (*) with other text. For example, if you enter a value of PAYROLL*, then all available queues with names that start with PAYROLL are displayed.

   b. Specify a WebSphere MQ queue name.

      Select a queue name from the filtered list. If the list does not include the queue that you want, select the last entry in the list labeled **other, please specify**. A text entry box is displayed next to the drop-down list. Type the queue name into the text entry box.

      If the queue is found on the remote WebSphere MQ system, the properties of the queue as defined within WebSphere MQ are displayed as read-only fields. This should help you to confirm that you have found the queue that you want, and that it is configured as you intend. If the queue is not found, these read-only fields are removed from view.

   c. Specify the reliability levels that you require when inbound nonpersistent and inbound persistent WebSphere MQ messages are converted to service integration format messages.

      Mediations receive messages direct from the specified WebSphere MQ queue, so in general the reliability level for a message is of no interest to the mediation because the message has already been delivered successfully. However, the message is converted to a service integration format message (and typically to a JMS format service integration message) as it is received, and this

option specifies the reliability level for the service integration format message. For information about the available reliability levels, see “WebSphere MQ queue points [Settings]” on page 2241.

d. Specify whether you want WebSphere MQ to include an MQRFH2 message header when sending messages to the queue.

   The MQRFH2 header stores service integration messaging information that does not have a corresponding WebSphere MQ message header field. When a message is sent to the destination, service integration instructs WebSphere MQ to write the message to the queue. This option specifies whether service integration instructs WebSphere MQ to write the message with an MQRFH2 header.

   If the consumer of the message (in this case, the mediation) is a JMS application running in WebSphere MQ or service integration, or a WebSphere MQ XMS application, or a WebSphere MQ MQI application that expects an MQRFH2 header, select this option. If the mediation is a WebSphere MQ MQI application that does not expect an MQRFH2 header, do not select this option.

e. Click **Next**.

7. Check the summary of your selections, then click **Finish** to confirm mediation of the destination.

Results

You have mediated a destination by using a WebSphere MQ queue as the mediation point.

Enabling WebSphere Application Server Version 5.1 JMS usage of messaging resources in later versions of the product

To enable JMS applications developed for WebSphere Application Server Version 5.1 to use messaging resources of the default messaging provider, a WebSphere MQ client link is created on the node of the later version of the product. Each WebSphere MQ client link presents itself as a queue manager and transforms between the WebSphere MQ client protocols used by Version 5.1 and the protocols used by the default messaging provider in later versions.

Before you begin

Throughout this topic, the abbreviation “Version 5.1” refers to “WebSphere Application Server Version 5.1”. For example, “Version 5.1 JMS resources” refers to JMS resources provided by WebSphere Application Server Version 5.1.

This task refers to the *default messaging provider*. For related information, see “Managing messaging with the default messaging provider” on page 515.

JMS connectivity between the Version 5.1 messaging provider and the default messaging provider in later versions of the product is enabled and managed by a *WebSphere MQ client link*. This does not mean that a WebSphere MQ system is involved. The Version 5.1 messaging provider uses WebSphere MQ client protocols, and is therefore handled as if it were a WebSphere MQ client by the default messaging provider in later versions of the product. The WebSphere MQ client link is provided only for use with JMS applications developed for WebSphere Application Server Version 5.1. Moreover, this JMS connectivity is only intended as an aid to migration from the Version 5.1 messaging provider to the default messaging provider of later versions. For more information about migrating from the Version 5.1 messaging provider, see Migrating from WebSphere Application Server Version 5 embedded messaging.

Applications running in later versions can use the messaging resources of the Version 5.1 messaging provider without any need for a WebSphere MQ client link.

About this task

The following figure shows a JMS application running on Version 5.1 and using JMS resources provided by the default messaging provider on a Version 7.0 node. The JMS queue hosted by Version 5.1 is backed by a service integration bus queue, which is normal for a JMS queue hosted by Version 7.0, but there is no configured link between the Version 5.1 JMS queue and the bus queue. The JMS application communicates with the bus queue through the WebSphere MQ client link and the messaging engine. To send messages to the bus queue or receive messages from the queue, the JMS application opens a connection on the WebSphere MQ client link. This is all invisible to the JMS application, but can be displayed and managed by the administrator.

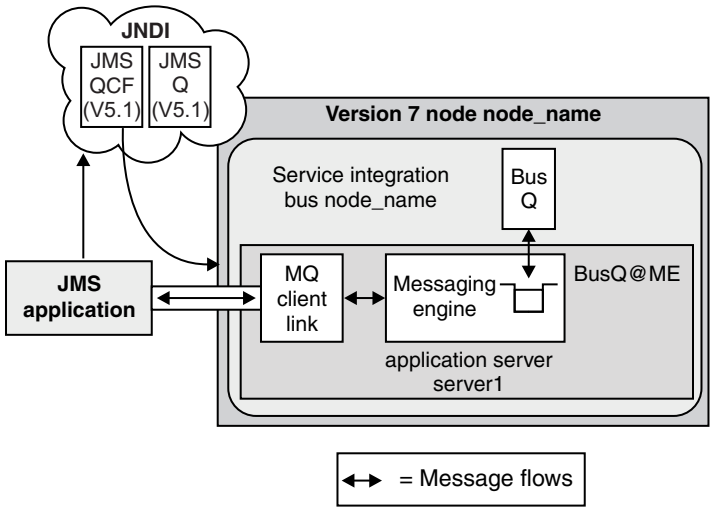


Figure 3. WebSphere Application Server Version 5.1 JMS application scenario

Procedure

- Configure a node on the later version to support Version 5.1 applications that use JMS resources. If you want a node on the later version to provide JMS destinations for use by applications running on Version 5.1, complete the following steps:
  1. Create an application server. You can use an existing application server on the node; for example, an application server onto which a Version 5.1 application is to be deployed.
  2. Create a service integration bus. You can use an existing bus.
  3. Add the application server as a bus member. This automatically creates a messaging engine on the application server.
  4. Create a WebSphere MQ client link on the messaging engine. Specify the following property values:

     Name This can be any name that is useful for your administrative purposes. It is not used by the application environment.

     MQ channel name
     This is the name of the channel for the WebSphere MQ client link, used to flow messages between the application that is running on Version 5.1 and the bus. This name must match the receiving channel name configured for Version 5.1:

     `WAS.JMS.SVRCONN`

     This is the default value shown when you first display the WebSphere MQ client link settings panel.

Queue manager name
This is the virtual queue manager name that is associated with the messaging engine, and by which the messaging engine is known to applications running on Version 5.1 . Type the queue manager name in the form:

`WAS_node_name_server_name`

Where:

node_name
is the name of the node on the later version of the product.

server_name
is the name of the application server.

The correct value is shown by default when you first display the WebSphere MQ client link settings panel.

Default queue manager
Select this check box if you want the WebSphere MQ client link to be used as the default for applications that cannot find a suitable WebSphere MQ client link to use.

If an application running on Version 5.1 specifies that it is to connect to a non-default queue manager name, you can configure a WebSphere MQ client link with that queue manager name. If a WebSphere MQ client link cannot be found with the required queue manager name, the connection is rejected. Alternatively, you can select this option on another WebSphere MQ client link, which is used instead of rejecting the connection.

5. Define a port called JMSSERVER_QUEUED_ADDRESS on the application server. The port number must be the same used by the SIB_MQ_ENDPOINT_ADDRESS port.

   Specify the following property values:

   Port name
   For **Well-known Port**, select JMSSERVER_QUEUED_ADDRESS

   Host Type the IP address, domain name server (DNS) host name with domain name suffix, or the short DNS host name of the node of the later version of the product.

   Port Type the port number used by the SIB_MQ_ENDPOINT_ADDRESS port. By default, this is 5558.

- Configure a managed node on the later version of the product to support applications running on Version 5.1 that use JMS resources. If you want a managed node to provide JMS destinations for use by applications running on Version 5.1, complete the following steps:
  1. Create an application server. Specify the name `jmsserver`.
  2. Create a service integration bus. You can use an existing bus.
  3. Add the application server as a bus member. This automatically creates a messaging engine on the application server.
  4. Create a WebSphere MQ client link on the messaging engine. Specify the following property values:

     Name This can be any name that is useful for your administrative purposes. It is not used by the application environment.

     MQ channel name
     This is the name of the channel for the WebSphere MQ client link, used to flow messages between the application running on Version 5.1 and the bus. This name must match the receiving channel name configured for Version 5.1:

     `WAS.JMS.SVRCONN`

     This is the default value shown when you first display the WebSphere MQ client link settings panel.

Queue manager name
This is the virtual queue manager name that is associated with the messaging engine, and by which the messaging engine is known to applications running on Version 5.1. Type the queue manager name in the form:

`WAS_node_name_jmsserver`

Where:

node_name
is the name of the node on the later version of the product.

The correct value is shown by default when you first display the WebSphere MQ client link settings panel.

Default queue manager
Select this check box if you want the WebSphere MQ client link to be used as the default for applications that cannot find a suitable WebSphere MQ client link to use.

If an application developed for WebSphere Application Server Version 5.1 specifies that it is to connect to a non-default queue manager name, you can configure another WebSphere MQ client link with that queue manager name. If a WebSphere MQ client link cannot be found with the required queue manager name, the connection is rejected. Alternatively, you can select this option on a WebSphere MQ client link, which is used instead of rejecting the connection.

5. Define a port called JMSSERVER_QUEUED_ADDRESS on the application server. The port number must be the same used by the SIB_MQ_ENDPOINT_ADDRESS port.

   Specify the following property values:

   Port name
   For **Well-known Port**, select JMSSERVER_QUEUED_ADDRESS

   Host Type the IP address, domain name server (DNS) host name with domain name suffix, or the short DNS host name of the node on the later version of the product.

   Port Type the port number used by the SIB_MQ_ENDPOINT_ADDRESS port. By default, this is 5558.

- If the application looks up JMS resources in JNDI on the application server, configure the JMS resources on the application server of the later version as Version 5.1 default messaging JMS resources.
  1. For each JMS queue destination that the application uses, create a V5 default messaging provider queue destination.
  2. For each JMS queue destination that the application uses, create a bus destination with the same name. Assign the bus destination to a bus member in the same bus as the `jmsserver` bus member.You must also create an alias destination with an identifier `WQ_<destination_name>`, that points to the service integration destination that has been created. The WQ_ prefix is needed because all destination names are prefixed with WQ_. If you are manually migrating the WebSphere JMS provider resources, you also have to create the “WQ_” queues.
  3. Configure JMS connection factories as Version 5.1 default messaging queue connection factories and topic connection factories.
- If the application looks up JMS resources outside the JNDI on the application server, configure the JMS connection factory to point to the node on the later version of the product.

Results

The application running on Version 5.1 can continue to access the JMS resources on the later level of the product, which are now implemented through the default messaging provider, as shown in the figure Figure 3 on page 584. The JMS application communicates with the Version 5.1 JMS resources through the WebSphere MQ client link and the messaging engine. This is invisible to the JMS application. The JMS

resources, a JMS queue connection factory, shown as JMS QCF(V5), and a JMS queue, shown as JMS Q(V5), are managed as Version 5.1 default messaging JMS resources. The new bus queue, shown as JMS Q, is managed as a resource of the service integration bus. Messages for JMS Q are stored and processed by the message point for the associated bus destination, a queue shown as Bus Q. The WebSphere MQ client link presents itself as a queue manager and transforms between the WebSphere MQ client protocols used by JMS applications developed for WebSphere Application Server Version 5.1 and the protocols used by messaging engines on the later version.

Creating a WebSphere MQ client link

Use this task to create a link that enables a messaging engine to handle message requests from JMS applications developed for WebSphere Application Server Version 5.1.

Before you begin

The WebSphere MQ client link is provided only for use with JMS applications developed for WebSphere Application Server Version 5.1.

About this task

The WebSphere MQ client link enables WebSphere Application Server Version 5.1 Java EE applications to use messaging resources of the default messaging provider of later versions that are backed by destinations on the service integration bus.

Each WebSphere MQ client link presents itself as a queue manager and transforms between the WebSphere MQ client protocols used by WebSphere Application Server Version 5.1[1] JMS applications.

If you migrate a Version 5.1 node to a later version, a default WebSphere MQ client link, with the name Default.MQClientLink, is created for the application servers on that node. You only have to create another WebSphere MQ client link if you want some Version 5.1 JMS applications to use a different channel to connect to the messaging engine, or want to present a messaging engine as a non-default queue manager name.

If you create a WebSphere MQ client link, you only have to manually specify values for a subset of the available properties. You can choose to specify values for other optional properties in this task, or if wanted at a later time by changing the configuration of the client link.

Tip: Creating a WebSphere MQ client link is only part of the task to enable WebSphere Application Server Version 5.1 applications to use messaging resources of the default messaging provider on a later version of the product. For more information about the overall task, see “Enabling WebSphere Application Server Version 5.1 JMS usage of messaging resources in later versions of the product” on page 583.

To create a WebSphere MQ client link, use the administrative console to complete the following steps.

Procedure

1. List the WebSphere MQ client links for the messaging engine that the Version 5.1 JMS applications are to connect to. Click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional Properties] WebSphere MQ client links**. This displays any existing WebSphere MQ client links in the content pane.
2. Click **New** in the content pane.
3. Specify the following required properties for the WebSphere MQ client link:

---

1. To make reading easier in this topic, the abbreviation “Version 5.1” is sometimes used to refer to “WebSphere Application Server Version 5.1”. For example, “Version 5.1 JMS resources” refers to JMS resources provided by WebSphere Application Server Version 5.1.

Name This can be any name that is useful for your administrative purposes. It is not used by the application environment.

MQ channel name
This is the name of the channel for the WebSphere MQ client link, used to flow messages between the JMS application developed for WebSphere Application Server Version 5.1 and the bus. This name must match the receiving channel name configured for WebSphere Application Server Version 5.1:

```
WAS.JMS.SVRCONN
```

This is the default value shown when you first display the WebSphere MQ client link settings panel.

Queue manager name
This is the virtual queue manager name that is associated with the messaging engine, and by which the messaging engine is known to WebSphere Application Server Version 5.1 applications. Type the queue manager name in the form:

```
WAS_node_name_server_name
```

Where:

node_name
is the name of the WebSphere Application Server node on the later version of the product.

server_name
is the name of the application server.

The correct value is shown by default when you first display the WebSphere MQ client link settings panel.

Default queue manager
Select this check box if you want the MQ client link to be used as the default for applications that cannot find a suitable MQ client link to use.

If a JMS application developed for WebSphere Application Server Version 5.1 specifies that it is to connect to a non-default queue manager name, you can configure a WebSphere MQ client link with that queue manager name. If a WebSphere MQ client link cannot be found with the required queue manager name, the connection is rejected. Alternatively, you can select this option on another WebSphere MQ client link, which is used instead of rejecting the connection.

4. Optional: If you want to specify other optional properties, see the property descriptions in “WebSphere MQ client link [Settings]” on page 2201.
5. Click **OK**.
6. Save your changes to the master configuration.

What to do next

To enable WebSphere Application Server Version 5.1 applications to use messaging resources of later versions, ensure you complete all the steps in the task “Enabling WebSphere Application Server Version 5.1 JMS usage of messaging resources in later versions of the product” on page 583.

Configuring a WebSphere MQ client link

Use this task to browse or change the properties of a client link that enables a messaging engine to handle message requests from JMS applications developed for WebSphere Application Server Version 5.1.

Before you begin

The WebSphere MQ client link is provided only for use with JMS applications developed for WebSphere Application Server Version 5.1.

About this task

The WebSphere MQ client link enables WebSphere Application Server Version 5.1 Java EE applications to use messaging resources of the default messaging provider in later versions that are backed by destinations on the service integration bus.

Each WebSphere MQ client link presents itself as a queue manager and transforms between the WebSphere MQ client protocols used by WebSphere Application Server Version 5.1[2] JMS applications.

Procedure

1. Start the administrative console.
2. Navigate to the settings page for the WebSphere MQ client link. Click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional Properties] WebSphere MQ client links -> *link_name***. This displays the properties of the selected WebSphere MQ client links in the content pane.
3. Optional: If you want to change any of the general properties, see the property descriptions in "WebSphere MQ client link [Settings]" on page 2201.
4. Optional: If you want to change any of the advanced properties, see the property descriptions in "WebSphere MQ client link advanced properties [Settings]" on page 2197, then complete the following steps.
5. If you have changed any properties, complete the following steps.
   a. Click **OK**.
   b. Save your changes to the master configuration.

Listing WebSphere MQ client links for a messaging engine

Use this task to display a list of WebSphere MQ links for a messaging engine.

About this task

To list the WebSphere MQ client links for a messaging engine, use the administrative console to complete the following steps.

Procedure

Display the WebSphere MQ client links collection page. Click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional Properties] WebSphere MQ client links**.

Results

This displays a list of WebSphere MQ client links for the messaging engine in the content pane, with the following subset of properties for the link:

Name The name of the WebSphere MQ client link.

Description
An optional description for the WebSphere MQ client link, for administrative purposes.

MQ channel name
The name of the channel for the WebSphere MQ client link, used to flow messages between WebSphere MQ clients and the bus.

---

2. To make reading easier in this topic, the abbreviation "Version 5.1" is sometimes used to refer to "WebSphere Application Server Version 5.1". For example, "Version 5.1 JMS resources" refers to JMS resources provided by WebSphere Application Server Version 5.1.

Queue manager name
The name of the WebSphere MQ queue manager on which the WebSphere MQ sender channel, that is connected to this MQ link receiver channel connection instance, is running.

Default queue manager
Whether or not this is the default queue manager for the WebSphere MQ clients.

Status
The runtime status of the WebSphere MQ client link.

What to do next

You can use this panel to create, delete, start, or stop client links, as described in related tasks.

Starting and stopping WebSphere MQ client links

Use this task to start or stop WebSphere MQ client links, to stop message flows between the default messaging provider and JMS applications developed for WebSphere Application Server Version 5.1, connected through the client links.

About this task

You can start a WebSphere MQ client link that is not running (has a runtime status of Stopped) or stop a client link that is running (has a runtime status of Started). This also starts or stops all client connections on the selected WebSphere MQ client links. Alternatively, you can start or stop individual client connections on the WebSphere MQ client link, as described in "Starting and stopping WebSphere MQ client connections" on page 592.

When stopping a client link, you can choose whether to force the client link to stop immediately or after any messages currently on its client connections have been processed. You can also choose the final state that you want the client link to be in when it has been stopped.

To start or stop one or more WebSphere MQ client links, use the administrative console to complete the following steps.

Procedure

1. Display the WebSphere MQ client links collection page. Click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional Properties] WebSphere MQ client links**.
2. Select the check box next to the name of each client link that you want to start or stop.
3. Click the appropriate button:

Start	Start selected items. This enables JMS applications to use the client link to access JMS resources provided by the default messaging provider.

Stop	Stop a selected WebSphere MQ client link. You must first have selected the link to be stopped. You can choose the mode of stop action and the required state when the link has been stopped: **Stop mode:** **Force** Stop the link immediately. **Quiesce** Stop the link after any messages currently on its client connections have been processed. **Target state:** **Inactive** Stop the link to an inactive state. If an application tries to use the link, the link is started again. **Stopped** Stop the link to a stopped state. Applications cannot use the client link. The link can only be started again by administrator action.

Results

The status of the client link changes and a message stating that the link has started or stopped is displayed at the top the page.

Listing client connections for a WebSphere MQ client link

Use this task to display a list of client connections for a WebSphere MQ client link. Each client connection is created automatically for a version 5 JMS application by using the WebSphere MQ client link.

About this task

To list the client connections for a WebSphere MQ client link, use the administrative console to complete the following steps.

Procedure

Display the client connections collection page. Click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional Properties] WebSphere MQ client links -> *link_name* [Additional Properties] Client connections**.

Results

This displays a list of client connections for the WebSphere MQ client link in the content pane, with the following subset of properties for the link:

IP address
The TCP/IP IP address of the WebSphere MQ client.

Status
The runtime status of the WebSphere MQ client connection.

What to do next

You can use this panel to start or stop client connections, as described in related tasks.

Starting and stopping WebSphere MQ client connections

Use this task to start or stop client connections on a WebSphere MQ client link, to stop message flows between the default messaging provider and the JMS application developed for WebSphere Application Server Version 5.1 that uses the connections.

About this task

You can start a WebSphere MQ client connection that is not running (has a runtime status of Inactive) or stop a client connection that is running (has a runtime status of Started). Alternatively, you can start or stop all client connections on the WebSphere MQ client link, as described in "Starting and stopping WebSphere MQ client links" on page 590.

When stopping a client connection, you can choose whether to force the client connection to stop immediately or after any messages currently on its client connections have been processed. Client connections are always stopped to an inactive state.

To start or stop one or more WebSphere MQ client connections, use the administrative console to complete the following steps.

Procedure

- Display the WebSphere MQ client connections collection page. Click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional Properties] WebSphere MQ client links -> *link_name* [Additional Properties] Client connections**.
- Select the check box next to the name of each client connection that you want to start or stop.
- Click the appropriate button:

Start	Start selected items.
Stop	Stop a selected WebSphere MQ client connection. You must first have selected the connection to be stopped. You can choose the mode of stop action, but connections are always stopped to an inactive state: **Stop mode:** **Force** Stop the connection immediately. **Quiesce** Stop the connection after any messages currently on the connection have been processed. **Target state:** **Inactive** Stop the link to an inactive state. If an application tries to use the link, the link is started again.

Results

The status of the client connection changes and a message stating that the connection has started or stopped is displayed at the top the page.

Deleting WebSphere MQ client links

Use this task to delete WebSphere MQ client links. This prevents JMS applications developed for WebSphere Application Server Version 5.1 from using those client links to exchange messages with the default messaging provider.

Before you begin

Before deleting a WebSphere Application Server Version 5 JMS applications using the client link.

- Stop all message-producing JMS applications in the WebSphere Application Server Version 5.1 environment that are using the client link. For example, you can use the administrative console to stop the applications, as described in Starting or stopping enterprise applications.
- Allow all message-consuming JMS applications (including those consuming publications as a result of durable subscriptions) to continue until all the JMS queues are drained, then stop those applications.

About this task

To start or stop one or more WebSphere MQ client links, use the administrative console to complete the following steps.

Procedure

1. Display the WebSphere MQ client links collection page. Click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional Properties] WebSphere MQ client links**.
2. Select the check box next to the name of each client link that you want to delete.
3. Click **Delete**
4. Click **OK**.
5. Save any changes to the master configuration.

Configuring the messaging engine selection process for JMS applications

Configure the JMS connection factory for your application, in order to tune the process through which messaging engine connections are selected for your application.

About this task

To use JMS destinations of the default messaging provider, a client application connects to a messaging engine on the service integration bus to which the destinations are assigned. For example, a JMS queue is assigned to a queue destination on a service integration bus.

By default, the environment automatically connects applications to an available messaging engine on the bus. However you can specify extra configuration details to influence the connection process; for example to identify special bootstrap servers, or to limit connection to a subgroup of available messaging engines, or to improve availability or performance, or to ensure sequential processing of messages received.

For a JMS application, you apply the extra configuration to the associated JMS connection factory. For a message-driven bean (MDB) application, you apply the equivalent extra configuration to the associated activation specification.

For the default configuration, you only have to specify the one required connection property **Bus name**, which sets the name of the bus to which the application is to connect. To further restrict the range of messaging engines to which your applications can connect, you can also configure the other connection properties:

- Target
- Target type
- Target significance
- Target inbound transport chain
- Connection proximity

For detailed information about these connection properties, and an overview of the process through which the default messaging provider chooses the messaging engine for your application, see How JMS applications connect to a messaging engine on a bus.

The steps for this task are based on an application that uses a unified JMS connection factory. You can use the same task to configure a JMS queue connection factory or JMS topic connection factory, but you select the appropriate type of connection factory instead of **JMS connection factory**.

Procedure

- If the client application uses a JMS connection factory in the client container, use the Client Resource Configuration tool (ACRCT) to configure the Provider endpoint property:
  1. Start the tool and open the EAR file for which you want to configure the JMS connection factory. The EAR file contents are displayed in a tree view.
  2. From the tree, select the JAR file in which you want to configure the JMS connection factory.
  3. Expand the JAR file to view its contents.
  4. Expand **Messaging Providers > Default Provider > Connection Factories**.
  5. Optional: Display the general properties of the connection factory:
     - If you want to use an existing JMS connection factory, click the name of the connection factory.
     - If you want to create a new JMS connection factory, click **New**.

       For more information about configuring a JMS connection factory in the JMS provider configuration for your application client, see “Configuring Java messaging client resources” on page 72.
  6. On the General tab, configure the connection properties.
  7. Click **OK**.
  8. To save your changes, click **File > Save**.
- If the client application uses a JMS connection factory on the server, use the WebSphere Application Server administrative console to configure the connection properties:
  1. Display the default messaging provider. In the navigation pane, expand **Resources -> JMS -> JMS providers**.
  2. Optional: Change the **Scope** check box to set the level at which the connection factory is to be visible, according to your needs.
  3. In the content pane click **Default messaging provider**. This displays a table of properties for the default messaging provider, including links to the types of JMS resources that it provides.
  4. In the content pane, under Additional Properties, click **Connection factories** This displays any existing connection factories in the content pane.
  5. Optional: Display the general properties of the connection factory:
     - If you want to use an existing JMS connection factory, click the name of the connection factory.
     - If you want to create a new JMS connection factory, click **New**.

For more information about configuring a JMS connection factory, see “Configuring a unified connection factory for the default messaging provider” on page 518.

6. Configure the connection properties.
7. Click **OK**.
8. Save your changes to the master configuration.

Managing messages and subscriptions for default messaging JMS destinations

You can manage the messages and subscriptions that exist for JMS destinations of the default messaging provider. You can manage the messages on a JMS queue by acting on the queue point for the bus destination to which JMS queue has been assigned. You can administer the durable subscriptions on a JMS topic by acting on a publication point for the topic space to which JMS topic has been assigned.

About this task

The **Bus name** property of the JMS connection factory identifies the service integration bus. For managing the messages on a JMS queue, note that the **Queue name** property of the JMS queue identifies the name of the bus destination. For administering the durable subscriptions on a JMS topic, note that the **Topic space** property of the JMS topic identifies the name of the topic space.

Queue points and publication points are examples of message points. For information about how to manage messages on message points, see the following subtopics.

Procedure

- Manage messages on message points.
- Administer durable subscriptions.

Managing messages on message points

Use these tasks to list and act on runtime messages that exist on message points in a service integration bus.

About this task

You can list the message points for bus destinations and messaging engines, and list the messages on a selected message point. You can use the list of messages as part of a troubleshooting task to find messages that need to be deleted.

- “Listing messages on a message point”
- “Deleting messages on a message point” on page 596

Listing messages on a message point:

Use this task to list the messages that exist on a message point for a selected bus destination or messaging engine.

About this task

To display a list of messages on a message point, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Service integration -> Buses**.
2. In the content pane, click the name of the service integration bus.
3. Optional: To list the message points for a bus destination, complete the following steps:

a. In the content pane, under **Destination resources**, click **Destinations**.
b. Click the destination name.

4. Optional: To list the message points for a messaging engine, complete the following steps:
   a. In the content pane, under **Topology**, click **Messaging engines**.
   b. Click the messaging engine name.
5. Under Additional Properties, click **Message points**. This displays a list of message points in the content pane.
6. Click the message point name. This displays the properties of the destination localization in the content pane.
7. Click the Runtime tab.
8. Under Additional Properties, click **Messages**.

Results

A list of messages on the selected message point is displayed in the content pane.

What to do next

You can select one or more messages to act on; for example, to display the message content, delete messages.

Deleting messages on a message point:

Use this task to delete one or more messages that exist on a message point for a selected bus destination or messaging engine.

About this task

You should not usually have to delete messages on a message point. This task is intended as part of a troubleshooting procedure.

To delete one or messages on a message point, use the administrative console to complete the following steps:

Procedure

1. List the messages on the message point.
2. In the content pane, select the check box next to each message that you want to delete. Alternatively, you can select all messages in the list by clicking **Select all items**  .
3. Click **Delete**.

Results

The selected messages are removed from the list.

Using JMS from stand-alone clients to interoperate with service integration resources

The Thin Client for JMS with WebSphere Application Server allows third party applications to interoperate with default messaging provider messaging engines on WebSphere Application Server.

Using JMS to connect to a WebSphere Application Server default messaging provider messaging engine

The Thin Client for JMS with WebSphere Application Server is an embeddable technology that provides Java Message Service (JMS) V1.1 connections to a WebSphere Application Server default messaging provider messaging engine.

Installing and configuring the Thin Client for JMS with WebSphere Application Server:

To use the Thin Client for JMS with WebSphere Application Server copy the com.ibm.ws.sib.client.thin.jms_7.0.0.jar and any other required files from the application server or application client %WAS_HOME%/runtimes directory.

About this task

The Thin Client for JMS with WebSphere Application Server can be used for default messaging provider messaging engines for WebSphere Application Server Version 6.0.2 or later. The connection to the messaging engine can be either TCP or SSL. HTTP connectivity is not supported.

Installation and configuration of the client in an OSGi environment is different and described in “Installing and configuring the Thin Client for JMS with WebSphere Application Server in an OSGi environment” on page 599.

You can install the client in any location and run it in any supported Java 2 Platform Standard Edition 1.5.0 (also known as 5.0) or above Java Runtime Environment (JRE). The client supports the following JREs:

- IBM JRE 1.5.0 and above
- Sun JRE 1.5.0 and above
- HP-UX JRE 1.5.0 and above
- Lotus® Expeditor Version 6.1 or above with J2SE 5.0 or above Device Runtime Environment. jclDesktop and jclDevice profiles are not supported.

The client does not require any further configuration after installation, apart from adding the jar file or files to the classpaths for your client application. You can choose either to create JMS connection factories programmatically, or use the Java Naming and Directory Interface (JNDI). If required, you can use secure connections by configuring Secure Sockets Layer (SSL) settings.

Procedure

1. Install the client in the required location. The client is always installed in the `/runtimes` directory of a WebSphere Application Server installation, and might optionally be installed by the Application Client for WebSphere Application Server, which is a separate WebSphere Application Server deliverable. The client is shipped as three files:
   - `com.ibm.ws.sib.client.thin.jms_7.0.0.jar` - the regular JMS Client.
   - `com.ibm.ws.sib.client_ExpeditorDRE_7.0.0.jar` - the JMS Client packaged for Lotus Expeditor.
   - `sibc.nls.zip` - language-specific resource bundles. You can extract any combination of these files. The client jar already includes US English, so you only need the additional language files from `sibc.nls.zip` if you require languages other than non-US English.
2. Include the appropriate jar file or files in the classpaths for your client application:
   a. To compile JMS code, include the client jar file in the CLASSPATH setting for the javac command.
   b. To run JMS code, include the client jar file and any required optional language files extracted from `sibx.nls.zip` in the CLASSPATH setting for the java command.
3. Configure the required JMS resources as described in “Using JMS resources with the Thin Client for JMS with WebSphere Application Server” on page 599.
4. If you require secure connections, configure SSL as described in “Securing JMS client and JMS resource adapter connections” on page 601.

Migration to the Thin Client for JMS with WebSphere Application Server:

There are a number of differences to consider when migrating to the Thin Client for JMS with WebSphere Application Server from an earlier version of the client.

Table 51. Migration from WebSphere Application Server Version 6.0.2 to WebSphere Application Server Version 7.0 or later. The first column of the table lists the areas where the differences are found between WebSphere Application Server Version 6.0.2 and WebSphere Application Server Version 7.0 or later. The second column lists the availability, applicability, file path, JRE level or the property names of the specific area of WebSphere Application Server Version 6.0.2 (Client for Java Message Service on Java 2 Platform, Standard Edition with WebSphere Application Server). The third column provides the file path, file names, JRE level or property names of the specific area of WebSphere Application Server Version 7.0 or later (Thin Client for JMS with WebSphere Application Server).

Area	**WebSphere Application Server Version 6.0.2 (Client for Java Message Service on Java 2 Platform, Standard Edition with WebSphere Application Server)**	**WebSphere Application Server Version 7.0 or later (Thin Client for JMS with WebSphere Application Server)**
Installation	Available for separate download and installation	Installed in the WebSphere Application Server or Application Client /runtimes directory
JMS jar file name	`sibc.jms.jar` file	`com.ibm.ws.sib.client.thin.jms_`*`version_number`*`.jar`
Performing JNDI lookups of JMS resources	Requires optional `sibc.jndi.jar` file (and ORB `sibc.orb.jar` file for non-IBM JREs)	Requires Thin Client for EJB with WebSphere Application Server jar file `com.ibm.ws.ejb.thinclient_`*`version_number`*`.jar` or `com.ibm.ws.ejb.thinclient.z_`*`version_number`*`.jar` (and ORB `com.ibm.ws.orb_`*`version_number`*`.jar` for non-IBM JREs)
SSL configuration	Secure connections are configured by using JRE global properties: **-Djavax.net.ssl.keyStore** **-Djavax.net.ssl.keyStorePassword** **-Djavax.net.ssl.trustStore** **-Djavax.net.ssl.trustStorePassword**	Two approaches to configuring secure connections. The first approach uses JRE global properties: **-Djavax.net.ssl.keyStore** **-Djavax.net.ssl.keyStorePassword** **-Djavax.net.ssl.trustStore** **-Djavax.net.ssl.trustStorePassword** The second approach is to specify security settings that are specific to Thin Client for JMS with WebSphere Application Server connections: **-Dcom.ibm.ssl.keyStoreType** **-Dcom.ibm.ssl.keyStore** **-Dcom.ibm.ssl.keyManager** **-Dcom.ibm.ssl.trustManager** **-Dcom.ibm.ssl.keyStorePassword** **-Dcom.ibm.ssl.protocol** **-Dcom.ibm.ssl.contextProvider** **-Dcom.ibm.ws.sib.jsseProvider**
Minimum JRE level	1.4.2	1.5
Enable trace (set trace specification)	**-Dcom.ibm.ws.sib.client.traceSetting**	**-Dcom.ibm.ejs.ras.lite.traceSpecification**
Set trace file name	**-Dcom.ibm.ws.sib.client.traceFile**	**-Dcom.ibm.ejs.ras.lite.traceFileName**
Set max trace file size	Not applicable	**-Dcom.ibm.ejs.ras.lite.maxFileSize**
Set max number of trace files	Not applicable	**-Dcom.ibm.ejs.ras.lite.maxFiles**
Set trace format	Not applicable	**-Dcom.ibm.ejs.ras.lite.traceFormat**

Table 51. Migration from WebSphere Application Server Version 6.0.2 to WebSphere Application Server Version 7.0 or later (continued). The first column of the table lists the areas where the differences are found between WebSphere Application Server Version 6.0.2 and WebSphere Application Server Version 7.0 or later. The second column lists the availability, applicability, file path, JRE level or the property names of the specific area of WebSphere Application Server Version 6.0.2 (Client for Java Message Service on Java 2 Platform, Standard Edition with WebSphere Application Server). The third column provides the file path, file names, JRE level or property names of the specific area of WebSphere Application Server Version 7.0 or later (Thin Client for JMS with WebSphere Application Server).

Area	WebSphere Application Server Version 6.0.2 (Client for Java Message Service on Java 2 Platform, Standard Edition with WebSphere Application Server)	WebSphere Application Server Version 7.0 or later (Thin Client for JMS with WebSphere Application Server)
Using alternative trace properties file	**-DtraceSettingsFile**	**-DtraceSettingsFile** Thin Client for JMS with WebSphere Application Server supports new options described in "Trace user interface for stand-alone clients" on page 603
Enable and specify FFDC file name	**-DffdcLogFile**	**-Dcom.ibm.ejs.ras.lite.ffdcLogFile**
NLS support	Installation option for NLS support	Non-English versions are available in the `sibc.nls.jar` file

Installing and configuring the Thin Client for JMS with WebSphere Application Server in an OSGi environment:

Use this information to install and configure the Thin Client for JMS with WebSphere Application Server in an OSGi environment.

About this task

To use the Thin Client for JMS with WebSphere Application Server in an OSGi environment import the required plug-ins into your development environment and add them to the list of required plug-ins in your product configuration.

A list of all packages exported by system.bundle can be obtained from the Execution Environment Profile being used. For example if the Execution Environment is J2SE-1.5 then the list of all packages exported by system.bundle can be obtained from the property org.osgi.framework.system.packages in the Execution Environment Profile file named J2SE-1.5.profile contained in the bundle org.eclipse.osgi_<version>.jar

Procedure

- Application plug-ins which use the Thin Client for JMS with WebSphere Application Server plug-ins must import the javax.jms packages in an OSGi environment.
- If you are using connection factories that are programmatically created, the application plug-in must import the com.ibm.websphere.sib.api.jms package.
- Alternatively, if you are using JNDI lookups via the Thin Client for EJB in WebSphere Application server then the application plug-in must import the com.ibm.websphere.naming package.
- When performing JNDI lookups it is necessary that the following system property be specified:
  ```
  -Dorg.osgi.framework.system.packages=sun.io,com.ibm.wsspi.channel.framework,
  com.ibm.CORBA.channel,com.ibm.CORBA.channel.giop,com.ibm.channel.orb,
  com.ibm.CORBA.poa,com.ibm.CORBA.ras,com.ibm.CORBA.iiop,com.ibm.CORBA.transport
  ```

Using JMS resources with the Thin Client for JMS with WebSphere Application Server:

Suitable JMS connection factories and references to JMS queues or topics might be obtained programmatically without using JNDI. Alternatively, full JNDI support might be obtained from the Thin Client for EJB with WebSphere Application Server.

Procedure

- To obtain suitable connection factories programmatically, without using JNDI, use code similar to that shown in the following example:

```
import com.ibm.websphere.sib.api.jms.*;
...
JmsConnectionFactory jmsCF =
  JmsFactoryFactory.getInstance().createQueueConnectionFactory();
jmsCF.setBusName("myBus");
jmsCF.setProviderEndpoints("1.2.3.4");
```

  To obtain a suitable reference to a JMS queue or topic programmatically, use code similar to that shown in the following example:

```
JmsQueue jmsQ = JmsFactoryFactory.getInstance().createQueue("myQueue");
```

  For further information, see the JmsFactoryFactory class API documentation available with WebSphere Application Server.

- To obtain full JNDI support from the Thin Client for EJB with WebSphere Application Server:
  1. Include the `/runtimes/com.ibm.ws.ejb.thinclient_7.0.0.jar` file in the compile and runtime classpaths for your enterprise application as described in “Installing and configuring the Thin Client for JMS with WebSphere Application Server” on page 597.
  2. Use the following code to create a suitable Initial Context, substituting the server IP address and port as appropriate:

```
import javax.naming.*;
...
Properties env = new Properties();
env.put(Context.PROVIDER_URL,"iiop:
  //<server IP address>:<server bootstrap address port>");
env.put(Context.INITIAL_CONTEXT_FACTORY,
  "com.ibm.websphere.naming.WsnInitialContextFactory");
InitialContext ctx = new InitialContext(env);
```

     In certain situations, for example when running with a Sun JRE, an additional ORB jar is also required. For additional information about when this jar is required, see “Running the IBM Thin Client for Enterprise JavaBeans (EJB)” on page 155.

Obtaining WebSphere MQ JMS resources in the thin client environment:

A stand-alone Java SE JMS thin client application that connects to an external WebSphere MQ queue manager can get administratively-created WebSphere MQ messaging provider JMS resources from the WebSphere Application Server Java Naming and Directory Interface (JNDI) namespace.

Procedure

1. To obtain WebSphere MQ messaging provider JMS resources from the WebSphere Application Server JNDI namespace in the thin client environment, include the following jar files in the runtime classpath of your application:
   - A copy of the `/runtimes/com.ibm.ws.ejb.thinclient_7.0.0.jar` file.
   - A copy of the `/runtimes/com.ibm.ws.messagingClient.jar` file.
   - WebSphere MQ client jar files, which must be obtained from the WebSphere MQ product.
2. Use the following code to create a suitable Initial Context, substituting the server IP address and port as appropriate:

```
import javax.naming.*;
...
Properties env = new Properties();
env.put(Context.PROVIDER_URL,"iiop:
  //<server IP address>:<server bootstrap address port>");
env.put(Context.INITIAL_CONTEXT_FACTORY,
  "com.ibm.websphere.naming.WsnInitialContextFactory");
InitialContext ctx = new InitialContext(env);
```

In certain situations, for example when running with a Sun JRE, an additional ORB jar is also required. For additional information about when this jar is required, see the Thin Client for EJB with WebSphere Application Server information.

Securing JMS client and JMS resource adapter connections

There are two approaches to configuring Secure Sockets Layer (SSL) for the Thin Client for JMS with WebSphere Application Server and the Resource Adapter for JMS with WebSphere Application Server. The global configuration approach affects all stand-alone outbound connections from the process, and the private approach applies only to client or resource adapter connections from the process.

About this task

The Thin Client for JMS with WebSphere Application Server and the Resource Adapter for JMS with WebSphere Application Server use the standard Java Secure Socket Extension (JSSE) that all supported JREs provide for making Secure Sockets Layer (SSL) connections. For information about JSSE, see the JSSE documentation.

The global configuration approach uses JRE global properties and affects all outbound SSL connections that your application initiates. For a JRE configured to use SSL connections to connect to WebSphere Application Server, you typically have to set the following javax.net.ssl system properties:

```
-Djavax.net.ssl.keyStore=key.p12
-Djavax.net.ssl.keyStorePassword={xor}Lz4sLCgwLTs=
-Djavax.net.ssl.trustStore=trust.p12
-Djavax.net.ssl.trustStorePassword={xor}PSo4LSov
```

You can use the private configuration approach to specify security settings that are specific to the Thin Client for JMS with WebSphere Application Server or the Resource Adapter for JMS with WebSphere Application Server connections. You can configure the com.ibm.ws.sib.client.ssl.properties system property to specify the location of an IBM SSL properties file. If this system property is not configured, an attempt is made load the properties file from the classpath instead.

The client obtains the value that it uses for any particular SSL property as follows:

- If the property has a value defined in the properties file containing the IBM SSL properties, the client uses this value.
- If there is no value for the property in the properties file, and there is a suitable property in the associated JRE system properties, the client uses this value.
- If there is no suitable javax.net.ssl property, the client uses the default value.

The table below summarizes the IBM SSL property keys that can be configured inside the IBM SSL properties file, and the corresponding javax.net.ssl.* system property keys and default values.

Table 52. IBM SSL property values and corresponding JRE global property and default values. The first column of the table lists the IBM SSL property keys and the second column lists the corresponding JRE global property keys. The third column provides the default values of the properties.

IBM SSL property	JRE global property	Default value
com.ibm.ssl.keyStoreType	javax.net.ssl.keyStoreType	JKS
com.ibm.ssl.keyStore	javax.net.ssl.keyStore	None

Table 52. IBM SSL property values and corresponding JRE global property and default values (continued). The first column of the table lists the IBM SSL property keys and the second column lists the corresponding JRE global property keys. The third column provides the default values of the properties.

IBM SSL property	JRE global property	Default value
com.ibm.ssl.keyManager	javax.net.ssl.keyStoreProvider	IbmX509
com.ibm.ssl.trustManager	javax.net.ssl.trustStoreProvider	IbmX509
com.ibm.ssl.keyStorePassword	javax.net.ssl.keyStorePassword	None
com.ibm.ssl.protocol	None	SSL
com.ibm.ssl.contextProvider	None	IBMJSSE2
com.ibm.ws.sib.jsseProvider	None	com.ibm.jsse2.IBMJSSEProvider2
com.ibm.ssl.trustStore	javax.net.ssl.trustStore	None
com.ibm.ssl.trustStoreType	javax.net.ssl.trustStoreType	JKS
com.ibm.ssl.trustStorePassword	javax.net.ssl.trustStorePassword	None

For example, you might create an ssl.properties file that contains the following properties and values:

```
com.ibm.ssl.keyStore=/thinclient/key.p12
com.ibm.ssl.keyStoreType=PKCS12
com.ibm.ssl.keyStorePassword=WebAS
com.ibm.ssl.trustStore=/thinclient/trust.p12
com.ibm.ssl.trustStoreType=PKCS12
com.ibm.ssl.trustStorePassword=WebAS
```

You can use the PropFilePasswordEncoder tool in the WebSphere Application Server bin directory to encode passwords stored in plain text property files. For further information see Encoding passwords in files.

Notes:

1. SSL connections from SUN JREs that use the Thin Client for JMS with WebSphere Application Server cannot use the default WebSphere Application Server PKCS12 key and trust stores. If you are running the client securely from SUN JREs, you must first extract the certificates from the trust store by using an IBM software development kit (SDK). You can then import these certificates into a keystore that the Sun JRE can recognize correctly, such as a JKS keystore.
2. SSL connections are not supported by the IBM JRE shipped with WebSphere Application Server - a non-WebSphere Application Server installed JRE must be used.

Procedure

1. Obtain the necessary key and trust store files.
2. Set the javax.net.ssl system properties required for the global configuration approach.
3. For the private configuration approach, use the com.ibm.ws.sib.client.ssl.properties system property to specify the file from which the SSL properties are to be loaded, as shown in the following example:

   ```
   -Dcom.ibm.ws.sib.client.ssl.properties=c:/ssl.properties
   ```

Adding tracing and logging for stand-alone clients

You can add tracing and logging to help analyze performance and diagnose problems.

About this task

This information applies to the following WebSphere Application Server stand-alone clients:

- Thin Client for JMS with WebSphere Application Server
- Thin Client for EJB with WebSphere Application Server
- Thin Client for JAX-WS with WebSphere Application Server

- Thin Client for JAX-RPC with WebSphere Application Server

Procedure

- To enable trace, use either a long form or short form system property.

  Note: Trace settings are determined from the system property values the first time that a WebSphere Application Server client is called. The trace settings are then fixed. Therefore, any subsequent changes to the system property settings do not change the trace settings that the WebSphere Application Server client uses.
- To enable First Failure Data Capture (FFDC), use either a long or short form system property.

  Note: FFDC settings are determined from the system property values the first time that a WebSphere Application Server client performs an FFDC. The FFDC settings are then fixed. Therefore, any subsequent changes to the system property settings do not change the FFDC settings that the WebSphere Application Server client uses.

Trace user interface for stand-alone clients:

To enable trace, you can either use a long form or a short form system property.

Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

Long form system properties

The long form system property takes priority over the short form and uses system properties that are unique to WebSphere Application Server.

Table 53. Long form system properties. The table contains the list of long form system properties and the descriptions of the properties.

Property	Description
com.ibm.ejs.ras.lite.traceSpecification	The trace specification string
com.ibm.ejs.ras.lite.traceFileName	The trace destination (<*file*>, stdout, stderr, java,util.logging)
com.ibm.ejs.ras.lite.maxFileSize	The maximum trace file size in MB (if the trace destination is a file)
com.ibm.ejs.ras.lite.maxFiles	The maximum number of trace files kept (if the trace destination is a file)
com.ibm.ejs.ras.lite.traceFormat	The trace output format, which can be either basic or advanced (the default is basic)

Long form example:

```
-Dcom.ibm.ejs.ras.lite.traceSpecification=SIB*=all
-Dcom.ibm.ejs.ras.lite.traceFileName=c:/trace.log
-Dcom.ibm.ejs.ras.lite.maxFileSize=20
-Dcom.ibm.ejs.ras.lite.maxFiles=8
```

Short form system property

The short form uses a system property that is compatible with existing WebSphere Application Server clients but that, because this property is unqualified, might clash with other third party technologies that are running in the same Java runtime environment (JRE).

The short form system property is:

```
traceSettingsFile
```

This property must specify a loadable properties file that can contain the following properties:

Table 54. Properties in loadable system properties file. The table includes the list of loadable system properties and the descriptions of the properties.

Property	Description
traceFileName	The trace destination (file, stdout, stderr, java,util.logging)
maxFilesSize	The maximum trace file size in MB (if the trace destination is a file)
maxFiles	The maximum number of trace files kept (if the trace destination is a file)
<traceSpec>	The trace specification
traceFormat	The trace output format, which can be either basic or advanced (the default is basic)

The following example shows how to use the short form system property:

```
SIBTrm=all:SIBMfp=all
traceFileName=c:/trace.log
```

Special meanings for trace file name values

Some trace file name values have a special meaning:

- stdout - causes trace records to be written to stdout
- stderr - causes trace records to be written to stderr
- java.util.logging - causes trace records to be written to java.util.logging

Using any other name causes the trace records to be written to a file of that name.

First Failure Data Capture user interface for stand-alone clients:

To enable First Failure Data Capture (FFDC) output, you can either use a long or short form system property.

Long form system property

The long form takes priority over the short form and uses a system property that is unique to WebSphere Application Server to specify the FFDC dump file name. This property is:

```
com.ibm.ejs.ras.lite.ffdcLogFile
```

The following example shows how to use the long form system property to enable FFDC output:

```
-Dcom.ibm.ejs.ras.lite.ffdcLogFile=c:\ffdc.log
```

Short form system property

The short form system property is:

```
ffdcLogFile
```

The following example shows how to use the short form system property to enable FFDC output:

```
-DffdcLogFile=c:\ffdc.log
```

Using JMS from a third party application server to interoperate with service integration resources

The Resource Adapter for JMS with WebSphere Application Server provides first class connectivity to service integration resources from the third party application server on which it is deployed.

About this task

The Resource Adapter for JMS with WebSphere Application Server is designed to be deployed into third party application servers, that is, into non-WebSphere Application Server application servers, that support Java EE Connector Architecture (JCA) 1. 5 and are Java 2 Platform, Enterprise Edition (J2EE) 1.4 compliant. The stand-alone resource adapter provides these third party application servers with full connectivity to service integration resources running inside WebSphere Application Server Version 6.0.2 and later.

Supported third party application servers are:

- WebSphere Application Server Community Edition Version 2.0 and later
- Apache Geronimo v2.0 and later
- JBoss Application Server v4.0.5 and later

Restriction:

- The resource adapter does not support the unmanaged JCA environment. In an unmanaged environment use the Thin Client for JMS with WebSphere Application Server.
- If you want to use XA connections to a WebSphere Application Server Version 6.0.2 application server, contact IBM Support to obtain a required service update.

Deploying the Resource Adapter for JMS with WebSphere Application Server to a third party application server

To provide connections to service integration resources running inside WebSphere Application Server, the Resource Adapter for JMS with WebSphere Application Server must be installed into the third party application server.

Before you begin

The Resource Adapter for JMS with WebSphere Application Server requires JRE 1.5 or later. The resource adapter is called sibc.jmsra.rar and is available from the following runtime directories:

- WebSphere Application Server install
- Application Client for WebSphere Application Server install

Before starting the deployment of the resource adapter, you must first obtain the following information from the WebSphere Application Server administrator:

- Bus name
- Endpoint provider address
- Target transport chain
- Messaging engine name

- Any other required connection and destination properties
- One or more destination names

The general approach to deploying the resource adapter is to write a deployment XML file to configure the required and optional properties for the JMS connection factory and JMS resources that will be accessed, and then deploy the resource adapter by using the deployment XML file. The installation process varies, depending on the particular application server that you are using. Before starting this task, see the documentation specific to your application server for information about how to install and use a JMS resource adapter RAR file.

About this task

An enterprise application that looks up a Resource Adapter for JMS with WebSphere Application Server connection factory in the local Java Naming and Directory Interface (JNDI) repository can access service integration resources through the resource adapter, provided that the required messaging engine is available in WebSphere Application Server. All outbound connections must access all queues and topics by using Queue or Topic resources. These resources are configured using your particular application server configuration mechanism when the resource adapter is deployed.

The Resource Adapter for JMS with WebSphere Application Server supports full two-phase XA transactional connections (except under the JBoss Application Server) but can also be run using local transactions or no transaction connections.

Multiple deployments of the resource adapter are possible.

Procedure

1. To deploy an outbound JMS resource on the Resource Adapter for JMS with WebSphere Application Server, use your particular application server configuration mechanism to configure the following service integration bus properties:
   - Bus name
   - Provider endpoints
2. If you want to use XA resources over a Resource Adapter for JMS with WebSphere Application Server connection, use your particular application server configuration mechanism to configure the following additional service integration bus properties:
   - Target type must be set to "ME"
   - Target significance must be set to "Required"
   - Target must be set to the name of the required messaging engine

   These properties permit the recovery of indoubt transactions, should this be necessary. For further information about indoubt transactions, see ../ae/tjm0165_.dita.

   See “Configuration properties for the Resource Adapter for JMS with WebSphere Application Server” on page 607 for a description of these property names and other properties that might also be configured.

Results

Subsequent usage of the resource adapter is in accordance with the Java EE programming specifications. That is, any enterprise bean or message-driven bean might obtain a Resource Adapter for JMS with WebSphere Application Server connection factory or use an activation specification to connect to a service integration messaging engine. Message-driven beans behave in just the same way as they would in any other Java EE environment.

What to do next

You can turn trace and First Failure Data Capture (FFDC) on for the resource adapter in the same way as for the Thin Client for JMS with WebSphere Application Server. For further information, see “Adding tracing and logging for stand-alone clients” on page 602.

You can configure secure connections by configuring connection factories that require a secure bootstrap and/or connection transport chain in the same way as for the Thin Client for JMS with WebSphere Application Server. For further information, see “Securing JMS client and JMS resource adapter connections” on page 601.

Configuration properties for the Resource Adapter for JMS with WebSphere Application Server:

As part of deploying the Resource Adapter for JMS with WebSphere Application Server, you must configure a set of JMS resources that the deployed resource adapter instance supports.

The following tables list the JMS properties and their values.

Note: Not all properties available to applications running inside the WebSphere Application Server environment are available in third party environments. Some properties have no meaning outside of the WebSphere Application Server environment and some have no meaning for remotely connected clients.

Table 55. Connection factory properties. The first column of the table lists the connection factory property names. The second column provides the description of the properties. The third column provides the permitted values for the properties if they are available. The fourth column includes the default values if they are available for the properties.

Property name	Description	Permitted values	Default
BusName	The name of the service integration bus to connect to.		
ClientID	The JMS client identifier needed for durable topic subscriptions on all connections created using this connection factory.		
UserName			
Password			
NonPersistentMapping	The reliability applied to nonpersistent JMS messages sent using this connection factory.	BestEffortNonPersistent, ExpressNonPersistent, ReliableNonPersistent	ExpressNonPersistent
PersistentMapping	The reliability applied to persistent JMS messages sent using this connection factory.	ReliablePersistent, AssuredPersistent	ReliablePersistent
DurableSubscriptionHome	The name of the messaging engine used to store messages delivered to durable subscriptions for objects created from this JMS connection factory.		
ReadAhead	Read ahead is an optimization that preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.	AlwaysOn, AlwaysOff, Default	Default

Table 55. Connection factory properties (continued). The first column of the table lists the connection factory property names. The second column provides the description of the properties. The third column provides the permitted values for the properties if they are available. The fourth column includes the default values if they are available for the properties.

Property name	Description	Permitted values	Default
Target	The name of a target that identifies a group of messaging engines. Specify the type of target by using the Target type property.		
TargetType	The type of target named in the Target property.	BusMember, Custom, ME	BusMember
TargetSignificance	The significance of the target group.	Required, Preferred	Required
TargetTransportChain	The name of the protocol that resolves to a group of messaging engines.		
ProviderEndpoints	The list of comma separated endpoints used to connect to a bootstrap server.		
ConnectionProximity	The proximity of messaging engines that can accept connection requests, in relation to the bootstrap messaging engine.	Server, Cluster, Host, Bus	Bus
TemporaryQueueNamePrefix	The prefix of up to twelve characters used for names of temporary queues created by applications that use this connection factory.		
TemporaryTopicNamePrefix	The prefix used at the start of temporary topics created by applications that use this connection factory.		
ShareDurableSubscriptions	Controls whether durable subscriptions are shared across connections with members of a server cluster.	InCluster, AlwaysShared, NeverShared	InCluster (always resolves to AlwaysOff as the client is always outside of a WebSphere Application Server clustered server)
ProducerDoesNotModify PayloadAfterSet	When enabled, Object or Bytes messages sent by a message producing application that has connected to the bus by using this connection factory will not have their data copied when set and the system will only serialize the message data when absolutely necessary. Applications sending such messages must not modify the data once it has been set into the message.	true, false	false

Table 56. Queue Connection factory properties. The first column of the table lists the queue connection factory property names. The second column provides the description of the properties. The third column provides the permitted values for the properties if they are available. The fourth column includes the default values if they are available for the properties.

Property name	Description	Permitted values	Default
BusName	The name of the service integration bus to connect to.		

Table 56. Queue Connection factory properties (continued). The first column of the table lists the queue connection factory property names. The second column provides the description of the properties. The third column provides the permitted values for the properties if they are available. The fourth column includes the default values if they are available for the properties.

Property name	Description	Permitted values	Default
UserName			
Password			
NonPersistentMapping	The reliability applied to nonpersistent JMS messages sent using this connection factory.	BestEffortNonPersistent, ExpressNonPersistent, ReliableNonPersistent	ExpressNonPersistent
PersistentMapping	The reliability applied to persistent JMS messages sent using this connection factory.	ReliablePersistent, AssuredPersistent	ReliablePersistent
ReadAhead	Read ahead is an optimization that preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.	AlwaysOn, AlwaysOff, Default	Default
Target	The name of a target that identifies a group of messaging engines. Specify the type of target by using the Target type property.		
TargetType	The type of target named in the Target property.	BusMember, Custom, ME	BusMember
TargetSignificance	The significance of the target group.	Required, Preferred	Required
TargetTransportChain	The name of the protocol that resolves to a group of messaging engines.		
ProviderEndpoints	The list of comma separated endpoints used to connect to a bootstrap server.		
ConnectionProximity	The proximity of messaging engines that can accept connection requests, in relation to the bootstrap messaging engine.	Server, Cluster, Host, Bus	Bus
TemporaryQueueNamePrefix	The prefix of up to twelve characters used for names of temporary queues created by applications that use this connection factory.		
ProducerDoesNotModify PayloadAfterSet	When enabled, Object or Bytes messages sent by a message producing application that has connected to the bus by using this connection factory will not have their data copied when set and the system will only serialize the message data when absolutely necessary. Applications sending such messages must not modify the data once it has been set into the message.	true, false	false

Table 57. Topic Connection factory properties. The first column of the table lists the topic connection factory property names. The second column provides the description of the topic connection factory properties. The third column provides the permitted values for the properties if they are available. The fourth column includes the default values if they are available for the properties.

Property name	Description	Permitted values	Default
BusName	The name of the service integration bus to connect to.		
ClientID	The JMS client identifier needed for durable topic subscriptions on all connections created by using this connection factory.		
UserName			
Password			
NonPersistentMapping	The reliability applied to nonpersistent JMS messages sent using this connection factory.	BestEffortNonPersistent, ExpressNonPersistent, ReliableNonPersistent	ExpressNonPersistent
PersistentMapping	The reliability applied to persistent JMS messages sent using this connection factory.	ReliablePersistent, AssuredPersistent	ReliablePersistent
DurableSubscriptionHome	The name of the messaging engine used to store messages delivered to durable subscriptions for objects created from this JMS connection factory.		
ReadAhead	Read ahead is an optimization that preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.	AlwaysOn, AlwaysOff, Default	Default
Target	The name of a target that identifies a group of messaging engines. Specify the type of target by using the Target type property.		
TargetType	The type of target named in the Target property.	BusMember, Custom, ME	BusMember
TargetSignificance	The significance of the target group.	Required, Preferred	Required
TargetTransportChain	The name of the protocol that resolves to a group of messaging engines.		
ProviderEndpoints	The list of comma separated endpoints used to connect to a bootstrap server.		
ConnectionProximity	The proximity of messaging engines that can accept connection requests, in relation to the bootstrap messaging engine.	Server, Cluster, Host, Bus	Bus
TemporaryTopicNamePrefix	The prefix used at the start of temporary topics created by applications that use this connection factory.		

Table 57. Topic Connection factory properties (continued). The first column of the table lists the topic connection factory property names. The second column provides the description of the topic connection factory properties. The third column provides the permitted values for the properties if they are available. The fourth column includes the default values if they are available for the properties.

Property name	Description	Permitted values	Default
ShareDurableSubscriptions	Controls whether durable subscriptions are shared across connections with members of a server cluster.	InCluster, AlwaysShared, NeverShared	InCluster (always resolves to AlwaysOff as the client is always outside of a WebSphere Application Server clustered server)
ProducerDoesNotModify PayloadAfterSet	When enabled, Object or Bytes messages sent by a message producing application that has connected to the bus by using this connection factory will not have their data copied when set and the system will only serialize the message data when absolutely necessary. Applications sending such messages must not modify the data once it has been set into the message.	true, false	false

Table 58. Queue properties. The first column of the table lists the queue property names. The second column provides the description of the queue properties. The third column provides the permitted values for the properties if they are available. The fourth column includes the default values if they are available for the properties.

Property name	Description	Permitted values	Default
QueueName	The name of the associated queue on the service integration bus.		
DeliveryMode	The delivery mode for messages sent to this destination. This controls the persistence of messages on this destination.	Application, Persistent, NonPersistent	
TimeToLive	The default length of time in milliseconds from its dispatch time that a message sent to this destination should be kept by the system.		
Priority	The relative priority for messages sent to this destination, in the range 0 to 9, with 0 as the lowest priority and 9 as the highest priority.		
ReadAhead	Read ahead is an optimization that preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.	AlwaysOn, AlwaysOff, AsConnection, Default	AsConnection
BusName	The name of the service integration bus to connect to.		
ScopeToLocalQP	Sets whether the service integration bus queue destination identified by this Queue is dynamically scoped to a single queue point if one exists on the messaging engine that the application is connected to.	On, Off	Off

Table 58. Queue properties (continued). The first column of the table lists the queue property names. The second column provides the description of the queue properties. The third column provides the permitted values for the properties if they are available. The fourth column includes the default values if they are available for the properties.

Property name	Description	Permitted values	Default
ProducerPreferLocal	Sets whether a MessageProducer for this Queue should prefer a locally connected queue point of the service integration bus queue destination over any other queue points.	On, Off	On
ProducerBind	Set whether messages sent by a single MessageProducer to this Queue will go to the same service integration bus queue point, or whether no such restriction will be applied, and different messages will be sent to different queue points.	On, Off	Off
GatherMessages	Set whether messages on all service integration bus queue points or only a single queue point are visible to MessageConsumers and QueueBrowsers that use this Queue.	On, Off	Off

Table 59. Topic properties. The first column of the table lists the topic property names. The second column provides the description of the topic properties. The third column provides the permitted values for the properties if they are available. The fourth column includes the default values if they are available for the properties.

Property name	Description	Permitted values	Default
TopicSpace	The name of the topic space that contains the topic, on the service integration bus defined by the BusName property.		Default.Topic.Space
TopicName	The name of the topic that this JMS topic is assigned to, in the topic space defined by the TopicSpace property		
DeliveryMode	The delivery mode for messages sent to this destination. This controls the persistence of messages on this destination.	Application, Persistent, NonPersistent	
TimeToLive	The default length of time in milliseconds from its dispatch time that a message sent to this destination should be kept by the system.		
Priority	The relative priority for messages sent to this destination, in the range 0 to 9, with 0 as the lowest priority and 9 as the highest priority.		
ReadAhead	Read ahead is an optimization that preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.	AlwaysOn, AlwaysOff, AsConnection, Default	AsConnection
BusName	The name of the service integration bus to connect to.		

Table 60. Activation configuration properties. The first column of the table lists the activation configuration property names. The second column provides the description of the activation configuration properties. The third column provides the permitted values for the properties if they are available. The fourth column includes the default values if they are available for the properties.

Property name	Description	Permitted values	Default	Required/optional
Destination	The name of the destination on the service integration bus.			Required
ProviderEndpoints	The list of comma separated endpoints used to connect to a bootstrap server.			Required
DestinationType	Whether the message-driven bean uses a queue or topic destination.	javax.jms.Queue, javax.jms.Topic		Required
BusName	The name of the service integration bus to connect to.			Required
MessageSelector	The JMS message selector used to determine which messages the message-driven bean receives. The value is a string that is used to select a subset of the available messages. The syntax is based on a subset of the SQL 92 conditional expression syntax, as described in the JMS specification.			Optional
AcknowledgeMode	How the session acknowledges any messages it receives.	Auto-acknowledge, Dups-ok-acknowledge	Auto-acknowledge	Optional
SubscriptionDurability	Whether a JMS topic subscription is durable or nondurable.	Durable, Nondurable	Nondurable	Optional
SubscriptionName	The subscription name needed for durable topic subscriptions. Required field when using a durable topic subscription.			Optional
MaxBatchSize	The maximum number of messages received from the messaging engine in a single batch.	1 through 2147483647	1	Optional
MaxConcurrency	The maximum number of endpoints to which messages are delivered concurrently	1 through 2147483647	10	Optional
RetryInterval	The delay (in seconds) between attempts to connect to a messaging engine.	1 through 2147483647	30	Optional
UserName				Optional

Table 60. Activation configuration properties (continued). The first column of the table lists the activation configuration property names. The second column provides the description of the activation configuration properties. The third column provides the permitted values for the properties if they are available. The fourth column includes the default values if they are available for the properties.

Property name	Description	Permitted values	Default	Required/optional
Password				Optional
DurableSubscriptionHome	The name of the messaging engine used to store messages delivered to durable subscriptions for objects created from this JMS connection factory.			Optional
ShareDurableSubscriptions	Controls whether durable subscriptions are shared across connections with members of a server cluster.	InCluster, AlwaysShared, NeverShared	InCluster (always resolves to AlwaysOff as the client is always outside of a WebSphere Application Server clustered server)	Optional
ClientID	The JMS client identifier needed for durable topic subscriptions on all connections created by using this connection factory.			Optional
TargetTransportChain	The name of the protocol that resolves to a group of messaging engines.			Optional
ReadAhead	Read ahead is an optimization that preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.	AlwaysOn, AlwaysOff, Default	Default	Optional
Target	The name of a target that identifies a group of messaging engines. Specify the type of target by using the Target type property.			Optional
TargetType	The type of target named in the Target property.	BusMember, Custom, ME	BusMember	Optional
TargetSignificance	This property specifies the significance of the target group.	Required, Preferred	Required	Optional
TopicSpace	The name of the topic space that contains the topic, on the service integration bus defined by the BusName property.		Default.Topic.Space	Optional

Table 60. Activation configuration properties (continued). The first column of the table lists the activation configuration property names. The second column provides the description of the activation configuration properties. The third column provides the permitted values for the properties if they are available. The fourth column includes the default values if they are available for the properties.

Property name	Description	Permitted values	Default	Required/optional
ForwarderDoesNotModify PayloadAfterSet	When enabled, Object/Bytes messages forwarded through this activation specification that have their payload modified will not have the data copied when it is set into the message and the system will only serialize the message data when absolutely necessary. Applications sending such messages must not modify the data once it has been set into the message.	true, false	false	Optional

Deploying inbound connections for the Resource Adapter for JMS with WebSphere Application Server

When deploying inbound connections, you must configure message-driven beans to use the Resource Adapter for JMS with WebSphere Application Server. A JMS activation configuration associated with one or more message-driven beans provides the configuration necessary for them to receive messages.

About this task

You can deploy message-driven beans within your application with a JMS activation configuration to access the Resource Adapter for JMS with WebSphere Application Server connection factories and destinations. When the message-driven bean is started, it uses the resource adapter to connect to the service integration bus, provided that the required messaging engine is available in WebSphere Application Server.

The Resource Adapter for JMS with WebSphere Application Server supports full two-phase XA transactional connections but it might also be run using local transactions or no transaction connections.

Procedure

1. Configure the following properties for the activation configuration:
   - Destination
   - ProviderEndpoints
   - DestinationType
   - BusName

   The Destination property value is the name of the destination from which the message-driven bean will be receiving messages.

   See “Configuration properties for the Resource Adapter for JMS with WebSphere Application Server” on page 607 for a description of these property names and other properties that might also be configured.
2. Configure the following additional properties if the message-driven bean will use XA resources over the Resource Adapter for JMS with WebSphere Application Server connection.
   - TargetType must be set to "ME"
   - TargetSignificance must be set to "Required"
   - Target value must be the name of the required ME

See “Configuration properties for the Resource Adapter for JMS with WebSphere Application Server” on page 607 for a description of these property names and other properties that might also be configured.

These properties permit the recovery of indoubt transactions, should this be necessary. For further information about indoubt transactions, see ../ae/tjm0165_.dita.

Default messaging provider [Settings]

A JMS provider enables messaging based on the Java Messaging Service (JMS). It provides Java EE connection factories to create connections for JMS destinations. This panel is used to manage the default messaging provider and its JMS resources.

To view this page in the console, click the following path:

Resources -> JMS -> JMS providers -> *a_messaging_provider*.

The default messaging provider uses service integration technologies to supply the messaging infrastructure. For example, the JMS queues and topics are assigned to destinations on a service integration bus.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Scope:

Specifies the highest topological level at which application servers can use this resource object.

Required	No
Data type	String

Name:

The name of the resource provider.

Required	No
Data type	String

Description:

A description of the resource adapter.

Required	No
Data type	Text area

JMS activation specification [Settings]

A JMS activation specification is associated with one or more message-driven beans and provides the configuration necessary for them to receive messages.

To view this page in the console, click one of the following paths:

- **Resources -> JMS -> Activation specifications -> *activation_specification_name***
- **Resources -> JMS -> JMS providers -> *a_messaging_provider* -> [Additional Properties] Activation specifications -> *activation_specification_name***

Use this panel to browse or change the configuration properties of the selected JMS activation specification for use with the default messaging provider.

You create a JMS activation specification if you want to use a message-driven bean to communicate with the default messaging provider through Java EE Connector Architecture (JCA) 1.5. JCA provides Java connectivity between application servers such as WebSphere Application Server, and enterprise information systems. It provides a standardized way of integrating JMS providers with Java EE application servers, and provides a framework for exchanging data with enterprise systems, where data is transferred in the form of messages.

All the activation specification configuration properties apart from **Name**, **JNDI name**, **Destination JNDI name**, and **Authentication alias** are overridden by appropriately named activation-configuration properties in the deployment descriptor of an associated EJB 2.1 or later message-driven bean. For an EJB 2.0 message-driven bean, the **Destination type**, **Subscription durability**, **Acknowledge mode** and **Message selector** properties are overridden by the corresponding elements in the deployment descriptor. For either type of bean the **Destination JNDI name** property can be overridden by a value specified in the message-driven bean bindings.

The activation specification properties influence how the default messaging provider chooses the messaging engine to which your message-driven bean application connects. By default, the environment automatically connects applications to an available messaging engine on the bus. However you can specify extra configuration details to influence the connection process; for example to identify special bootstrap servers, or to limit connection to a subgroup of available messaging engines, or to improve availability or performance, or to ensure sequential processing of messages received. For information about why and how to do this, see the topic How JMS applications connect to a messaging engine on a bus.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Scope:

Specifies the highest topological level at which application servers can use this resource object.

Required	No
Data type	String

Provider:

Specifies a JMS provider, which enables asynchronous messaging based on the Java Message Service (JMS). It provides J2EE connection factories to create connections for specific JMS queue or topic destinations. JMS provider administrative objects are used to manage JMS resources for the associated JMS provider.

Required No
Data type String

Name:

The required display name for the resource.

Required Yes
Data type String

JNDI name:

The JNDI name for the resource.

Type the JNDI name that is specified in the bindings for message-driven beans associated with this activation specification.

Required Yes
Data type String

Description:

An optional description for the resource.

Required No
Data type Text area

Destination type:

Whether the message-driven bean uses a queue or topic destination.

Required Yes
Data type drop-down list
Range

Queue The message-driven bean uses a JMS queue. The JNDI name of the JMS queue is specified on the **Destination JNDI name** property.

Topic The message-driven bean uses a JMS topic. The JNDI name of the JMS topic is specified on the **Destination JNDI name** property.

Destination JNDI name:

JNDI Name of destination

Type the JNDI name that the message-driven bean uses to look up the JMS destination in the JNDI namespace.

Select the type of destination on the “Destination type” on page 618 property.

Required	Yes
Data type	String

Message selector:

The JMS message selector used to determine which messages the message-driven bean receives. The value is a string that is used to select a subset of the available messages. The syntax is based on a subset of the SQL 92 conditional expression syntax, as described in the JMS specification. Refer to the information center for more information.

For example:

```
JMSType='car' AND color='blue' AND weight>2500
```

The selector string can refer to fields in the JMS message header and fields in the message properties. Message selectors cannot reference message body values.

A null value (an empty string) indicates that there is no message selector for the message consumer.

Required	No
Data type	String

Bus name:

The name of the bus to connect to.

Type the name of the service integration bus to which connections are made. This must be the name of the bus on which the destination identified by the “Destination JNDI name” on page 618 property is defined.

Required	No
Data type	Custom

Acknowledge mode:

How the session acknowledges any messages it receives.

The acknowledge mode indicates how a message received by a message-driven bean should be acknowledged.

Note:

The acknowledgement is sent when the message is deleted.

If you have a non-transactional message-driven bean, the system either deletes the message when the bean starts, or when the bean completes. If the bean generates an exception, and therefore does not complete, the system takes one of the following actions:

- If the system is configured to delete the message when the bean completes, then the message is despatched to a new instance of the bean, so the message has another opportunity to be processed.
- If the system is configured to delete the message when the bean starts, then the message is lost.

The message is deleted when the bean starts if the quality of service is set to Best effort nonpersistent. For all other qualities of service, the message is deleted when the bean completes.

Required No
Data type drop-down list
Range

Auto-acknowledge
The session automatically acknowledges the delivery of a message.

Duplicates-ok auto-acknowledge
The session lazily acknowledges the delivery of messages, which can improve performance, but can lead to a message-driven bean receiving a message more than once.

Target:

The name of a target that identifies a group of messaging engines. Specify the type of target using the Target type property.

Required No
Data type String

Target type:

The type of target named in the Target property.

Required No
Data type drop-down list
Range

Bus member name
The name of a bus member. This option retrieves the active messaging engines that are hosted by the named bus member (an application server or server cluster).

Custom messaging engine group name
The name of a custom group of messaging engines (that form a self-declaring cluster). This option retrieves the active messaging engines that have registered with the named custom group.

Messaging engine name
The name of a messaging engine. This option retrieves the available endpoints that can be used to reach the named messaging engine.

Target significance:

This property specifies the significance of the target group.

Required No
Data type drop-down list

Range

Preferred
It is preferred that a messaging engine is selected from the target group. A messaging engine in the target group is selected if one is available. If a messaging engine is not available in the target group, a messaging engine outside the target group is selected if available in the same service integration bus.

Required
It is required that a messaging engine is selected from the target group. A messaging engine in the target group is selected if one is available. If a messaging engine is not available in the target group, the connection process fails.

Target inbound transport chain:

The name of the inbound transport chain that the application should target when connecting to a messaging engine in a separate process to the application. If a messaging engine in another process is chosen, a connection can be made only if the messaging engine is in a server that runs the specified inbound transport chain. Refer to the information center for more information.

If the selected messaging engine is in the same server as the application, a direct in-process connection is made and this transport chain property is ignored.

The transport chains represent network protocol stacks operating within a server. The name you specify must be one of the transport chains available in the server that hosts the messaging engine, as listed on the **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] Messaging engine inbound transports** panel. The following transport chains are provided, but you can define your own transport chains on that panel.

InboundBasicMessaging
This is a connection-oriented protocol that uses a standard TCP/IP connection (JFAP-TCP/IP). It includes support for two-phase transactional (remote XA) flows, so that a message producer or consumer, running on a client or server system, can participate in a global transaction managed on that client or server system. The specific use for the XA flows is to support access from an application running in one server to a messaging engine on second server, perhaps because the first server does not have a suitable messaging engine. If the remote XA flows are used, a transaction coordinator must be available local to the application.

InboundSecureMessaging
This is the InboundBasicMessaging protocol wrapped in SSL.

For more information about using this property with other connection factory properties for workload management of connections, see the topic Administrative properties for JMS connections to a bus.

Required No
Data type String

Provider endpoints:

A comma-separated list of endpoint triplets, with the syntax hostName:portNumber:chainName, used to connect to a bootstrap server. For example Merlin:7276:BootstrapBasicMessaging,Gandalf:5557:BootstrapSecureMessaging.

Provider endpoints are not used unless the specified bus cannot be found in the local cell. Message-driven bean (MDB) applications first attempt to connect the specified bus in the local cell. If this attempt fails, provider endpoints are used to allow the applications to consume messages from a remote cell.

If the host name is not specified, `localhost` is used as a default value.

If the port number is not specified, `7276` is used as the default value.

If the protocol is not specified, a predefined chain such as `BootstrapBasicMessaging` is used as the default value.

Required	No
Data type	Text area

Maximum batch size:

The maximum number of messages received from the messaging engine in a single batch.

The maximum number of messages in a single batch delivered serially to a single message-driven bean instance. Batching of messages can improve performance particularly when used with Acknowledge mode set to Duplicates-ok auto-acknowledge. If message-ordering must be retained across failed deliveries, set the batch size to `1`.

Required	No
Data type	Integer
Range	1 through 2147483647

Maximum concurrent MDB invocations per endpoint:

The maximum number of endpoints to which messages are delivered concurrently.

Increasing this number can improve performance but can increase the number of threads that are in use at any one time. If message ordering must be retained across failed deliveries, set the maximum concurrent endpoints to `1`. Message ordering applies only if the destination that the message-driven bean is consuming from is not a partitioned destination. Partitioned destinations are used in a workload sharing scenario in a cluster.

Required	No
Data type	Integer
Range	1 through 2147483647

Automatically stop endpoints on repeated message failure:

These parameters enable an endpoint to stop automatically when the number of sequentially failing messages reaches a limit that you specify. This helps to distinguish between one or two messages that fail because of problems with the messages themselves, and a system resource problem that results in many sequentially failing messages.

Stopping the endpoint reduces the number of messages being moved unnecessarily to an exception destination when the problem is not caused by messages that are failing to be processed.

When an endpoint is stopped automatically, its Status on the administrative console panel is red. It must be restarted manually by clicking **Resume**.

After an endpoint is restarted, any failing messages that caused the endpoint to be stopped are retried. If they continue to fail they are moved to an exception destination, if configured.

Enable:

Enable automatic stopping of an endpoint based on the parameters below.

Required	No
Data type	Boolean

Sequential failed message threshold:

The endpoint will be stopped when the number of sequentially failing messages reaches the configured limit. Due to processing dependencies in the MDB the actual number of messages processed may exceed this value.

This property is not enabled unless the Automatically stop endpoints on repeated message failure property is enabled.

Required	No
Data type	Integer

Delay between failing message retries:

Any message that fails to be processed by the MDB but has not reached its maximum failed delivery limit will only be retried after this period of time (in milliseconds) has passed. Other messages may be tried during this period, unless the sequential failure threshold and the maximum concurrency is set to 1.

Setting a delay between failing message retries reduces the number of messages unnecessarily moved to the exception destination before the MDB is stopped. To minimize the number of messages that are moved, make this delay greater than the expected time interval between messages arriving on the destination.

This property is not enabled unless the Automatically stop endpoints on repeated message failure property is enabled.

Required	No
Data type	Integer
Range	The time in milliseconds. A value of `0` indicates no delay between retries.

Subscription durability:

Whether a JMS topic subscription is durable or nondurable

Usually, only one application at a time can have a consumer for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers.

Required	No
Data type	drop-down list

Range

Durable
The messaging provider stores messages while the message-driven bean is not available, and delivers the messages when the message-driven bean becomes available again.

Nondurable
The messaging provider does not store and redeliver messages if a message-driven bean is not available.

Subscription name:

The subscription name needed for durable topic subscriptions. Required field when using a durable topic subscription.

Each JMS durable subscription is identified by a subscription name (specified on this property). A JMS connection also has an associated client identifier (specified on the Client identifier property), which is used to associate a connection and its objects with the list of messages (on the durable subscription) that is maintained by the JMS provider for the client.

This subscription name must be unique within a given client identifier.

Required No
Data type String

Client identifier:

The JMS client identifier needed for durable topic subscriptions on all connections created using this activation specification.

The value specified is a unique identifier for a client (message-driven bean). The client identifier is used to associate a client connection with the list of messages (on a durable subscription) that the messaging provider keeps for the client. When a client becomes available again, after a being unavailable, the messaging provider uses the client identifier to redeliver stored messages to the correct client.

Required No
Data type String

Durable subscription home:

The name of the messaging engine used to store messages delivered to durable subscriptions for objects created from this JMS activation specification. This is a required field when using a durable topic subscription.

Administrators can manage the runtime state of durable subscriptions through publication points for this messaging engine.

Required No
Data type String

Pass message payload by reference:

When large object messages or bytes messages are sent, the cost in memory and processor use of serializing, deserializing, and copying the message payload can be significant.If you enable the **pass message payload by reference** properties on a connection factory or activation specification, you tell the default messaging provider to override the JMS 1.1 specification and potentially reduce or bypass this data copying.

CAUTION:
The parts of the JMS Specification that are bypassed by these properties are defined to ensure message data integrity. Any of your JMS applications that use these properties must strictly follow the rules that are described in the topic Why and when to pass the JMS message payload by reference, or you risk losing data integrity.

Applications that use this activation specification to receive messages must obey the following rule::

- The application does not modify the data object obtained from a JMS object message. The data object is treated as read only.

When enabled, Object Messages received through this activation spec will only have their message data serialized by the system when absolutely necessary. The data obtained from those messages must be treated as readOnly by applications.

Required	No
Data type	Boolean

Applications resending messages that were originally received using this activation specification must obey the following rules::

- The application can replace the data object in a JMS object message, provided that the data object has not yet been set in the message. The application does not modify or replace the data object after it is set in the message.
- The application can replace the byte array in a JMS bytes message, but only by using a single call to writeBytes(byte[]), and provided that the byte array has not yet been set in the message. The application does not modify or replace the byte array after it is set in the message.

When enabled, Object/Bytes Messages forwarded through this activation specification that have their payload modified will not have the data copied when it is set into the message and the system will only serialize the message data when absolutely necessary. Applications sending such messages must not modify the data once it has been set into the message.

Required	No
Data type	Boolean

Share durable subscriptions:

Controls whether or not durable subscriptions are shared across connections with members of a server cluster.

Usually, only one session at a time can have a TopicSubscriber for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers, one on each application server in the server cluster.

This option should be changed from its default only in WebSphere Application Server environments that support server clusters.

Required	No

Data type drop-down list

Range

In cluster
Allows sharing of durable subscriptions when connections are made from within a server cluster.

Always shared
Durable subscriptions can be shared across connections.

Never shared
Durable subscriptions are never shared across connections.

Share data source with CMP:

Allow sharing of connections between JMS and container-managed persistence (CMP) entity beans.

This option is used as part of the task to enable container-managed persistence (CMP) entity beans to share the database connections used by the data store of a messaging engine. This has been estimated as a potential performance improvement of 15% for overall message throughput, but can only be used for entity beans connected to the application server that contains the messaging engine.

For more information about using this option, see the topic Enabling CMP entity beans and messaging engine data stores to share database connections.

Required No
Data type Boolean

Read ahead:

Read ahead is an optimization that preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.

Messages that are assigned to a consumer are locked on the server and cannot be consumed by any other consumers for that destination. Messages that are assigned to a consumer, but not consumed before that consumer is closed, are subsequently unlocked on the server and then available for receipt by other consumers.

You can override this property for individual JMS destinations by setting the **Read ahead** property on the JMS destination.

Required No
Data type drop-down list

Range

Default The message provider preemptively assigns messages to consumers on nondurable subscriptions and unshared durable subscriptions. That is, read ahead optimization is turned on only when there can only be a single consumer.

Enabled
The messaging provider preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.

Disabled
The messaging provider does not preemptively assign messages to consumers.

Always activate MDBs in all servers:

This property is only used when the MDB application is running on a server that is a member of the bus that the application is targeting. It has no effect when the MDB is running on a server that is not a member of the target bus.

If the MDB application is running on a server that is a member of the target bus, enabling this option allows the MDB application to process messages whether or not the server also hosts a running messaging engine. If this option is not enabled, then MDB applications on servers that do not have a local ME running do not process messages.

Required No
Data type Boolean

Retry interval:

The delay (in seconds) between attempts to connect to a messaging engine, both for the initial connection, and any subsequent attempts to establish a better connection.

Required No
Data type Integer
Range 1 through 2147483647

Authentication alias

The name of a J2C authentication alias used for component-managed authentication of connections to the service integration bus.

A Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) authentication alias specifies the user ID and password that is used to authenticate the creation of a new connection to the JMS provider.

Required No
Data type drop-down list

Related Items

JAAS - J2C authentication data
Specifies a list of user identities and passwords for Java 2 connector security to use.

Buses
A service integration bus supports applications using message-based and service-oriented architectures. A bus is a group of interconnected servers and clusters that have been added as members of the bus. Applications connect to a bus at one of the messaging engines associated with its bus members.

Default messaging provider unified connection factory [Settings]

A JMS connection factory is used to create connections to the associated JMS provider of JMS destinations, for both point-to-point and publish/subscribe messaging. Use connection factory administrative objects to manage JMS connection factories for the default messaging provider.

To view this page in the console, click one of the following paths:

- **Resources -> JMS -> Connection factories -> *factory_name***
- **Resources -> JMS -> JMS providers -> *a_messaging_provider* -> [Additional Properties] Connection factories -> *factory_name***

Set, browse or change the configuration properties of a JMS connection factory for use with the default messaging JMS provider. These configuration properties control how connections are created to associated JMS queues and topics.

By default, connections created by using this JMS connection factory in the server containers (for example, from an enterprise bean) are pooled by using Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) connection pooling. You can modify the connection pool settings for this connection factory by selecting **Connection pool properties** in the Additional properties section of the administrative console panel.

The connection factory properties influence how the default messaging provider chooses the messaging engine to which your JMS application connects. By default, the environment automatically connects applications to an available messaging engine on the bus. However you can specify extra configuration details to influence the connection process; for example to identify special bootstrap servers, or to limit connection to a subgroup of available messaging engines, or to improve availability or performance, or to ensure sequential processing of messages received. For information about how to do this, see the topic Configuring the messaging engine selection process for JMS applications.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Scope:

Specifies the highest topological level at which application servers can use this resource object.

Required	No
Data type	String

Provider:

Specifies a JMS provider, which enables asynchronous messaging based on the Java Message Service (JMS). It provides J2EE connection factories to create connections for specific JMS queue or topic destinations. JMS provider administrative objects are used to manage JMS resources for the associated JMS provider.

Required	No
Data type	String

Name:

The required display name for the resource.

Required	Yes
Data type	String

JNDI name:

The JNDI name for the resource.

Required	Yes
Data type	String

Description:

An optional description for the resource.

Required	No
Data type	Text area

Category:

An optional category string to use when classifying or grouping the resource.

Required	No
Data type	String

Bus name:

The name of the service integration bus to connect to.

Enter the name of the local bus in situations where an application makes connection to foreign buses.

Required	Yes
Data type	Custom

Target:

The name of a target that identifies a group of messaging engines. Specify the type of target using the Target type property.

Before the connection proximity search is performed to select a suitable messaging engine, the set of messaging engines that are members of the specified target group are selected. The connection proximity

search is then restricted to these messaging engines. If a target group is not specified (the default), then all messaging engines in the bus are considered during the connection proximity search.

For example, if the Target type property is set to Bus member name, the Target property specifies the name of the bus member from which suitable messaging engines can be chosen.

Required No
Data type String

Target type:

The type of target named in the Target property.

Required No
Data type drop-down list
Range

Bus member name
The name of a bus member. This option retrieves the active messaging engines that are hosted by the named bus member (an application server or server cluster).

To specify a non-clustered bus member the Target property must be set to `<Node01>.<server1>`, for example Node01.server1. For a cluster bus member the Target property must be set to the cluster name.

Custom messaging engine group name
The name of a custom group of messaging engines (that form a self-declaring cluster). This option retrieves the active messaging engines that have registered with the named custom group.

Messaging engine name
The name of a messaging engine. This option retrieves the available endpoints that can be used to reach the named messaging engine.

Target significance:

This property specifies the significance of the target group.

This property defines whether the connection proximity search is restricted to only the messaging engines in the target group.

Required No
Data type drop-down list

Range

Preferred

It is preferred that a messaging engine is selected from the target group. A messaging engine in the target group is selected if one is available. If a messaging engine is not available in the target group, a messaging engine outside the target group is selected if available in the same service integration bus.

Note: A connection to a non-preferred target might be returned even if a preferred one is available. This can happen when connection pooling is enabled for a ConnectionFactory, which it is by default when you use a JMS ConnectionFactory in a server environment:

- When a preferred messaging engine is not available, a connection to a non-preferred one can be created and stored in the connection pool.
- The next time the application requests a connection it receives this pooled connection even if the preferred messaging engine has subsequently become available.

You can modify the connection pool settings to regularly discard all unused connections in the pool. After the connection pool is emptied, connections are made to the preferred messaging engine if one is available. For example, set the **ReapTime**, **AgedTimeout** and **UnusedTimeout** to 300 seconds, and the **PurgePolicy** to EntirePool. This refreshes the connection pool every 5 minutes, after which time the application selects a preferred messaging engine if one is available.

Required

It is required that a messaging engine is selected from the target group. A messaging engine in the target group is selected if one is available. If a messaging engine is not available in the target group, the connection process fails.

Target inbound transport chain:

The name of the inbound transport chain that the application should target when connecting to a messaging engine in a separate process to the application. If a messaging engine in another process is chosen, a connection can be made only if the messaging engine is in a server that runs the specified inbound transport chain. Refer to the information center for more information.

These transport chains specify the communication protocols that can be used to communicate with the application server to which the client application is connected.

If the selected messaging engine is in the same server as the application, a direct in-process connection is made and this transport chain property is ignored.

The transport chains represent network protocol stacks operating within a server. The name you specify must be one of the transport chains available in the server that hosts the messaging engine, as listed on the **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] Messaging engine inbound transports** panel. The following transport chains are provided, but you can define your own transport chains on that panel.

InboundBasicMessaging
This is a connection-oriented protocol that uses a standard TCP/IP connection (JFAP-TCP/IP). It includes support for two-phase transactional (remote XA) flows, so that a message producer or consumer, running on a client or server system, can participate in a global transaction managed on that client or server system. The specific use for the XA flows is to support access from an application running in one server to a messaging engine on second server, perhaps because the first server does not have a suitable messaging engine. If the remote XA flows are used, a transaction coordinator must be available local to the application.

InboundSecureMessaging
This is the InboundBasicMessaging protocol wrapped in SSL.

For more information about using this property with other connection factory properties for workload management of connections, see the topic Administrative properties for JMS connections to a bus.

Required	No
Data type	String

Provider endpoints:

A comma-separated list of endpoint triplets, with the syntax hostName:portNumber:chainName, used to connect to a bootstrap server. For example Merlin:7276:BootstrapBasicMessaging,Gandalf:5557:BootstrapSecureMessaging. If hostName is not specified, the default is localhost. If portNumber is not specified, the default is 7276. If chainName is not specified, the default is BootstrapBasicMessaging. Refer to the information center for more information.

You only have to modify this property if you have client applications running outside of an application server, or applications on a server in another cell, that want to use this connection factory to connect to the target service integration bus specified on the connection factory.

To use JMS destinations of the default messaging provider, an application connects to a messaging engine on the target service integration bus to which the destinations are assigned. For example, a JMS queue is assigned to a queue destination on a service integration bus.

Client applications running outside of an application server - for example, running in a client container or outside the WebSphere Application Server environment - cannot locate directly a suitable messaging engine to connect to in the target bus. Similarly, an application running on a server in one cell to connect to a target bus in another cell cannot locate directly a suitable messaging engine to connect to in the target bus.

In these scenarios, the clients (or servers in another bus) must complete a bootstrap process through a *bootstrap server* that is a member of the target bus. A bootstrap server is an application server running the SIB Service, but does not have to be running any messaging engines. The bootstrap server selects a messaging engine that is running in an application server that supports the required *target transport chain*. For the bootstrap process to be possible, you must configure one or more *provider end points* in the connection factory used by the client.

A bootstrap server uses a specific port and bootstrap transport chain. The port is the **SIB_ENDPOINT_ADDRESS** (or **SIB_ENDPOINT_SECURE_ADDRESS** if security is enabled), of the messaging engine that hosts the remote end of the link. Together with host name, these form the *endpoint address* of the bootstrap server.

The properties of a JMS connection factory used by an application control the selection of a suitable messaging engine and how the application connects to the selected messaging engine.

- If no security credentials are provided, then by default
  - If no host is specified then localhost is used
  - If no port is specified then port 7276 is used
  - If no bootstrap channel chain is specified then bootstrap transport chain called BootstrapBasicMessaging is used
- If security credentials are provided, then by default
  - If no host is specified then localhost is used
  - If no port is specified then port 7286 is used
  - If no bootstrap channel chain is specified then bootstrap transport chain called BootstrapBasicMessaging is used

Note: For the IBM i platform, you must (at least) change the default host name from localhost to *your.server.name*.

If you want an application to use a bootstrap server with a different endpoint address, you must specify the required endpoint address on the **Provider endpoints** property of the JMS connection factories that the client application uses. You can specify one or more endpoint addresses of bootstrap servers.

The endpoint addresses for bootstrap servers must be specified in every JMS connection factory that is used by applications outside of an application server. To avoid having to specify a long list of bootstrap servers, you can provide a few highly-available servers as dedicated bootstrap servers. Then you only have to specify a short list of bootstrap servers on each connection factory.

Note: When configuring a connection to a non-default bootstrap server, specify the required values for the endpoint address and use colons as separators.

For example: for a server assigned non-secure port 7278, on host boothost1, that uses the default transport chain BootstrapBasicMessaging:

```
boothost1:7278:BootstrapBasicMessaging
or
boothost1:7278
```

and for a server assigned secure port 7289, on host boothost2, that uses the predefined transport chain BootstrapTunneledSecureMessaging:

```
boothost2:7289:BootstrapTunneledSecureMessaging
```

The syntax for an endpoint address is as follows:

```
[ [host_name] [ ":" [port_number] [ ":" chain_name] ] ]
```

where:

host_name
: is the name of the host on which the server runs. It can be an IP address. For an IPv6 address, put square braces ([]) around *host_name* as shown in the example below:

  ```
  [2002:914:fc12:179:9:20:141:42]:7276:BootstrapBasicMessaging
  ```

  . If a value is not specified, the default is localhost.

Note: For the IBM i platform, you must (at least) change the default host name from localhost to *your.server.name*.

port_number
where specified, is one of the following addresses of the messaging engine that hosts the remote end of the link:

- **SIB_ENDPOINT_ADDRESS** if security is not enabled
- For secure connections, **SIB_ENDPOINT_SECURE_ADDRESS** if security is enabled.

If *port_number* is not specified, the default is 7276.

To find either of these values by using the administrative console, click **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Communications] Ports**.

chain_name
is the name of a predefined bootstrap transport chain used to connect to the bootstrap server. If not specified, the default is BootstrapBasicMessaging.

The following predefined bootstrap transport chains are provided:

BootstrapBasicMessaging
This corresponds to the server transport chain InboundBasicMessaging (JFAP-TCP/IP)

BootstrapSecureMessaging
This corresponds to the server transport chain InboundSecureMessaging (JFAP-SSL-TCP/IP)

BootstrapTunneledMessaging
Before you can use this bootstrap transport chain, you must define a corresponding server transport chain on the bootstrap server. (See **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] Messaging engine inbound transports**.) This transport chain tunnels JFAP and uses HTTP wrappers.

BootstrapTunneledSecureMessaging
Before you can use this bootstrap transport chain, you must define a corresponding server transport chain on the bootstrap server. (See**Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] Messaging engine inbound transports**.) This transport chain tunnels JFAP and uses HTTP wrappers.

Specifying *host_name* : *chain_name* instead of *host_name* : : *chain_name* (with two colons) is incorrect. It is valid to enter nothing, or to enter any of the following: "a", "a:", ":7276", "::chain", and so on. The default value applies if you do not specify a value, but you must separate the fields with ":"s.

If you want to provide more than one bootstrap server, identify all the required endpoint addresses. Separate each endpoint address by a comma character. For example, to use the servers from the earlier example:

```
boothost1:7278:BootstrapBasicMessaging,
  boothost2:7289:BootstrapTunneledSecureMessaging,
  [2002:914:fc12:179:9:20:141:42]:7276:BootstrapBasicMessaging
```

Required	No
Data type	Text area

Connection proximity:

The proximity of messaging engines that can accept connection requests, in relation to the bootstrap messaging engine.

When a client issues a client connect request, the processing attaches to the required bus according to the following logic:

- If a target group is specified, connect to the first messaging engine that satisfies the following conditions for the target type:
  - **Server** Look for a messaging engine in the same server.
  - **Cluster** Look for a messaging engine in the same server, then on other servers in the same cluster.
  - **Host** Look for a messaging engine in the same server, then on other servers in the same cluster, then on other servers in the same host.
  - **Bus** Look for a messaging engine in the same server, then on other servers in the same cluster, then on other servers in same host, then any other messaging engine on the same bus.
- If a target group is not specified, or a target group is specified but no suitable messaging engine is found and target significance is Preferred, connect to the first messaging engine that satisfies the following conditions for the target type:
  - **Server** Look for a messaging engine in the same server.
  - **Cluster** Connection fails.
  - **Host** Look for a messaging engine in the same server, then on other servers in the same host.
  - **Bus** Look for a messaging engine in the target group in same server, then on other servers in same host, then any other messaging engine on the same bus.

For more information about using this property with other connection factory properties for workload management of connections, see the topic Administrative properties for JMS connections to a bus.

Required No
Data type drop-down list
Range

Bus Connections can be made to messaging engines in the same bus.

Cluster Connections can be made to messaging engines in the same server cluster.

Host Connections can be made to messaging engines in the same host.

Server Connections can be made to messaging engines in the same application server.

Client identifier:

The JMS client identifier needed for durable topic subscriptions on all connections created using this connection factory. This identifier is required if the application is doing durable pub/sub

Required No
Data type String

Durable subscription home:

The name of the messaging engine used to store messages delivered to durable subscriptions for objects created from this JMS connection factory.

Required No
Data type Custom

Nonpersistent message reliability:

The reliability applied to nonpersistent JMS messages sent using this connection factory.

You can change the delivery reliability option for the destination of a message that is sent by a JMS application as Nonpersistent. The default is Express nonpersistent but you have a range of other options, including those with persistent characteristics, with Assured persistent being the most reliable. For more information see the topic Message reliability levels - JMS delivery mode and service integration quality of service.

Required No

Data type drop-down list

Range

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages might be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

As bus destination
Use the delivery option configured for the bus destination.

Persistent message reliability:

The reliability applied to persistent JMS messages sent using this connection factory.

You can change the delivery reliability option for the destination of a message that is sent by a JMS application as Persistent. The default is Reliable persistent but you have a range of other options including those with nonpersistent characteristics, with Best effort nonpersistent being the least reliable. For more information see the topic Message reliability levels - JMS delivery mode and service integration quality of service.

Important: If you change the delivery reliability options of a message sent by a JMS application from one of the **Persistent message reliability** options (Assured persistent and Reliable persistent) to one of the **Nonpersistent message reliability** options (Best effort nonpersistent, Express nonpersistent, and Reliable nonpersistent), you risk losing messages in certain circumstances. For example, at server restart, or when there is heavy workload.

Required No

Data type drop-down list

Range

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages might be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

As bus destination
Use the delivery option configured for the bus destination.

Read ahead:

Read ahead is an optimization that preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.

Messages that are assigned to a consumer are locked on the server and cannot be consumed by any other consumers for that destination. Messages that are assigned to a consumer, but not consumed before that consumer is closed, are subsequently unlocked on the server and then available for receipt by other consumers.

You can override this property for individual JMS destinations by setting the **Read ahead** property on the JMS destination.

Required No
Data type drop-down list

Range

Default The message provider preemptively assigns messages to consumers on nondurable subscriptions and unshared durable subscriptions. That is, read ahead optimization is turned on only when there can only be a single consumer.

Enabled
The messaging provider preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.

Disabled
The messaging provider does not preemptively assign messages to consumers.

Temporary queue name prefix:

The prefix of up to twelve characters used for names of temporary queues created by applications that use this connection factory.

Required No
Data type String

Temporary topic name prefix:

The prefix of up to twelve characters used for names of temporary topics created by applications that use this connection factory.

Required No
Data type String

Share durable subscriptions:

Controls whether or not durable subscriptions are shared across connections with members of a server cluster.

Usually, only one session at a time can have a TopicSubscriber for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers.

Required No
Data type drop-down list

Range

In cluster
Allows sharing of durable subscriptions when connections are made from within a server cluster.

Always shared
Durable subscriptions can be shared across connections.

Never shared
Durable subscriptions are never shared across connections.

Pass message payload by reference: When large object messages or bytes messages are sent, the cost in memory and processor use of serializing, deserializing, and copying the message payload can be significant. If you enable the **pass message payload by reference** properties on a connection factory or activation specification, you tell the default messaging provider to override the JMS 1.1 specification and potentially reduce or bypass this data copying.

CAUTION:
The parts of the JMS Specification that are bypassed by these properties are defined to ensure message data integrity. Any of your JMS applications that use these properties must strictly follow the rules that are described in the topic Why and when to pass the JMS message payload by reference, or you risk losing data integrity.

Applications that use this connection factory to send messages must obey the following rules::

- The application does not modify the data object contained in a JMS object message.
- The application populates a JMS bytes message by using a single call to writeBytes(byte[]) and does not modify the byte array after it is set in the message.

When enabled, Object/Bytes Messages sent by a message producing application that has connected to the bus using this connection factory will not have their data copied when set and the system will only serialize the message data when absolutely necessary. Applications sending such messages must not modify the data once it has been set into the message.

Required No
Data type Boolean

Applications that use this connection factory to receive messages must obey the following rule::

- The application does not modify the data object obtained from a JMS object message. The data object is treated as read only.

When enabled, Object Messages received by a message consuming application that has connected to this connection factory will only have their message data serialized by the system when absolutely necessary. The data obtained from these messages must be treated as readOnly by applications.

Required No
Data type Boolean

Log missing transaction contexts:

Whether or not the container logs that there is a missing transaction context when a connection is obtained.

The Java EE programming model indicates that connections should always have a transaction context. However, some applications do not correctly have a transaction context associated with them.

Select this property to log connections being created without a transaction context.

Required	No
Data type	Boolean

Manage cached handles:

Whether cached handles (handles held in instance variables in a bean) should be tracked by the container.

Select this option to track handle management, which can be useful for debugging purposes. However, tracking handles can significantly reduce performance if used at run time.

Required	No
Data type	Boolean

Share data source with CMP:

Allow sharing of connections between JMS and container-managed persistence (CMP) entity beans.

This option is used as part of the task to enable container-managed persistence (CMP) entity beans to share the database connections used by the data store of a messaging engine. This has been estimated as a potential performance improvement of 15% for overall message throughput, but can only be used for entity beans connected to the application server that contains the messaging engine.

For more information about using this option, see the topic Enabling CMP entity beans and messaging engine data stores to share database connections.

Required	No
Data type	Boolean

Authentication alias for XA recovery:

Specifies the alias that the connection factory uses to authenticate with the EIS for transaction recovery.

Select the alias to be used during transaction recovery processing.

This property provides a list of the JCA authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate during XA recovery processing.

If you have enabled security for the associated service integration bus, select the alias that specifies the user ID and password used for XA recovery that is valid in the user registry for WebSphere Application Server. This property must be set if bus security is enabled and XA transactions are to be used.

Required	No
Data type	drop-down list

Mapping-configuration alias:

Specifies the mapping configuration alias for the Java Authentication and Authorization Service (JAAS) mapping configuration that is used by this connection factory.

This field will be used only in the absence of a loginConfiguration on the component resource reference. The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container.If the DefaultPrincipalMapping login configuration is specified, the associated property will be a JAAS - J2C authentication data entry alias. See related item JAAS - J2C authentication data entry to define a new alias.

Required	No
Data type	drop-down list

Container-managed authentication alias:

This alias specifies a user ID and password to be used to authenticate connections to the JMS provider for container-managed authentication. This setting is only used when the res-auth value is container, and the authentication alias was not set when the application was deployed.

Required	No
Data type	drop-down list

Additional Properties

Connection pool properties
An optional set of connection pool settings.

Related Items

JAAS - J2C authentication data
Specifies a list of user identities and passwords for Java 2 connector security to use.

Buses
A service integration bus supports applications using message-based and service-oriented architectures. A bus is a group of interconnected servers and clusters that have been added as members of the bus. Applications connect to a bus at one of the messaging engines associated with its bus members.

Default messaging provider queue connection factory [Settings]

A JMS queue connection factory is used to create connections to the associated JMS provider of JMS queues, for point-to-point messaging. Use queue connection factory administrative objects to manage JMS queue connection factories for the default messaging provider.

To view this page in the console, click one of the following paths:

- **Resources -> JMS -> Queue connection factories -> *factory_name***
- **Resources -> JMS -> JMS providers -> *a_messaging_provider* -> [Additional Properties] Queue connection factories -> *factory_name***

Use this panel to browse or change the configuration properties of the selected JMS queue connection factory for use with the default messaging JMS provider. These configuration properties control how connections are created to associated JMS queues.

By default, connections created by using this JMS connection factory in the server containers (for example, from an enterprise bean) are pooled by using Java Platform, Enterprise Edition (Java EE)

Connector Architecture (JCA) connection pooling. You can modify the connection pool settings for this connection factory by selecting **Connection pool properties** link in the Additional properties section of the administrative console panel.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Scope:

Specifies the highest topological level at which application servers can use this resource object.

Required	No
Data type	String

Provider:

Specifies a JMS provider, which enables asynchronous messaging based on the Java Message Service (JMS). It provides J2EE connection factories to create connections for specific JMS queue or topic destinations. JMS provider administrative objects are used to manage JMS resources for the associated JMS provider.

Required	No
Data type	String

Name:

The required display name for the resource.

Required	Yes
Data type	String

JNDI name:

The JNDI name for the resource.

As a convention, use a JNDI name of the form jms/*Name*, where *Name* is the logical name of the resource. For more information about the use of JNDI and its syntax, see the topic JNDI support in WebSphere Application Server.

Required	Yes
Data type	String

Description:

An optional description for the resource.

Required	No
Data type	Text area

Category:

An optional category string to use when classifying or grouping the resource.

Required	No
Data type	String

Bus name:

The name of the service integration bus to connect to.

This is the name of the service integration bus that this connection factory is used to create connections to.

Enter the name of the local bus in situations where an application makes connection to foreign buses.

Required	Yes
Data type	Custom

Target:

The name of a target that identifies a group of messaging engines. Specify the type of target using the Target type property.

Required	No
Data type	String

Target type:

The type of target named in the Target property.

This indicates the name of a target that is to be used to determine one or messaging engines to handle work. The type of target is indicated by the Target type property

Connections are load balanced across the available messaging engines that satisfy the selection criteria.

If want applications to be able to connect to any messaging engine in the bus, do not set this property.

For more information about using this property with other connection factory properties for workload management of connections, see the topic Administrative properties for JMS connections to a bus.

Required	No
Data type	drop-down list

Range

Bus member name
The name of a bus member. This option retrieves the active messaging engines that are hosted by the named bus member (an application server or server cluster).

To specify a non-clustered bus member the Target property must be set to `<Node01>.<server1>`, for example Node01.server1. For a cluster bus member the Target property must be set to the cluster name.

Custom messaging engine group name
The name of a custom group of messaging engines (that form a self-declaring cluster). This option retrieves the active messaging engines that have registered with the named custom group.

Messaging engine name
The name of a messaging engine. This option retrieves the available endpoints that can be used to reach the named messaging engine.

Target significance:

This property specifies the significance of the target group.

For more information about using this property with other connection factory properties for workload management of connections, see the topic Administrative properties for JMS connections to a bus.

Required No
Data type drop-down list
Range

Preferred
It is preferred that a messaging engine is selected from the target group. A messaging engine in the target group is selected if one is available. If a messaging engine is not available in the target group, a messaging engine outside the target group is selected if available in the same service integration bus.

Required
It is required that a messaging engine is selected from the target group. A messaging engine in the target group is selected if one is available. If a messaging engine is not available in the target group, the connection process fails.

Target inbound transport chain:

The name of the inbound transport chain that the application should target when connecting to a messaging engine in a separate process to the application. If a messaging engine in another process is chosen, a connection can be made only if the messaging engine is in a server that runs the specified inbound transport chain. Refer to the information center for more information.

If the selected messaging engine is in the same server as the application, a direct in-process connection is made and this transport chain property is ignored.

The transport chains represent network protocol stacks operating within a server. The name you specify must be one of the transport chains available in the server that hosts the messaging engine, as listed on the **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] Messaging engine inbound transports** panel. The following transport chains are provided, but you can define your own transport chains on that panel.

InboundBasicMessaging
This is a connection-oriented protocol that uses a standard TCP/IP connection (JFAP-TCP/IP). It includes support for two-phase transactional (remote XA) flows, so that a message producer or consumer, running on a client or server system, can participate in a global transaction managed on that client or server system. The specific use for the XA flows is to support access from an application running in one server to a messaging engine on second server, perhaps because the first server does not have a suitable messaging engine. If the remote XA flows are used, a transaction coordinator must be available local to the application.

InboundSecureMessaging
This is the InboundBasicMessaging protocol wrapped in SSL.

For more information about using this property with other connection factory properties for workload management of connections, see the topic Administrative properties for JMS connections to a bus.

Required	No
Data type	String

Provider endpoints:

A comma-separated list of endpoint triplets, with the syntax hostName:portNumber:chainName, used to connect to a bootstrap server. For example Merlin:7276:BootstrapBasicMessaging,Gandalf:5557:BootstrapSecureMessaging. If hostName is not specified, the default is localhost. If portNumber is not specified, the default is 7276. If chainName is not specified, the default is BootstrapBasicMessaging. Refer to the information center for more information.

You only have to modify this property if you have client applications running outside of an application server, or applications on a server in another cell, that want to use this connection factory to connect to the target service integration bus specified on the connection factory.

To use JMS destinations of the default messaging provider, an application connects to a messaging engine on the target service integration bus to which the destinations are assigned. For example, a JMS queue is assigned to a queue destination on a service integration bus.

Client applications running outside of an application server - for example, running in a client container or outside the WebSphere Application Server environment - cannot locate directly a suitable messaging engine to connect to in the target bus. Similarly, an application running on a server in one cell to connect to a target bus in another cell cannot locate directly a suitable messaging engine to connect to in the target bus.

In these scenarios, the clients (or servers in another bus) must complete a bootstrap process through a *bootstrap server* that is a member of the target bus. A bootstrap server is an application server running the SIB Service, but does not have to be running any messaging engines. The bootstrap server selects a messaging engine that is running in an application server that supports the required *target transport chain*. For the bootstrap process to be possible, you must configure one or more *provider end points* in the connection factory used by the client.

A bootstrap server uses a specific port and bootstrap transport chain. The port is the **SIB_ENDPOINT_ADDRESS** (or **SIB_ENDPOINT_SECURE_ADDRESS** if security is enabled), of the messaging engine that hosts the remote end of the link. Together with host name, these form the *endpoint address* of the bootstrap server.

The properties of a JMS connection factory used by an application control the selection of a suitable messaging engine and how the application connects to the selected messaging engine.

- If no security credentials are provided, then by default
  - If no host is specified then localhost is used
  - If no port is specified then port 7276 is used
  - If no bootstrap channel chain is specified then bootstrap transport chain called BootstrapBasicMessaging is used
- If security credentials are provided, then by default
  - If no host is specified then localhost is used
  - If no port is specified then port 7286 is used
  - If no bootstrap channel chain is specified then bootstrap transport chain called BootstrapBasicMessaging is used

Note: For the IBM i platform, you must (at least) change the default host name from localhost to *your.server.name*.

If you want an application to use a bootstrap server with a different endpoint address, you must specify the required endpoint address on the **Provider endpoints** property of the JMS connection factories that the client application uses. You can specify one or more endpoint addresses of bootstrap servers.

The endpoint addresses for bootstrap servers must be specified in every JMS connection factory that is used by applications outside of an application server. To avoid having to specify a long list of bootstrap servers, you can provide a few highly-available servers as dedicated bootstrap servers. Then you only have to specify a short list of bootstrap servers on each connection factory.

Note: When configuring a connection to a non-default bootstrap server, specify the required values for the endpoint address and use colons as separators.

For example: for a server assigned non-secure port 7278, on host boothost1, that uses the default transport chain BootstrapBasicMessaging:

```
boothost1:7278:BootstrapBasicMessaging
or
boothost1:7278
```

and for a server assigned secure port 7289, on host boothost2, that uses the predefined transport chain BootstrapTunneledSecureMessaging:

```
boothost2:7289:BootstrapTunneledSecureMessaging
```

The syntax for an endpoint address is as follows:

```
[ [host_name] [ ":" [port_number] [ ":" chain_name] ] ]
```

where:

host_name
: is the name of the host on which the server runs. It can be an IP address. For an IPv6 address, put square braces ([]) around *host_name* as shown in the example below:

  ```
  [2002:914:fc12:179:9:20:141:42]:7276:BootstrapBasicMessaging
  ```

  . If a value is not specified, the default is localhost.

Note: For the IBM i platform, you must (at least) change the default host name from localhost to *your.server.name*.

port_number
where specified, is one of the following addresses of the messaging engine that hosts the remote end of the link:

- **SIB_ENDPOINT_ADDRESS** if security is not enabled
- For secure connections, **SIB_ENDPOINT_SECURE_ADDRESS** if security is enabled.

If *port_number* is not specified, the default is 7276.

To find either of these values by using the administrative console, click **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Communications] Ports**.

chain_name
is the name of a predefined bootstrap transport chain used to connect to the bootstrap server. If not specified, the default is BootstrapBasicMessaging.

The following predefined bootstrap transport chains are provided:

BootstrapBasicMessaging
This corresponds to the server transport chain InboundBasicMessaging (JFAP-TCP/IP)

BootstrapSecureMessaging
This corresponds to the server transport chain InboundSecureMessaging (JFAP-SSL-TCP/IP)

BootstrapTunneledMessaging
Before you can use this bootstrap transport chain, you must define a corresponding server transport chain on the bootstrap server. (See **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] Messaging engine inbound transports**.) This transport chain tunnels JFAP and uses HTTP wrappers.

BootstrapTunneledSecureMessaging
Before you can use this bootstrap transport chain, you must define a corresponding server transport chain on the bootstrap server. (See**Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] Messaging engine inbound transports**.) This transport chain tunnels JFAP and uses HTTP wrappers.

Specifying *host_name* : *chain_name* instead of *host_name* : : *chain_name* (with two colons) is incorrect. It is valid to enter nothing, or to enter any of the following: "a", "a:", ":7276", "::chain", and so on. The default value applies if you do not specify a value, but you must separate the fields with ":"s.

If you want to provide more than one bootstrap server, identify all the required endpoint addresses. Separate each endpoint address by a comma character. For example, to use the servers from the earlier example:

```
boothost1:7278:BootstrapBasicMessaging,
  boothost2:7289:BootstrapTunneledSecureMessaging,
  [2002:914:fc12:179:9:20:141:42]:7276:BootstrapBasicMessaging
```

Required	No
Data type	Text area

Connection proximity:

The proximity of messaging engines that can accept connection requests, in relation to the bootstrap messaging engine.

When a client issues a client connect request, the processing attaches to the required bus according to the following logic:

- If a target group is specified, connect to the first messaging engine that satisfies the following conditions for the target type:
  - **Server** Look for a messaging engine in the same server.
  - **Cluster** Look for a messaging engine in the same server, then on other servers in the same cluster.
  - **Host** Look for a messaging engine in the same server, then on other servers in the same cluster, then on other servers in the same host.
  - **Bus** Look for a messaging engine in the same server, then on other servers in the same cluster, then on other servers in same host, then any other messaging engine on the same bus.
- If a target group is not specified, or a target group is specified but no suitable messaging engine is found and target significance is Preferred, connect to the first messaging engine that satisfies the following conditions for the target type:
  - **Server** Look for a messaging engine in the same server.
  - **Cluster** Connection fails.
  - **Host** Look for a messaging engine in the same server, then on other servers in the same host.
  - **Bus** Look for a messaging engine in the target group in same server, then on other servers in same host, then any other messaging engine on the same bus.

For more information about using this property with other connection factory properties for workload management of connections, see the topic Administrative properties for JMS connections to a bus.

Required No
Data type drop-down list
Range

Bus Connections can be made to messaging engines in the same bus.

Cluster Connections can be made to messaging engines in the same server cluster.

Host Connections can be made to messaging engines in the same host.

Server Connections can be made to messaging engines in the same application server.

Nonpersistent message reliability:

The reliability applied to nonpersistent JMS messages sent using this connection factory.

You can change the delivery reliability option for the destination of a message that is sent by a JMS application as Nonpersistent. The default is Express nonpersistent but you have a range of other options, including those with persistent characteristics, with Assured persistent being the most reliable. For more information see the topic Message reliability levels - JMS delivery mode and service integration quality of service.

Required No
Data type drop-down list

Range

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages might be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

As bus destination
Use the delivery option configured for the bus destination.

Persistent message reliability:

The reliability applied to persistent JMS messages sent using this connection factory.

You can change the delivery reliability option for the destination of a message that is sent by a JMS application as Persistent. The default is Reliable persistent but you have a range of other options including those with nonpersistent characteristics, with Best effort nonpersistent being the least reliable. For more information see the topic Message reliability levels - JMS delivery mode and service integration quality of service.

Important: If you change the delivery reliability options of a message sent by a JMS application from one of the **Persistent message reliability** options (Assured persistent and Reliable persistent) to one of the **Nonpersistent message reliability** options (Best effort nonpersistent, Express nonpersistent, and Reliable nonpersistent), you risk losing messages in certain circumstances. For example, at server restart, or when there is heavy workload.

Required No
Data type drop-down list

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages might be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

As bus destination
Use the delivery option configured for the bus destination.

Read ahead:

Read ahead is an optimization that preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.

Messages that are assigned to a consumer are locked on the server and cannot be consumed by any other consumers for that destination. Messages that are assigned to a consumer, but not consumed before that consumer is closed, are subsequently unlocked on the server and then available for receipt by other consumers.

You can override this property for individual JMS destinations by setting the **Read ahead** property on the JMS destination.

Required No
Data type drop-down list

Range

Default The message provider preemptively assigns messages to consumers on nondurable subscriptions and unshared durable subscriptions. That is, read ahead optimization is turned on only when there can only be a single consumer.

Enabled
The messaging provider preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.

Disabled
The messaging provider does not preemptively assign messages to consumers.

Temporary queue name prefix:

The prefix used at the start of temporary queues created by applications using this connection factory.

Required	No
Data type	String

Pass message payload by reference: When large object messages or bytes messages are sent, the cost in memory and processor use of serializing, deserializing, and copying the message payload can be significant. If you enable the **pass message payload by reference** properties on a connection factory or activation specification, you tell the default messaging provider to override the JMS 1.1 specification and potentially reduce or bypass this data copying.

CAUTION:
The parts of the JMS Specification that are bypassed by these properties are defined to ensure message data integrity. Any of your JMS applications that use these properties must strictly follow the rules that are described in the topic Why and when to pass the JMS message payload by reference, or you risk losing data integrity.

Applications that use this connection factory to send messages must obey the following rules::

- The application does not modify the data object contained in a JMS object message.
- The application populates a JMS bytes message by using a single call to writeBytes(byte[]) and does not modify the byte array after it is set in the message.

When enabled, Object/Bytes Messages sent by a message producing application that has connected to the bus using this connection factory will not have their data copied when set and the system will only serialize the message data when absolutely necessary. Applications sending such messages must not modify the data once it has been set into the message.

Required	No
Data type	Boolean

Applications that use this connection factory to receive messages must obey the following rule::

- The application does not modify the data object obtained from a JMS object message. The data object is treated as read only.

When enabled, Object Messages received by a message consuming application that has connected to this connection factory will only have their message data serialized by the system when absolutely necessary. The data obtained from these messages must be treated as readOnly by applications.

Required	No
Data type	Boolean

Log missing transaction contexts:

Whether or not the container logs that there is a missing transaction context when a connection is obtained.

The Java EE programming model indicates that connections should always have a transaction context. However, some applications do not correctly have a transaction context associated with them.

Select this property to log connections being created without a transaction context.

Required	No
Data type	Boolean

Manage cached handles:

Whether cached handles (handles held in instance variables in a bean) should be tracked by the container.

Select this option to track handle management, which can be useful for debugging purposes. However, tracking handles can significantly reduce performance if used at run time.

Required	No
Data type	Boolean

Share data source with CMP:

Allow sharing of connections between JMS and container-managed persistence (CMP) entity EJB beans.

This option is used as part of the task to enable container-managed persistence (CMP) entity beans to share the database connections used by the data store of a messaging engine. This has been estimated as a potential performance improvement of 15% for overall message throughput, but can only be used for entity beans connected to the application server that contains the messaging engine.

For more information about using this option, see the topic Enabling CMP entity beans and messaging engine data stores to share database connections.

Required	No
Data type	Boolean

XA recovery authentication alias:

The authentication alias used during XA recovery processing.

Select the alias to be used during transaction recovery processing.

This property provides a list of the JCA authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate during XA recovery processing.

If you have enabled security for the associated service integration bus, select the alias that specifies the user ID and password used for XA recovery that is valid in the user registry for WebSphere Application Server. This property must be set if bus security is enabled and XA transactions are to be used.

Required	No
Data type	drop-down list

Mapping-configuration alias:

Specifies the mapping configuration alias for the Java Authentication and Authorization Service (JAAS) mapping configuration that is used by this connection factory.

This field will be used only in the absence of a loginConfiguration on the component resource reference. The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container.If the DefaultPrincipalMapping login configuration is specified, the associated property will be a JAAS - J2C authentication data entry alias. See related item JAAS - J2C authentication data entry to define a new alias.

Required	No
Data type	drop-down list

Container-managed authentication alias:

This alias specifies a user ID and password to be used to authenticate connections to the JMS provider for container-managed authentication. This setting is only used when the res-auth value is container, and the authentication alias was not set when the application was deployed.

Required	No
Data type	drop-down list

Additional Properties

Connection pool properties
An optional set of connection pool settings.

Related Items

JAAS - J2C authentication data
Specifies a list of user identities and passwords for Java 2 connector security to use.

Buses
A service integration bus supports applications using message-based and service-oriented architectures. A bus is a group of interconnected servers and clusters that have been added as members of the bus. Applications connect to a bus at one of the messaging engines associated with its bus members.

Default messaging provider queue [Settings]

A JMS queue is used as a destination for point-to-point messaging. Use JMS queue destination administrative objects to manage JMS queues for the default messaging provider.

To view this page in the console, click one of the following paths:

- **Resources -> JMS -> Queues -> *queue_name***
- **Resources -> JMS -> JMS providers -> *a_messaging_provider* -> [Additional Properties] Queues -> *queue_name***

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Scope:

Specifies the highest topological level at which application servers can use this resource object.

Required	No
Data type	String

Provider:

Specifies a JMS provider, which enables asynchronous messaging based on the Java Message Service (JMS). It provides J2EE connection factories to create connections for specific JMS queue or topic destinations. JMS provider administrative objects are used to manage JMS resources for the associated JMS provider.

Required	No
Data type	String

Name:

The required display name for the resource.

Required	Yes
Data type	String

JNDI name:

The JNDI name for the resource.

As a convention, use a JNDI name of the form jms/*Name*, where *Name* is the logical name of the resource. For more information about the use of JNDI and its syntax, see the topic JNDI support in WebSphere Application Server.

Required	Yes
Data type	String

Description:

An optional description for the resource.

Required No
Data type Text area

Bus name:

Enter the name of the bus on which the associated queue exists, or leave blank to use the bus to which the application connects.

Required No
Data type Custom

Queue name:

The name of the associated queue on the service integration bus.

Type the name of a queue that has been created on the service integration bus.

Required Yes
Data type Custom

Delivery mode:

The delivery mode for messages sent to this destination. This controls the persistence of messages on this destination.

Required No
Data type drop-down list
Range

Application
The persistence of messages on this topic is defined by the producing application.

Nonpersistent
All messages sent to this topic are treated as nonpersistent.

Persistent
All messages sent to this topic are treated as persistent.

Time to live:

The default length of time in milliseconds from its dispatch time that a message sent to this destination should be kept by the system.

Required No
Data type Integer
Range 0 through 574476389546486783

A value of 0 (zero) means that messages are kept indefinitely. The default for this property is null, which allows the application to determine the time to keep messages.

Priority:

The relative priority for messages sent to this destination, in the range 0 to 9, with 0 as the lowest priority and 9 as the highest priority.

If a value is not specified for this property, the message priority set by the producing application is used.

Required No
Data type Integer
Range 0 through 9

The message priority range is from 0 (lowest) through 9 (highest).

Read ahead:

Read ahead is an optimization that preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.

Messages that are assigned to a consumer are locked on the server and cannot be consumed by any other consumers for that destination. Messages that are assigned to a consumer, but not consumed before that consumer is closed, are subsequently unlocked on the server and then available for receipt by other consumers.

This property overrides the value set by the **Read ahead** property on the JMS connection factory.

Required No
Data type drop-down list
Range

Enabled
The messaging provider preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests for this destination.

Disabled
The messaging provider does not preemptively assign messages to consumers for this destination.

Inherit from connection factory
Read ahead optimization is defined on the connection.

Restrict messages to the local queue point if a queue point is configured on the connected messaging engine:

Indicates whether the underlying service integration bus queue destination is scoped to a local queue point when addressed by using this JMS queue. A local queue point is a queue point of the service integration bus queue that is configured on the messaging engine to which the JMS application is connected.

This option applies when using this JMS queue to send and receive messages, and when setting a reply queue in a request message. When a reply queue is set in a request message, the local queue point is on the messaging engine to which the application setting the reply queue is connected, not the messaging

engine to which the application that uses the reply queue sends the reply message. If the connected messaging engine does not have a queue point for the destination this option is ignored. The default value is FALSE.

This option is supported only when used by a JMS application that is running with a WebSphere Application Server Version 7.0 or later server or client, and that is connected to a messaging engine running on WebSphere Application Server Version 7.0 or later server. Use on previous versions of WebSphere Application Server will result in an exception to the application.

Required	Yes
Data type	Boolean
Default	FALSE

Local queue point preference:

Prefer to send messages to a local queue point

If a queue point for this queue exists on the messaging engine that the application is connected to, prefer to send all messages to it to improve performance. If this local queue point is not accepting new messages, the messages are sent to other queue points, if possible.

Required	No
Data type	Radio button

Do not prefer a local queue point over other queue points

All available queue points are treated equally, with no preference given to a local queue point. Messages are workload balanced across all queue points. This option is supported only when used by a JMS application that is running with a WebSphere Application ServerVersion 7.0 or later server or client, and that is connected to a messaging engine running on WebSphere Application ServerVersion 7.0 or later server. Use on previous versions of WebSphere Application Server will result in an exception to the application.

Required	No
Data type	Radio button

Message affinity across queue points:

Send all messages to the same queue point

A message producer created to use this queue sends all messages to the same queue point. This option does not influence the initial choice of queue point. This option applies to a message producer only if the queue is identified at the time the message producer is created, not at the time of sending messages. This option is supported only when used by a JMS application that is running with a WebSphere Application ServerVersion 7.0 or later server or client, and that is connected to a messaging engine running on WebSphere Application ServerVersion 7.0 or later server. Use on previous versions of WebSphere Application Server will result in an exception to the application.

Required	No
Data type	Radio button

Messages may be sent to different queue points

A message producer can send messages to different queue points, based on the availability of the queue points and workload balancing of the system.

Required	No
Data type	Radio button

Message visibility:

Only messages on a single queue point are visible

A consumer or browser has access to messages on only one queue point, not the entire queue. The single queue point is chosen by the messaging system. A queue point that is defined on the same messaging engine that the application is connected to is preferred to other queue points.

Required	No
Data type	Radio button

Messages on all queue points are visible

A consumer or browser has access to messages on all queue points of the queue. If you enable this option, all queue points are actively checked for messages. This means that no messages are left on an unattended queue point. However, there is a performance cost in scanning all queue points for messages, and you can no longer control the order in which messages are taken off the queue. This option is supported only when used by a JMS application that is running with a WebSphere Application ServerVersion 7.0 or later server or client, and that is connected to a messaging engine running on WebSphere Application ServerVersion 7.0 or later server. Use on previous versions of WebSphere Application Server will result in an exception to the application.

Required	No
Data type	Radio button

Buses

A service integration bus supports applications using message-based and service-oriented architectures. A bus is a group of interconnected servers and clusters that have been added as members of the bus. Applications connect to a bus at one of the messaging engines associated with its bus members.

Default messaging provider topic connection factory [Settings]

A JMS topic connection factory is used to create connections to the associated JMS provider of JMS topics, for publish/subscribe messaging. Use topic connection factory administrative objects to manage JMS topic connection factories for the default messaging provider.

To view this page in the console, click one of the following paths:

- **Resources -> JMS -> Topic connection factories -> *factory_name***
- **Resources -> JMS -> JMS providers -> *a_messaging_provider* -> [Additional Properties] Topic connection factories -> *factory_name***

Use this panel to browse or change the configuration properties of the selected JMS topic connection factory for use with the default messaging JMS provider. These configuration properties control how connections are created to associated JMS topics.

By default, connections created by using this JMS connection factory in the server containers (for example, from an enterprise bean) are pooled by using Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) connection pooling. You can modify the connection pool settings for this connection factory by selecting **Connection pool properties** in the Additional properties section of the administrative console panel.

The configuration of a container-managed authentication alias and mapping module on a connection factory are deprecated. You now set these properties in the bindings for the resource reference of the application. If you do not want to modify the bindings for an existing application, locate this connection factory in the J2C panels where you can still find these properties.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Scope:

Specifies the highest topological level at which application servers can use this resource object.

Required	No
Data type	String

Provider:

Specifies a JMS provider, which enables asynchronous messaging based on the Java Message Service (JMS). It provides J2EE connection factories to create connections for specific JMS queue or topic destinations. JMS provider administrative objects are used to manage JMS resources for the associated JMS provider.

Required	No
Data type	String

Name:

The required display name for the resource.

Required	Yes
Data type	String

JNDI name:

The JNDI name for the resource.

As a convention, use a JNDI name of the form jms/*Name*, where *Name* is the logical name of the resource. For more information about the use of JNDI and its syntax, see the topic JNDI support in WebSphere Application Server.

Required	Yes
Data type	String

Description:

An optional description for the resource.

Required	No
Data type	Text area

Category:

An optional category string to use when classifying or grouping the resource.

Required	No
Data type	String

Bus name:

The name of the bus to connect to.

This is the name of the service integration bus that this connection factory is used to create connections to.

Enter the name of the local bus in situations where an application makes connection to foreign buses.

Required	Yes
Data type	Custom

Target:

The name of a target that identifies a group of messaging engines. Specify the type of target using the Target type property.

This indicates the name of a target that is to be used to determine one or messaging engines to handle work. The type of target is indicated by the Target type property

Connections are load balanced across the available messaging engines that satisfy the selection criteria.

If want applications to be able to connect to any messaging engine in the bus, do not set this property.

For more information about using this property with other connection factory properties for workload management of connections, see the topic Administrative properties for JMS connections to a bus.

Required	No
Data type	String

Target type:

The type of target named in the Target property.

Required	No
Data type	drop-down list

Range

Bus member name
The name of a bus member. This option retrieves the active messaging engines that are hosted by the named bus member (an application server or server cluster).

To specify a non-clustered bus member the Target property must be set to `<Node01>.<server1>`, for example Node01.server1. For a cluster bus member the Target property must be set to the cluster name.

Custom messaging engine group name
The name of a custom group of messaging engines (that form a self-declaring cluster). This option retrieves the active messaging engines that have registered with the named custom group.

Messaging engine name
The name of a messaging engine. This option retrieves the available endpoints that can be used to reach the named messaging engine.

Target significance:

This property specifies the significance of the target group.

For more information about using this property with other connection factory properties for workload management of connections, see the topic Administrative properties for JMS connections to a bus.

Required No
Data type drop-down list
Range

Preferred
It is preferred that a messaging engine is selected from the target group. A messaging engine in the target group is selected if one is available. If a messaging engine is not available in the target group, a messaging engine outside the target group is selected if available in the same service integration bus.

Required
It is required that a messaging engine is selected from the target group. A messaging engine in the target group is selected if one is available. If a messaging engine is not available in the target group, the connection process fails.

Target inbound transport chain:

The name of the inbound transport chain that the application should target when connecting to a messaging engine in a separate process to the application. If a messaging engine in another process is chosen, a connection can be made only if the messaging engine is in a server that runs the specified inbound transport chain. Refer to the information center for more information.

If the selected messaging engine is in the same server as the application, a direct in-process connection is made and this transport chain property is ignored.

The transport chains represent network protocol stacks operating within a server. The name you specify must be one of the transport chains available in the server that hosts the messaging engine, as listed on the **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] Messaging engine inbound transports** panel. The following transport chains are provided, but you can define your own transport chains on that panel.

InboundBasicMessaging
: This is a connection-oriented protocol that uses a standard TCP/IP connection (JFAP-TCP/IP). It includes support for two-phase transactional (remote XA) flows, so that a message producer or consumer, running on a client or server system, can participate in a global transaction managed on that client or server system. The specific use for the XA flows is to support access from an application running in one server to a messaging engine on second server, perhaps because the first server does not have a suitable messaging engine. If the remote XA flows are used, a transaction coordinator must be available local to the application.

InboundSecureMessaging
: This is the InboundBasicMessaging protocol wrapped in SSL.

For more information about using this property with other connection factory properties for workload management of connections, see the topic Administrative properties for JMS connections to a bus.

Required	No
Data type	String

Provider endpoints:

A comma-separated list of endpoint triplets, with the syntax hostName:portNumber:chainName, used to connect to a bootstrap server. For example Merlin:7276:BootstrapBasicMessaging,Gandalf:5557:BootstrapSecureMessaging. If hostName is not specified, the default is localhost. If portNumber is not specified, the default is 7276. If chainName is not specified, the default is BootstrapBasicMessaging. Refer to the information center for more information.

You only have to modify this property if you have client applications running outside of an application server, or applications on a server in another cell, that want to use this connection factory to connect to the target service integration bus specified on the connection factory.

To use JMS destinations of the default messaging provider, an application connects to a messaging engine on the target service integration bus to which the destinations are assigned. For example, a JMS queue is assigned to a queue destination on a service integration bus.

Client applications running outside of an application server - for example, running in a client container or outside the WebSphere Application Server environment - cannot locate directly a suitable messaging engine to connect to in the target bus. Similarly, an application running on a server in one cell to connect to a target bus in another cell cannot locate directly a suitable messaging engine to connect to in the target bus.

In these scenarios, the clients (or servers in another bus) must complete a bootstrap process through a *bootstrap server* that is a member of the target bus. A bootstrap server is an application server running the SIB Service, but does not have to be running any messaging engines. The bootstrap server selects a messaging engine that is running in an application server that supports the required *target transport chain*. For the bootstrap process to be possible, you must configure one or more *provider end points* in the connection factory used by the client.

A bootstrap server uses a specific port and bootstrap transport chain. The port is the **SIB_ENDPOINT_ADDRESS** (or **SIB_ENDPOINT_SECURE_ADDRESS** if security is enabled), of the messaging engine that hosts the remote end of the link. Together with host name, these form the *endpoint address* of the bootstrap server.

The properties of a JMS connection factory used by an application control the selection of a suitable messaging engine and how the application connects to the selected messaging engine.

- If no security credentials are provided, then by default
  - If no host is specified then localhost is used
  - If no port is specified then port 7276 is used
  - If no bootstrap channel chain is specified then bootstrap transport chain called BootstrapBasicMessaging is used
- If security credentials are provided, then by default
  - If no host is specified then localhost is used
  - If no port is specified then port 7286 is used
  - If no bootstrap channel chain is specified then bootstrap transport chain called BootstrapBasicMessaging is used

Note: For the IBM i platform, you must (at least) change the default host name from localhost to *your.server.name*.

If you want an application to use a bootstrap server with a different endpoint address, you must specify the required endpoint address on the **Provider endpoints** property of the JMS connection factories that the client application uses. You can specify one or more endpoint addresses of bootstrap servers.

The endpoint addresses for bootstrap servers must be specified in every JMS connection factory that is used by applications outside of an application server. To avoid having to specify a long list of bootstrap servers, you can provide a few highly-available servers as dedicated bootstrap servers. Then you only have to specify a short list of bootstrap servers on each connection factory.

Note: When configuring a connection to a non-default bootstrap server, specify the required values for the endpoint address and use colons as separators.

For example: for a server assigned non-secure port 7278, on host boothost1, that uses the default transport chain BootstrapBasicMessaging:

```
boothost1:7278:BootstrapBasicMessaging
or
boothost1:7278
```

and for a server assigned secure port 7289, on host boothost2, that uses the predefined transport chain BootstrapTunneledSecureMessaging:

```
boothost2:7289:BootstrapTunneledSecureMessaging
```

The syntax for an endpoint address is as follows:

```
[ [host_name] [ ":" [port_number] [ ":" chain_name] ] ]
```

where:

host_name
: is the name of the host on which the server runs. It can be an IP address. For an IPv6 address, put square braces ([]) around *host_name* as shown in the example below:

  ```
  [2002:914:fc12:179:9:20:141:42]:7276:BootstrapBasicMessaging
  ```

  . If a value is not specified, the default is localhost.

Note: For the IBM i platform, you must (at least) change the default host name from localhost to *your.server.name*.

port_number
where specified, is one of the following addresses of the messaging engine that hosts the remote end of the link:

- **SIB_ENDPOINT_ADDRESS** if security is not enabled
- For secure connections, **SIB_ENDPOINT_SECURE_ADDRESS** if security is enabled.

If *port_number* is not specified, the default is 7276.

To find either of these values by using the administrative console, click **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Communications] Ports**.

chain_name
is the name of a predefined bootstrap transport chain used to connect to the bootstrap server. If not specified, the default is BootstrapBasicMessaging.

The following predefined bootstrap transport chains are provided:

BootstrapBasicMessaging
This corresponds to the server transport chain InboundBasicMessaging (JFAP-TCP/IP)

BootstrapSecureMessaging
This corresponds to the server transport chain InboundSecureMessaging (JFAP-SSL-TCP/IP)

BootstrapTunneledMessaging
Before you can use this bootstrap transport chain, you must define a corresponding server transport chain on the bootstrap server. (See **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] Messaging engine inbound transports**.) This transport chain tunnels JFAP and uses HTTP wrappers.

BootstrapTunneledSecureMessaging
Before you can use this bootstrap transport chain, you must define a corresponding server transport chain on the bootstrap server. (See**Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] Messaging engine inbound transports**.) This transport chain tunnels JFAP and uses HTTP wrappers.

Specifying *host_name* : *chain_name* instead of *host_name* : : *chain_name* (with two colons) is incorrect. It is valid to enter nothing, or to enter any of the following: "a", "a:", ":7276", "::chain", and so on. The default value applies if you do not specify a value, but you must separate the fields with ":"s.

If you want to provide more than one bootstrap server, identify all the required endpoint addresses. Separate each endpoint address by a comma character. For example, to use the servers from the earlier example:

```
boothost1:7278:BootstrapBasicMessaging,
  boothost2:7289:BootstrapTunneledSecureMessaging,
  [2002:914:fc12:179:9:20:141:42]:7276:BootstrapBasicMessaging
```

Required	No
Data type	Text area

Connection proximity:

The proximity of messaging engines that can accept connection requests, in relation to the bootstrap messaging engine.

When a client issues a client connect request, the processing attaches to the required bus according to the following logic:

- If a target group is specified, connect to the first messaging engine that satisfies the following conditions for the target type:
  - **Server** Look for a messaging engine in the same server.
  - **Cluster** Look for a messaging engine in the same server, then on other servers in the same cluster.
  - **Host** Look for a messaging engine in the same server, then on other servers in the same cluster, then on other servers in the same host.
  - **Bus** Look for a messaging engine in the same server, then on other servers in the same cluster, then on other servers in same host, then any other messaging engine on the same bus.
- If a target group is not specified, or a target group is specified but no suitable messaging engine is found and target significance is Preferred, connect to the first messaging engine that satisfies the following conditions for the target type:
  - **Server** Look for a messaging engine in the same server.
  - **Cluster** Connection fails.
  - **Host** Look for a messaging engine in the same server, then on other servers in the same host.
  - **Bus** Look for a messaging engine in the target group in same server, then on other servers in same host, then any other messaging engine on the same bus.

For more information about using this property with other connection factory properties for workload management of connections, see the topic Administrative properties for JMS connections to a bus.

Required No
Data type drop-down list
Range

Bus Connections can be made to messaging engines in the same bus.

Cluster Connections can be made to messaging engines in the same server cluster.

Host Connections can be made to messaging engines in the same host.

Server Connections can be made to messaging engines in the same application server.

Client identifier:

The JMS client identifier needed for durable topic subscriptions on all connections created using this connection factory.

Required No
Data type String

Durable subscription home:

The name of the messaging engine used to store messages delivered to durable subscriptions for objects created from this JMS connection factory.

To enable applications to use durable subscriptions, you must set this property.

Required No
Data type Custom

Nonpersistent message reliability:

The reliability applied to nonpersistent JMS messages sent using this connection factory.

You can change the delivery reliability option for the destination of a message that is sent by a JMS application as Nonpersistent. The default is Express nonpersistent but you have a range of other options, including those with persistent characteristics, with Assured persistent being the most reliable. For more information see the topic Message reliability levels - JMS delivery mode and service integration quality of service.

Required
No

Data type
drop-down list

Range

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages might be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

As bus destination
Use the delivery option configured for the bus destination.

Persistent message reliability:

The reliability applied to persistent JMS messages sent using this connection factory.

You can change the delivery reliability option for the destination of a message that is sent by a JMS application as Persistent. The default is Reliable persistent but you have a range of other options including those with nonpersistent characteristics, with Best effort nonpersistent being the least reliable. For more information see the topic Message reliability levels - JMS delivery mode and service integration quality of service.

Important: If you change the delivery reliability options of a message sent by a JMS application from one of the **Persistent message reliability** options (Assured persistent and Reliable persistent) to one of the **Nonpersistent message reliability** options (Best effort nonpersistent, Express nonpersistent, and Reliable nonpersistent), you risk losing messages in certain circumstances. For example, at server restart, or when there is heavy workload.

Required
No

Data type
drop-down list

Range

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages might be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

As bus destination
Use the delivery option configured for the bus destination.

Read ahead:

Read ahead is an optimization that preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.

Messages that are assigned to a consumer are locked on the server and cannot be consumed by any other consumers for that destination. Messages that are assigned to a consumer, but not consumed before that consumer is closed, are subsequently unlocked on the server and then available for receipt by other consumers.

You can override this property for individual JMS destinations by setting the **Read ahead** property on the JMS destination.

Required
No

Data type
drop-down list

Range

Default The message provider preemptively assigns messages to consumers on nondurable subscriptions and unshared durable subscriptions. That is, read ahead optimization is turned on only when there can only be a single consumer.

Enabled
The messaging provider preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.

Disabled
The messaging provider does not preemptively assign messages to consumers.

Temporary topic name prefix:

The prefix used at the start of temporary topics created by applications using this connection factory.

Required No
Data type String

Share durable subscriptions:

Controls whether or not durable subscriptions are shared across connections with members of a server cluster.

Usually, only one session at a time can have a TopicSubscriber for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers.

Required No
Data type drop-down list
Range

In cluster
Allows sharing of durable subscriptions when connections are made from within a server cluster.

Always shared
Durable subscriptions can be shared across connections.

Never shared
Durable subscriptions are never shared across connections.

Pass message payload by reference: When large object messages or bytes messages are sent, the cost in memory and processor use of serializing, deserializing, and copying the message payload can be significant. If you enable the **pass message payload by reference** properties on a connection factory or activation specification, you tell the default messaging provider to override the JMS 1.1 specification and potentially reduce or bypass this data copying.

CAUTION:
The parts of the JMS Specification that are bypassed by these properties are defined to ensure message data integrity. Any of your JMS applications that use these properties must strictly follow the rules that are described in the topic Why and when to pass the JMS message payload by reference, or you risk losing data integrity.

Applications that use this connection factory to send messages must obey the following rules::

- The application does not modify the data object contained in a JMS object message.
- The application populates a JMS bytes message by using a single call to writeBytes(byte[]) and does not modify the byte array after it is set in the message.

When enabled, Object/Bytes Messages sent by a message producing application that has connected to the bus using this connection factory will not have their data copied when set and the system will only serialize the message data when absolutely necessary. Applications sending such messages must not modify the data once it has been set into the message.

Required	No
Data type	Boolean

Applications that use this connection factory to receive messages must obey the following rule::

- The application does not modify the data object obtained from a JMS object message. The data object is treated as read only.

When enabled, Object Messages received by a message consuming application that has connected to this connection factory will only have their message data serialized by the system when absolutely necessary. The data obtained from these messages must be treated as readOnly by applications.

Required	No
Data type	Boolean

Log missing transaction contexts:

Whether or not the container logs that there is a missing transaction context when a connection is obtained.

The Java EE programming model indicates that connections should always have a transaction context. However, some applications do not correctly have a transaction context associated with them.

Select this property to log connections being created without a transaction context.

Required	No
Data type	Boolean

Manage cached handles:

Whether cached handles (handles held in instance variables in a bean) should be tracked by the container.

Select this option to track handle management, which can be useful for debugging purposes. However, tracking handles can significantly reduce performance if used at run time.

Required	No
Data type	Boolean

Share data source with CMP:

Allow sharing of connections between JMS and container-managed persistence (CMP) entity EJB beans.

This option is used as part of the task to enable container-managed persistence (CMP) entity beans to share the database connections used by the data store of a messaging engine. This has been estimated as a potential performance improvement of 15% for overall message throughput, but can only be used for entity beans connected to the application server that contains the messaging engine.

For more information about using this option, see the topic Enabling CMP entity beans and messaging engine data stores to share database connections.

Required	No
Data type	Boolean

XA recovery authentication alias:

The authentication alias used during XA recovery processing.

Select the alias to be used during transaction recovery processing.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate during XA recovery processing.

If you have enabled security for the associated service integration bus, select the alias that specifies the user ID and password used for XA recovery that is valid in the user registry for WebSphere Application Server. This property must be set if bus security is enabled and XA transactions are to be used.

Required	No
Data type	drop-down list

Mapping-configuration alias:

Specifies the mapping configuration alias for the Java Authentication and Authorization Service (JAAS) mapping configuration that is used by this connection factory.

This field will be used only in the absence of a loginConfiguration on the component resource reference. The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container.If the DefaultPrincipalMapping login configuration is specified, the associated property will be a JAAS - J2C authentication data entry alias. See related item JAAS - J2C authentication data entry to define a new alias.

Required	No
Data type	drop-down list

Container-managed authentication alias:

This alias specifies a user ID and password to be used to authenticate connections to the JMS provider for container-managed authentication. This setting is only used when the res-auth value is container, and the authentication alias was not set when the application was deployed.

Required	No

Data type drop-down list

Additional Properties

Connection pool properties
An optional set of connection pool settings.

Related Items

JAAS - J2C authentication data
Specifies a list of user identities and passwords for Java 2 connector security to use.

Buses
A service integration bus supports applications using message-based and service-oriented architectures. A bus is a group of interconnected servers and clusters that have been added as members of the bus. Applications connect to a bus at one of the messaging engines associated with its bus members.

Default messaging provider topic [Settings]

A JMS topic is used as a destination for publish/subscribe messaging. Use topic destination administrative objects to manage JMS topics for the default messaging provider.

To view this page in the console, click one of the following paths:

- **Resources -> JMS -> Topics -> *topic_name***
- **Resources -> JMS -> JMS providers -> *a_messaging_provider* -> [Additional Properties] Topics** > ***topic_name***

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Scope:

Specifies the highest topological level at which application servers can use this resource object.

Required No
Data type String

Provider:

Specifies a JMS provider, which enables asynchronous messaging based on the Java Message Service (JMS). It provides J2EE connection factories to create connections for specific JMS queue or topic destinations. JMS provider administrative objects are used to manage JMS resources for the associated JMS provider.

Required No
Data type String

Name:

The required display name for the resource.

Required Yes
Data type String

JNDI name:

The JNDI name for the resource.

As a convention, use a JNDI name of the form jms/*Name*, where *Name* is the logical name of the resource. For more information about the use of JNDI and its syntax, see the topic JNDI support in WebSphere Application Server.

Required Yes
Data type String

Description:

An optional description for the resource.

Required No
Data type Text area

Topic name:

The name of the topic that this JMS topic is assigned to, in the topic space defined by the Topic space property.

To specify a multi-level topic name, separate each level by a forward slash character (/); for example:
`schools/eton/subjects/maths`

Required No
Data type String

Bus name:

Name of bus hosting topic.

Required No
Data type Custom

Topic space:

The name of the topic space that contains the topic, on the service integration bus defined by the Bus name property

Type the name of a topic space that has been created on the service integration bus.

Required Yes
Data type Custom

JMS delivery mode:

The delivery mode for messages sent to this destination. This controls the persistence of messages on this destination.

Required No
Data type drop-down list
Range

Application
The persistence of messages on this topic is defined by the producing application.

Nonpersistent
All messages sent to this topic are treated as nonpersistent.

Persistent
All messages sent to this topic are treated as persistent.

Time to live:

The default length of time in milliseconds from its dispatch time that a message sent to this destination should be kept by the system.

Messages are deleted after the specified time. If a value is not specified for this property, the time limit set by the producing application is used.

Required No
Data type Long
Range 0 through 574476389546486783

A value of 0 (zero) means that messages are kept indefinitely. The default for this property is null, which allows the application to determine the time to keep messages.

Message priority:

The relative priority for messages sent to this destination, in the range 0 to 9, with 0 as the lowest priority and 9 as the highest priority.

If a value is not specified for this property, the message priority set by the producing application is used.

Required No
Data type Integer
Range 0 through 9

The message priority range is from 0 (lowest) through 9 (highest).

Read ahead:

Read ahead is an optimization that preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.

Messages that are assigned to a consumer are locked on the server and cannot be consumed by any other consumers for that destination. Messages that are assigned to a consumer, but not consumed before that consumer is closed, are subsequently unlocked on the server and then available for receipt by other consumers.

This property overrides the value set by the **Read ahead** property on the JMS connection factory.

Required
No

Data type
drop-down list

Range

Enabled
The messaging provider preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests for this destination.

Disabled
The messaging provider does not preemptively assign messages to consumers for this destination.

Inherit from connection factory
Read ahead optimization is defined on the connection.

Related Items

Buses
A service integration bus supports applications using message-based and service-oriented architectures. A bus is a group of interconnected servers and clusters that have been added as members of the bus. Applications connect to a bus at one of the messaging engines associated with its bus members.

SIBJMSAdminCommands command group for the AdminTask object

You can use these administrative commands to manage JMS resources for the default messaging provider.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('SIBJMSAdminCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

createSIBJMSActivationSpec command

Use the createSIBJMSActivationSpec command to create a new JMS activation specification for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBJMSAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The createSIBJMSActivationSpec command creates a new JMS activation specification at a specific scope.

Target object

The scope of the default messaging provider at which the JMS activation specification is to be created.

Required parameters

-name
The administrative name assigned to this activation specification.

-jndiName
The JNDI name that is specified in the bindings for message-driven beans associated with this activation specification.

-destinationJndiName
The JNDI name of the destination JMS queue or topic used by the message-driven bean.

Optional parameters

-description
An optional description for the activation specification.

-destinationType
An option to determine whether the message_driven bean uses a JMS queue or a JMS topic. Select one of the following values:

Queue
The message-driven bean uses a JMS queue. The JNDI name of the JMS queue is specified on the **Destination JNDI name** property.

Topic The message-driven bean uses a JMS topic. The JNDI name of the JMS topic is specified on the **Destination JNDI name** property.

-messageSelector
The JMS message selector used to determine which messages the message-driven bean receives. The value is a string that is used to select a subset of the available messages. The syntax is based on a subset of the SQL 92 conditional expression syntax, as described in the JMS specification. Refer to the information center for more information.

The selector string can refer to fields in the JMS message header and fields in the message properties. Message selectors cannot reference message body values.

A null value (an empty string) indicates that there is no message selector for the message consumer.

-busName
The name of the service integration bus to which connections are made. This must be the name of the bus on which the destination identified by the **-destinationJndiName** property is defined.

-acknowledgeMode
The acknowledge mode indicates how a message received by a message-driven bean should be acknowledged. Select one of the following values:

Auto-acknowledge
The session automatically acknowledges the delivery of a message.

Duplicates-ok auto-acknowledge
The session lazily acknowledges the delivery of messages, which can improve performance, but can lead to a message-driven bean receiving a message more than once.

-target
The name of a target that identifies a group of messaging engines. Specify the type of target by using the **Target type** property.

-targetType
The type of target named in the **-target** property. Select one of the following values:

Bus member name
The name of a bus member. This option retrieves the active messaging engines that are hosted by the named bus member (an application server or server cluster).

Custom messaging engine group name
The name of a custom group of messaging engines (that form a self-declaring cluster). This option retrieves the active messaging engines that have registered with the named custom group.

Messaging engine name
The name of a messaging engine. This option retrieves the available endpoints that can be used to reach the named messaging engine.

-targetSignificance
This property specifies the significance of the target group. Select one of the following values:

Preferred
It is preferred that a messaging engine is selected from the target group. A messaging engine in the target group is selected if one is available. If a messaging engine is not available in the target group, a messaging engine outside the target group is selected if available in the same service integration bus.

Required
It is required that a messaging engine is selected from the target group. A messaging engine in the target group is selected if one is available. If a messaging engine is not available in the target group, the connection process fails.

-targetTransportChain
The name of the inbound transport chain that the application should target when connecting to a messaging engine in a separate process to the application. If a messaging engine in another process

is chosen, a connection can be made only if the messaging engine is in a server that runs the specified inbound transport chain. Refer to the information center for more information.

If the selected messaging engine is in the same server as the application, a direct in-process connection is made and this transport chain property is ignored.

The transport chains represent network protocol stacks operating within a server. The name you specify must be one of the transport chains available in the server that hosts the messaging engine, as listed on the **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] Messaging engine inbound transports** panel. The following transport chains are provided, but you can define your own transport chains on that panel.

InboundBasicMessaging
This is a connection-oriented protocol that uses a standard TCP/IP connection (JFAP-TCP/IP). It includes support for two-phase transactional (remote XA) flows, so that a message producer or consumer, running on a client or server system, can participate in a global transaction managed on that client or server system. The specific use for the XA flows is to support access from an application running in one server to a messaging engine on second server, perhaps because the first server does not have a suitable messaging engine. If the remote XA flows are used, a transaction coordinator must be available local to the application.

InboundSecureMessaging
This is the InboundBasicMessaging protocol wrapped in SSL.

For more information about using this property with other connection factory properties for workload management of connections, see the topic Administrative properties for JMS connections to a bus.

-providerEndPoints
A comma-separated list of endpoint triplets, with the syntax *host_name*:*port_number*:*chain_name*, that is used to connect to a bootstrap server. For example `Merlin:7276:BootstrapBasicMessaging,Gandalf:5557:BootstrapSecureMessaging`.

Provider endpoints are used if the specified bus cannot be found in the local cell. Message-driven bean applications first attempt to connect the specified bus in the local cell. If this attempt fails, provider endpoints are used to allow the applications to consume messages from a remote cell.

If the host name is not specified, localhost is used as a default value.

If the port number is not specified, 7276 is used as the default value.

If the protocol is not specified, a predefined chain such as BootstrapBasicMessaging is used as the default value.

-authenticationAlias
The name of a J2C authentication alias used for component-managed authentication of connections to the service integration bus.

A Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) authentication alias specifies the user ID and password that is used to authenticate the creation of a new connection to the JMS provider.

-maxBatchSize
The maximum number of messages in a single batch delivered serially to a single message-driven bean instance. Batching of messages can improve performance particularly when used with Acknowledge mode set to Duplicates-ok auto-acknowledge. If message ordering must be retained across failed deliveries, set the batch size to 1.

-maxConcurrency
The maximum number of endpoints to which messages are delivered concurrently.

Increasing this number can improve performance but can increase the number of threads that are in use at any one time. If message ordering must be retained across failed deliveries, set the maximum

concurrent endpoints to 1. Message ordering applies only if the destination that the message-driven bean is consuming from is not a partitioned destination. Partitioned destinations are used in a workload sharing scenario in a cluster.

-subscriptionDurability
This option specifies whether a JMS topic subscription is durable or nondurable.

Usually, only one application at a time can have a consumer for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers. Select one of the following values:

Durable
The messaging provider stores messages while the message-driven bean is not available, and delivers the messages when the message-driven bean becomes available again.

Nondurable
The messaging provider does not store and redeliver messages if a message-driven bean is not available.

-subscriptionName
The subscription name needed for durable topic subscriptions. Required field when using a durable topic subscription.

Each JMS durable subscription is identified by a subscription name (specified on this property). A JMS connection also has an associated client identifier (specified on the Client identifier property), which is used to associate a connection and its objects with the list of messages (on the durable subscription) that is maintained by the JMS provider for the client.

This subscription name must be unique within a given client identifier.

-clientId
The JMS client identifier needed for durable topic subscriptions on all connections created using this activation specification.

The value specified is a unique identifier for a client (message-driven bean). The client identifier is used to associate a client connection with the list of messages (on a durable subscription) that the messaging provider keeps for the client. When a client becomes available, after it has been unavailable, the messaging provider uses the client identifier to re-deliver stored messages to the correct client.

-durableSubscriptionHome
The name of the messaging engine used to store messages delivered to durable subscriptions for objects created from this JMS activation specification. This is a required field when using a durable topic subscription.

Administrators can manage the runtime state of durable subscriptions through publication points for this messaging engine.

-shareDurableSubscriptions
Controls whether or not durable subscriptions are shared across connections with members of a server cluster.

Usually, only one session at a time can have a TopicSubscriber for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers, one on each application server in the server cluster.

This option should be changed from its default only in WebSphere Application Server environments that support server clusters.

Select one of the following values:

In cluster
Allows sharing of durable subscriptions when connections are made from within a server cluster.

Always shared
Durable subscriptions can be shared across connections.

Never shared
Durable subscriptions are never shared across connections.

-shareDataSourceWithCmp
Allow sharing of connections between JMS and container-managed persistence (CMP) entity beans.

True | False

This option is used as part of the task to enable container-managed persistence (CMP) entity beans to share the database connections used by the data store of a messaging engine. This has been estimated as a potential performance improvement of 15% for overall message throughput, but can only be used for entity beans connected to the application server that contains the messaging engine.

For more information about using this option, see "Enabling CMP entity beans and messaging engine data stores to share database connections" on page 530.

-readAhead
Read ahead is an optimization that preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.

Messages that are assigned to a consumer are locked on the server and cannot be consumed by any other consumers for that destination. Messages that are assigned to a consumer, but not consumed before that consumer is closed, are subsequently unlocked on the server and then available for receipt by other consumers.

You can override this property for individual JMS destinations by setting the **Read ahead** property on the JMS destination.

Select one of the following values:

Enabled
The messaging provider preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.

Disabled
The messaging provider does not preemptively assign messages to consumers.

Default
The message provider preemptively assigns messages to consumers on nondurable subscriptions and unshared durable subscriptions. That is, read ahead optimization is turned on only when there can only be a single consumer.

The "pass message payload by reference" properties:

-forwarderDoesNotModifyPayloadAfterSet
true | false (default false)

Applications resending messages that were originally received using this activation specification must obey the following rules:

- The application can replace the data object in a JMS object message, provided that the data object has not yet been set in the message. The application does not modify or replace the data object after it is set in the message.
- The application can replace the byte array in a JMS bytes message, but only by using a single call to writeBytes(byte[]), and provided that the byte array has not yet been set in the message. The application does not modify or replace the byte array after it is set in the message.

-consumerDoesNotModifyPayloadAfterGet
true | false (default false)

Applications that use this activation specification to receive messages must obey the following rule: The application does not modify the data object obtained from a JMS object message. The data object is treated as read only.

When large object messages or bytes messages are sent, the cost in memory and processor use of serializing, deserializing, and copying the message payload can be significant. If you enable the **pass message payload by reference** properties on a connection factory or activation specification, you tell the default messaging provider to override the JMS 1.1 specification and potentially reduce or bypass this data copying.

CAUTION: The parts of the JMS Specification that are bypassed by these properties are defined to ensure message data integrity. Any of your JMS applications that use these properties must strictly follow the rules that are described in the topic Why and when to pass the JMS message payload by reference, or you risk losing data integrity.

-alwaysActivateAllMDBs
True | False

This property is only used when the MDB application is running on a server that is a member of the bus that the application is targeting. It has no effect when the MDB is running on a server that is not a member of the target bus.

If the MDB application is running on a server that is a member of the target bus, enabling this option allows the MDB application to process messages whether or not the server also hosts a running messaging engine. If this option is not enabled, then MDB applications on servers that do not have a local ME running do not process messages.

-retryInterval
The delay (in seconds) between attempts to connect to a messaging engine, both for the initial connection, and any subsequent attempts to establish a better connection.

-userName
The user identity for Java 2 connector security to use.

-password
The password for Java 2 connector security to use.

-WAS_EndpointInitialState
ACTIVE |INACTIVE

This property determines whether the endpoint is activated when the endpoint is registered. If the property is set to active, message consumption begins from the JMS destination as soon as the activation specification is used for a message-driven bean to connect with the destination.

Example

- The following example shows an activation specification being created using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01" )
'9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)'

wsadmin>AdminTask.createSIBJMSActivationSpec("9994GKCNode01(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|node.xml)", ["-name", "myjmsas", "-jndiName", "jms/myjmsas",
 "-destinationJndiName", "jms/mqueue", "-busName", "abus"])
'myjmsas(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098726667851)'

wsadmin>AdminTask.listSIBJMSActivationSpecs("9994GKCNode01(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|node.xml)")
'myjmsas(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098726667851)'
```

- The following example shows an activation specification being created using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask createSIBJMSActivationSpec
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
{-name myjmsas -jndiName jms/myjmsas -destinationJndiName jms/mqueue -busName
```

```
abus} myjmsas(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098726667851)

wsadmin>$AdminTask listSIBJMSActivationSpecs 9994GKCNode01
(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
myjmsas(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098726667851)
```

- The following example creates an activation specification with the WAS_EndpointInitialState optional parameter activated, using Jython:

```
wsadmin>attrs = '[[name "WAS_EndpointInitialState"] [required "false"] [type "java.lang.String"] [value "ACTIVE"]]'
wsadmin>AdminConfig.getid("/Node:myNode01")
myNode01(cells/myCell01/nodes/myNode01|node.xml#Node_1)'
wsadmin>theActSpec = AdminTask.createSIBJMSActivationSpec("myNode01(cells/myCell01/nodes/myNode01|node.xml#Node_1)",
        '-name testas -jndiName testas -destinationJndiName testq -destinationType javax.jms.Queue')
wsadmin>AdminConfig.create('J2EEResourceProperty',theActSpec, attrs)
'WAS_EndpointInitialState(cells/myCell01/nodes/myNode01|resources.xml#J2EEResourceProperty_1298546239332)'
```

deleteSIBJMSActivationSpec command

Use the deleteSIBJMSActivationSpec command to delete a JMS activation specification for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  `print AdminTask.help('SIBJMSAdminCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:

  `print AdminTask.help('`*command_name*`')`

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command deletes the specified JMS activation specification.

Target object

A JMS activation specification.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminTask.listSIBJMSActivationSpecs("9994GKCNode01(cells/
9994GKCNode01Cell/nodes/9994GKCNode01|node.xml)")
'myjmsas(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098726667851)
anojmsas(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098729538669)
test(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098729811201)'

wsadmin>AdminTask.deleteSIBJMSActivationSpec("anojmsas(cells/
9994GKCNode01Cell/nodes/
9994GKCNode01|resources.xml#J2CActivationSpec_1098729538669)")
'myjmsas(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098729538669)'

wsadmin>AdminTask.listSIBJMSActivationSpecs("9994GKCNode01(cells/
9994GKCNode01Cell/nodes/9994GKCNode01|node.xml)")
'myjmsas(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098726667851)
test(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098729811201)'
```

- Using Jacl:

```
wsadmin>$AdminTask listSIBJMSActivationSpecs
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
myjmsas(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098726667851)
anojmsas(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098729538669)
test(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098729811201)

wsadmin>$AdminTask deleteSIBJMSActivationSpec
anojmsas(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098729538669)
myjmsas(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098729538669)

wsadmin>$AdminTask listSIBJMSActivationSpecs
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
myjmsas(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098726667851)
test(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098729811201)
```

listSIBJMSActivationSpecs command

Use the listSIBJMSActivationSpecs command to list all JMS activation specifications for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBJMSAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command lists all JMS activation specifications for the default messaging provider at a specific scope.

Target object

Scope of the default messaging provider at which the JMS activation specifications were created.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01" )
'9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)'

wsadmin>AdminTask.listSIBJMSActivationSpecs("9994GKCNode01(cells/
9994GKCNode01Cell/nodes/9994GKCNode01|node.xml)")
'myjmsas(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098726667851)'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask listSIBJMSActivationSpecs
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
myjmsas(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098726667851)
```

modifySIBJMSActivationSpec command

Use the modifySIBJMSActivationSpec command to change properties of a JMS activation specification for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBJMSAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command changes the properties of a JMS activation specification.

Target object

The scope of the default messaging provider at which the JMS activation specification is to be modified.

Required parameters

None.

Optional parameters

-name
The administrative name assigned to this activation specification.

-jndiName
The JNDI name that is specified in the bindings for message-driven beans associated with this activation specification.

-description
An optional description for the activation specification.

-destinationType
Use this parameter to determine whether the message-driven bean uses a JMS queue or a JMS topic. Select one of the following values:

Queue
The message-driven bean uses a JMS queue. The JNDI name of the JMS queue is specified on the **Destination JNDI name** property.

Topic The message-driven bean uses a JMS topic. The JNDI name of the JMS topic is specified on the **Destination JNDI name** property.

-destinationJndiName
The JNDI name of the destination JMS queue or topic used by the message-driven bean.

-messageSelector
string

-busName
Enter the name of the service integration bus to which connections are made. This must be the name of the bus on which the destination identified by the **-destinationJndiName** property is defined.

-acknowledgeMode
The acknowledge mode indicates how a message received by a message-driven bean should be acknowledged. Select one of the following values:

Auto-acknowledge
The session automatically acknowledges the delivery of a message.

Duplicates-ok auto-acknowledge
The session lazily acknowledges the delivery of messages, which can improve performance, but can lead to a message-driven bean receiving a message more than once.

-target
The name of a target that identifies a group of messaging engines. Specify the type of target using the Target type property.

-targetType
The type of target named in the **-target** property. Select one of the following values:

Bus member name
The name of a bus member. This option retrieves the active messaging engines that are hosted by the named bus member (an application server or server cluster).

Custom messaging engine group name
The name of a custom group of messaging engines (that form a self-declaring cluster). This option retrieves the active messaging engines that have registered with the named custom group.

Messaging engine name
The name of a messaging engine. This option retrieves the available endpoints that can be used to reach the named messaging engine.

-targetSignificance
This property specifies the significance of the target group. Select one of the following values:

Preferred
It is preferred that a messaging engine is selected from the target group. A messaging engine in the target group is selected if one is available. If a messaging engine is not available in the target group, a messaging engine outside the target group is selected if available in the same service integration bus.

Required
It is required that a messaging engine is selected from the target group. A messaging engine in the target group is selected if one is available. If a messaging engine is not available in the target group, the connection process fails.

-targetTransportChain
The name of the inbound transport chain that the application should target when connecting to a messaging engine in a separate process to the application. If a messaging engine in another process is chosen, a connection can be made only if the messaging engine is in a server that runs the specified inbound transport chain. Refer to the information center for more information.

If the selected messaging engine is in the same server as the application, a direct in-process connection is made and this transport chain property is ignored.

The transport chains represent network protocol stacks operating within a server. The name you specify must be one of the transport chains available in the server that hosts the messaging engine, as listed on the **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] Messaging engine inbound transports** panel. The following transport chains are provided, but you can define your own transport chains on that panel.

InboundBasicMessaging
This is a connection-oriented protocol that uses a standard TCP/IP connection (JFAP-TCP/IP). It includes support for two-phase transactional (remote XA) flows, so that a message producer or consumer, running on a client or server system, can participate in a global transaction managed on that client or server system. The specific use for the XA flows is to support access from an application running in one server to a messaging engine on second server, perhaps because the first server does not have a suitable messaging engine. If the remote XA flows are used, a transaction coordinator must be available local to the application.

InboundSecureMessaging
This is the InboundBasicMessaging protocol wrapped in SSL.

For more information about using this property with other connection factory properties for workload management of connections, see the topic Administrative properties for JMS connections to a bus.

-providerEndPoints
A comma-separated list of endpoint triplets, with the syntax *host_name*:*port_number*:*chain_name*, used to connect to a bootstrap server. For example
`Merlin:7276:BootstrapBasicMessaging,Gandalf:5557:BootstrapSecureMessaging`.

Provider endpoints are not used unless the specified bus cannot be found in the local cell. MDB applications first attempt to connect the specified bus in the local cell. If this attempt fails, provider endpoints are used to allow the applications to consume messages from a remote cell.

If the host name is not specified, localhost is used as a default value.

If the port number is not specified, 7276 is used as the default value.

If the protocol is not specified, a predefined chain such as BootstrapBasicMessaging is used as the default value.

-authenticationAlias
The name of a J2C authentication alias used for component-managed authentication of connections to the service integration bus.

A Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) authentication alias specifies the user ID and password that is used to authenticate the creation of a new connection to the JMS provider.

-maxBatchSize
The maximum number of messages in a single batch delivered serially to a single message-driven bean instance. Batching of messages can improve performance particularly when used with Acknowledge mode set to Duplicates-ok auto-acknowledge. If message-ordering must be retained across failed deliveries, set the batch size to 1

-maxConcurrency
The maximum number of endpoints to which messages are delivered concurrently.

Increasing this number can improve performance but can increase the number of threads that are in use at any one time. If message ordering must be retained across failed deliveries, set the maximum concurrent endpoints to 1. Message ordering applies only if the destination that the message-driven bean is consuming from is not a partitioned destination. Partitioned destinations are used in a workload sharing scenario in a cluster.

-subscriptionDurability
Whether a JMS topic subscription is durable or nondurable

Usually, only one application at a time can have a consumer for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers. Select one of the following values:

Durable
The messaging provider stores messages while the message-driven bean is not available, and delivers the messages when the message-driven bean becomes available again.

Nondurable
The messaging provider does not store and redeliver messages if a message-driven bean is not available.

-subscriptionName
The subscription name needed for durable topic subscriptions. Required field when using a durable topic subscription.

Each JMS durable subscription is identified by a subscription name (specified on this property). A JMS connection also has an associated client identifier (specified on the Client identifier property), which is used to associate a connection and its objects with the list of messages (on the durable subscription) that is maintained by the JMS provider for the client.

This subscription name must be unique within a given client identifier.

-clientId
The JMS client identifier needed for durable topic subscriptions on all connections created using this activation specification.

The value specified is a unique identifier for a client (message-driven bean). The client identifier is used to associate a client connection with the list of messages (on a durable subscription) that the messaging provider keeps for the client. When a client becomes available again, after a being unavailable, the messaging provider uses the client identifier to redeliver stored messages to the correct client.

-durableSubscriptionHome
The name of the messaging engine used to store messages delivered to durable subscriptions for objects created from this JMS activation specification. This is a required field when using a durable topic subscription.

Administrators can manage the runtime state of durable subscriptions through publication points for this messaging engine.

-shareDurableSubscriptions
Controls whether or not durable subscriptions are shared across connections with members of a server cluster.

Usually, only one session at a time can have a TopicSubscriber for a particular durable subscription. This property enables you to override this behavior, to enable a durable subscription to have multiple simultaneous consumers, one on each application server in the server cluster.

This option should be changed from its default only in WebSphere Application Server environments that support server clusters.

Select one of the following values:

In cluster
Allows sharing of durable subscriptions when connections are made from within a server cluster.

Always shared
Durable subscriptions can be shared across connections.

Never shared
Durable subscriptions are never shared across connections.

-shareDataSourceWithCmp
Allow sharing of connections between JMS and container-managed persistence (CMP) entity beans.

True | False

This option is used as part of the task to enable container-managed persistence (CMP) entity beans to share the database connections used by the data store of a messaging engine. This has been estimated as a potential performance improvement of 15% for overall message throughput, but can only be used for entity beans connected to the application server that contains the messaging engine.

For more information about using this option, see Enabling CMP entity beans and messaging engine data stores to share database connections..

-readAhead
Read ahead is an optimization that preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.

Messages that are assigned to a consumer are locked on the server and cannot be consumed by any other consumers for that destination. Messages that are assigned to a consumer, but not consumed before that consumer is closed, are subsequently unlocked on the server and then available for receipt by other consumers.

You can override this property for individual JMS destinations by setting the **Read ahead** property on the JMS destination.

Select one of the following values:

Enabled
The messaging provider preemptively assigns messages to consumers. This improves the time taken to satisfy consumer requests.

Disabled
The messaging provider does not preemptively assign messages to consumers.

Default
The message provider preemptively assigns messages to consumers on nondurable subscriptions and unshared durable subscriptions. That is, read ahead optimization is turned on only when there can only be a single consumer.

The “pass message payload by reference” properties:

-forwarderDoesNotModifyPayloadAfterSet
true | false (default false)

Applications resending messages that were originally received using this activation specification must obey the following rules:

- The application can replace the data object in a JMS object message, provided that the data object has not yet been set in the message. The application does not modify or replace the data object after it is set in the message.
- The application can replace the byte array in a JMS bytes message, but only by using a single call to writeBytes(byte[]), and provided that the byte array has not yet been set in the message. The application does not modify or replace the byte array after it is set in the message.

-consumerDoesNotModifyPayloadAfterGet
true | false (default false)

Applications that use this activation specification to receive messages must obey the following rule: The application does not modify the data object obtained from a JMS object message. The data object is treated as read only.

When large object messages or bytes messages are sent, the cost in memory and processor use of serializing, deserializing, and copying the message payload can be significant. If you enable the **pass message payload by reference** properties on a connection factory or activation specification, you tell the default messaging provider to override the JMS 1.1 specification and potentially reduce or bypass this data copying.

CAUTION: The parts of the JMS Specification that are bypassed by these properties are defined to ensure message data integrity. Any of your JMS applications that use these properties must strictly follow the rules that are described in the topic Why and when to pass the JMS message payload by reference, or you risk losing data integrity.

-alwaysActivateAllMDBs
True | False

This property is only used when the MDB application is running on a server that is a member of the bus that the application is targeting. It has no effect when the MDB is running on a server that is not a member of the target bus.

If the MDB application is running on a server that is a member of the target bus, enabling this option allows the MDB application to process messages whether or not the server also hosts a running messaging engine. If this option is not enabled, then MDB applications on servers that do not have a local ME running do not process messages.

-retryInterval
The delay (in seconds) between attempts to connect to a messaging engine, both for the initial connection, and any subsequent attempts to establish a better connection.

-userName
The user identity for Java 2 connector security to use.

-password
The password for Java 2 connector security to use.

-WAS_EndpointInitialState
This property determines whether the endpoint is activated when the endpoint is registered. If the property is set to active, message consumption begins from the JMS destination as soon as the activation specification is used for a message-driven bean to connect with the destination.

The value of this parameter must be ACTIVE or INACTIVE.

Example

- The following example shows an activation specification being modified using Jython:

```
wsadmin>AdminTask.modifySIBJMSActivationSpec("myjmsas(cells/
9994GKCNode01Cell/nodes/
9994GKCNode01|resources.xml#J2CActivationSpec_1098726667851)",
 ["-jndiName", "jms/jmsas4q1",
 "-description", "JMS activation specification for myqueue1",
 "-destinationJndiName", "jms/myqueue1"])
'myjmsas(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivation Spec_1098726667851)'
```

- The following example shows an activation specification being modified using Jacl:

```
wsadmin>$AdminTask modifySIBJMSActivationSpec
myjmsas(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098726667851)
{-jndiName jms/jmsas4q1 -description "JMS activation specification
for myqueue1" -destinationJndiName jms/myqueue1}
myjmsas(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivation Spec_1098726667851)
```

- The following example modifies an activation specification by activating the WAS_EndpointInitialState optional parameter, using Jython:

```
wsadmin>attrs = '[[name "WAS_EndpointInitialState"] [required "false"] [type "java.lang.String"] [value "ACTIVE"]]'
wsadmin>AdminConfig.getid("/Node:myNode01")
'myNode01(cells/myCell01/nodes/myNode01|node.xml#Node_1)'
wsadmin>AdminTask.listSIBJMSActivationSpecs("myNode01(cells/myCell01/nodes/myNode01|node.xml#Node_1)")
'newas(cells/myCell01/nodes/myNode01|resources.xml#J2CActivationSpec_1298546034140)'
wsadmin>AdminConfig.create('J2EEResourceProperty',
"testas(cells/myCell01/nodes/myNode01|resources.xml#J2CActivationSpec_1298546034140)", attrs)
'WAS_EndpointInitialState(cells/myCell01/nodes/myNode01|resources.xml#J2EEResourceProperty_1298546239332)'
```

showSIBJMSActivationSpec command

Use the showSIBJMSActivationSpec command to show properties of a JMS activation specification for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  `print AdminTask.help('SIBJMSAdminCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:

  `print AdminTask.help('command_name')`

Purpose

This command returns a set of property-value pairs for the specified JMS activation specification.

Target object

A JMS activation specification.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01" )
'9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)'

wsadmin>AdminTask.listSIBJMSActivationSpecs("9994GKCNode01(cells/
9994GKCNode01Cell/nodes/9994GKCNode01|node.xml)")
'myjmsas(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098726667851)'

wsadmin>AdminTask.showSIBJMSActivationSpec("myjmsas(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|resources.xml#J2CActivationSpec_1098726667851)")
myjmsas(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098726667851)
'{busName=abus, subscriptionDurability=Nondurable, description=,
destinationType=, password=, targetTransportChain=,
acknowledgeMode=Auto-acknowledge, readAhead=Default, clientId=,
authenticationAlias=, name=myjmsas, maxConcurrency=10, maxBatchSize=1,
durableSubscriptionHome=, userName=, messageSelector=,
shareDurableSubscriptions=InCluster, jndiName=jms/myjmsas,
shareDataSourceWithCMP=false, destination=, destinationJndiName=jms/mqueue,
subscriptionName=}'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask listSIBJMSActivationSpecs
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
myjmsas(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098726667851)

wsadmin>$AdminTask showSIBJMSActivationSpec
myjmsas(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098726667851)
{busName=abus, subscriptionDurability=Nondurable, description=,
destinationType=, password=, targetTransportChain=,
acknowledgeMode=Auto-acknowledge, readAhead=Default, clientId=,
authenticationAlias=, name=myjmsas, maxConcurrency=10, maxBatchSize=1,
durableSubscriptionHome=, userName=, messageSelector=,
shareDurableSubscriptions=InCluster, jndiName=jms/myjmsas,
shareDataSourceWithCMP=false, destination=, destinationJndiName=jms/mqueue,
subscriptionName=}
```

createSIBJMSConnectionFactory command

Use the createSIBJMSConnectionFactory command to create a new JMS connection factory for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBJMSAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command creates a new JMS connection factory at a specific scope.

Target object

Scope of the default messaging provider at which the JMS connection factory is to be created.

Required parameters

-name
The administrative name assigned to this connection factory.

-jndiName
The JNDI name that is specified in the bindings for message-driven beans associated with this connection factory.

-busName
Enter the name of the service integration bus to which connections are made. This must be the name of the bus on which the destination identified by the **-destinationJndiName** property is defined.

Optional parameters

-type
queue | topic

The **type** parameter is used to specify the type of connection factory to create. To create a queue connection factory, set this parameter to queue. To create a topic connection factory, set this parameter to topic. Leave this parameter unset to create a generic connection factory.

-category
An optional category string to use when classifying or grouping the resource.

-description
text

-logMissingTransactionContext
True | False

-manageCachedHandles
True | False

-clientID
id

-userName
name

-password
password

-target
The name of a target that identifies a group of messaging engines. Specify the type of target using the Target type property.

Before the connection proximity search is performed to select a suitable messaging engine, the set of messaging engines that are members of the specified target group are selected. The connection proximity search is then restricted to these messaging engines. If a target group is not specified (the default), then all messaging engines in the bus are considered during the connection proximity search. For example, if the Target type property is set to Bus member name, the Target property specifies the name of the bus member from which suitable messaging engines can be chosen.

-targetType
The type of target named in the Target property.

Select one of the following values:

Bus member name
The name of a bus member. This option retrieves the active messaging engines that are hosted by the named bus member (an application server or server cluster).

To specify a non-clustered bus member the **-target** property must be set to *node_name*.*server_name*, for example `Node01.server1`. For a cluster bus member the **-target** property must be set to the cluster name.

Custom messaging engine group name
The name of a custom group of messaging engines (that form a self-declaring cluster). This option retrieves the active messaging engines that have registered with the named custom group.

Messaging engine name
The name of a messaging engine. This option retrieves the available endpoints that can be used to reach the named messaging engine.

-targetSignificance
This property specifies the significance of the target group.

This property defines whether the connection proximity search is restricted to only the messaging engines in the target group.

Select one of the following values:

Preferred
It is preferred that a messaging engine is selected from the target group. A messaging engine in the target group is selected if one is available. If a messaging engine is not available in the target group, a messaging engine outside the target group is selected if available in the same service integration bus.

Note: A connection to a non-preferred target might be returned even if a preferred one is available. This can happen when connection pooling is enabled for a ConnectionFactory, which it is by default when you use a JMS ConnectionFactory in a server environment:

- When a preferred messaging engine is not available, a connection to a non-preferred one can be created and stored in the connection pool.
- The next time the application requests a connection it receives this pooled connection even if the preferred messaging engine has subsequently become available.

You can modify the connection pool settings to regularly discard all unused connections in the pool. After the connection pool is emptied, connections are made to the preferred messaging engine if one is available. For example, set the **ReapTime**, **AgedTimeout** and **UnusedTimeout** to 300 seconds, and the **PurgePolicy** to EntirePool. This refreshes the connection pool every 5 minutes, after which time the application selects a preferred messaging engine if one is available.

Required
It is required that a messaging engine is selected from the target group. A messaging engine in the target group is selected if one is available. If a messaging engine is not available in the target group, the connection process fails.

-targetTransportChain
The name of the inbound transport chain that the application should target when connecting to a messaging engine in a separate process to the application. If a messaging engine in another process is chosen, a connection can be made only if the messaging engine is in a server that runs the specified inbound transport chain. Refer to the information center for more information.

These transport chains specify the communication protocols that can be used to communicate with the application server to which the client application is connected.

If the selected messaging engine is in the same server as the application, a direct in-process connection is made and this transport chain property is ignored.

The transport chains represent network protocol stacks operating within a server. The name you specify must be one of the transport chains available in the server that hosts the messaging engine, as listed on the **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] Messaging engine inbound transports** panel. The following transport chains are provided, but you can define your own transport chains on that panel.

InboundBasicMessaging
This is a connection-oriented protocol that uses a standard TCP/IP connection (JFAP-TCP/IP). It includes support for two-phase transactional (remote XA) flows, so that a message producer or consumer, running on a client or server system, can participate in a global transaction managed on that client or server system. The specific use for the XA flows is to support access from an application running in one server to a messaging engine on second server, perhaps because the first server does not have a suitable messaging engine. If the remote XA flows are used, a transaction coordinator must be available local to the application.

InboundSecureMessaging
This is the InboundBasicMessaging protocol wrapped in SSL.

For more information about using this property with other connection factory properties for workload management of connections, see the topic Administrative properties for JMS connections to a bus.

-providerEndPoints
A comma-separated list of endpoint triplets, with the syntax hostName:portNumber:chainName, used to connect to a bootstrap server. For example Merlin:7276:BootstrapBasicMessaging,Gandalf:5557:BootstrapSecureMessaging. If hostName is not specified, the default is localhost. If portNumber is not specified, the default is 7276. If chainName is not specified, the default is BootstrapBasicMessaging. Refer to the information center for more information.

-connectionProximity
Bus | Host | Cluster | Server

-durableSubscriptionHome
me_name

-nonPersistentMapping
BestEffortNonPersistent | ExpressNonPersistent | ReliableNonPersistent | ReliablePersistent | AssuredPersistent | AsSIBDestination | None

-persistentMapping
BestEffortNonPersistent | ExpressNonPersistent | ReliableNonPersistent | ReliablePersistent | AssuredPersistent | AsSIBDestination | None

-readAhead
Default | AlwaysOn | AlwaysOff

-tempQueueNamePrefix
prefix

-tempTopicNamePrefix
prefix

-shareDurableSubscriptions
AsCluster | AlwaysShared | NeverShared

The “pass message payload by reference” properties:

-producerDoesNotModifyPayloadAfterSet
true | false (default false)

Applications that use this connection factory to send messages must obey the following rules:

- The application does not modify the data object contained in a JMS object message.
- The application populates a JMS bytes message by using a single call to writeBytes(byte[]) and does not modify the byte array after it is set in the message.

-consumerDoesNotModifyPayloadAfterGet
true | false (default false)

Applications that use this connection factory to receive messages must obey the following rule: The application does not modify the data object obtained from a JMS object message. The data object is treated as read only.

When large object messages or bytes messages are sent, the cost in memory and processor use of serializing, deserializing, and copying the message payload can be significant. If you enable the **pass message payload by reference** properties on a connection factory or activation specification, you tell the default messaging provider to override the JMS 1.1 specification and potentially reduce or bypass this data copying.

CAUTION: The parts of the JMS Specification that are bypassed by these properties are defined to ensure message data integrity. Any of your JMS applications that use these properties must strictly follow the rules that are described in the topic Why and when to pass the JMS message payload by reference, or you risk losing data integrity.

-authDataAlias
alias_name

-shareDataSourceWithCMP
True | False

-xaRecoveryAuthAlias
alias_name

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01" )
'9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)'

wsadmin>AdminTask.createSIBJMSConnectionFactory("9994GKCNode01(cells/
9994GKCNode01Cell/nodes/9994GKCNode01|node.xml)", ["-name", "jmscf1",
 "-jndiName", "jms/jmscf1", "-busName", "abus"])
'jmscf1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CConnectionFactory_1098733325084)'

wsadmin>AdminTask.createSIBJMSConnectionFactory("9994GKCNode01(cells/
9994GKCNode01Cell/nodes/9994GKCNode01|node.xml)", ["-name", "jmsqcf2",
 "-jndiName", "jms/jmsqcf1", "-busName", "abus", "-type", "queue"])
'jmsqcf2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CConnectionFactory_1098733675578)'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask createSIBJMSConnectionFactory
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
 {-name jmscf1 -jndiName jms/jmscf1 -busName abus}
jmscf1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CConnectionFactory_1098733325084)

wsadmin>$AdminTask createSIBJMSConnectionFactory
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
 {-name jmsqcf2 -jndiName jms/jmsqcf1 -busName abus -type queue}
jmsqcf2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CConnectionFactory_1098733675578)
```

deleteSIBJMSConnectionFactory command

Use the deleteSIBJMSConnectionFactory command to delete a JMS connection factory for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  `print AdminTask.help('SIBJMSAdminCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:

  `print AdminTask.help('`*command_name*`')`

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command deletes the specified JMS connection factory.

Target object

A JMS connection factory.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01" )
'9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)'

wsadmin>AdminTask.deleteSIBJMSConnectionFactory("jmsqcf2(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|resources.xml#J2CConnectionFactory_1098736176544)")
'jmsqcf2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CConnectionFactory_1098736176544)'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask deleteSIBJMSConnectionFactory
jmsqcf2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CConnectionFactory_1098736176544)
jmsqcf2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CConnectionFactory_1098736176544)
```

listSIBJMSConnectionFactories command

Use the listSIBJMSConnectionFactories command to list all JMS connection factories for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBJMSAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command lists all JMS connection factories for the default messaging provider at a specific scope

Target object

Scope of the default messaging provider at which the JMS connection factories were created.

Required parameters

None.

Optional parameters

-type

The **-type** parameter is used to filter the list of connection factories.

Select one of the following values:

all List all JMS connection factories (generic, queue, and topic) at the specified scope.

queue List all JMS queue connection factories at the specified scope.

topic List all JMS topic connection factories at the specified scope.

If the **-type** parameter is not supplied, then only generic JMS connection factories at the scope are listed.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01" )
'9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)'

AdminTask.listSIBJMSConnectionFactories("9994GKCNode01(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|node.xml#Node_1)")
'qcf1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CConnectionFactory_1098730054140)'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask listSIBJMSConnectionFactories
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
qcf1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CConnectionFactory_1098730054140)
```

modifySIBJMSConnectionFactory command

Use the modifySIBJMSConnectionFactory command to modify the properties of a JMS connection factory for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBJMSAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command changes the properties of a JMS connection factory.

Target object

A JMS connection factory.

Required parameters

None.

Optional parameters

-name
factory_name

-jndiName
jndi_name

-category
category

-description
text

-logMissingTransactionContext
True | False

-manageCachedHandles
True | False

-busName
name

-clientID
id

-userName
name

-password
password

-target
target_name

-targetType
BusMember | Custom | ME

-targetSignificance
Preferred | Required

-targetTransportChain
transport_chain

-providerEndPoints
tuple_list

-connectionProximity
Bus | Host | Cluster | Server

-durableSubscriptionHome
me_name

-nonPersistentMapping
BestEffortNonPersistent | ExpressNonPersistent | ReliableNonPersistent | ReliablePersistent | AssuredPersistent | AsSIBDestination | None

-persistentMapping
BestEffortNonPersistent | ExpressNonPersistent | ReliableNonPersistent | ReliablePersistent | AssuredPersistent | AsSIBDestination | None

-readAhead
Default | AlwaysOn | AlwaysOff

-tempQueueNamePrefix
prefix

-tempTopicNamePrefix
prefix

-shareDurableSubscriptions
AsCluster | AlwaysShared | NeverShared

The “pass message payload by reference” properties:

-producerDoesNotModifyPayloadAfterSet
true | false (default false)

Applications that use this connection factory to send messages must obey the following rules:

- The application does not modify the data object contained in a JMS object message.
- The application populates a JMS bytes message by using a single call to writeBytes(byte[]) and does not modify the byte array after it is set in the message.

-consumerDoesNotModifyPayloadAfterGet
true | false (default false)

Applications that use this connection factory to receive messages must obey the following rule: The application does not modify the data object obtained from a JMS object message. The data object is treated as read only.

When large object messages or bytes messages are sent, the cost in memory and processor use of serializing, deserializing, and copying the message payload can be significant. If you enable the **pass message payload by reference** properties on a connection factory or activation specification, you tell the default messaging provider to override the JMS 1.1 specification and potentially reduce or bypass this data copying.

CAUTION: The parts of the JMS Specification that are bypassed by these properties are defined to ensure message data integrity. Any of your JMS applications that use these properties must strictly follow the rules that are described in the topic Why and when to pass the JMS message payload by reference, or you risk losing data integrity.

-authDataAlias
alias_name

-shareDataSourceWithCMP
True | False

-xaRecoveryAuthAlias
alias_name

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01" )
'9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)'

wsadmin>AdminTask.modifySIBJMSConnectionFactory("jmsqcf2(cells/9994GKCNode01Cell/
```

```
nodes/9994GKCNode01|resources.xml#J2CConnectionFactory_1098736176544)",
 ["-manageCachedHandles", "True"])
'jmsqcf2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CConnectionFactory_1098733675578)'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask modifySIBJMSConnectionFactory
jmsqcf2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CConnectionFactory_1098736176544)
 {-manageCachedHandles True}
jmsqcf2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CConnectionFactory_1098733675578)
```

showSIBJMSConnectionFactory command

Use the showSIBJMSConnectionFactory command to show the properties of a JMS connection factory for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBJMSAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command returns a set of property-value pairs for the specified JMS connection factory.

Target object

A JMS connection factory.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01" )
'9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)'

wsadmin>AdminTask.showSIBJMSConnectionFactory("jmsqcf2(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|resources.xml#J2CConnectionFactory_1098733675578)")
'{target=, targetTransportChain=, readAhead=Default, password=,
targetType=BusMember, tempQueueNamePrefix=, connectionProximity=Bus,
```

```
nonPersistentMapping=ExpressNonPersistent, name=jmsqcf2,
targetSignificance=Preferred, shareDurableSubscriptions=InCluster,
providerEndPoints=, shareDataSourceWithCMP=false, userName=,
logMissingTransactionContext=false, busName=abus,
persistentMapping=ReliablePersistent, clientID=,
jndiName=jms/jmsqcf1, manageCachedHandles=false}'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask showSIBJMSConnectionFactory
jmsqcf2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CConnectionFactory_1098733675578)
{target=, targetTransportChain=, readAhead=Default, password=,
targetType=BusMember, tempQueueNamePrefix=, connectionProximity=Bus,
nonPersistentMapping=ExpressNonPersistent, name=jmsqcf2,
targetSignificance=Preferred, shareDurableSubscriptions=InCluster,
providerEndPoints=, shareDataSourceWithCMP=false, userName=,
logMissingTransactionContext=false, busName=abus,
persistentMapping=ReliablePersistent, clientID=,
jndiName=jms/jmsqcf1, manageCachedHandles=false}
```

createSIBJMSQueue command

Use the createSIBJMSQueue command to create a new JMS queue for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBJMSAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The createSIBJMSQueue command creates a JMS queue for the default messaging provider at a specific scope.

Target object

The scope of the default messaging provider at which the JMS queue is to be created.

Required parameters

-name
The identifier by which this JMS queue is known for administrative purposes.

-jndiName
The JNDI name that is used to bind the queue into the application server namespace.

-queueName
The name of the service integration bus destination to which the JMS queue maps.

Optional parameters

-description
An optional description for the bus, for administrative purposes.

-deliveryMode Application | NonPersistent | Persistent
The delivery mode to be used by MessageProducers for messages sent to this queue.

-timeToLive
The default length of time from its dispatch time that a message sent to this queue should be retained by the system, where 0 indicates that time to live value does not expire. The value from the producer is used if the **Time to Live** parameter is not supplied.

-priority
The priority for messages sent to this queue. The value from the producer is used if not completed. In the range 0 to 9 where 0 is the lowest priority and 9 is the highest priority

-readAhead AsConnection | AlwaysOn | AlwaysOff
Used to control read-ahead optimization during message delivery. The default is AsConnection.

-busName
The name of the service integration bus that the service integration bus destination, identified by **queueName**, is configured on. If not set, the bus that the application is connected to is used.

-scopeToLocalQP TRUE | FALSE
Indicates whether the underlying service integration bus queue destination is scoped to a local queue point when addressed using this JMS queue. A local queue point is a queue point that is configured on the messaging engine to which the JMS application is connected. The option applies when using this JMS queue to send and receive messages and when setting a reply queue in a request message. When a reply queue is set in a request message, the local queue point is on the messaging engine to which the application setting the reply queue is connected, not the messaging engine to which the application that uses the reply queue sends the reply message. If the connected messaging engine does not have a queue point for the destination this option is ignored. The default value is FALSE.

Changing the default setting of this option is supported only when used by a JMS application that is running with a WebSphere Application Server Version 7.0 or later server or client, and that is connected to a messaging engine running on a WebSphere Application Server Version 7.0 or later server. Use on previous versions of WebSphere Application Server will result in an exception to the application.

-producerBind TRUE | FALSE
Indicates how JMS producers bind to queue points of the clustered queue. The default value is FALSE.

Changing the default setting of this option is supported only when used by a JMS application that is running with a WebSphere Application Server Version 7.0 or later server or client, and that is connected to a messaging engine running on a WebSphere Application Server Version 7.0 or later server. Use on previous versions of WebSphere Application Server will result in an exception to the application.

TRUE The messaging system selects a queue point when the session is opened. All messages produced by the session are sent to the chosen queue point. The messaging system uses the **producerPreferLocal** setting when selecting the queue point.

FALSE
The messaging system selects a queue point each time a message is sent, potentially

workload balancing the messages across all available queue points. The messaging system uses the **producerPreferLocal** setting when selecting the queue point.

-producerPreferLocal TRUE | FALSE
Indicates whether a queue point local to the producer is preferred to other available queue points when the messaging system selects a queue point to produce messages to. A local queue point is a queue point that is configured on the messaging engine to which the JMS application is connected. The default value is TRUE.

Changing the default setting of this option is supported only when used by a JMS application that is running with a WebSphere Application Server Version 7.0 or later server or client, and that is connected to a messaging engine running on a WebSphere Application Server Version 7.0 or later server. Use on previous versions of WebSphere Application Server will result in an exception to the application.

-consumerGatherMessages TRUE | FALSE
A JMS consumer or browser is attached to a single queue point of the service integration bus destination by the messaging system. This parameter indicates whether a JMS consumer or browser take messages from any available queue points of the service integration bus destination (TRUE), or the single queue point to which it is attached (FALSE). The default value is FALSE. Gathering messages from multiple queue points results in an increased performance cost and message order cannot be maintained.

Changing the default setting of this option is supported only when used by a JMS application that is running with a WebSphere Application Server Version 7.0 or later server or client, and that is connected to a messaging engine running on a WebSphere Application Server Version 7.0 or later server. Use on previous versions of WebSphere Application Server will result in an exception to the application.

Examples

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01" )
'9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)'

wsadmin>AdminTask.createSIBJMSQueue("WASINSTALL2Node01(cells/WASINSTALL2Cell01/
nodes/WASINSTALL2Node01|node.xml#Node_1)", ["-name", "jmsq2", "-jndiName",
 "jms/jnmsq2", "-queueName", "busq4jmsq2"])
'jmsq2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml
#J2CAdminObject_1098737234986)'

wsadmin>AdminTask.listSIBJMSQueues("WASINSTALL2Node01(cells/WASINSTALL2Cell01
/nodes/WASINSTALL2Node01|node.xml#Node_1)")
'queue1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098711838691)
jmsq2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098737234986)'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask createSIBJMSQueue
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
 {-name jmsq2 -jndiName jms/jnmsq2 -queueName busq4jmsq2}
jmsq2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098737234986)

wsadmin>$AdminTask listSIBJMSQueues
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
queue1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098711838691)
jmsq2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098737234986)
```

The following example shows how to create a default messaging provider JMS queue that selects a queue point when a session is opened and never changes:

- Using Jython:

```
wsadmin>AdminTask.createSIBJMSQueue("9994GKCNode01(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|node.xml#Node_1)", ["-name", "MyJMSQueue", "-jndiName",
 "MyJMSQueue", "-busName bus1", "-queueName", "MyExistingQueue", "-deliveryMode",
 "Application", "-readAhead", "AsConnection", "-producerBind", "TRUE"])
```

- Using Jacl:

```
wsadmin>$AdminTask createSIBJMSQueue 9994GKCNode01(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|node.xml#Node_1 {-name MyJMSQueue -jndiName MyJMSQueue
-busName bus1 -queueName MyExistingQueue -deliveryMode Application
-readAhead AsConnection -producerBind TRUE }
```

The following example shows how to create a default messaging provider JMS queue that selects a queue point every time a message is sent. There is no preference over which queue point is selected and the consumers take messages from any queue point:

- Using Jython:

```
wsadmin>AdminTask.createSIBJMSQueue("9994GKCNode01(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|node.xml#Node_1)", ["-name", "MyJMSQueue", "-jndiName",
 "MyJMSQueue", "-busName bus1", "-queueName", "MyExistingQueue", "-deliveryMode",
 "Application", "-readAhead", "AsConnection", "-producerBind", "FALSE",
 "-producerPreferLocal", "FALSE", "-gatherMessages", "TRUE"])
```

- Using Jacl:

```
wsadmin>$AdminTask createSIBJMSQueue 9994GKCNode01(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|node.xml#Node_1 {-name MyJMSQueue -jndiName MyJMSQueue
-busName bus1 -queueName MyExistingQueue -deliveryMode Application
-readAhead AsConnection -producerBind FALSE -producerPreferLocal FALSE
-gatherMessages TRUE}
```

The following example shows how to create a default messaging provider JMS queue that scopes all operations on it down to the queue point local to the user of the JMS queue:

- Using Jython:

```
wsadmin>AdminTask.createSIBJMSQueue("9994GKCNode01(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|node.xml#Node_1)", ["-name", "MyJMSQueue", "-jndiName",
 "MyJMSQueue", "-busName bus1", "-queueName", "MyExistingQueue", "-deliveryMode",
 "Application", "-readAhead", "AsConnection", "-scopeToLocalQP", "TRUE"])
```

- Using Jacl:

```
wsadmin>$AdminTask createSIBJMSQueue 9994GKCNode01(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|node.xml#Node_1 {-name MyJMSQueue -jndiName MyJMSQueue
-busName bus1 -queueName MyExistingQueue -deliveryMode Application
-readAhead AsConnection -scopeToLocalQP TRUE}
```

deleteSIBJMSQueue command

Use the deleteSIBJMSQueue command to delete a JMS queue for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('SIBJMSAdminCommands')
```

- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command deletes the specified JMS queue.

Target object

A JMS queue.

The JMS queue is deleted at the specified scope.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01" )
'9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)'

wsadmin>AdminTask.deleteSIBJMSQueue("jmsq2(cells/9994GKCNode01Cell/nodes/
9994GKCNode01|resources.xml#J2CAdminObject_1098737234986)")
'jmsq2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098737234986)'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask deleteSIBJMSQueue
jmsq2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098737234986)
jmsq2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098737234986)
```

listSIBJMSQueues command

Use the listSIBJMSQueues command to list all JMS queues for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBJMSAdminCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command returns a list of all JMS queues for the default messaging provider at a specific scope.

Target object

Scope of the default messaging provider at which the JMS queues were created.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

  ```
  wsadmin>AdminConfig.getid("/Node:9994GKCNode01" )
  '9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)'

  wsadmin>AdminTask.listSIBJMSQueues("9994GKCNode01(cells/9994GKCNode01Cell/
  nodes/9994GKCNode01|node.xml#Node_1)")
  'queue1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
  J2CAdminObject_1098711838691)'
  ```
- Using Jacl:

  ```
  wsadmin>$AdminConfig getid /Node:9994GKCNode01
  9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

  wsadmin>$AdminTask listSIBJMSQueues
  9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
  queue1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
  J2CAdminObject_1098711838691)
  ```

modifySIBJMSQueue command

Use the modifySIBJMSQueue command to change the properties of a JMS queue for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBJMSAdminCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The modifySIBJMSQueue command changes the properties of a JMS queue for the default messaging provider at a specific scope.

Target object

A JMS queue.

Required parameters

None.

Optional parameters

-name
The identifier by which this JMS queue is known for administrative purposes.

-jndiName
The JNDI name that is used to bind the queue into the application server namespace.

-queueName
The name of the service integration bus destination to which the JMS queue maps.

-description
An optional description for the bus, for administrative purposes.

-deliveryMode Application | NonPersistent | Persistent
The delivery mode to be used by MessageProducers for messages sent to this queue.

-timeToLive
The default length of time from its dispatch time that a message sent to this queue should be retained by the system, where 0 indicates that time to live value does not expire. Value from the producer is used if this parameter is not supplied.

-priority
The priority for messages sent to this queue. The value from the producer is used if not completed. In the range 0 to 9 where 0 is the lowest priority and 9 is the highest priority

-readAhead AsConnection | AlwaysOn | AlwaysOff
Used to control read-ahead optimization during message delivery. The default is AsConnection.

-busName
The name of the service integration bus that the bus destination, identified by **queueName**, is configured on. If not set, the bus that the application is connected to is used.

-scopeToLocalQP TRUE | FALSE
Indicates whether the underlying service integration bus queue destination is scoped to a local queue point when addressed using this JMS queue. A local queue point is a queue point that is configured on the messaging engine to which the JMS application is connected. The option applies when using this JMS queue to send and receive messages and when setting a reply queue in a request message. When a reply queue is set in a request message, the local queue point is on the messaging engine to which the application setting the reply queue is connected, not the messaging engine to which the

application using the reply queue sends the reply message. If the connected messaging engine does not have a queue point for the destination this option is ignored. The default value is FALSE.

Changing the default setting of this option is supported only when used by a JMS application that is running with a WebSphere Application Server Version 7.0 or later server or client, and that is connected to a messaging engine running on a WebSphere Application Server Version 7.0 or later server. Use on previous versions of WebSphere Application Server results in an exception to the application.

-producerBind TRUE | FALSE
Indicates how JMS producers bind to queue points of the clustered queue. The default value is FALSE.

Changing the default setting of this option is supported only when used by a JMS application that is running with a WebSphere Application Server Version 7.0 or later server or client, and that is connected to a messaging engine running on a WebSphere Application Server Version 7.0 or later server. Use on previous versions of WebSphere Application Server results in an exception to the application.

TRUE The messaging system selects a queue point when the session is opened. All messages produced by the session are sent to the chosen queue point. The messaging system uses the **producerPreferLocal** setting when selecting the queue point.

FALSE
The messaging system selects a queue point each time a message is sent, potentially workload balancing the messages across all available queue points. The messaging system uses the **producerPreferLocal** setting when selecting the queue point.

-producerPreferLocal TRUE | FALSE
Indicates whether a queue point local to the producer is preferred to other available queue points when the messaging system selects a queue point to produce messages to. A local queue point is a queue point that is configured on the messaging engine to which the JMS application is connected. The default value is TRUE.

Changing the default setting of this option is supported only when used by a JMS application that is running with a WebSphere Application Server Version 7.0 or later server or client, and that is connected to a messaging engine running on a WebSphere Application Server Version 7.0 or later server. Use on previous versions of WebSphere Application Server results in an exception to the application.

-consumerGatherMessages TRUE | FALSE
A JMS consumer or browser is attached to a single queue point of the service integration bus destination by the messaging system. This parameter indicates whether a JMS consumer or browser take messages from any available queue points of the service integration bus destination (TRUE), or the single queue point to which it is attached (FALSE). The default value is FALSE. Gathering messages from multiple queue points results in an increased performance cost and message order cannot be maintained.

Changing the default setting of this option is supported only when used by a JMS application that is running with a WebSphere Application Server Version 7.0 or later server or client, and that is connected to a messaging engine running on a WebSphere Application Server Version 7.0 or later server. Use on previous versions of WebSphere Application Server results in an exception to the application.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01" )
'9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)'

wsadmin>AdminTask.modifySIBJMSQueue("jmsq2(cells/9994GKCNode01Cell/nodes/
```

```
9994GKCNode01|resources.xml#J2CAdminObject_1098737234986)",
["-queueName", "q2forjms"])
'jmsq2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098737234986)'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask modifySIBJMSQueue
jmsq2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098737234986)
 {-queueName q2forjms}
jmsq2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098737234986)
```

showSIBJMSQueue command

Use the showSIBJMSQueue command to show properties of a JMS queue for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBJMSAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command returns a set of property-value pairs for the specified JMS queue.

Target object

A JMS queue.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01" )
'9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)'

wsadmin>AdminTask.showSIBJMSQueue("jmsq2(cells/9994GKCNode01Cell/nodes/
9994GKCNode01|resources.xml#J2CAdminObject_1098737234986)")
'{jndiName=jms/jnmsq2, deliveryMode=Application, busName=, name=jmsq2,
readAhead=AsConnection, timeToLive=, priority=, queueName=busq4jmsq2}'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask showSIBJMSQueue
jmsq2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098737234986)
{jndiName=jms/jnmsq2, deliveryMode=Application, busName=, name=jmsq2,
readAhead=AsConnection, timeToLive=, priority=, queueName=busq4jmsq2}
```

createSIBJMSTopic command

Use the createSIBJMSTopic command to create a new JMS topic for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBJMSAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command creates a JMS topic for the default messaging provider at a specific scope.

Target object

Scope of the default messaging provider at which the JMS topic is to be created.

Required parameters

```
-name jmstopic_name
-jndiName jndi_name
```

Optional parameters

```
-description text
-topicName topic_name
-topicSpace topicspace_name
-deliveryMode Application | NonPersistent | Persistent
-timeToLive time
-priority priority
-readAhead AsConnection | AlwaysOn | AlwaysOff
-busName name
```

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01" )
'9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)'

wsadmin>AdminTask.createSIBJMSTopic("9994GKCNode01(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|node.xml#Node_1)", ["-name", "jmstopic2", "-jndiName",
 "jms/jnmstopic2", "-topicSpace", "sportshall"])
'jmstopic2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098738992263)'

wsadmin>AdminTask.listSIBJMSTopics("9994GKCNode01(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|node.xml#Node_1)")
'topic1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098738449292)
jmstopic2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098738992263)'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask createSIBJMSTopic
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
 {-name jmstopic2 -jndiName jms/jnmstopic2 -topicSpace sportshall}
jmstopic2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098738992263)

wsadmin>$AdminTask listSIBJMSTopics
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
topic1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098738449292)
jmstopic2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098738992263)
```

deleteSIBJMSTopic command

Use the deleteSIBJMSTopics command to delete a JMS topic for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  `print AdminTask.help('SIBJMSAdminCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:

  `print AdminTask.help('`*command_name*`')`

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command deletes the specified JMS topic.

Target object

A JMS topic.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01")
'9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)'

wsadmin>AdminTask.deleteSIBJMSTopic("jmstopic2(cells/9994GKCNode01Cell/nodes/
9994GKCNode01|resources.xml#J2CAdminObject_1098738992263)")
'jmstopic2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098738992263)'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask deleteSIBJMSTopic
jmstopic2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098738992263)
jmstopic2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098738992263)
```

listSIBJMSTopics command

Use the listSIBJMSTopics command to list all JMS topics for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBJMSAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command returns a list of all JMS topics for the default messaging provider at a specific scope.

Target object

Scope of the default messaging provider at which the JMS topics were created.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01")
'9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)'

wsadmin>AdminTask.listSIBJMSTopics("9994GKCNode01(cells/9994GKCNode01Cell/nodes/
9994GKCNode01|node.xml#Node_1)")
'topic1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098738449292)'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask listSIBJMSTopics
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
topic1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098738449292)
```

modifySIBJMSTopic command

Use the modifySIBJMSTopic command to change the properties of a JMS topic for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBJMSAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command changes the properties of a JMS topic for the default messaging provider at a specific scope.

Target object

A JMS topic.

Required parameters

None.

Optional parameters

```
-name jmstopic_name
-jndiName jndi_name
-description text
-topicName topic_name
-topicSpace topicspace_name
-deliveryMode Application | NonPersistent | Persistent
-timeToLive time
-priority priority
-readAhead AsConnection | AlwaysOn | AlwaysOff
-busName name
```

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01")
'9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)'

wsadmin>AdminTask.modifySIBJMSTopic("jmstopic2(cells/9994GKCNode01Cell/nodes/
9994GKCNode01|resources.xml#J2CAdminObject_1098738992263)", ["-jndiName",
 "jms/jnmstopic2", "-topicName", "archery", "-readAhead", "AlwaysOn"])
'jmstopic2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098738992263)'

wsadmin>AdminTask.showSIBJMSTopic("jmstopic2(cells/9994GKCNode01Cell/nodes/
9994GKCNode01|resources.xml#J2CAdminObject_1098738992263)")
'{topicSpace=sportshall, deliveryMode=Application, jndiName=jms/jnmstopic2,
busName=, readAhead=AlwaysOn, name=jmstopic2, timeToLive=, priority=,
topicName=archery}'
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask modifySIBJMSTopic
jmstopic2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098738992263)
 {-jndiName jms/jnmstopic2 -topicName archery -readAhead AlwaysOn}
jmstopic2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098738992263)

wsadmin>$AdminTask showSIBJMSTopic
jmstopic2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CAdminObject_1098738992263)
{topicSpace=sportshall, deliveryMode=Application, jndiName=jms/jnmstopic2,
busName=, readAhead=AlwaysOn, name=jmstopic2, timeToLive=, priority=,
topicName=archery}
```

showSIBJMSTopic command

Use the showSIBJMSTopic command to show properties of a JMS topic for the default messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus JMS commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBJMSAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command returns a set of property-value pairs for the specified JMS topic.

Target object

A JMS topic.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

  ```
  wsadmin>AdminConfig.getid("/Node:9994GKCNode01" )
  '9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)'

  wsadmin>AdminTask.showSIBJMSTopic("jmstopic2(cells/9994GKCNode01Cell/nodes/
  9994GKCNode01|resources.xml#J2CAdminObject_1098738992263)")
  '{topicSpace=sportshall, deliveryMode=Application, jndiName=jms/jnmstopic2,
  busName=, readAhead=AsConnection, name=jmstopic2, timeToLive=, priority=,
  topicName=jmstopic2}'
  ```

- Using Jacl:

  ```
  wsadmin>$AdminConfig getid /Node:9994GKCNode01
  9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

  wsadmin>$AdminTask showSIBJMSTopic
  jmstopic2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
  J2CAdminObject_1098738992263)
  {topicSpace=sportshall, deliveryMode=Application, jndiName=jms/jnmstopic2,
  busName=, readAhead=AsConnection, name=jmstopic2, timeToLive=, priority=,
  topicName=jmstopic2}
  ```

Chapter 13. Managing messaging with the WebSphere MQ messaging provider

Through the WebSphere MQ messaging provider in WebSphere Application Server, Java Message Service (JMS) messaging applications can use your WebSphere MQ system as an external provider of JMS messaging resources. To enable this approach, you configure the WebSphere MQ messaging provider in WebSphere Application Server to define JMS resources for connecting to any queue manager on the WebSphere MQ network.

Before you begin

If your business uses WebSphere MQ, and you want to integrate WebSphere Application Server messaging applications into a predominantly WebSphere MQ network, the WebSphere MQ messaging provider is a logical choice. However, there can be benefits in using another provider. If you are not sure which provider combination is best suited to your requirements, see Choosing messaging providers for a mixed environment.

The preferred solution for publish and subscribe messaging with WebSphere MQ as an external JMS messaging provider is to use a message broker such as WebSphere MQ Event Broker.

About this task

The WebSphere MQ messaging provider supports JMS 1.1 domain-independent interfaces (sometimes referred to as “unified” or “common” interfaces), and also supports the Java EE Connector Architecture (JCA) 1.5 activation specification mechanism for message-driven beans (MDBs) across all platforms supported by WebSphere Application Server.

You can use WebSphere Application Server to configure WebSphere MQ resources for applications (for example queue connection factories) and to manage messages and subscriptions associated with JMS destinations. You administer security through WebSphere MQ.

You can use WebSphere Application Server to coordinate global transactions including WebSphere MQ without configuring the extended transactional client.

For publish and subscribe messaging with WebSphere MQ as an external JMS messaging provider you have several options:

- With WebSphere MQ Version 7 on any platform you can use the built-in publish and subscribe capability of WebSphere MQ. Note that you cannot use WebSphere MQ Message Broker Version 7 for this because it no longer provides a publish and subscribe capability.

Procedure

- Learn about the WebSphere MQ messaging provider.
- Configure JMS resources for the WebSphere MQ messaging provider.

  You can do this through the WebSphere Application Server administrative console, or through the WebSphere Application Server set of WebSphere MQ administrative commands.
- List JMS resources for the WebSphere MQ messaging provider.

JMS provider settings

Use this panel to view the configuration properties of a selected JMS provider.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** > **JMS->JMS providers**. This displays a list of JMS providers in the content pane. For each JMS provider in the list, the entry indicates the *scope* level at which JMS resource definitions are visible to applications. You can create the same type of JMS provider at different Scope settings, to offer JMS resources at different levels of visibility to applications.
2. (optional) If you want to manage JMS resources that are defined at a different scope setting, change the **Scope** setting to the required level.
3. In the Providers column of the list displayed, click the name of a JMS provider.

If you want to browse or change JMS resources of the JMS provider, click the link for the type of resource under Additional Properties. For more information about the administrative console panels for the types of JMS resources, see the related topics.

For the default messaging provider (which is based on service integration technologies) and the WebSphere MQ messaging provider, the scope, name, and description properties are displayed for information only. You cannot change these properties.

For a third-party non-JCA provider that you have defined yourself, the properties of that provider are displayed.

Scope

The level (cell, node, or server level) at which this resource definition is available.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates that are defined at more general scopes. For more information about the scope setting, see Scope settings.

Name

The name by which the JMS provider is known for administrative purposes.

Data type

String

Default

- Default messaging provider.

  For JMS resources to be provided by a service integration bus, as part of WebSphere Application Server.
- *My JMSprovider*

  For JMS resources to be provided by a third-party JMS provider that you specify, rather than by the default messaging provider or the WebSphere MQ messaging provider that are available as part of WebSphere Application Server. You assign the name, for example “My JMSprovider”, when you define the third-party JMS provider to WebSphere Application Server. You must also have installed and configured the third-party JMS provider before applications can use its JMS resources.
- WebSphere MQ messaging provider

  For JMS resources to be provided by WebSphere MQ. You must have installed and configured WebSphere MQ before applications can use its JMS resources.
- V5 default messaging provider.

  For JMS resources to be provided by a WebSphere Application Server Version 5 node.

Description

A description of the JMS provider, for administrative purposes within WebSphere Application Server.

Data type String

Classpath

A list of paths or JAR file names that together form the location for the JMS provider classes. Each class path entry is on a separate line (separated by using the Enter key) and must not contain path separator characters (such as ';' or ': '). Class paths can contain variable (symbolic) names to be substituted by using a variable map. Check your driver installation notes for specific JAR file names that are required.

Note: This property is only available for third-party messaging providers.

Data type String

Native library path

An optional path to any native libraries (*.dll, *.so). Each native path entry is on a separate line (separated by using the Enter key) and must not contain path separator characters (such as ';' or ': '). Native paths can contain variable (symbolic) names to be substituted by using a variable map.

Note: This property is only available for the WebSphere MQ messaging provider and third-party messaging providers.

Data type String

Update resource adapter

This button can be used to update the WebSphere MQ resource adapter that provides the function made available by the WebSphere MQ messaging provider. This button must only be used as directed by a member of IBM service, otherwise it may result in the use of an unsupported level of the WebSphere MQ resource adapter.

Normally the WebSphere MQ resource adapter is automatically updated by applying WebSphere Application Server fix packs. It is important to note that use of the **Update resource adapter** button prevents these automatic updates from happening for future fix packs for any node on which the button is used. If, in the future, you require the WebSphere MQ resource adapter used by the node to receive updates when a fix pack is applied then you must re-establish the recommended resource adapter configuration. For more information see “Maintaining the WebSphere MQ resource adapter” on page 724.

Note: This property is only available for the WebSphere MQ messaging provider.

Data type Button

External initial context factory

The Java classname of the initial context factory for the JMS provider.

For example, for an LDAP service provider the value has the form: com.sun.jndi.ldap.LdapCtxFactory.

Note: This property is only available for third-party messaging providers.

Data type String
Default Null

External provider URL

The JMS provider URL for external JNDI lookups.

For example, an LDAP URL for a messaging provider has the form: `ldap://hostname.company.com/contextName`.

Note: This property is only available for third-party messaging providers.

Data type	String
Default	Null

Disable WebSphere MQ

This check box is only valid for the WebSphere MQ messaging provider. When selected, this check box disables all WebSphere MQ functionality on affected application servers. Note that you must restart the affected application server processes for this change to take effect.

In a single server environment this check box is only available on the WebSphere MQ messaging provider panel where the scope is set to server, and has the effect of disabling all WebSphere MQ functionality in that application server.

In a network deployment environment this check box is available on all WebSphere MQ messaging provider panels. The effect of selecting the check box depends on the scope at which you select it:

- At the cell scope, all WebSphere MQ functionality is disabled on all application servers in the cell.
- At the node scope, all WebSphere MQ functionality is disabled on all application servers that are part of that node.
- At the cluster scope, all WebSphere MQ functionality is disabled on all application servers in that cluster.
- At the server scope, all WebSphere MQ functionality is disabled in that particular application server.

The value of the check box at a higher scope takes precedence over the value at a lower scope. For example, if you do not select the check box for a WebSphere MQ messaging provider at the server scope, but do select it for a WebSphere MQ messaging provider at a higher scope (such as the cell scope), the value of the check box at the cell scope takes precedence and WebSphere MQ functionality is therefore disabled in all application servers in the cell, regardless of whether the check box is selected at the server scope.

An informational message indicating that WebSphere MQ has been disabled is added to all WebSphere MQ messaging provider panels that are at affected scopes, but this message does not appear on those panels where the check box is selected. In a single server environment this informational message is only displayed after a server restart is performed. In a network deployment environment the informational message is displayed immediately.

For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

Data type	Check box
Default	Not selected

Additional properties

Connection factories

A connection factory is used to create connections to the associated JMS provider. These connection factories can be used for accessing JMS Queue and JMS Topic destinations.

Queue connection factories
A queue connection factory is used to create connections to the associated JMS provider of the JMS queue destinations, for point-to-point messaging.

Topic connection factories
A topic connection factory is used to create connections to the associated JMS provider of JMS topic destinations, for publish and subscribe messaging.

Queues
A JMS queue is used as a destination for point-to-point messaging.

Topics
A JMS topic is used as a destination for publish/subscribe messaging.

Activation specifications
A JMS activation specification is associated with one or more message-driven beans and provides configuration necessary for them to receive messages.

Resource adapter properties
These properties are used to configure the WebSphere MQ resource adapter, which is used by the WebSphere MQ messaging provider. In particular most of these settings affect the behavior of WebSphere MQ messaging provider activation specifications.

Resource adapter properties

Use this page to configure the WebSphere MQ resource adapter that underlies the WebSphere MQ messaging provider.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** > **JMS->JMS providers** to display a list of JMS providers in the content pane.
2. (optional) If you want to manage JMS resources that are defined at a different scope setting, change the **Scope** setting to the required level.
3. In the Providers column of the displayed list of JMS providers, click the name of the WebSphere MQ messaging provider that you want to work with.
4. In the content pane under Additional properties, click **Resource adapter properties** to view the configuration page for the properties.

The resource adapter properties are used to configure the WebSphere MQ resource adapter, which is used by the WebSphere MQ messaging provider. These properties affect the connection pool, which is used by the WebSphere MQ messaging provider activation specifications. They do not affect the WebSphere MQ messaging provider queues, topics, or connection factories.

These properties only have an effect on the WebSphere MQ messaging provider objects that are defined at the same scope as the messaging provider and resource adapter on which they are set. So, for example, if you set the max connections property to a particular setting at the server scope, only the server scoped WebSphere MQ messaging provider activation specifications are affected by this setting.

For further information about these properties, see Configuration of the ResourceAdapter object in the WebSphere MQ information center.

If you want to configure a WebSphere MQ resource adapter custom property that is not exposed in WebSphere Application Server, click **Custom properties** under Additional properties.

Connection pool properties

Max connections

The maximum number of connections to a WebSphere MQ queue manager.

Data type	String
Default	10

Connection concurrency

The maximum number of message-driven beans that can be supplied by each connection.

Data type	String
Default	5

Reconnection retry count

The maximum number of attempts made by a WebSphere MQ messaging provider activation specification to reconnect to a WebSphere MQ queue manager if a connection fails.

Data type	String
Default	5

Reconnection retry interval

The time, in milliseconds, that a WebSphere MQ messaging provider activation specification waits before making another attempt to reconnect to a WebSphere MQ queue manager.

Data type	String
Default	300000

Additional properties

Custom properties

The full set of custom properties that are used to configure the WebSphere MQ resource adapter. Use this page to configure custom properties that are not exposed in WebSphere Application Server.

Installing WebSphere MQ to interoperate with WebSphere Application Server

When you install a new WebSphere MQ network, you can tune the installation for working with WebSphere Application Server. If you have an established WebSphere MQ network, you can choose whether to modify some of the settings for better interoperation.

About this task

This topic provides installation instructions for setting up a new WebSphere MQ installation to interoperate with WebSphere Application Server. If you have an established WebSphere MQ network, treat this task as a source of tips to tune your existing WebSphere MQ installation.

Procedure

1. Install a supported version of WebSphere MQ, as described in the installation instructions provided with WebSphere MQ.

To identify the supported version of WebSphere MQ, see the following article: Detailed system requirements page.

You should not install Rational Application Developer and WebSphere Application Server on the same machine when using WebSphere MQ.

For other installation prerequisites, see the *Quick Beginnings* section for your platform, in the WebSphere MQ information center.

2. Follow the WebSphere MQ instructions for verifying your installation setup.
3. Configure WebSphere Application Server and WebSphere MQ to interoperate effectively.

   For information about the prerequisites and requirements for effective interoperation, see the following technote: Information about using the WebSphere MQ messaging provider for WebSphere Application Server Version 7.0.
4. Configure the WebSphere MQ messaging provider with native libraries information.

   To connect to a WebSphere MQ queue manager or queue-sharing group in bindings mode, the WebSphere MQ messaging provider needs to know where to load native libraries from. For more information, see "Configuring the WebSphere MQ messaging provider with native libraries information."

   Note: For migration purposes only, you can also specify native path information, when in an application server environment, by setting the *MQ_INSTALL_ROOT* WebSphere Application Server environment variable. For more information see, Installing WebSphere MQ to interoperate with WebSphere Application Server.
5. Optional: At Cell scope or Node scope, set the WebSphere Application Server MQ_CLEAR_MQ_FROM_OSGI_CACHE_ON_SHUTDOWN environment variable to `True`. This allows application server startup to automatically take account of changes that are made to the MQ_INSTALL_ROOT environment variable and WebSphere MQ JMS client libraries while the application server is stopped.

   If you do not set this variable, you must restart the application server a second time after any changes of this type, to enable the application to perform messaging by using the WebSphere MQ messaging provider.

   Note: If you set the MQ_CLEAR_MQ_FROM_OSGI_CACHE_ON_SHUTDOWN environment variable, the startup time might increase because, on startup, each application server needs to initialize an additional state associated with WebSphere MQ installation.

What to do next

You are now ready to configure a messaging provider. If your business uses WebSphere MQ, and you want to integrate WebSphere Application Server messaging applications into a predominantly WebSphere MQ network, the WebSphere MQ messaging provider is the natural choice. However, there can be benefits in using another provider. If you are not sure which provider combination is best suited to your needs, see Choosing messaging providers for a mixed environment.

To create WebSphere MQ messaging provider resources, see "Configuring JMS resources for the WebSphere MQ messaging provider" on page 734.

Configuring the WebSphere MQ messaging provider with native libraries information

To connect to a WebSphere MQ queue manager or queue-sharing group in bindings mode, the WebSphere MQ messaging provider needs to know where to load native libraries from. This information is known as native path information. The way native path information is set depends on whether the connection is established in an application client or in an application server environment.

About this task

If you are running in a client environment, use launchClient to start a client application. In the system property `MQ_INSTALL_ROOT` enter the name of a directory that contains the WebSphere MQ native libraries, in a subdirectory of java/lib or java/lib64 depending on whether you are using 32 bit or 64 bit native libraries. For example, on Linux specify `./launchClient.sh myappclient.ear -CCDMQ_INSTALL_ROOT=/opt/mqm/`.

If you are running in an application server environment, you can configure the WebSphere MQ messaging provider with native path information by using the command line, as described in "WMQAdminCommands command group for the AdminTask object" on page 870, or you can use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, expand **Resources** > **JMS** > **JMS providers**.
2. Select the WebSphere MQ messaging provider that is at the correct **Scope** for the connection factory or activation specification that will create the bindings mode connection.

   Note:

   - Native path information at **Server** scope is used in preference to native path information at all other scopes.
   - Native path information at **Cluster** scope is used in preference to native path information at **Node** and **Cell** scopes.
   - Native path information at **Node** scope is used in preference to native path information at **Cell** scope.
3. Under General Properties, in the **Native library path** property, enter the full name of the directory that contains the WebSphere MQ native libraries. For example, on Linux enter `/opt/mqm/java/lib`. Enter only one directory name.
4. Click **OK**.
5. Save any changes to the master configuration.
6. If you are running in an application server environment, you must restart all affected servers twice when you have changed the native path information. Otherwise, a WMSG1623E message is produced, indicating that the WebSphere MQ messaging provider is not available.

   If you are running in a client environment, you must rerun the client program twice. Otherwise, a WMSG2013E message is produced.

   Whichever environment you are running in, until you perform these restarts any attempt to use a WebSphere MQ messaging provider resource (for example, a connection factory) from one of the affected servers causes a javax.naming.NamingException and a WMSG2003E message.

What to do next

Note: For migration purposes only, you can also specify native path information, when in an application server environment, by setting the *MQ_INSTALL_ROOT* WebSphere Application Server environment variable. For more information, see the following topic in the WebSphere Application Server Version 6.1 information center: Installing WebSphere MQ to interoperate with WebSphere Application Server (Version 6.1).

Maintaining the WebSphere MQ resource adapter

The WebSphere MQ resource adapter is used by all applications that perform JMS messaging with the WebSphere MQ messaging provider. The WebSphere MQ resource adapter is usually updated automatically when you apply WebSphere Application Server fix packs, but if you have previously manually updated the resource adapter you must manually update your configuration to ensure that maintenance is applied correctly.

About this task

Applying a WebSphere Application Server fix pack does not automatically update the version of the WebSphere MQ resource adapter used by servers on nodes where the WebSphere MQ resource adapter has previously been manually updated.

Procedure

- To migrate the configuration of all servers in the cell to use the latest version of the WebSphere MQ resource adapter contained in the WebSphere Application Server installation, see “Ensuring that servers use the latest available WebSphere MQ resource adapter maintenance level.”
- If you want a specific version of the WebSphere MQ resource adapter to be installed, and the version you require is not available in a WebSphere Application Server fix pack, or an interim fix, see “Installing a specific maintenance level of the WebSphere MQ resource adapter” on page 726.

Ensuring that servers use the latest available WebSphere MQ resource adapter maintenance level

To ensure that the WebSphere MQ resource adapter is automatically updated to the latest available maintenance level when you apply WebSphere Application Server fix packs, you can configure all servers in your environment to use the latest version of the resource adapter contained in the WebSphere Application Server fix pack that you have applied to the installation of each node.

About this task

Use this task if any of the following circumstances apply to your configuration, and you want to configure all servers in your environment to use the latest version of the WebSphere MQ resource adapter:

- The JVM logs of any application server in your environment contain the following entry:

  ```
  WMSG1625E: It was not possible to detect
  the WebSphere MQ messaging provider code at the specified path <null>
  ```

- One or more nodes has previously been manually updated to use a specific maintenance level of the WebSphere MQ resource adapter that is now superseded by the latest version of the resource adapter contained in the current WebSphere Application Server maintenance level.

When you have performed the following steps for all cells and single server installations in your environment, your servers will automatically receive maintenance to the WebSphere MQ resource adapter when a new WebSphere Application Server fix pack is applied.

Procedure

1. Start the application server.
2. Copy the following Jython script into a file called `convertWMQRA.py`, then save it into the *profile_root*`/bin` directory.

   ```
   ras = AdminUtilities.convertToList(AdminConfig.list('J2CResourceAdapter'))

   for ra in ras :
      desc = AdminConfig.showAttribute(ra, "description")
      if (desc == "WAS 7.0 Built In WebSphere MQ Resource Adapter") or
         (desc == "WAS 7.0.0.1 Built In WebSphere MQ Resource Adapter") or
         (desc == "WAS Built In WebSphere MQ Resource Adapter"):
         print "Updating archivePath and classpath of " + ra
         AdminConfig.modify(ra, [['archivePath', "${WAS_INSTALL_ROOT}/installedConnectors/wmq.jmsra.rar"]])
         AdminConfig.unsetAttributes(ra, ['classpath'])
         AdminConfig.modify(ra, [['classpath', "${WAS_INSTALL_ROOT}/installedConnectors/wmq.jmsra.rar"]])
         AdminConfig.save()
      #end if
   #end for
   ```

3. Use the wsadmin tool to run the Jython script that you have just created.

Open a command prompt and navigate to the *profile_root*/bin directory, then enter the following command:

```
wsadmin -lang jython -f convertWMQRA.py
```

4. Stop all servers in the profile.
5. Run the osgiCfgInit command from the *profile_root*/bin directory.

   Note: The osgiCfgInit command resets the class cache used by the OSGi runtime environment.
6. Restart all servers in the profile.

What to do next

If you continue to experience problems after performing the steps described in this topic, and you have previously used the **Update resource adapter...** button on the JMS Provider Settings panel in the administrative console to update the WebSphere MQ resource adapter on any nodes in your environment, it is possible that you are experiencing the issue described in APAR PM10308.

Installing a specific maintenance level of the WebSphere MQ resource adapter

If you require a specific version of the WebSphere MQ resource adapter to be installed and the version you require is unavailable in a WebSphere Application Server fix pack, or an interim fix, you can install the resource adapter using the administrative console.

Before you begin

The minimum version of the WebSphere MQ resource adapter required for this version of WebSphere Application Server is WebSphere MQ Version 7.0.

About this task

Use this task only if you have a requirement to use a specific maintenance level of the WebSphere MQ resource adapter that is unavailable in a WebSphere Application Server fix pack, or an interim fix.

You do not need to use this task if you want to restore the configuration of all servers in your cell to use the latest version of the WebSphere MQ resource adapter contained in the WebSphere Application Server installation. In this case, see “Ensuring that servers use the latest available WebSphere MQ resource adapter maintenance level” on page 725 for further information.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Resources** > **JMS->JMS providers** The JMS providers collection panel opens.
3. Change the scope to the node that you want to update.
4. Select the WebSphere MQ messaging provider entry in the list. The settings panel for this provider opens.
5. Click **Update resource adapter...**.

   Note: **Update resource adapter...** is only available for the WebSphere MQ messaging provider at node scope.
6. Specify the installation path for the resource adapter archive (RAR) file, then click **Next**:
   - If your RAR file is located on the same workstation as your browser, select **Local file system**, and browse to find the file.
   - If your RAR file is located on the server workstation where the application server is installed, select **Remote file system**, and specify the fully qualified path to the file.

7. Review the configuration information that is provided for the RAR file then, when you have finished your review, click **Next**. The following information is displayed for the RAR file:
   - Name
   - Current RAR version
   - New RAR version
   - Scope
   - Any existing copies of the resource adapter. The resource adapters shown with an asterisk (*) are copies of the resource adapter and must also be updated at the same time.
8. Optional: Edit any properties that were added by the new version of the resource adapter. You can also edit these properties after you have completed the update.
   a. From the displayed list, select the resource for which you want to edit the new properties. Only resources with new properties are included in the list.
   b. Edit the resource properties. Use the table that is provided to set the values for new properties of the selected resource.
      - Select **Set for all** to apply the property value to all resources of the same type.
      - Click **Reset to Default** to reset all the properties to the default values that are defined in the RAR file. This resetting of property values only affects the selected resource.
   c. Click **Next**.
9. Review the summary panel and then, when you are satisfied with the configuration settings, click **Finish**. When you click **Finish**, all the configuration changes are saved automatically. To revert to an older version of the resource adapter you must perform the update process again, and specify the older version of the RAR file that you want to revert to.
10. Restart the servers that contain the updated RAR file.

Listing JMS resources for the WebSphere MQ messaging provider

Use the WebSphere Application Server administrative console to list JMS resources for the WebSphere MQ provider, for administrative purposes.

About this task

You use the WebSphere Application Server administrative console to list JMS resources, if you want to view, modify or delete any of the following resources:

- Activation specifications
- Unified connection factories
- Queue connection factories
- Topic connection factories
- Queues
- Topics

When you use the administrative console to locate these resources, two different navigation pathways are available:

- **Provider-centric navigation** lets you view all providers, or just those for a specified scope, then navigate to a specific resource for a specific provider. This is the traditional way of navigating to a resource when you know which provider supports it. Any navigation that starts with **Resources** > **JMS->JMS providers** is provider-centric.
- **Resource-centric navigation** lets you view all resources of a specified type, then navigate to a resource. This is useful if you want to find a resource, but you do not know which provider supports it (you can list all resources of a given type across all scopes, for all providers, in a single panel). Any navigation that follows the pattern **Resources** > **JMS** > ***resource_type*** is resource-centric, where *resource_type* is one of the resource types previously listed.

You can use either of these navigation pathways to locate JMS resources of any type.

Procedure

- Use provider-centric navigation, for example to navigate to a specified queue connection factory.
  1. Start the administrative console.
  2. In the navigation pane, click **Resources** > **JMS->JMS providers**.

     The JMS providers collection panel is displayed. This lists all currently configured messaging providers across all scopes (you can modify the scope if required).
  3. Select the required JMS provider.

     The settings panel for this provider is displayed. The configuration tab contains a set of links to all the JMS resources owned by this provider.
  4. Click the link for a JMS resource type. For example, click **Queue connection factories**.

     The queue connection factories collection panel is displayed. This panel lists all the queue connection factories for this provider.
  5. Select the required queue connection factory.
- Use resource-centric navigation, for example to navigate to a specified queue connection factory.
  1. Start the administrative console..
  2. In the navigation pane, click **Resources** > **JMS->Queue connection factories**.

     The queue connection factories collection panel is displayed. This panel lists all the queue connection factories across all messaging providers.
  3. Select the required queue connection factory.

Results

You can now view and work with the resource properties.

JMS providers collection

Use this panel to list JMS providers, or to select a JMS provider to view or change its configuration properties.

To view this administrative console page, click **Resources** > **JMS->JMS providers**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS providers that are available to WebSphere applications. For each JMS provider in the list, the entry indicates the *scope* level at which JMS resource definitions are visible to applications. You can create the same type of JMS provider at different Scope settings, to offer JMS resources at different levels of visibility to applications.

If you want to manage existing JMS resource definitions, or create a new JMS resource definition, you can select the name of one of the JMS providers in the list.

If you want to define a new third-party JMS provider (that is, a provider other than the default messaging provider or the WebSphere MQ messaging provider), select the Scope setting at which JMS resource definitions are to be visible for that provider, then click **New**.

Name The name by which this JMS provider is known for administrative purposes.

Description
A description of this JMS provider for administrative purposes.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Activation specification collection

A JMS activation specification is associated with one or more message-driven beans and provides the configuration necessary for them to receive messages. The default messaging provider and the WebSphere MQ messaging provider both support use of activation specifications.

In the administrative console, to view this page click **Resources** > **JMS->Activation specifications**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

This page lists the JMS activation specifications that are available to WebSphere applications at the scope indicated by the **Scope** field.

Name The display name of each activation specification instance.

JNDI name
The Java Naming and Directory Interface (JNDI) name of each activation specification instance.

Provider
The messaging provider that supports each activation specification instance. This is either the default messaging provider (service integration) or the WebSphere MQ messaging provider.

Description
An optional description of each activation specification instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.

Delete	Delete the selected items.

Connection factory collection

A JMS connection factory is used to create connections to the associated messaging provider of JMS destinations, for both point-to-point and publish/subscribe messaging. Use connection factory administrative objects to manage JMS connection factories for the default messaging provider, the WebSphere MQ messaging provider or a third-party messaging provider.

In the administrative console, to view this page click **Resources** > **JMS->Connection factories**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS connection factories that are available to WebSphere Application Server applications at the scope indicated by the **Scope** field.

A JMS connection factory is used to create connections to JMS destinations. When an application needs a JMS connection, an instance can be created by the factory of the messaging provider named in the **Provider** column of the list.

This type of connection factory is for applications that use the JMS 1.1 domain-independent interfaces (referred to as the “common interfaces” in the JMS specification).

This type of JMS connection factory can also be used by the domain-specific (queue and topic) interfaces, as used in JMS 1.0.2, so applications can still use those interfaces without the need for you to create a domain-specific connection factory, such as a queue connection factory.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

Name The display name of each connection factory instance.

JNDI name
The Java Naming and Directory Interface (JNDI) name of each connection factory instance.

Provider
The messaging provider that supports each connection factory instance. This is the default messaging provider (service integration), the WebSphere MQ messaging provider or a third-party messaging provider.

Description
An optional description of each connection factory instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Queue connection factory collection

A queue connection factory is used to create connections to the associated JMS provider of the JMS queue destinations, for point-to-point messaging.

In the administrative console, to view this page click **Resources** > **JMS->Queue connection factories**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS queue connection factories that are available to WebSphere Application Server applications at the scope indicated by the **Scope** field.

A JMS queue connection factory is used to create connections to JMS destinations. When an application needs a JMS queue connection, an instance can be created by the factory for the JMS provider that is named in the **Provider** column of the list.

This type of connection factory is for applications that use the JMS 1.0.2 queue-specific interfaces.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

Name The display name of each queue connection factory instance.

JNDI name
The Java Naming and Directory Interface (JNDI) name of each queue connection factory instance.

Provider
The messaging provider that supports each queue connection factory instance.

Description
An optional description of each queue connection factory instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Topic connection factory collection

A JMS topic connection factory is used to create connections to the associated messaging provider of JMS topic destinations, for publish and subscribe messaging.

In the administrative console, to view this page click **Resources** > **JMS->Topic connection factories**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS topic connection factories that are available to WebSphere Application Server applications at the scope indicated by the **Scope** field.

A JMS connection factory is used to create connections to JMS destinations. When an application needs a JMS connection, an instance can be created by the factory for the JMS provider that is named in the Provider column of the list.

This type of connection factory is for applications that use the JMS 1.0.2 topic-specific interfaces.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

General properties

Name The display name of each topic connection factory instance.

JNDI name
The Java Naming and Directory Interface (JNDI) name of each topic connection factory instance.

Provider
The messaging provider that supports each topic connection factory instance.

Description
An optional description of each topic connection factory instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Queue collection

A JMS queue destination is used for point-to-point messaging. Use this panel to create or delete queue destinations, or to select a queue destination to view or change its configuration properties.

In the administrative console, to view this page click **Resources** > **JMS->Queues**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS queue destinations that are available to WebSphere Application Server applications at the scope indicated by the **Scope** field.

Use a queue destination to manage JMS queues for the JMS provider that is named in the **Provider** column of the list. Connections to the queue are created by a unified connection factory or queue connection factory for that JMS provider.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

General properties

Name The display name of each queue destination instance.

JNDI name
The Java Naming and Directory Interface (JNDI) name of each queue destination instance.

Provider
The messaging provider that supports each queue destination instance.

Description
An optional description of each queue destination instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Topic collection

A JMS topic destination is used for publish and subscribe messaging. Use this panel to create or delete topic destinations, or to select a topic destination to view or change its configuration properties.

In the administrative console, to view this page click **Resources** > **JMS->Topics**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS topic destinations that are available to WebSphere Application Server applications at the scope indicated by the **Scope** field.

Use a topic destination to manage JMS topics for the JMS provider that is named in the **Provider** column of the list. Connections to the topic are created by a unified connection factory or topic connection factory for that JMS provider.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. For more information see "Disabling WebSphere MQ functionality in WebSphere Application Server" on page 868.

General properties

Name The display name of each topic destination instance.

JNDI name
The Java Naming and Directory Interface (JNDI) name of each topic destination instance.

Provider
The messaging provider that supports each topic destination instance.

Description
An optional description of each topic destination instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Configuring JMS resources for the WebSphere MQ messaging provider

Use the WebSphere Application Server administrative console to configure activation specifications, connection factories and destinations for the WebSphere MQ JMS provider.

Before you begin

This task assumes that you are working in a mixed WebSphere Application Server and WebSphere MQ environment, and that you have decided to use the WebSphere MQ messaging provider to handle JMS messaging between the two systems. If your business uses WebSphere MQ, and you want to integrate WebSphere Application Server messaging applications into a predominately WebSphere MQ network, the WebSphere MQ messaging provider is the natural choice. However, there can be benefits in using another provider. If you are not sure which provider combination is best suited to your needs, see Choosing messaging providers for a mixed environment.

You can configure JMS resources for the WebSphere MQ messaging provider through the administrative console as described in this task, or you can configure JMS resources for the WebSphere MQ messaging provider through the WebSphere MQ administrative commands.

About this task

Using the administrative console, you can set the scope of the WebSphere MQ messaging provider to restrict the range of resources that are displayed:

- If you set the scope to contain only WebSphere Application Server Version 6 or Version 7.0 or later nodes, you can configure JMS 1.1 resources and properties. This includes unified JMS connection factories for use by both point-to-point and publish/subscribe JMS 1.1 applications. With JMS 1.1, this approach is preferred to the domain-specific queue connection factory and topic connection factory.
- If you set the scope to contain only WebSphere Application Server Version 7.0 or later nodes, you can also configure JMS activation specifications.
- If you set the scope to a WebSphere Application Server Version 5 node, you can only configure domain-specific JMS resources, and the subset of properties that apply to WebSphere Application Server Version 5.

Note:

There are two ways of specifying the information needed by WebSphere MQ messaging provider messaging resources so that they can connect to a WebSphere MQ queue manager. It can either be specified manually, or by providing the WebSphere MQ messaging provider resource with a uniform resource locator (URL) that points to a client channel definition table (CCDT).

A CCDT is a binary file that contains information about how to create a client connection channel to one or more queue managers. The file contains information such as the hostname, port, and name of the target queue manager, as well as more advanced configuration information like the SSL attributes that should be used.

Creating WebSphere MQ messaging provider resources using CCDTs provides the following benefits:

- Flexibility, because client connection channel information is contained in a single place. If any of the information changes, such as the host name of the machine on which the WebSphere MQ queue manager resides, only the CCDT needs to be updated. When it is updated, all WebSphere MQ messaging provider resources that make use of the CCDT pick up the change.
- Reliability, because less information is needed for a CCDT there is a reduced chance of configuration errors. When using a CCDT to enter connection information, all that is required are the CCDT URL and an optional queue manager name. If you configure a WebSphere MQ messaging provider resource manually, much more information is required -- especially if you are configuring SSL.

For further information about generating a CCDT, see the WebSphere MQ information center.

Maintenance note: The WebSphere MQ messaging provider uses code provided by the WebSphere MQ resource adapter, which is automatically installed as part of the product.

Procedure

- “Creating an activation specification for the WebSphere MQ messaging provider” on page 736
- “Configuring an activation specification for the WebSphere MQ messaging provider” on page 738
- “Migrating a listener port to an activation specification for use with the WebSphere MQ messaging provider” on page 758
- “Creating a connection factory for the WebSphere MQ messaging provider” on page 759

- “Configuring a unified connection factory for the WebSphere MQ messaging provider” on page 761
- “Configuring a queue connection factory for the WebSphere MQ messaging provider” on page 789
- “Configuring a topic connection factory for the WebSphere MQ messaging provider” on page 813

Creating an activation specification for the WebSphere MQ messaging provider

Use this task to create an activation specification for use with the WebSphere MQ messaging provider.

About this task

To create an activation specification for use with the WebSphere MQ messaging provider, use the administrative console to complete the following steps. You can choose either to enter all the required connection information using the Create WebSphere MQ JMS resource wizard or to use a client channel definition table (CCDT) to establish a connection to the WebSphere MQ messaging provider.

For information about modifying an existing activation specification, see the related tasks.

Procedure

1. In the navigation pane, click **Resources** > **JMS** > **Activation specifications**.
2. Select the **Scope** setting corresponding to the scope of the activation specification that you want to create.
3. Click **New** in the content pane.
4. Select **WebSphere MQ messaging provider**, then click **OK** to start the Create WebSphere MQ JMS resource wizard.
5. On the “Configure basic attributes” page, enter the following information, then click **Next**.

   Name The name by which this activation specification is known for administrative purposes within WebSphere Application Server.

   JNDI name
   The name that is used to bind this activation specification into the JNDI namespace.

   Description
   Optional. A description of this activation specification for administrative purposes within WebSphere Application Server.
6. On the “Specify MDB destination data” page, enter the following information, then click **Next**.

   Destination JNDI name
   The JNDI name for the JMS destination from which messages are delivered to a message-driven bean (MDB) that is configured to use this activation specification.

   Message selector
   Optional. A message selector expression specifying which messages are to be delivered.

   Destination type
   The type of destination (queue or topic) from which to consume messages.
7. On the “Select connection method” page, choose how you want to specify the connection details for to the WebSphere MQ messaging provider by selecting one of the following options, then click **Next**.

   Enter all the required information into this wizard
   Choosing this option takes you to the “Supply queue manager details” page (see step 8), where you can start entering the connection details using the Create WebSphere MQ JMS resource wizard.

Use a client channel definition table

Choosing this option takes you to the "Specify client channel definition table" page (see step 9), where you can enter details of the client channel definition table that you want to use.

8. If you have chosen to enter all the required information using the wizard, complete the following steps:
   a. On the "Supply queue manager details" page, enter the name of the queue manager or queue-sharing group that you want to connect to then click **Next**.
   b. On the "Enter connection details" page, specify the details for the connection, then click **Next** to continue to the "Test connection" page. You can choose either to enter host and port information separately, or enter host and port information in the form of a connection name list. You must only choose the option to use a connection name list if you are creating a connection to a multi-instance queue manager. You must not use this option for connections to non-multi-instance queue managers as that can result in transaction integrity issues.

      Transport

      Optional. The WebSphere MQ transport type for the connection. The option that you select is used to determine the exact mechanisms used to connect to WebSphere MQ. If you are configuring a transport type of *bindings, then client* or *bindings*, see "Configuring the WebSphere MQ messaging provider with native libraries information" on page 723 for more information.

      Enter host and port information in the form of separate hostname and port values

      This radio button is selected by default and enables the **Hostname** and **Port** fields and disables the **Connection name list** field. Leave this radio button selected if you want to enter host and port information in the form of separate hostname and port values.

      Hostname

      The host name, IPv4, or IPv6 address of the WebSphere MQ queue manager to connect to. Complete this field if you have selected **Enter host and port information in the form of separate hostname and port values**.

      Port Optional. The port number on which WebSphere MQ is listening. If you do not specify a value for the port number, the default value of 1414 is used.Complete this field if you have selected **Enter host and port information in the form of separate hostname and port values**.

      Enter host and port information in the form of a connection name list

      This radio button is cleared by default and, if selected, disables the **Hostname** and **Port** fields and enables the **Connection name list** field.
      - Click this radio button to select it if you want to enter host and port information in the form of a connection name list.
      - Leave this radio button cleared if you want to enter host and port information in the form of separate host name and port values.

      Connection name list

      The connection name list specifying the host name and port details to use when you want the connection factory to connect to a multi-instance queue manager. Complete this field if you have selected **Enter host and port information in the form of a connection name list**. Enter the host name and port details in the following form:

      `host[(port)][,host(port)]`

      host must be a valid TCP/IP host name or IPv4 or IPv6 address.

      port must be an integer value in the range 1 - 65536 (inclusive). The port information is optional, and if not specified, defaults to 1414.

      For example: `localhost(1234),remotehost1(1234),remotehost2`

Server connection channel
Optional. The WebSphere MQ server connection channel name used when connecting to WebSphere MQ queue manager or queue-sharing group.

9. If you are using a channel client definition table to establish a connection to the WebSphere MQ messaging provider, complete the following fields on the “Specify client channel definition table” page, then click **Next** to continue to the “Test connection” page.

   Client channel definition table URL
   The URL to the client channel definition table that you want to use when connecting to WebSphere MQ.

   Queue manager
   Optional. The name of the queue manager to be used to select one or more entries from the CCDT.

10. Optional: On the “Test connection” page, if you want to test establishing the connection, click **Test connection**. This test can take several seconds to perform.
11. On the “Summary” page, complete the creation of the new activation specification by clicking **Finish**.
12. Stop then restart the application server.

JMS resource provider selection panel

Select the messaging provider with which to create this JMS activation specification, connection factory or destination.

You select the scope setting on an earlier page. The choice of JMS provider depends on the scope that you selected. You might see a choice such as the following list:

- Default messaging provider.

  Select this option if you want the JMS resource to be provided by the service integration bus, as part of WebSphere Application Server.
- WebSphere MQ messaging provider

  Select this option if you want the JMS resource to be provided by WebSphere MQ. You must have installed and configured a WebSphere MQ network in order to use this provider.
- “My JMS provider”

  Select this option if you want the JMS resource to be provided by a third-party JMS provider. This option is only available if you have installed and configured a third-party provider. The name that is displayed (for example“My JMS provider”) is the name you gave to the provider when you installed and configured it.
- V5 default messaging provider

  Select this option if you want to manage the JMS connection factories and destinations for JMS applications that were designed to work with WebSphere Application Server Version 5.1, and are still running on a Version 5.1 or Version 6 node that is part of a Version 7.0 or later mixed cell.

Configuring an activation specification for the WebSphere MQ messaging provider

Configure a JMS activation specification to enable a message-driven bean (MDB) to communicate with the WebSphere MQ messaging provider.

About this task

To view or change the configuration of an activation specification for use with WebSphere MQ, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click **Resources** > **JMS->Activation specifications**. A list of existing activation specifications, with a summary of their properties, is displayed in an "Activation specification collection" on page 729 form.
2. Select the **Scope** setting corresponding to the scope of the activation specifications that you want to view or change.
3. Select the name of the activation specification that you want to view or change. Configuration details for the activation specification are displayed in an "WebSphere MQ messaging provider activation specification settings" form.
4. Under **General Properties** make modifications as necessary.

   For information about each of the available fields, see "WebSphere MQ messaging provider activation specification settings."

   Note: There are four WebSphere MQ connection properties that are used to configure the WebSphere MQ resource adapter used by the WebSphere MQ messaging provider. These properties affect the connection pool that is used by activation specifications:
   - maxConnections
   - connectionConcurrency
   - reconnectionRetryCount
   - reconnectionRetryInterval

   For more information about these four properties, and how to configure them, see "Resource adapter properties" on page 721.
5. Click **Apply** to save the configuration.
6. Optional: Click **Advanced properties** to display or change the list of advanced properties of your activation specification.
7. Optional: Click **Broker properties** to display or change the list of broker properties of your activation specification.
8. Optional: Click **Custom properties** to display or change the list of custom properties of your activation specification. For example, you would use this option to set the custom property WAS_EndpointInitialState for an activation specification. WAS_EndpointInitialState determines whether or not message consumption begins from the JMS destination as soon as the activation specification is used for a message-driven bean to connect with the destination.
9. Optional: Click **Client transport properties** to display or change the list of client transport properties of your activation specification. This link is only present on the explicitly-defined variation of this panel, where you enter all information required to connect to WebSphere MQ. This link does not appear for the CCDT-based variation.
10. Click **OK**.
11. Save your changes to the master configuration.
12. To have the changed configuration take effect, stop then restart the application server.

WebSphere MQ messaging provider activation specification settings

Use this panel to view or change the configuration properties of the selected activation specification for use with the WebSphere MQ messaging provider. These configuration properties control how connections are created to associated queues and topics.

To view WebSphere MQ activation specification settings, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** > **JMS->Activation specifications** to display existing activation specifications.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the activation specifications are defined. This restricts the set of activation specifications displayed.

3. Select the name of the activation specification that you want to work with.

Under General Properties there are five groups of properties:
- "Administration"
- "Connection" on page 741
- "Destination" on page 747
- "Advanced" on page 748
- "Security settings" on page 748

Make any required changes to the Administration, Connection, Destination, Advanced, and Security settings groups of properties, and then click **Apply** to save the configuration before, in the content pane under Additional Properties, you click any of the following links:
- **Advanced properties** to display or change the advanced properties of your WebSphere MQ activation specification.
- **Broker properties** to display or change the broker properties of your WebSphere MQ activation specification.
- **Custom properties** to display or change the custom properties of your WebSphere MQ activation specification. For example, you would use this option to set the custom property WAS_EndpointInitialState for an activation specification. WAS_EndpointInitialState determines whether or not message consumption begins from the JMS destination as soon as the activation specification is used for a message-driven bean to connect with the destination.
- **Client transport properties** to display or change the client transport properties of your WebSphere MQ activation specification. If the selected activation specification was not created using a Client Channel Definition Table (CCDT), follow this link to enter all the information required to connect to WebSphere MQ. If the selected activation specification was created using a CCDT, you do not need to supply the client transport properties, and so the link is absent.

Under Related Items, you can click **JAAS - J2C authentication data** to configure authentication information for use with the activation specification.

You can also specify the **-localAddress** property by using the createWMQActivationSpec WebSphere MQ administrative command.

Note: When specifying WebSphere MQ properties, the following restrictions apply:
- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information, see the *Using Java* and *System Administration* sections of the WebSphere MQ information center.

If WebSphere MQ functionality has been disabled at a scope that affects this WebSphere MQ messaging provider resource, then an informational message indicating that WebSphere MQ has been disabled appears. In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see "Disabling WebSphere MQ functionality in WebSphere Application Server" on page 868.

A WebSphere MQ activation specification has the following properties.

Administration:

Scope:

The level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates that are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the WebSphere MQ activation specification collection panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Provider:

The JMS provider assigned when the activation specification is created.

For all activation specifications created using this panel, the provider is the WebSphere MQ messaging provider.

The provider is displayed for information only.

Data type String

Name:

The name by which this activation specification is known for administrative purposes within WebSphere Application Server.

Data type String
Range The name must be unique within the set of activation specifications defined to the cell.

JNDI name:

The JNDI name that is used to bind the activation specification into the JNDI namespace.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

Data type String

Description:
