A description of this activation specification for administrative purposes within WebSphere Application Server.

Data type String
Default Null

Connection:

The information required to configure a connection depends on whether the selected activation specification was created using a Client Channel Definition Table (CCDT).

If the selected activation specification was created using a CCDT, only the following properties are displayed:

- Client channel definition table URL
- Queue manager
- SSL configuration

If the selected activation specification was not created using a CCDT, the following properties are displayed:

- Queue manager
- Transport
- If **Enter host and port information in the form of separate host and port values** is selected, the connection name list property cannot be used and the following properties can be used:
  - Host name
  - Port
- If **Enter host and port information in the form of a connection name list** is selected, the connection name list property can be used and the following properties cannot be used:
  - Host name
  - Port
- Server connection channel
- If you clear the check box for the **Use SSL to secure communication with Websphere MQ** property, the following properties cannot be used:
  - Centrally managed
  - Specific configuration
  - SSL configuration

For more information about setting the SSL properties for WebSphere MQ, see *SSL properties* in the *WebSphere MQ Using Java* section of the WebSphere MQ information center.

Note: There are four WebSphere MQ connection properties that are used to configure the WebSphere MQ resource adapter used by the WebSphere MQ messaging provider. These properties affect the connection pool that is used by activation specifications:

- maxConnections
- connectionConcurrency
- reconnectionRetryCount
- reconnectionRetryInterval

For more information about these four properties, and how to configure them, see “Resource adapter properties” on page 721.

Client channel definition table URL:

A URL that specifies the location of a WebSphere MQ CCDT.

Data type String

Queue manager:

If the specified activation specification is based on a CCDT, this property is used to select an entry in the CCDT. Otherwise, this property specifies the name of the queue manager or queue-sharing group to connect to. A connection is established to the specified WebSphere MQ resource to receive messages.

Data type String

Range
If this activation specification is not based on a CCDT, the value must be a valid queue manager name.

If this activation specification is based on a CCDT, the value must be one of the following:

- A valid queue manager name
- An asterisk (*) followed by the name of a queue manager group[1]
- An asterisk (*)
- Blank[1]

[1]When you specify the value of the Queue manager property in this form in combination with a CCDT, individual connections established by using the activation specification might connect to different queue managers. Selection from multiple queue managers occurs when the CCDT contains multiple client connection channel definitions with a matching queue manager name (QMNAME) parameter, and these connection channel definitions define the network connection details of different queue managers.

If the specified connection factory is based on a CCDT, and the CCDT can select from more than one queue manager, you might not be able to recover global transactions. Therefore, for connection factories that specify a CCDT, you have two alternatives:

- Avoid any ambiguity about the target queue manager when specifying the Queue manager property, which means that the specified value of this property must not include an asterisk (*).
- Avoid using the resources with applications that enlist in global transactions.

Transport:

The WebSphere MQ transport type for the connection. The transport type is used to determine the exact mechanisms used to connect to WebSphere MQ.

Data type Drop-down list

Default **Bindings, then client**

Range

Client Use a TCP/IP-based network connection to communicate with the WebSphere MQ queue manager.

Bindings, then client
Attempt a bindings mode connection to the queue manager. If this is not possible, revert to the client transport.

Bindings
Establish a cross-memory connection to a queue manager running on the same node. The following Client Transport Mode properties are disabled:
- Host name
- Port
- Connection name list
- Server connection channel

For more information about configuring a transport type of *Bindings, then client* or *Bindings*, refer to "Configuring the WebSphere MQ messaging provider with native libraries information" on page 723.

Enter host and port information in the form of separate host and port values:

If this radio button is selected, this means that the connection to the WebSphere MQ queue manager is made using the information supplied by the host name and port properties.

Selecting this option enables the host name and port properties, and disables the connection name list property. To enter connection name list information, click **Enter host and port information in the form of a connection name list**.

This radio button is only available if the scope property specifies a cell, or if the scope property specifies a node or server and that node or server is running WebSphere Application Server Version 8.0.

Data type Radio button

Hostname:

The host name, IPv4, or IPv6 address of the WebSphere MQ queue manager to connect to.

Data type String

Port:

The port number on which WebSphere MQ is listening.

Data type Integer
Default 1414
Range The value must be in the range 1 to 65536 (inclusive).

Enter host and port information in the form of a connection name list:

If this radio button is selected, this means that the connection to the WebSphere MQ queue manager is made using the information supplied by the connection name list property.

Connection name lists can be used to connect to a single queue manager or to a multi-instance queue manager. For more information on using a multi-instance queue manager, see the WebSphere MQ information centre. Selecting this option enables the connection name list property and disables the host name and port properties. To enter separate host and port information, click **Enter host and port information in the form of separate host and port values**.

This radio button is only available if the scope property specifies a cell, or if the scope property specifies a node or server and that node or server is running WebSphere Application Server Version 8.0.

Data type	Radio button

Connection name list:

The connection name list specifying the host name and port details to use when you want the activation specification to connect to a multi-instance queue manager.

This property must only be used to allow connection to a multi-instance queue manager. It must not be used to allow connections to non-multi-instance queue managers as that can result in transaction integrity issues.

Data type	String
Default	Unset
Range	This field must be set to a string in the following form: *host*[(*port*)][,*host*(*port*)] The port information is optional, and if not specified, defaults to 1414. *host* must be a valid TCP/IP host name or IPv4 or IPv6 address. *port* must be an integer value in the range 1 to 65536 (inclusive). For example: `localhost(1234),remotehost1(1234),remotehost2`

When the connection name list property is specified, the host name or port properties are automatically set to the host name and port number of the first entry in the connection name list. So if you specified `localhost(1234),remotehost1(1234),remotehost2`, the host name would be set to localhost and port would be set to 1234.

This property is only available if the scope property specifies a cell, or if the scope property specifies a node or server and that node or server is running WebSphere Application Server Version 8.0.

When used in a mixed cell environment, the information in the connection name list property, for cell scope activation specifications, is available to WebSphere Application Server Version 7.0 nodes. The exact behaviour depends on the fix pack level of the node:

- For nodes running at a fix pack level of WebSphere Application Server Version 7.0 Fix Pack 7 or later, the connection name list property can be used to connect to multi-instance queue managers.
- For nodes running at a fix pack level earlier than Version 7.0, the connection name list property is not recognized, and a warning message similar to the following example is output:

```
[29/09/10 12:15:27:468 BST] 00000018 J2CUtilityCla W
J2CA0008W: Class com.ibm.mq.connector.inbound.ActivationSpecImpl used by resource
cells/L3A3316Node01Cell/resources.xml#J2CResourceAdapter_1284547647859 did not contain
method setConnectionNameList. Processing continued.
```

In this case the information in the host name and port properties are used to connect to a queue manager.

Server connection channel:

The WebSphere MQ server connection channel name used when connecting to WebSphere MQ.

Data type	String
Default	SYSTEM.DEF.SVRCONN
Range	The value must be a server connection channel defined to the WebSphere MQ queue manager that is being connected to.

Use SSL to secure communications with WebSphere MQ:

This option determines whether the SSL (Secure Sockets Layer) protocol is used to secure network communications with the WebSphere MQ queue manager or queue-sharing group.

When using a WebSphere MQ messaging provider activation specification in the application server environment, the application server manages SSL configuration. To change SSL configuration parameters, use the administrative console to navigate to the **Security** > **SSL certificate and key management** panel.

You can only use one cipher suite in the SSL configuration for a WebSphere MQ messaging provider activation specification . If you specify more than one cipher suite, only the first one is used.

Data type	Check box. If this check box is cleared, the following SSL properties are disabled: • Centrally managed • Specific configuration • SSL configuration

Centrally managed:

When the SSL protocol is used to communicate with WebSphere MQ, select this radio button to specify that the SSL configuration is taken from the centrally managed WebSphere Application Server SSL configuration.

When you select this radio button, the host name and port attributes from the WebSphere MQ messaging provider activation specification are used to select an appropriate SSL configuration. If host and port information has been supplied to the activation specification by a connection name list this means that the host name and port information of the first element in the list are used to select an appropriate SSL configuration. To provide the SSL configuration which will be matched to the activation specification, see the Dynamic outbound endpoint SSL configuration settings topic listed under related reference.

Data type	Radio button

Specific configuration:

Select this radio button when you want to specify a particular SSL configuration for use when SSL is to be used to secure network communications with the WebSphere MQ queue manager or queue-sharing group.

Data type	Radio button

SSL configuration:

The SSL configuration to use when SSL is to be used to secure network communications with the WebSphere MQ queue manager or queue-sharing group.

This property is disabled if the **Centrally managed** radio button is selected and the WebSphere MQ messaging provider resource has been explicitly defined.

This property is always enabled if the WebSphere MQ messaging provider resource is based on a CCDT.

If this WebSphere MQ messaging provider resource is based on a CCDT, this parameter is only used if the relevant entries in the CCDT have been configured to use SSL.

Additionally, if an SSL configuration of `none` is selected, the default centrally managed WebSphere Application Server SSL configuration for the WebSphere MQ messaging provider is used.

Data type Drop-down list

Destination:

Note: The property WAS_EndpointInitialState is a custom property. This property determines whether or not message consumption begins from the JMS destination as soon as the activation specification is used for a message-driven bean to connect with the destination. To set custom properties, when you have completed your changes in this content pane and clicked **Apply** to save the configuration, then click the link **Custom properties** in the content pane under Additional Properties.

Destination JNDI name:

The JNDI name for the JMS destination from which messages are consumed for delivery to a message-driven bean (MDB) that is configured to use this activation specification.

Data type String

Message selector:

A message selector expression specifying which messages are to be delivered.

Data type String

Destination type:

The type of destination (queue or topic) from which to consume messages.

Data type Drop-down list

Range

Queue The Destination JNDI name refers to a JMS destination that is a queue.

Topic The Destination JNDI name refers to a JMS destination that is a topic.

Durable subscription:

An option to specify whether a durable or nondurable subscription is used to deliver messages to an MDB subscribing to the topic.

Data type Check box

Default Cleared (nondurable)

Range

Cleared
Nondurable.
Selected
Durable.

Subscription name:

The name of a durable subscription. This is available only when the **Durable subscription** check box is selected.

Data type String

Advanced:

Client ID:

The client identifier to specify when connecting to the WebSphere MQ messaging provider.

Data type String

Allow cloned durable subscriptions:

An option that determines whether multiple instances of a durable subscription can be accessed concurrently by different servers.

Data type Check box
Default Cleared
Range

Selected
Multiple instances of a durable subscription can be accessed concurrently by different servers.
Cleared
Multiple instances of a durable subscription cannot be accessed concurrently by different servers.

Provider version:

The WebSphere MQ messaging provider version. This is used to determine whether to connect to a particular version of a queue manager. It is also used to determine the type of functions required by the client.

Data type String
Range
The value entered must either be the empty string or be in one of the following formats:

n.n.n.n

n.n.n

n.n

n

where n is a numeric value greater than or equal to zero.

For example 6.0.0.0.

Security settings:

Authentication alias:

The user name and password to use when connecting to WebSphere MQ.

Data type	Drop-down list
Default	(none)
Range	All authentication aliases defined to the cell and the value "(none)", which specifies that no credentials are passed to WebSphere MQ.

WebSphere MQ messaging provider activation specification advanced properties:

Use this panel to view or change the advanced properties of the selected activation specification for use with the WebSphere MQ messaging provider. These advanced properties control the behavior of connections made to WebSphere MQ messaging provider destinations.

To view WebSphere MQ activation specification advanced properties, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** > **JMS->Activation specifications** to display existing activation specifications.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the activation specifications are defined. This restricts the set of activation specifications displayed.
3. Select the name of the activation specification that you want to work with.
4. In the content pane, under Additional properties, click **Advanced properties** to view a list of the advanced properties of the WebSphere MQ activation specification.

Under General Properties there are four groups of properties:

- Message compression
- Connection consumer
- Message format
- Additional

Make any required changes to these groups and then click **Apply** to return to the activation specification.

Note: When specifying WebSphere MQ properties, the following restrictions apply:
- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the WebSphere MQ *Using Java* section of the WebSphere MQ library.

A WebSphere MQ activation specification has the following advanced properties.

Compress message headers:

An option that enables the compression of message headers.

Data type	Check box
Default	Cleared
Range	**Cleared** Do not compress message headers. **Selected** Compress message headers.

Compression algorithm for message payloads:

The compression algorithm that is used to compress message payloads.

Data type Drop-down list
Default NONE
Range
RLE Message data compression is performed using run-length encoding.
ZLIBFAST Message data compression is performed using ZLIB encoding with speed prioritized.
ZLIBHIGH Message data compression is performed using ZLIB encoding with compression prioritized.
NONE No message data compression is performed.

Retain messages, even if no matching consumer is available:

An option that determines whether messages for which there is no matching consumer are retained on the input queue or dealt with according with their disposition options.

Data type Check box
Default Selected
Range
Cleared Do not retain messages.
Selected Retain messages.

Rescan interval:

When using a WebSphere MQ version 6 queue manager (or WebSphere MQ version 5.3 for z/OS), this setting configures the mechanism that is used to dispatch messages to JMS asynchronous consumers.

This setting is used when the set of WebSphere MQ queues that is being asynchronously consumed from exceeds the number of threads that are available internally to synchronously get messages from the WebSphere MQ queue. The setting determines how long a thread retrieves messages from a WebSphere MQ queue before switching to consume messages from another WebSphere MQ queue in the set.

Data type Integer
Units Milliseconds
Default 5000
Range A value greater than zero.

Maximum server sessions:

The maximum number of server sessions in the server session pool that is used by the connection consumer.

Data type Integer
Default 10
Range A value greater than zero.

Server session pool timeout:

The period of time, in milliseconds, that an unused server session is held open in the server session pool before being closed due to inactivity.

Data type	Integer
Units	Milliseconds
Default	300,000
Range	A value greater than zero.

Start timeout:

The period of time, in milliseconds, within which delivery of a message to a message-driven bean (MDB) must start after the work to deliver the message has been scheduled. If this period of time elapses, the message is rolled back onto the queue.

Data type	Integer
Units	Milliseconds
Default	10,000
Range	A value greater than zero.

Coded character set identifier:

The character set to use when you are encoding strings in the message.

Data type	Integer
Default	819
Range	A value greater than zero. The value must be one of the CCSIDs supported by WebSphere MQ.

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *WebSphere MQ System Administration* and the *WebSphere MQ Application Programming Reference* sections of the WebSphere MQ library.

Fail JMS method calls if the WebSphere MQ queue manager is quiescing:

An option that enables selected JMS operations to fail when the queue manager is put into a quiescing state. Selecting this option enables the queue manager to quiesce successfully and shut down.

Data type	Check box
Default	Selected
Range	**Cleared** Do not fail JMS operations if the queue manager is quiescing. **Selected** Fail JMS operations if the queue manager is quiescing.

Stop endpoint if message delivery fails:

An option that determines whether message delivery is suspended to a failing endpoint.

Data type	Check box
Default	Selected

Range

Cleared
Message delivery is not suspended to a failing endpoint.

Selected
Message delivery is suspended to a failing endpoint when the value for the **Number of sequential delivery failures before suspending endpoint** is exceeded.

Number of sequential delivery failures before suspending endpoint:

The number of sequential message delivery failures to an endpoint that are allowed before message delivery to that endpoint is suspended. This property is enabled only when **Suspend message delivery to failing endpoints** is selected.

Data type	Integer
Default	0
Range	A value greater than or equal to zero.

WebSphere MQ messaging provider activation specification broker properties:

Use this panel to view or change the broker settings of the selected activation specification for use with the WebSphere MQ messaging provider. These broker settings determine how the WebSphere MQ messaging provider interacts with a broker for the purposes of publishing messages and subscribing to topics. Updates to the settings take effect when the server is restarted.

To view WebSphere MQ activation specification broker properties, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** > **JMS->Activation specifications** to display existing activation specifications.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the activation specifications are defined. This restricts the set of activation specifications displayed.
3. Select the name of the activation specification that you want to work with.
4. In the content pane under Additional properties, click **Broker properties** to view a list of the broker properties of the WebSphere MQ activation specification.

Under General Properties there are four groups of properties:
- Queues
- Capabilities
- Tuning
- Additional

Make any required changes to these groups and then click **Apply** to return to the activation specification.

Note: When specifying WebSphere MQ properties, the following restrictions apply:
- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the WebSphere MQ *Using Java* section of the WebSphere MQ library.

A WebSphere MQ activation specification has the following broker properties.

Broker control queue:

The queue to which broker control messages are sent.

Data type String
Default SYSTEM.BROKER.CONTROL.QUEUE

Broker subscriber queue:

The queue from which subscription messages are received.

Data type String
Default SYSTEM.JMS.ND.SUBSCRIBER.QUEUE

Broker connection consumer subscription queue:

The queue to receive subscription messages for connection consumers from.

Data type String
Default SYSTEM.JMS.ND.CC.SUBSCRIBER.QUEUE

Broker connection consumer durable subscription queue:

The queue to receive subscription messages for durable connection consumers from.

Data type String
Default SYSTEM.JMS.D.CC.SUBSCRIBER.QUEUE

Version:

The version of the broker that is used. This determines some of the capabilities that the broker is assumed to have. For example, whether to use an RFH version 1 or version 2 header in publications.

Data type Radio button
Default Version 1 broker
Range

Version 1 broker
Message selection cannot be specified.

Version 2 broker
Message selection can be specified. If you select this option, you must also complete **Specify where message selection occurs**.

Specify where message selection occurs:

The process in which message selection is performed. This property is enabled only if **Version 2 broker** was selected.

Data type Drop-down list
Default CLIENT

Range

CLIENT
Message selection is performed in the application server process.

BROKER
Message selection is performed in the broker process.

Subscription store:

The process for tracking subscriptions.

Data type Drop-down list
Default MIGRATE
Range

MIGRATE
Any information that is held on queues is migrated to the broker mechanism for persisting subscription information. If subscription information is already persisted using the broker mechanism then specifying a value of `Migrate` is equivalent to specifying a value of `Broker`.

BROKER
Internal broker mechanisms are used to track subscription information.

QUEUE
A designated WebSphere MQ queue is used to record information about current subscriptions.

Durable subscription state refresh interval:

How often a long running transaction is recreated and used to clean up durable subscriptions, for some versions of the queue manager.

Data type Integer
Default 60000
Range Any positive integer

Subscription cleanup level:

How aggressively messages are cleaned up if the subscriber that is expected to consume the messages terminates unexpectedly.

Data type Drop-down list
Default SAFE

Range

SAFE A conservative algorithm is used to clean up subscriptions.

ASPROP
The cleanup algorithm is determined by a system property.

NONE No cleanup of subscriptions is performed.

STRONG
An aggressive algorithm is used to clean up subscriptions.

Subscription cleanup interval:

How often to check for orphaned subscriptions and clean up messages.

Data type Integer
Default 3600000
Range Any positive integer

Subscription wildcard format:

The wildcard format used for subscribing to more than one topic in a topic hierarchy.

Data type Drop-down list
Default character wildcards
Range

character wildcards
You can use an asterisk (*) or question mark (?) to represent characters, or strings of characters, in a topic name.

* is interpreted as matching many characters.

? is interpreted as matching a single character.

topic level wildcards
You can use a plus sign (+) or number sign (#) to represent topics in a multilevel topic hierarchy.

+ is interpreted as matching a single topic name.

is interpreted as matching many topics in the hierarchy. / is used to delimit topics.

Optimize for sparse subscription patterns:

An option to specify whether this activation specification is anticipated to receive a high proportion of messages that match its selection criteria. This information can be used to optimize message delivery.

Data type Check box
Default Cleared
Range

Cleared
Subscriptions frequently receive matching messages.

Selected
Subscriptions do not frequently receive matching messages.

Broker queue manager:

The name of the queue manager that is running the broker, if it is not the same as the queue manager to which the activation specification connects.

Data type	String
Default	The queue manager name that was specified in the activation specification.

WebSphere MQ messaging provider activation specification client transport properties:

Use this panel to view or change the client transport properties of an activation specification for use with the WebSphere MQ messaging provider. These properties affect how a client connection is established with a WebSphere MQ queue manager or queue-sharing group. Updates to the properties take effect when the server is restarted.

To view WebSphere MQ activation specification client transport properties, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** > **JMS->Activation specifications** to display existing activation specifications.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the activation specifications are defined. This restricts the set of activation specifications displayed.
3. Select the name of the activation specification that you want to work with.
4. In the content pane, under Additional properties, click **Client transport properties** to display a list of the client transport properties of the WebSphere MQ activation specification.

Under General Properties there are two groups of properties:

- Additional SSL settings (for more information about setting the SSL properties for WebSphere MQ, see *SSL properties* in the *Using Java* section of the WebSphere MQ information center)
- Channel exits

Make any required changes to these groups and then click **Apply** to return to the activation specification.

Note: When specifying WebSphere MQ properties, the following restrictions apply:
- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the *Using Java* section of the WebSphere MQ information center.

A WebSphere MQ activation specification has the following client transport properties:

Certificate revocation list:

A list of LDAP URLs pointing to LDAP repositories of SSL certificates that might have been revoked.

Data type	String
Default	No certificate revocation list
Range	The value must be a space-separated list of LDAP URLs.

Reset count:

The total number of bytes to transfer over an SSL connection before renegotiating the symmetric encryption keys used to secure the connection.

Data type Integer
Default 0 (do not renegotiate)
Range The value must be in the range 0 through 999,999,999 (inclusive).

Peer name:

A name (possibly including wildcards) that must match the distinguished name of the peer SSL certificate for a connection to be established.

Data type String
Default Do not check the distinguished name of the peer certificate.
Range Validated using the rules for a WebSphere MQ SSLPEER channel parameter.

Receive exit or exits:

A comma-separated list of Java class names corresponding to receive exits to be loaded.

Data type String

Receive exit initialization data:

Initialization data to be passed to the receive exit.

Data type String

Send exit or exits:

A comma-separated list of Java class names corresponding to send exits to be loaded.

Data type String

Send exit initialization data:

Initialization data to be passed to the send exit.

Data type String

Security exit:

A Java class name corresponding to the security exit to be loaded.

Data type String

Security exit initialization data:

Initialization data to be passed to the security exit.

Data type String

Migrating a listener port to an activation specification for use with the WebSphere MQ messaging provider

For WebSphere Application Server Version 7 and later, listener ports are stabilized. You must therefore plan to migrate your WebSphere MQ message-driven bean deployment configurations from using listener ports to using activation specifications.

Before you begin

EJB 2.0 message-driven beans cannot be configured against JCA 1.5-compliant resources. If your bean is an EJB 2.0 application, upgrade it to EJB 3 or EJB 2.1 before you complete this task.

Note: You can continue to configure EJB 3, EJB 2.1, and EJB 2.0 message-driven beans against a listener port. You might want to do this for compatability with existing message-driven bean applications. However, listener ports are stabilized, and you should plan to migrate all your message-driven beans to use JCA 1.5-compliant resources. For more information about when to use listener ports rather than activation specifications, see Message-driven beans, activation specifications, and listener ports.

About this task

For WebSphere Application Server Version 7 and later, listener ports are stabilized. For more information, read the article on stabilized features. You should plan to migrate your WebSphere MQ message-driven bean deployment configurations from using listener ports to using activation specifications. However, you should not begin this migration until you are sure the application does not have to work on application servers earlier than WebSphere Application Server Version 7. For example, if you have an application server cluster with some members at Version 6.1 and some at Version 7, you should not migrate applications on that cluster to use activation specifications until after you migrate all the application servers in the cluster to Version 7.

Note that the **Maximum retries** listener port setting is not migrated to the new activation specification as there is no exact equivalent.

When you are migrating a listener port associated with a message-driven bean (MDB) that has the subscriptionDurability activation configuration property set to Durable, and that MDB already has an active durable subscription, the durable subscription is not migrated. This is because listener ports and WebSphere MQ activation specifications use incompatible forms of subscription name. As a result there can be two active durable subscriptions subscribed to the relevant topic for the same MDB. As part of the migration process, you must delete the old durable subscription that was associated with the listener port and manually clean up any messages associated with it. For information on how do to this see the WebSphere MQ and WebSphere Message Broker information centres.

Procedure

1. Start the administrative console.
2. In the navigation pane, expand**Servers** > **Server Types** > **WebSphere application servers->*server_name*** > **[Communications] Messaging** > **Message listener service** > **[Additional Properties] Listener Ports**

   The “Message listener port collection” on page 425 panel is displayed.
3. Select the listener port that you want to work with by selecting the check box to the left of the listener port name.
4. Click **Convert to activation specification** to start the "Convert listener port to activation specification" wizard.
5. On the "Step1: Supply activation specification name" page, enter the following information then click **Next** to continue:

- The name of the new activation specification to be created.
- The JNDI name of the new activation specification.
- The scope of the new activation specification (Server, Node, Cluster, Cell). Note that Cluster only appears when the server is in a cluster.

6. On the "Step2: Summary" page, click **Finish** to complete the creation of the new activation specification.
7. Stop then restart the application server.
8. To complete the configuration of the activation specification, see “Configuring an activation specification for the WebSphere MQ messaging provider” on page 738.

Creating a connection factory for the WebSphere MQ messaging provider

Use this task to create a connection factory, a queue connection factory, or a topic connection factory for use with the WebSphere MQ messaging provider.

About this task

With JMS 1.1, domain-independent connection factories are preferred to domain-specific queue connection factories and topic connection factories.

To create a connection factory, a queue connection factory, or a topic connection factory for use with the WebSphere MQ messaging provider, use the administrative console to complete the following steps. You can choose either to enter all the required connection information using the Create WebSphere MQ JMS resource wizard or to use a client channel definition table (CCDT) to establish a connection to the WebSphere MQ messaging provider.

For information about modifying an existing connection factory, see the related tasks.

Procedure

1. In the navigation pane, select the type of connection factory you want to create:
   - To create a connection factory, click **Resources** > **JMS->Connection factories**.
   - To create a queue connection factory, click **Resources** > **JMS->Queue connection factories**.
   - To create a topic connection factory, click **Resources** > **JMS->Topic connection factories**.
2. Select the **Scope** setting corresponding to the scope of the connection factory that you want to create.
3. Click **New** in the content pane to start the Create WebSphere MQ JMS resource wizard.
4. Select **WebSphere MQ messaging provider**, then click **OK**.
5. On the “Configure basic attributes” page, specify the following properties, then click **Next**.

   Name The name by which this connection factory is known for administrative purposes within WebSphere Application Server.

   JNDI name
   The name that is used to bind this connection factory into the Java Naming and Directory Interface (JNDI) namespace.

   Description
   Optional. A description of this connection factory for administrative purposes within WebSphere Application Server.
6. On the “Select connection method” page, choose how you want to specify the connection details for to the WebSphere MQ messaging provider by selecting one of the following options, then click **Next**.

Enter all the required information into this wizard
Choosing this option takes you to the “Supply queue manager details” page (see step 7), where you can start entering the connection details using the Create WebSphere MQ JMS resource wizard.

Use a client channel definition table
Choosing this option takes you to the “Specify client channel definition table” page (see step 8), where you can enter details of the client channel definition table that you want to use.

7. If you have chosen to enter all the required information using the wizard, complete the following steps:
   a. On the “Supply queue manager details” page, enter the name of the queue manager or queue-sharing group that you want to connect to then click **Next**.
   b. On the “Enter connection details” page, specify the details for the connection, then click **Next** to continue to the “Test connection” page. You can choose either to enter host and port information separately, or enter host and port information in the form of a connection name list. You must only choose the option to use a connection name list if you are creating a connection to a multi-instance queue manager. You must not use this option for connections to non-multi-instance queue managers as that can result in transaction integrity issues.

      Transport
      Optional. The WebSphere MQ transport type for the connection. The option that you select is used to determine the exact mechanisms used to connect to WebSphere MQ. If you are configuring a transport type of *bindings, then client* or *bindings*, see “Configuring the WebSphere MQ messaging provider with native libraries information” on page 723 for more information.

      Enter host and port information in the form of separate hostname and port values
      This radio button is selected by default and enables the **Hostname** and **Port** fields and disables the **Connection name list** field. Leave this radio button selected if you want to enter host and port information in the form of separate host name and port values.

      Hostname
      The host name, IPv4, or IPv6 address of the WebSphere MQ queue manager to connect to. Complete this field if you have selected **Enter host and port information in the form of separate hostname and port values**.

      Port Optional. The port number on which WebSphere MQ is listening. Complete this field if you have selected **Enter host and port information in the form of separate hostname and port values**.

      Enter host and port information in the form of a connection name list
      This radio button is cleared by default and, if selected, disables the **Hostname** and **Port** fields and enables the **Connection name list** field.
      - Click this radio button to select it if you want to enter host and port information in the form of a connection list.
      - Leave this radio button cleared if you want to enter host and port information in the form of separate hostname and port values.

      Connection name list
      The connection name list specifying the host name and port details to use when you want the connection factory to connect to a multi-instance queue manager. Complete this field if you have selected **Enter host and port information in the form of a connection name list**. Enter the host name and port details in the following form:

      `host[(port)][,host(port)]`

      host must be a valid TCP/IP host name or IPv4 or IPv6 address.

      port must be an integer value in the range 1 - 65536 (inclusive). The port information is optional, and if not specified, defaults to 1414.

For example: `localhost(1234),remotehost1(1234),remotehost2`

Server connection channel
Optional. The WebSphere MQ server connection channel name used when connecting to WebSphere MQ queue manager or queue-sharing group.

8. If you are using a channel client definition table to establish a connection to the WebSphere MQ messaging provider, complete the following fields on the “Specify client channel definition table” page, then click **Next** to continue to the “Test connection” page.

   Client channel definition table URL
   The URL to the client channel definition table that you want to use when connecting to WebSphere MQ.

   Queue manager
   Optional. The name of the queue manager to be used to select one or more entries from the CCDT.
9. Optional: On the “Test connection” page, if you want to test establishing the connection, click **Test connection**. This test can take several seconds to perform.
10. On the “Summary” page, complete the creation of the new connection factory by clicking **Finish**.
11. Stop then restart the application server.

JMS resource provider selection panel

Select the messaging provider with which to create this JMS activation specification, connection factory or destination.

You select the scope setting on an earlier page. The choice of JMS provider depends on the scope that you selected. You might see a choice such as the following list:

- Default messaging provider.

  Select this option if you want the JMS resource to be provided by the service integration bus, as part of WebSphere Application Server.
- WebSphere MQ messaging provider

  Select this option if you want the JMS resource to be provided by WebSphere MQ. You must have installed and configured a WebSphere MQ network in order to use this provider.
- “My JMS provider”

  Select this option if you want the JMS resource to be provided by a third-party JMS provider. This option is only available if you have installed and configured a third-party provider. The name that is displayed (for example“My JMS provider”) is the name you gave to the provider when you installed and configured it.
- V5 default messaging provider

  Select this option if you want to manage the JMS connection factories and destinations for JMS applications that were designed to work with WebSphere Application Server Version 5.1, and are still running on a Version 5.1 or Version 6 node that is part of a Version 7.0 or later mixed cell.

Configuring a unified connection factory for the WebSphere MQ messaging provider

Use this task to view or change the configuration of an existing domain-independent connection factory for the WebSphere MQ messaging provider on a WebSphere Application Server node.

About this task

This task applies to unified connection factories. With JMS 1.1, domain-independent (unified) connection factories are preferred to domain-specific queue connection factories and topic connection factories. If you want to view or change a queue connection factory or topic connection factory, see the related tasks.

To view or change the configuration of an existing connection factory for use with the WebSphere MQ messaging provider, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click **Resources** > **JMS->Connection factories**. A list of existing unified connection factories, with a summary of their properties, is displayed.
2. Select the **Scope** corresponding to the scope at which the connection factory is visible to applications.
3. Click the name of the connection factory that you want to view or change. Configuration details for the unified connection factory are displayed.
4. Under **General Properties** make any required changes.

   For information about each of the available fields, see "WebSphere MQ messaging provider connection factory settings."
5. Click **Apply** to save the configuration.
6. Optional: Click **Advanced properties** to display or change the list of advanced properties of your connection factory.
7. Optional: Click **Broker properties** to display or change the list of broker properties of your connection factory.
8. Optional: Click **Custom properties** to display or change the list of custom properties of your connection factory.
9. Optional: Click **Client transport properties** to display or change the list of client transport properties of your connection factory. This link is only appears if, when you created the connection factory, you chose to enter all the information required to connect to WebSphere MQ. This link does not appear if you have chosen to use a client channel definition table (CCDT) to establish a connection to WebSphere MQ.
10. Optional: Click **Connection pools** to display or change the connection pools detail of your connection factory.
11. Optional: Click **Session pools** to display or change the session pools detail of your connection factory.

    There is a mechanism (session.sharing.scope custom property) to make JMS sessions unshareable. This means that whenever an application calls Session.close(), the JMS session is automatically released from any transaction that is associated with and returned to the session pool. This means that sessions can be cleaned up and removed from the session pool even if the servlet or asynchronous bean that created it is still running.
12. Click **OK**.
13. Save your changes to the master configuration.
14. To make the changed configuration take effect, stop then restart the application server.

WebSphere MQ messaging provider connection factory settings

Use this panel to view or change the configuration properties of the selected connection factory for use with the WebSphere MQ messaging provider. These configuration properties control how connections are created to associated JMS queues and topics.

The WebSphere MQ messaging provider supports JMS 1.1 domain-independent interfaces, such as the unified JMS connection factory. A domain-independent application can use the same interface for both point-to-point and publish/subscribe messaging, and can support both point-to-point and publish/subscribe messaging within the same transaction. With JMS 1.1, you are recommended to use domain-independent unified JMS connection factories for new applications. A domain-specific interface extends the domain-independent equivalent, so an application that uses domain-specific queue and topic connection factories can choose to use either interface.

To view WebSphere MQ connection factory settings, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** > **JMS->Connection factories** to display existing connection factories.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the connection factories are defined. This restricts the set of connection factories displayed.
3. Select the name of the connection factory that you want to work with.

Under General Properties there are four groups of properties:

- "Administration" on page 764
- "Connection" on page 765
- "Advanced" on page 770
- "Security settings" on page 771

Make any required changes to the Administration, Connection, Advanced, and Security settings groups of properties, and then click **Apply** to save the configuration before, in the content pane under Additional Properties, you click any of the following links:

- **Advanced properties** to display or change the advanced properties of your WebSphere MQ connection factory.
- **Broker properties** to display or change the broker properties of your WebSphere MQ connection factory.
- **Custom properties** to display or change the custom properties of your WebSphere MQ connection factory.
- **Client transport properties** to display or change the client transport properties of your WebSphere MQ connection factory. If the selected connection factory was not created using a Client Channel Definition Table (CCDT), follow this link to enter all the information required to connect to WebSphere MQ. If the selected connection factory was created using a CCDT, you do not need to supply the client transport properties, and so the link is absent.
- **Connection pools** to display or change the connection pools detail of your WebSphere MQ connection factory.
- **Session pools** to display or change the session pools detail of your WebSphere MQ connection factory.

Under Related Items, you can click **JAAS - J2C authentication data** to configure authentication information for use with the connection factory.

You can specify the following additional properties by using WebSphere MQ administrative commands:

- **-localAddress**
- **-clonedSubs**
- **-componentAuthAlias**

For more information about these properties, refer to the "createWMQConnectionFactory command" on page 888.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ JMS resources, see the *Using Java* and *WebSphere MQ System Administration* sections of the WebSphere MQ information center.

If WebSphere MQ functionality has been disabled at a scope that affects this WebSphere MQ messaging provider resource, then an informational message indicating that WebSphere MQ has been disabled appears. In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

A WebSphere MQ unified connection factory has the following properties.

Administration:

Scope:

The level at which this connection factory definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates that are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change other resources at a different scope, change the scope on the WebSphere MQ connection factory collection panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Provider:

The JMS provider assigned when the queue connection factory is created.

For all connection factories that use this panel, the provider is the WebSphere MQ messaging provider.

The provider is displayed for information only.

Data type String

Name:

The name by which this connection factory is known for administrative purposes within WebSphere Application Server.

Data type String
Range The name must be unique within the set of connection factories defined to the cell.

JNDI name:

The JNDI name that is used to bind the connection factory into the JNDI namespace.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

Data type String

Description:

A description of this connection factory for administrative purposes within WebSphere Application Server.

Data type String
Default Null

Connection:

The information required to configure a connection depends on whether the selected queue connection factory was created using a Client Channel Definition Table (CCDT).

If the selected connection factory was created using a CCDT, only the following properties are displayed:
- Client channel definition table URL
- Queue manager
- SSL configuration

If the selected connection factory was not created using a CCDT, the following properties are displayed:
- Queue manager
- Transport
- If **Enter host and port information in the form of separate host and port values** is selected, the connection name list property cannot be used and the following properties can be used:
  - Host name
  - Port
- If **Enter host and port information in the form of a connection name list** is selected, the connection name list property can be used and the following properties cannot be used:
  - Host name
  - Port
- Server connection channel
- If you clear the check box for the **Use SSL to secure communication with Websphere MQ** property, the following properties cannot be used:
  - Centrally managed
  - Specific configuration
  - SSL configuration

For more information about setting the SSL properties for WebSphere MQ, see *SSL properties* in the *Using Java* section of the WebSphere MQ information center.

Client channel definition table URL:

A URL that specifies the location of a WebSphere MQ CCDT.

Data type String

Queue manager:

If the specified connection factory is based on a CCDT, this property is used to select an entry in the CCDT. Otherwise, this property specifies the name of the queue manager or queue-sharing group to connect to. A connection is established to the specified WebSphere MQ resource to send or receive messages.

Data type String

Range

If this connection factory is not based on a CCDT, the value must be a valid queue manager name.

If this connection factory is based on a CCDT, the value must be one of the following:

- A valid queue manager name
- An asterisk (*) followed by the name of a queue manager group[1]
- An asterisk (*)
- Blank[1]

[1]When you specify the value of the Queue manager property in this form in combination with a CCDT, individual connections established by using the connection factory might connect to different queue managers. Selection from multiple queue managers occurs when the CCDT contains multiple client connection channel definitions with a matching queue manager name (QMNAME) parameter, and these connection channel definitions define the network connection details of different queue managers.

If the specified connection factory is based on a CCDT, and the CCDT can select from more than one queue manager, you might not be able to recover global transactions. Therefore, for connection factories that specify a CCDT, you have two alternatives:

- Avoid any ambiguity about the target queue manager when specifying the Queue manager property, which means that the specified value of this property must not include an asterisk (*).
- Avoid using the resources with applications that enlist in global transactions.

Transport:

The WebSphere MQ transport type for the connection. The transport type is used to determine the exact mechanisms used to connect to WebSphere MQ.

Data type Drop-down list
Default **Bindings, then client**

Range

Client Use a TCP/IP-based network connection to communicate with the WebSphere MQ queue manager.

Bindings, then client
Attempt a bindings mode connection to the queue manager. If this is not possible, revert to the client transport.

Bindings
Establish a cross-memory connection to a queue manager running on the same node. The following Client Transport Mode properties are disabled:
- Host name
- Port
- Connection name list
- Server connection channel

For more information about configuring a transport type of *Bindings, then client* or *Bindings*, refer to "Configuring the WebSphere MQ messaging provider with native libraries information" on page 723.

Enter host and port information in the form of separate host and port values:

If this radio button is selected, this means that the connection to the WebSphere MQ queue manager is made using the information supplied by the host name and port properties.

Selecting this option enables the host name and port properties, and disables the connection name list property. To enter connection name list information, click **Enter host and port information in the form of a connection name list**.

This radio button is only available if the scope property specifies a cell, or if the scope property specifies a node or server and that node or server is running WebSphere Application Server Version 8.0.

Data type Radio button

Hostname:

The host name, IPv4, or IPv6 address of the WebSphere MQ queue manager to connect to.

Data type String

Port:

The port number on which WebSphere MQ is listening.

Data type Integer
Default 1414
Range The value must be in the range 1 to 65536 (inclusive).

Enter host and port information in the form of a connection name list:

If this radio button is selected, this means that the connection to the WebSphere MQ queue manager is made using the information supplied by the connection name list property.

Connection name lists can be used to connect to a single queue manager or to a multi-instance queue manager. For more information on using a multi-instance queue manager, see the WebSphere MQ information centre. Selecting this option enables the connection name list property and disables the host name and port properties. To enter separate host and port information, click **Enter host and port information in the form of separate host and port values**.

This radio button is only available if the scope property specifies a cell, or if the scope property specifies a node or server and that node or server is running WebSphere Application Server Version 8.0.

Data type Radio button

Connection name list:

The connection name list specifying the host name and port details to use when you want the connection factory to connect to a multi-instance queue manager.

This property must only be used to allow connection to a multi-instance queue manager. It must not be used to allow connections to non-multi-instance queue managers as that can result in transaction integrity issues.

Data type String
Default Unset
Range This field must be set to a string in the following form:

host[(*port*)][,*host*(*port*)]

The port information is optional, and if not specified, defaults to 1414.

host must be a valid TCP/IP host name or IPv4 or IPv6 address.

port must be an integer value in the range 1 to 65536 (inclusive).

For example:
`localhost(1234),remotehost1(1234),remotehost2`

When the connection name list property is specified, the host name or port properties are automatically set to the host name and port number of the first entry in the connection name list. So if you specified `localhost(1234),remotehost1(1234),remotehost2`, the host name would be set to localhost and port would be set to 1234.

This property is only available if the scope property specifies a cell, or if the scope property specifies a node or server and that node or server is running WebSphere Application Server Version 8.0.

When used in a mixed cell environment, the information in the connection name list property is not available to versions of WebSphere Application Server earlier than Version 8.0. In this case, the information in the host name and port name fields, based on the first element in the connection name list, is used instead.

Server connection channel:

The WebSphere MQ server connection channel name used when connecting to WebSphere MQ.

Data type String
Default SYSTEM.DEF.SVRCONN

Range

The value must be a server connection channel defined to the WebSphere MQ queue manager that is being connected to.

Use SSL to secure communications with WebSphere MQ:

This option determines whether the SSL (Secure Sockets Layer) protocol is used to secure network communications with the WebSphere MQ queue manager or queue-sharing group.

When using a WebSphere MQ messaging provider connection factory in the application server environment, the application server manages SSL configuration. To change SSL configuration parameters, use the administrative console to navigate to the **Security** > **SSL certificate and key management** panel.

When using a WebSphere MQ messaging provider connection factory in the client environment, the client takes SSL configuration information from the ssl.client.props file. Use of this file is detailed in the related reference information for this topic.

You can only use one cipher suite in the SSL configuration for a WebSphere MQ messaging provider connection factory. If you specify more than one cipher suite, only the first one is used.

Data type

Check box. If this check box is cleared, the following SSL properties are disabled:

- Centrally managed
- Specific configuration
- SSL configuration

Centrally managed:

When the SSL protocol is used to communicate with WebSphere MQ, select this radio button to specify that the SSL configuration is taken from the centrally managed WebSphere Application Server SSL configuration.

When you select this radio button, the host name and port attributes from the WebSphere MQ messaging provider connection factory are used to select an appropriate SSL configuration. If host and port information has been supplied by a connection name list this means that the host name and port information of the first element in the list are used to select an appropriate SSL configuration. To provide the SSL configuration which will be matched to the connection factory, see the Dynamic outbound endpoint SSL configuration settings topic listed under related reference.

Data type

Radio button

Specific configuration:

Select this radio button when you want to specify a particular SSL configuration for use when SSL is to be used to secure network communications with the WebSphere MQ queue manager or queue-sharing group.

Data type

Radio button

SSL configuration:

The SSL configuration to use when SSL is to be used to secure network communications with the WebSphere MQ queue manager or queue-sharing group.

This property is disabled if the **Centrally managed** radio button is selected and the WebSphere MQ messaging provider resource has been explicitly defined.

This property is always enabled if the WebSphere MQ messaging provider resource is based on a CCDT.

If this WebSphere MQ messaging provider resource is based on a CCDT, this parameter is only used if the relevant entries in the CCDT have been configured to use SSL.

Additionally, if an SSL configuration of `none` is selected, the default centrally managed WebSphere Application Server SSL configuration for the WebSphere MQ messaging provider is used.

Data type Drop-down list

Advanced:

Client ID:

The client identifier to specify when connecting to the WebSphere MQ messaging provider.

The client identity is not a user ID in the conventional sense, and is not related to security. It is used by durable subscriptions in publish-subscribe messaging. A durable subscription continues to collect up messages while the subscriber is "away" (for example, not running or failed) and delivers those messages when the subscriber reconnects. The client identity is the token that says which subscriber you are when you reconnect so that you get the messages that have been saved up for you in your absence.

Data type String

Allow cloned durable subscriptions:

An option that determines whether multiple instances of a durable subscription can be accessed concurrently by different servers.

Data type Check box
Default Cleared
Range
Selected
Multiple instances of a durable subscription can be accessed concurrently by different servers.
Cleared
Multiple instances of a durable subscription cannot be accessed concurrently by different servers.

Provider version:

The WebSphere MQ messaging provider version. This value is used to determine whether to connect to a particular version of a queue manager. It is also used to determine the type of functions required by the client.

Data type String

Range

The value entered must either be the empty string or be in one of the following formats:

n.n.n.n

n.n.n

n.n

n

where n is a numeric value greater than or equal to zero.

For example 6.0.0.0.

Support distributed two-phase commit protocol:

An option that specifies whether the connection factory supports XA coordination of messaging transactions. Enable this option if multiple resources, including this connection factory, are to be used in the same transaction.

If you clear this property, you disable support for distributed two-phase commit protocol. The JMS session can still be enlisted in a transaction, but it uses the resource manager local transaction calls session.commit and session.rollback, instead of XA calls. This can lead to an improvement in performance. However, only a single resource can be enlisted in a transaction in WebSphere Application Server.

Last participant support enables you to enlist one non-XA resource with other XA-capable resources.

Data type Check box

Default Selected

Range

Selected
The connection factory supports the use of distributed two-phase commit protocols for the coordination of transacted work.

Cleared
The connection factory does not support the use of distributed two-phase commit protocols for the coordination of transacted work.

Keep this option selected if transactions involve other resources, including other queues or topics. Clear this option only when you are certain that the queue manager that is the target for this queue connection is the only resource in the transaction.

Security settings:

Authentication alias for XA recovery:

The user name and password to use when connecting to WebSphere MQ during XA recovery.

Data type Drop-down list

Default (none)

Range All authentication aliases defined to the cell and the value "(none)", which specifies that no credentials are passed to WebSphere MQ during XA recovery.

Mapping-configuration alias:

This field is used only in the absence of a login configuration on the component resource reference.

When the resource authority value is "container", the preferred way to define the authentication strategy is by specifying a login configuration and associated properties on the component resource reference.

If the **DefaultPrincipalMapping** login configuration is specified, the associated property is a JAAS - J2C authentication data entry alias. To configure authentication information for use with the connection factory, under Related Items, click **JAAS - J2C authentication data** .

Data type	Drop-down list
Default	(none)
Range	The following options are available: ClientContainer WSLogin WSKRB5Login DefaultPrincipalMapping TrustedConnectionMapping KerberosMapping

Container-managed authentication alias:

The authentication alias which specifies the user name and password to use when connecting to the WebSphere MQ messaging provider.

Data type	Drop-down list
Default	(none)
Range	All authentication aliases defined to the cell and the value "(none)", which specifies that no credentials are passed to WebSphere MQ.

WebSphere MQ messaging provider connection factory advanced properties:

Use this panel to view or change the advanced properties of the selected connection factory for use with the WebSphere MQ messaging provider. These advanced properties control the behavior of connections made to WebSphere MQ messaging provider destinations.

To view WebSphere MQ connection factory advanced properties, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** > **JMS->Connection factories** to display existing connection factories.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the connection factories are defined. Setting the scope in this way restricts the set of queue connection factories displayed.
3. Select the name of the connection factory that you want to work with.
4. In the content pane, under Additional properties, click **Advanced properties** to view a list of the advanced properties of the WebSphere MQ connection factory.

Under General Properties there are six groups of advanced properties:

- Client reconnect
- Message compression
- Temporary destinations
- Connection consumer
- Message format
- Additional

Make any required changes to these groups and then click **Apply** to return to the connection factory.

Note: When specifying WebSphere MQ properties, the following restrictions apply:
- Names can have a maximum of 48 characters, except for channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring JMS resources for WebSphere MQ. For more information about configuring JMS resources for WebSphere MQ, see the *Using Java* section of the WebSphere MQ information center.

A WebSphere MQ connection factory has the following advanced properties:

Client reconnect options:

This property specifies whether a client mode connection reconnects automatically, or not, in the event of a communications or queue manager failure. This parameter is ignored unless the connection factory is being used in a thin or managed client environment.

Data type Drop-down list
Default DISABLED
Range
DISABLED Client reconnection does not automatically occur.
ASDEF The value from the DefRecon attribute from the channels stanza of the client configuration file is used. If there is no DefRecon value specified in the client configuration file, ASDEF has the same effect as DISABLED.
QMGR Reconnection occurs only to the queue manager to which the connection was originally connected.
RECONNECT Reconnection occurs to any queue manager that is consistent with the value of the queue manager attribute. This queue manager might be a different queue manager from the one to which the connection was originally connected.

For more information about automatic client reconnection, see the WebSphere MQ information center.

Client reconnect timeout:

The maximum number of seconds that a client mode connection spends attempting to automatically reconnect to a queue manager after a communications or queue manager failure. This parameter is ignored unless the connection factory is being used in a thin or managed client environment. Whether this parameter is used or not depends on the value of the client reconnect options parameter.

Data type Integer
Units Seconds
Default 1800 (30 minutes)
Range A value greater than zero and up to 2147483647

For more information about automatic client reconnection, see the WebSphere MQ information center.

Compress message headers:

An option that enables the compression of message headers.

Data type Check box

Default Cleared

Range

Cleared
Do not compress message headers.

Selected
Compress message headers.

Compression algorithm for message payloads:

The compression algorithm that is used to compress message payloads.

Data type Drop-down list

Default NONE

Range

RLE Message data compression is performed using run-length encoding.

ZLIBFAST
Message data compression is performed using ZLIB encoding with speed prioritized.

ZLIBHIGH
Message data compression is performed using ZLIB encoding with compression prioritized.

NONE No message data compression is performed.

WebSphere MQ model queue name:

The model queue that is used as a basis for temporary queue creation.

Data type String

Default SYSTEM.DEFAULT.MODEL.QUEUE

Temporary queue prefix:

The prefix that is appended to the beginning of the names generated for temporary queues.

Data type String

Temporary topic prefix:

The prefix that is appended to the beginning of the names generated for temporary topics.

Data type String

Retain messages, even if no matching consumer is available:

An option that determines whether messages for which there is no matching consumer are retained on the input queue or dealt with according with their disposition options.

Data type Check box

Default Selected

Range

Cleared
Do not retain messages.

Selected
Retain messages.

Polling interval:

This setting is applicable in the client container only. When using aWebSphere MQ Version 6 queue manager (or WebSphere MQ Version 5.3 for z/OS), this setting configures the mechanism used to dispatch messages to JMS asynchronous consumers.

This setting is used when the set of WebSphere MQ queues that is being asynchronously consumed from exceeds the number of threads that are available internally to synchronously get messages from the WebSphere MQ queue. The setting determines how long a thread waits for a message to arrive at a WebSphere MQ queue before polling another WebSphere MQ queue in the set.

Data type	Integer
Units	Milliseconds
Default	5000
Range	A value greater than zero.

Rescan interval:

When using a WebSphere MQ Version 6 queue manager (or WebSphere MQ Version 5.3 for z/OS), this setting configures the mechanism used to dispatch messages to JMS asynchronous consumers.

This setting is used when the set of WebSphere MQ queues that is being asynchronously consumed from exceeds the number of threads that are available internally to synchronously get messages from the WebSphere MQ queue. The setting determines how long a thread retrieves messages from a WebSphere MQ queue before switching to use messages from another WebSphere MQ queue in the set.

Data type	Integer
Units	Milliseconds
Default	5000
Range	A value greater than zero.

Maximum batch size:

The maximum number of messages that can be removed from a queue before at least one must be delivered to an asynchronous consumer.

Data type	Integer
Default	10
Range	A value greater than zero.

Coded character set identifier:

The character set to use when you are encoding strings in the message.

Data type	Integer
Default	819
Range	A value greater than zero. The coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *System Administration* and *Application Programming Reference* sections of the WebSphere MQ information center.

Append an RFH version 2 header to reply messages:

The action required when sending a reply message to the reply-to queue obtained from a message that does not include an RFH version 2 header.

Data type Check box
Default Cleared
Range

Selected
Append an RFH version 2 header to reply messages regardless of whether the original message had an RFH version 2 header.

Cleared
Append an RFH version 2 header to reply messages only if the original message had an RFH version 2 header.

Fail JMS method calls if the WebSphere MQ queue manager is quiescing:

An option that enables selected JMS operations to fail when the queue manager is put into a quiescing state. Selecting this option enables the queue manager to quiesce successfully and shut down.

Data type Check box
Default Selected
Range

Cleared
Do not fail JMS operations if the queue manager is quiescing.

Selected
Fail JMS operations if the queue manager is quiescing.

WebSphere MQ messaging provider connection factory broker properties:

Use this panel to view or change the broker settings of the selected connection factory, or topic connection factory, for use with the WebSphere MQ messaging provider. These broker settings determine how the WebSphere MQ messaging provider interacts with a broker for the purposes of publishing messages and subscribing to topics. Updates to the settings take effect when the server is restarted.

To view WebSphere MQ connection factory, or topic connection factory, broker properties use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** > **JMS->Connection factories** to display existing connection factories, or click **Resources** > **JMS->Topic connection factories** to display existing topic connection factories.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the connection factories are defined. This restricts the set of connection factories displayed.
3. Select the name of the connection factory, or topic connection factory, that you want to work with.
4. In the content pane, under Additional Properties, click **Broker properties** to display the broker properties of the WebSphere MQ connection factory, or topic connection factory.

Under General Properties there are four groups of properties:
- Queues
- Capabilities
- Tuning
- Additional

Make any required changes to these groups and then click **Apply** to return to the connection factory, or topic connection factory.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the WebSphere MQ *Using Java* section of the WebSphere MQ library.

A WebSphere MQ connection factory, or topic connection factory, has the following broker properties:

Broker control queue:

The queue to which broker control messages are sent.

Data type String
Default SYSTEM.BROKER.CONTROL.QUEUE

Broker publication queue:

The queue to which publication messages are sent.

Data type String
Default SYSTEM.BROKER.DEFAULT.STREAM

Broker subscriber queue:

The queue to which subscription messages are sent.

Data type String
Default SYSTEM.JMS.ND.SUBSCRIBER.QUEUE

Broker connection consumer subscription queue:

The queue to which subscription messages that are destined for a connection consumer are sent.

Data type String
Default SYSTEM.JMS.ND.CC.SUBSCRIBER.QUEUE

Version:

The version of the broker that is used. This determines some of the capabilities that the broker is assumed to have. For example, whether to use an RFH version 1 or version 2 header in publications.

Data type Radio button
Default Version 1 broker
Range

Version 1 broker
Message selection cannot be specified.

Version 2 broker
Message selection can be specified. If you select this option, you must also complete **Specify where message selection occurs**.

Specify where message selection occurs:

The process in which message selection is performed. This property is enabled only if **Version 2 broker** was selected.

Data type Drop-down list
Default CLIENT
Range

CLIENT
Message selection is performed in the application server process.

BROKER
Message selection is performed in the broker process.

Subscription store:

The process for tracking subscriptions.

Data type Drop-down list
Default MIGRATE
Range

MIGRATE
Any information that is held on queues is migrated to the broker mechanism for persisting subscription information. If subscription information is already persisted using the broker mechanism then specifying a value of `Migrate` is equivalent to specifying a value of `Broker`.

BROKER
Internal broker mechanisms are used to track subscription information.

QUEUE
A designated WebSphere MQ queue is used to record information about current subscriptions.

Durable subscription state refresh interval:

How often a long running transaction is recreated and used to clean up durable subscriptions, for some versions of the queue manager.

Data type Integer
Default 60000
Range Any positive integer

Subscription cleanup level:

How aggressively messages are cleaned up if the subscriber that is expected to consume the messages terminates unexpectedly.

Data type Drop-down list
Default SAFE

Range

SAFE A conservative algorithm is used to clean up subscriptions.

ASPROP
The cleanup algorithm is determined by a system property.

NONE No cleanup of subscriptions is performed.

STRONG
An aggressive algorithm is used to clean up subscriptions.

Subscription cleanup interval:

How often to check for orphaned subscriptions and clean up messages.

Data type Integer
Default 3600000
Range Any positive integer

Subscription wildcard format:

The wildcard format used for subscribing to more than one topic in a topic hierarchy.

Data type Drop-down list
Default character wildcards
Range

character wildcards
You can use an asterisk (*) or question mark (?) to represent characters, or strings of characters, in a topic name.

* is interpreted as matching many characters.

? is interpreted as matching a single character.

topic level wildcards
You can use a plus sign (+) or number sign (#) to represent topics in a multilevel topic hierarchy.

+ is interpreted as matching a single topic name.

is interpreted as matching many topics in the hierarchy. / is used to delimit topics.

Publish acknowledgement window:

The number of messages to publish before publishing a message that requires broker acknowledgement

Data type Integer
Default 25
Range Any positive integer

Optimize for sparse subscription patterns:

An option to specify whether this connection factory is anticipated to receive a high proportion of messages that match its selection criteria. This information can be used to optimize message delivery.

Data type Check box
Default Cleared
Range
Cleared
Subscriptions frequently receive matching messages.
Selected
Subscriptions do not frequently receive matching messages.

Broker queue manager:

The name of the queue manager that is running the broker, if it is not the same as the queue manager to which the connection factory connects.

Data type String
Default The queue manager name that was specified in the connection factory.

WebSphere MQ messaging provider connection factory client transport settings:

Use this panel to view or change the client transport settings of a connection factory, queue connection factory, or topic connection factory for use with the WebSphere MQ messaging provider. Client transport properties affect how a client connection is established with a WebSphere MQ queue manager or queue-sharing group. Updates to the settings take effect when the server is restarted.

To view WebSphere MQ connection factory, queue connection factory, or topic connection factory client transport settings, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** > **JMS**.
2. Click **Connection factories**, **Queue connection factories**, or **Topic connection factories** to display existing connection factories, queue connection factories or topic connection factories.
3. Select the name of the connection factory, queue connection factory, or topic connection factory that you want to work with.
4. In the content pane under Additional Properties, click **Client transport properties** to view a list of the client transport settings of the WebSphere MQ connection factory, queue connection factory, or topic connection factory.

Under General Properties there are two groups of properties:

- Additional SSL settings (for more information about setting the SSL properties for WebSphere MQ, see *SSL properties* in the *Using Java* section of the WebSphere MQ information center)
- Channel exits

Make any required changes to these groups and then click **Apply** to return to the connection factory, queue connection factory or topic connection factory.

Note: When specifying WebSphere MQ properties, the following restrictions apply:
- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the *Using Java* section of the WebSphere MQ information center.

A WebSphere MQ connection factory, queue connection factory, or topic connection factory has the following client transport settings properties:

Certificate revocation list:

A list of LDAP URLs pointing to LDAP repositories of SSL certificates that might have been revoked.

Data type	String
Default	No certificate revocation list
Range	The value must be a space-separated list of LDAP URLs.

Peer name:

A name (possibly including wildcards) that must match the distinguished name of the peer SSL certificate for a connection to be established.

Data type	String
Default	Do not check the distinguished name of the peer certificate.
Range	Validated according to the rules for a WebSphere MQ SSLPEER channel parameter.

Reset count:

The total number of bytes to transfer over an SSL connection before renegotiating the symmetric encryption keys used to secure the connection.

Data type	Integer
Default	0 (do not renegotiate)
Range	The value must be in the range 0 through 999,999,999 (inclusive).

Receive exits:

A comma-separated list of Java class names corresponding to receive exits to be loaded.

Data type	String

Receive exit initialization data:

Initialization data to be passed to the receive exit.

Data type	String

Send exits:

A comma-separated list of Java class names corresponding to send exits to be loaded.

Data type	String

Send exit initialization data:

Initialization data to be passed to the send exit.

Data type	String

Security exit:

A Java class name corresponding to the security exit to be loaded.

Data type String

Security exit initialization data:

Initialization data to be passed to the security exit.

Data type String

Connection pool settings:

Use this page to configure connection pool settings.

This administrative console page is common to JDBC data sources and JMS connection factories (unified, queue, or topic connection factories). To view this page, the path depends on the type of resource, but generally you select an instance of the resource type then click **Connection Pool**. For example:

- Click **Resources** > **JDBC** > **Data Sources** > ***data_source*** > **[Additional Properties] Connection pool properties**
- Click **Resources** > **JMS->Queue connection factories->*queue_connection_factory*->[Additional Properties] Connection pool**

Note: Connection pooling is not supported in an application client. The application client calls the database directly and does not go through a data source. If you want to use the getConnection() request from the application client, configure the JDBC provider in the application client deployment descriptors, using Rational Application Developer or an assembly tool. The connection is established between application client and the database. Application clients do not have a connection pool, but you can configure JDBC provider settings in the client deployment descriptors.

Connection timeout:

Specifies the interval, in seconds, after which a connection request times out and a ConnectionWaitTimeoutException is thrown.

This value indicates the number of seconds that a connection request waits when there are no connections available in the free pool and no new connections can be created. This usually occurs because the maximum value of connections in the particular connection pool has been reached.

For example, if Connection timeout is set to 300, and the maximum number of connections are all in use, the pool manager waits for 300 seconds for a physical connection to become available. If a physical connection is not available within this time, the pool manager initiates a `ConnectionWaitTimeout` exception. In most cases, you should not retry the getConnection() method; if a longer wait time is required you should increase the Connection timeout setting value. If a `ConnectionWaitTimeout` exception is caught by the application, review the expected connection pool usage of the application and tune the connection pool and database accordingly.

If the Connection timeout is set to 0, the pool manager waits as long as necessary until a connection becomes available. This happens when the application completes a transaction and returns a connection to the pool, or when the number of connections falls below the value of Maximum Connections, and a new physical connection is created.

If Maximum Connections is set to 0, an infinite number of physical connections are enabled, and the Connection timeout value is ignored.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Maximum connections:

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. When this number is reached, no new physical connections are created. The requester waits until a physical connection that is currently in use returns to the pool, or until a ConnectionWaitTimeoutException error displays. For example, if the Max Connections value is set to 5, and there are 5 physical connections in use, the pool manager waits for the amount of time specified in Connection timeout for a physical connection to become free.

Knowing the number of connection pools that can potentially request connections from the backend, such as a DB2 database or a CICS server, helps you determine a value for the Maximum Connections property.

For multiple stand-alone application servers that use the same data source configuration, or J2C connection factory configuration, a separate physical connection pool exists for each server. If you clone these same application servers, WebSphere Application Server (base) implements a separate connection pool for each clone.

All of these connection pools correspond to the same data source or connection factory configuration. Therefore all of these connection pools can potentially request connections from the same backend resource, at the same time. The single Maximum Connections value that you set on this console panel applies to every one of these connection pools. Consequently, setting a high Maximum Connections value can result in a load of connection requests that overwhelms your backend resource.

Data type	Integer
Default	10
Range	0 to maximum integer If Max Connections is set to 0, the Connection timeout value is ignored.

Tip: For better performance, set the value for the connection pool lower than the value for the maximum thread pool connections of the web container. To configure this setting click **Servers** > **Server types** > **WebSphere application servers** > ***server*** > **Thread Pools**, and modify the web container property. Lower settings, such as 10-30 connections, perform better than higher settings, such as 100.

You can use the Tivoli Performance Viewer to find the optimal number of connections in a pool. If the number of concurrent waiters is greater than 0, but the processor load is not close to 100%, consider increasing the connection pool size. If the Percent Used value is consistently low under normal workload, consider decreasing the number of connections in the pool.

Minimum connections:

Specifies the minimum number of physical connections to maintain.

If the size of the connection pool is at or below the minimum connection pool size, the Unused timeout thread does not discard physical connections. However, the pool does not create connections solely to ensure that the minimum connection pool size is maintained. Also, if you set a value for Aged timeout, connections with an expired age are discarded, regardless of the minimum pool size setting.

For example, if the Minimum Connections value is set to 3, and one physical connection is created, the Unused timeout thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the Minimum Connections setting.

Data type	Integer
Default	1
Range	0 to max int

Reap time:

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if Reap Time is set to 60, the pool maintenance thread runs every 60 seconds. The Reap Time interval affects the accuracy of the Unused timeout and Aged timeout settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the Reap Time value less than the values of Unused timeout and Aged timeout. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value specified in Unused timeout, until it reaches the number of connections specified in Minimum Connections. The pool maintenance thread also discards any connections that remain active longer than the time value specified in Aged timeout.

The Reap Time interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread, set Reap Time to `0`, or set both Unused timeout and Aged timeout to `0`. The recommended way to disable the pool maintenance thread is to set Reap Time to `0`, and Unused timeout and Aged timeout are ignored. However, if Unused timeout and Aged timeout are set to `0`, the pool maintenance thread runs, but only physical connections that timeout, because of non-zero timeout values, are discarded.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Unused timeout:

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the Unused timeout value higher than the Reap timeout value for optimal performance. Unused physical connections are only discarded if the current number of connections exceeds the Minimum Connections setting. For example, if the unused timeout value is set to `120`, and the pool maintenance thread is enabled (Reap Time is not `0`), any physical connection that remains unused for 2 minutes is discarded.

The accuracy and performance of this timeout are affected by the Reap Time value. See “Reap time” on page 207 for more information.

Data type	Integer
Units	Seconds
Default	1800
Range	0 to max int

Aged timeout:

Specifies the interval in seconds before a physical connection is discarded.

Setting Aged timeout to 0 supports active physical connections remaining in the pool indefinitely. Set the Aged timeout value higher than the Reap timeout value for optimal performance.

For example, if the Aged timeout value is set to `1200`, and the Reap Time value is not `0`, any physical connection that remains in existence for 1200 seconds (20 minutes) is discarded from the pool. The only exception is if the connection is involved in a transaction when the aged timeout is reached, the application server will not discard the connection until after the transaction is completed and the connection is closed.

The accuracy and performance of this timeout are affected by the Reap Time value. See “Reap time” on page 207 for more information.

Data type	Integer
Units	Seconds
Default	0
Range	0 to max int

Purge policy:

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**.

Data type	String
Defaults	• EntirePool for J2C connection factories and JMS-related connection factories • EntirePool for WebSphere Version 4.0 data sources • EntirePool for current version data sources that you create through the administrative console • EntirePool for current version data sources that you script through wsadmin AdminConfig commands, starting JDBC templates that are built into WebSphere Application Server. For information about the command createUsingTemplate, see the topic, Commands for the AdminConfig object. • FailingConnectionOnly for data sources that you script in wsadmin tool without starting JDBC templates :

Range

EntirePool
All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and issues a stale connection Exception during the next operation on that connection. Subsequent getConnection() requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this closure is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice.

FailingConnectionOnly
Only the connection that caused the stale connection exception is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a possibility that the next getConnection() request from the application can return a connection from the pool that is also stale. The result is more stale connection exceptions.

The connection pretest function attempts to insulate an application from pooled connections that are not valid. When a backend resource, such as a database, goes down, pooled connections that are not valid might exist in the free pool. This is especially true when the purge policy is failingConnectionOnly; in this case, the failing connection is removed from the pool. Depending on the failure, the remaining connections in the pool might not be valid.

Session pool settings:

Use this page to configure session pool settings.

This administrative console page is common to JMS unified connection factories, queue connection factories and topic connection factories. To view this page, you select an instance of the resource type then click **Session pools**. For example, click **Resources** > **JMS->Queue connection factories->*queue_connection_factory*->[Additional Properties] Session pools**.

Connection Timeout:

Specifies the interval, in seconds, after which a connection request times out and a ConnectionWaitTimeoutException is thrown.

The wait is necessary when the maximum value of connections (**Max Connections**) to a particular connection pool is reached . For example, if *Connection Timeout* is set to 300 and the maximum number of connections is reached, the Pool Manager waits for 300 seconds for an available physical connection. If a physical connection is *not* available within this time, the Pool Manager throws a ConnectionWaitTimeoutException. It usually does not make sense to retry the getConnection() method, because if a longer wait time is required, you should set the **Connection Timeout** setting to a higher

value. Therefore, if this exception is caught by the application, the administrator should review the expected usage of the application and tune the connection pool and the database accordingly.

If Connection Timeout is set to 0, the Pool Manager waits as long as necessary until a connection is allocated (which happens when the number of connections falls below the value of **Max Connections**).

If Max Connections is set to 0, which enables an infinite number of physical connections, then the Connection Timeout value is ignored.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Max Connections:

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. Once this number is reached, no new physical connections are created and the requester waits until a physical connection that is currently in use returns to the pool, or a ConnectionWaitTimeoutException is thrown.

For example, if the Max Connections value is set to 5, and there are five physical connections in use, the pool manager waits for the amount of time specified in Connection Timeout for a physical connection to become free.

If Max Connections is set to 0, the Connection Timeout value is ignored.

For better performance, set the value for the connection pool lower than the value for the Max Connections option in the web container. Lower settings, such as 10-30 connections, perform better than higher settings, such as 100.

If clones are used, one data pool exists for each clone. Knowing the number of data pools is important when configuring the database maximum connections.

You can use the Tivoli Performance Viewer to find the optimal number of connections in a pool. If the number of concurrent waiters is greater than 0, but the CPU load is not close to 100%, consider increasing the connection pool size. If the Percent Used value is consistently low under normal workload, consider decreasing the number of connections in the pool.

Data type	Integer
Default	10
Range	0 to max int

Min Connections:

Specifies the minimum number of physical connections to maintain.

Until this number is reached, the pool maintenance thread does not discard physical connections. However, no attempt is made to bring the number of connections up to this number. If you set a value for Aged Timeout, the minimum is not maintained. All connections with an expired age are discarded.

For example if the **Min Connections** value is set to 3, and one physical connection is created, the Unused Timeout thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the **Min Connections** setting.

Data type	Integer
Default	1
Range	0 to max int

Reap Time:

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if **Reap Time** is set to 60, the pool maintenance thread runs every 60 seconds. The Reap Time interval affects the accuracy of the **Unused Timeout** and **Aged Timeout** settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the Reap Time value less than the values of Unused Timeout and Aged Timeout. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value specified in Unused Timeout, until it reaches the number of connections specified in **Min Connections**. The pool maintenance thread also discards any connections that remain active longer than the time value specified in Aged Timeout.

The Reap Time interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread set Reap Time to 0, or set both Unused Timeout and Aged Timeout to 0. The recommended way to disable the pool maintenance thread is to set Reap Time to 0, in which case Unused Timeout and Aged Timeout are ignored. However, if Unused Timeout and Aged Timeout are set to 0, the pool maintenance thread runs, but only physical connections that timeout due to non-zero timeout values are discarded.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Unused Timeout:

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the Unused Timeout value higher than the Reap Timeout value for optimal performance. Unused physical connections are only discarded if the current number of connections not in use exceeds the **Min Connections** setting. For example, if the unused timeout value is set to 120, and the pool maintenance thread is enabled (Reap Time is not 0), any physical connection that remains unused for two minutes is discarded. Note that accuracy of this timeout, as well as performance, is affected by the **Reap Time** value. For more information, see Reap Time.

Data type	Integer
Units	Seconds
Default	1800
Range	0 to max int

Aged Timeout:

Specifies the interval in seconds before a physical connection is discarded.

Setting **Aged Timeout** to 0 supports active physical connections remaining in the pool indefinitely. Set the Aged Timeout value higher than the **Reap Timeout** value for optimal performance. For example, if the Aged Timeout value is set to 1200, and the Reap Time value is not 0, any physical connection that

remains in existence for 1200 seconds (20 minutes) is discarded from the pool. Note that accuracy of this timeout, as well as performance, are affected by the Reap Time value. For more information, see Reap Time.

Data type	Integer
Units	Seconds
Default	0
Range	0 to max int

Purge Policy:

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**. Java EE Connector Architecture (JCA) data sources can have either option. WebSphere Version 4.0 data sources always have a purge policy of **EntirePool**.

Data type	String
Default	FailingConnectionOnly
Range	**EntirePool** All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and throws a *StaleConnectionException* during the next operation on that connection. Subsequent *getConnection* requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice. **FailingConnectionOnly** Only the connection that caused the *StaleConnectionException* is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a good possibility that the next *getConnection* request from the application can return a connection from the pool that is also stale, resulting in more stale connection exceptions.

Configuring a queue connection factory for the WebSphere MQ messaging provider

Use this task to view or change the configuration of an existing JMS queue connection factory for point-to-point messaging with the WebSphere MQ messaging provider.

About this task

This task applies to queue connection factories. With JMS 1.1, domain-independent (unified) connection factories are preferred to domain-specific queue connection factories and topic connection factories. To configure a unified connection factory, see “Configuring a unified connection factory for the WebSphere MQ messaging provider” on page 761.

To view or change the configuration of an existing queue connection factory for use with the WebSphere MQ messaging provider, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click **Resources** > **JMS->Queue connection factories**. A list of existing queue connection factories, with a summary of their properties, is displayed.
2. Select the **Scope** setting corresponding to the scope at which the queue connection factory is visible to applications.
3. Click the name of the queue connection factory that you want to view or change. Configuration details for the queue connection factory are displayed.
4. Under **General Properties** make any required changes.

   For information about each of the available fields, see “WebSphere MQ messaging provider queue connection factory settings.”
5. Click **Apply** to save the configuration.
6. Optional: Click **Advanced properties** to display or change the list of advanced properties of your queue connection factory.
7. Optional: Click **Custom properties** to display or change the list of custom properties of your queue connection factory.
8. Optional: Click **Client transport properties** to display or change the list of client transport properties of your queue connection factory. This link is only appears if, when you created the connection factory, you chose to enter all the information required to connect to WebSphere MQ. This link does not appear if you have chosen to use a client channel definition table (CCDT) to establish a connection to WebSphere MQ.
9. Optional: Click **Connection pools** to display or change the connection pools detail of your queue connection factory.
10. Optional: Click **Session pools** to display or change the session pools detail of your queue connection factory.

    There is a mechanism (session.sharing.scope custom property) to make JMS sessions unshareable. This means that whenever an application calls Session.close(), the JMS session is automatically released from any transaction that is associated with and returned to the session pool. This means that sessions can be cleaned up and removed from the session pool even if the servlet or asynchronous bean that created it is still running.
11. Click **OK**.
12. Save your changes to the master configuration.
13. To have the changed configuration take effect, stop then restart the application server.

WebSphere MQ messaging provider queue connection factory settings

Use this panel to view or change the configuration properties of the selected queue connection factory for use with the WebSphere MQ messaging provider. These configuration properties control how connections are created to associated JMS queue destinations.

A WebSphere MQ queue connection factory is used to create JMS connections to queues provided by WebSphere MQ for point-to-point messaging.

To view WebSphere MQ queue connection factory settings, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** > **JMS->Queue connection factories** to display existing queue connection factories.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the queue connection factories are defined. This restricts the set of queue connection factories displayed.
3. Select the name of the queue connection factory that you want to work with.

Under General Properties there are four groups of properties:

- "Administration"
- "Connection" on page 792
- "Advanced" on page 798
- "Security settings" on page 799

Make any required changes to the Administration, Connection, Advanced, and Security settings groups of properties, and then click **Apply** to save the configuration before, in the content pane under Additional Properties, you select any of the following links:

- **Advanced properties** to display the advanced properties of your WebSphere MQ queue connection factory.
- **Custom properties** to display the custom properties of your WebSphere MQ queue connection factory.
- **Client transport properties** to display or change the client transport properties of your WebSphere MQ queue connection factory. If the selected queue connection factory was not created using a Client Channel Definition Table (CCDT), follow this link to enter all the information required to connect to WebSphere MQ. If the selected queue connection factory was created using a CCDT, you do not need to supply the client transport properties, and so the link is absent.
- **Connection pools** to display the connection pool detail of your WebSphere MQ queue connection factory.
- **Session pools** to display the session pools detail of your WebSphere MQ queue connection factory.

Under Related Items, you can click **JAAS - J2C authentication data** to configure authentication information for use with the queue connection factory.

You can specify the following additional properties by using WebSphere MQ administrative commands:

- **-localAddress**
- **-componentAuthAlias**

For more information about these properties, refer to the "createWMQConnectionFactory command" on page 888.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ JMS resources, see the *Using Java* and *System Administration* sections of the WebSphere MQ information center.

A WebSphere MQ queue connection factory has the following properties.

Administration:

Scope:

The level at which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates that are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the WebSphere MQ queue connection factory collection panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Provider:

The JMS provider assigned when the queue connection factory is created.

For all queue connection factories created using this panel, the provider is the WebSphere MQ messaging provider.

The provider is displayed for information only.

Data type String

Name:

The name by which this queue connection factory is known for administrative purposes within WebSphere Application Server.

Data type String
Range The name must be unique within the set of queue connection factories defined to the cell.

JNDI name:

The JNDI name that is used to bind the queue connection factory into the namespace.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

Data type String

Description:

A description of this queue connection factory for administrative purposes within WebSphere Application Server.

Data type String
Default Null

Connection:

The information required to configure a connection depends on whether the selected queue connection factory was created using a Client Channel Definition Table (CCDT).

If the selected queue connection factory was created using a CCDT, only the following properties are displayed:

- Client channel definition table URL
- Queue manager
- SSL configuration

If the selected queue connection factory was not created using a CCDT, the following properties are displayed:

- Queue manager
- Transport
- If **Enter host and port information in the form of separate host and port values** is selected, the connection name list property cannot be used and the following properties can be used:
  - Host name
  - Port
- If **Enter host and port information in the form of a connection name list** is selected, the connection name list property can be used and the following properties cannot be used:
  - Host name
  - Port
- Host name
- Port
- Server connection channel
- If you clear the check box for the **Use SSL to secure communication with Websphere MQ** property, the following properties cannot be used:
  - Centrally managed
  - Specific configuration
  - SSL configuration

For more information about setting the SSL properties for WebSphere MQ, see *SSL properties* in the *Using Java* section of the WebSphere MQ information center.

Client channel definition table URL:

A URL that specifies the location of a WebSphere MQ CCDT.

Data type String

Queue manager:

If the specified queue connection factory is based on a CCDT, this property is used to select an entry in the CCDT. Otherwise, this property specifies the name of the queue manager or queue-sharing group to connect to. A connection is established to the specified WebSphere MQ resource to send or receive messages.

Data type String

Range

If this queue connection factory is not based on a CCDT, the value must be a valid queue manager name.

If this queue connection factory is based on a CCDT, the value must be one of the following:

- A valid queue manager name
- An asterisk (*) followed by the name of a queue manager group[1]
- An asterisk (*)
- Blank[1]

[1]When you specify the value of the Queue manager property in this form in combination with a CCDT, individual connections established by using the queue connection factory might connect to different queue managers. Selection from multiple queue managers occurs when the CCDT contains multiple client connection channel definitions with a matching queue manager name (QMNAME) parameter, and these connection channel definitions define the network connection details of different queue managers.

If the specified connection factory is based on a CCDT, and the CCDT can select from more than one queue manager, you might not be able to recover global transactions. Therefore, for connection factories that specify a CCDT, you have two alternatives:

- Avoid any ambiguity about the target queue manager when specifying the Queue manager property, which means that the specified value of this property must not include an asterisk (*).
- Avoid using the resources with applications that enlist in global transactions.

Transport:

The WebSphere MQ transport type for the connection. The transport type is used to determine the exact mechanisms used to connect to WebSphere MQ.

Data type Drop-down list
Default **Bindings, then client**

Range

Client Use a TCP/IP-based network connection to communicate with the WebSphere MQ queue manager.

Bindings, then client
Attempt a bindings mode connection to the queue manager. If this is not possible, revert to the client transport.

Bindings
Establish a cross-memory connection to a queue manager running on the same node. The following Client Transport Mode properties are disabled:
- Hostname
- Port
- Connection name list
- Server connection channel

For more information about configuring a transport type of *Bindings, then client* or *Bindings*, refer to "Configuring the WebSphere MQ messaging provider with native libraries information" on page 723.

Enter host and port information in the form of separate host and port values:

If this radio is button selected, this means that the connection to the WebSphere MQ queue manager is made using the information supplied by the host name and port properties.

Selecting this option enables the host name and port properties, and disables the connection name list property. To enter connection name list information, click **Enter host and port information in the form of a connection name list**.

This radio button is only available if the scope property specifies a cell, or if the scope property specifies a node or server and that node or server is running WebSphere Application Server Version 8.0.

Data type Radio button

Hostname:

The host name, IPv4, or IPv6 address of the WebSphere MQ queue manager to connect to.

Data type String

Port:

The port number on which WebSphere MQ is listening.

Data type Integer
Default 1414
Range The value must be in the range 1 to 65536 (inclusive).

Enter host and port information in the form of a connection name list:

If this radio button is selected, this means that the connection to the WebSphere MQ queue manager is made using the information supplied by the connection name list property.

Connection name lists can be used to connect to a single queue manager or to a multi-instance queue manager. For more information on using a multi-instance queue manager, see the WebSphere MQ information centre. Selecting this option enables the connection name list property and disables the host name and port properties. To enter separate host and port information, click **Enter host and port information in the form of separate host and port values**.

This radio button is only available if the scope property specifies a cell, or if the scope property specifies a node or server and that node or server is running WebSphere Application Server Version 8.0.

Data type	Radio button

Connection name list:

The connection name list specifying the host name and port details to use when you want the connection factory to connect to a multi-instance queue manager.

This property must only be used to allow connection to a multi-instance queue manager. It must not be used to allow connections to non-multi-instance queue managers as that can result in transaction integrity issues.

Data type	String
Default	Unset
Range	This field must be set to a string in the following form: *host*[(*port*)][,*host*(*port*)] The port information is optional, and if not specified, defaults to 1414. *host* must be a valid TCP/IP host name or IPv4 or IPv6 address. *port* must be an integer value in the range 1 to 65536 (inclusive). For example: `localhost(1234),remotehost1(1234),remotehost2`

When the connection name list property is specified, the host name or port properties are automatically set to the host name and port number of the first entry in the connection name list. So if you specified `localhost(1234),remotehost1(1234),remotehost2`, the host name would be set to localhost and port would be set to 1234.

This property is only available if the scope property specifies a cell, or if the scope property specifies a node or server and that node or server is running WebSphere Application Server Version 8.0.

When used in a mixed cell environment, the information in the connection name list property is not available to versions of WebSphere Application Server earlier than Version 8.0. In this case, the information in the host name and port name fields, based on the first element in the connection name list, is used instead.

Server connection channel:

The WebSphere MQ server connection channel name used when connecting to WebSphere MQ.

Data type	String
Default	SYSTEM.DEF.SVRCONN

Range

The value must be a server connection channel defined to the WebSphere MQ queue manager that is being connected to.

Use SSL to secure communications with WebSphere MQ:

This option determines whether the SSL (Secure Sockets Layer) protocol is used to secure network communications with the WebSphere MQ queue manager or queue-sharing group.

When using a WebSphere MQ messaging provider queue connection factory in the application server environment, the application server manages SSL configuration. To change SSL configuration parameters, use the administrative console to navigate to the **Security** > **SSL certificate and key management** panel.

When using a WebSphere MQ messaging provider queue connection factory in the client environment, the client takes SSL configuration information from the ssl.client.props file. Use of this file is detailed in the related reference information for this topic.

You can only use one cipher suite in the SSL configuration for a WebSphere MQ messaging provider queue connection factory. If you specify more than one cipher suite, only the first one is used.

Data type

Check box. If this check box is cleared, the following SSL properties are disabled:

- Centrally managed
- Specific configuration
- SSL configuration

Centrally managed:

When the SSL protocol is used to communicate with WebSphere MQ, select this radio button to specify that the SSL configuration is taken from the centrally managed WebSphere Application Server SSL configuration.

When you select this radio button, the host name and port attributes from the WebSphere MQ messaging provider connection factory are used to select an appropriate SSL configuration. If host and port information has been supplied by a connection name list this means that the host name and port information of the first element in the list are used to select an appropriate SSL configuration. To provide the SSL configuration which will be matched to the connection factory, see the Dynamic outbound endpoint SSL configuration settings topic listed under related reference.

Data type

Radio button

Specific configuration:

Select this radio button when you want to specify a particular SSL configuration for use when SSL is to be used to secure network communications with the WebSphere MQ queue manager or queue-sharing group.

Data type

Radio button

SSL configuration:

The SSL configuration to use when SSL is to be used to secure network communications with the WebSphere queue manager or queue-sharing group.

This property is disabled if the **Centrally managed** radio button is selected and the WebSphere MQ messaging provider resource has been explicitly defined.

This property is always enabled if the WebSphere MQ messaging provider resource is based on a CCDT.

If this WebSphere MQ messaging provider resource is based on a CCDT, this parameter is only used if the relevant entries in the CCDT have been configured to use SSL.

Additionally, if an SSL configuration of `none` is selected, the default centrally managed WebSphere Application Server SSL configuration for the WebSphere MQ messaging provider is used.

Data type Drop-down list

Advanced:

Client ID:

The client identifier to specify when connecting to the WebSphere MQ messaging provider.

Data type String

Provider version:

The WebSphere MQ messaging provider version. This is used to determine whether to connect to a particular version of a queue manager. It is also used to determine the type of functions required by the client.

Data type String

Range The value entered must either be the empty string or be in one of the following formats:

n.n.n.n

n.n.n

n.n

n

where n is a numeric value greater than or equal to zero.

For example 6.0.0.0.

Support distributed two-phase commit protocol:

An option that specifies whether the queue connection factory supports XA coordination of messaging transactions. Enable this option if multiple resources, including this queue connection factory, are to be used in the same transaction.

If you clear this property, you disable support for distributed two-phase commit protocol. The JMS session can still be enlisted in a transaction, but it uses the resource manager local transaction calls session.commit and session.rollback, instead of XA calls. This can lead to an improvement in performance. However, only a single resource can be enlisted in a transaction in WebSphere Application Server.

Last participant support enables you to enlist one non-XA resource with other XA-capable resources.

Data type Check box

Default Selected

Range

Selected
The queue connection factory supports the use of distributed two-phase commit protocols for the coordination of transacted work.

Cleared
The queue connection factory does not support the use of distributed two-phase commit protocols for the coordination of transacted work.

Keep this option selected if transactions involve other resources, including other queues or topics. Clear this option only when you are certain that the queue manager that is the target for this queue connection factory is the only resource in the transaction.

Security settings:

Authentication alias for XA recovery:

The user name and password to use when connecting to WebSphere MQ during XA recovery.

Data type Drop-down list
Default (none)
Range All authentication aliases defined to the cell and the value "(none)", which specifies that no credentials are passed to WebSphere MQ during XA recovery.

Mapping-configuration alias:

This field is used only in the absence of a login configuration on the component resource reference.

When the resource authority value is "container", the preferred way to define the authentication strategy is by specifying a login configuration and associated properties on the component resource reference.

If the **DefaultPrincipalMapping** login configuration is specified, the associated property will be a JAAS - J2C authentication data entry alias. To configure authentication information for use with the queue connection factory, under Related Items, click **JAAS - J2C authentication data** .

Data type Drop-down list
Default (none)
Range The following options are available:
- ClientContainer
- WSLogin
- WSKRB5Login
- DefaultPrincipalMapping
- TrustedConnectionMapping
- KerberosMapping

Container-managed authentication alias:

The authentication alias which specifies the user name and password to use when connecting to the WebSphere MQ messaging provider.

Data type Drop-down list
Default (none)

Range All authentication aliases defined to the cell and the value "(none)", which specifies that no credentials are passed to WebSphere MQ.

WebSphere MQ messaging provider queue connection factory advanced properties:

Use this panel to view or change the advanced properties of the selected queue connection factory for use with the WebSphere MQ messaging provider. These advanced properties control the behavior of connections made to WebSphere MQ messaging provider destinations.

To view WebSphere MQ queue connection factory advanced properties, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** > **JMS->Queue connection factories** to display existing queue connection factories.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the queue connection factories are defined. Setting the scope in this way restricts the set of queue connection factories displayed.
3. Select the name of the queue connection factory that you want to work with.
4. In the content pane, under Additional properties, click **Advanced properties** to view a list of the advanced properties of the WebSphere MQ queue connection factory.

Under General Properties there are six groups of advanced properties:
- Client reconnect
- Message compression
- Temporary destinations
- Connection consumer
- Message format
- Additional

Make any required changes to these groups and then click **Apply** to return to the queue connection factory.

Note: When specifying WebSphere MQ properties, the following restrictions apply:
- Names can have a maximum of 48 characters, except for channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring JMS resources for WebSphere MQ. For more information about configuring JMS resources for WebSphere MQ , see the *Using Java* section of the WebSphere MQ information center.

A WebSphere MQ queue connection factory has the following advanced properties:

Client reconnect options:

This property specifies whether a client mode connection reconnects automatically, or not, in the event of a communications or queue manager failure. This parameter is ignored unless the connection factory is being used in a thin or managed client environment.

Data type Drop-down list
Default DISABLED

Range

DISABLED
Client reconnection does not automatically occur.

ASDEF The value from the DefRecon attribute from the channels stanza of the client configuration file is used. If there is no DefRecon value specified in the client configuration file, ASDEF has the same effect as DISABLED.

QMGR Reconnection occurs only to the queue manager to which the connection was originally connected.

RECONNECT
Reconnection occurs to any queue manager that is consistent with the value of the queue manager attribute. This queue manager might be a different queue manager from the one to which the connection was originally connected.

For more information about automatic client reconnection, see the WebSphere MQ information center.

Client reconnect timeout:

The maximum number of seconds that a client mode connection spends attempting to automatically reconnect to a queue manager after a communications or queue manager failure. This parameter is ignored unless the connection factory is being used in a thin or managed client environment. Whether this parameter is used or not depends on the value of the client reconnect options parameter.

Data type Integer
Units Seconds
Default 1800 (30 minutes)
Range A value greater than zero and up to 2147483647

For more information about automatic client reconnection, see the WebSphere MQ information center.

Compress message headers:

An option that enables the compression of message headers.

Data type Check box
Default Cleared
Range

Cleared
Do not compress message headers.

Selected
Compress message headers.

Compression algorithm for message payloads:

The compression algorithm that is used to compress message payloads.

Data type Drop-down list
Default NONE

Range

RLE Message data compression is performed using run-length encoding.

ZLIBFAST Message data compression is performed using ZLIB encoding with speed prioritized.

ZLIBHIGH Message data compression is performed using ZLIB encoding with compression prioritized.

NONE No message data compression is performed.

WebSphere MQ model queue name:

The model queue that is used as a basis for temporary queue definitions.

Data type String
Default SYSTEM.DEFAULT.MODEL.QUEUE

Temporary queue prefix:

The prefix that is attached to the beginning of the names generated for temporary queues.

Data type String

Retain messages, even if no matching consumer is available:

An option that determines whether messages for which there is no matching consumer are retained on the input queue or dealt with according with their disposition options.

Data type Check box
Default Selected
Range

Cleared Do not retain messages.

Selected Retain messages.

Polling interval:

This setting is applicable in the client container only. When using a WebSphere MQ Version 6 queue manager (or WebSphere MQ Version 5.3 for z/OS), this setting configures the mechanism used to dispatch messages to JMS asynchronous consumers.

This setting is used when the set of WebSphere MQ queues that is being asynchronously consumed from exceeds the number of threads that are available internally to synchronously get messages from the WebSphere MQ queue. The setting determines how long a thread waits for a message to arrive at a WebSphere MQ queue before polling another WebSphere MQ queue in the set.

Data type Integer
Units Milliseconds
Default 5000
Range A value greater than zero.

Rescan interval:

When using a WebSphere MQ Version 6 queue manager (or WebSphere MQ Version 5.3 for z/OS), this setting configures the mechanism used to dispatch messages to JMS asynchronous consumers.

This setting is used when the set of WebSphere MQ queues that is being asynchronously consumed from exceeds the number of threads that are available internally to synchronously get messages from the WebSphere MQ queue. The setting determines how long a thread retrieves messages from a WebSphere MQ queue before switching to use messages from another WebSphere MQ queue in the set.

Data type	Integer
Units	Milliseconds
Default	5000
Range	A value greater than zero.

Maximum batch size:

The maximum number of messages that can be removed from a queue before at least one must be delivered to an asynchronous consumer.

Data type	Integer
Default	10
Range	A value greater than zero.

Coded character set identifier:

The character set to use when you are encoding strings in the message.

Data type	Integer
Default	819
Range	A value greater than zero. The coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *System Administration* and the *Application Programming Reference* sections of the WebSphere MQ information center.

Append an RFH version 2 header to reply messages:

The action required when sending a reply message to the reply-to queue obtained from a message that does not include an RFH version 2 header.

Data type	Check box
Default	Cleared
Range	**Selected** Append an RFH version 2 header to reply messages regardless of whether the original message had an RFH version 2 header. **Cleared** Append an RFH version 2 header to reply messages only if the original message had an RFH version 2 header.

Fail JMS method calls if the WebSphere MQ queue manager is quiescing:

An option that enables selected JMS operations to fail when the queue manager is put into a quiescing state. Selecting this option enables the queue manager to quiesce successfully and shut down.

Data type Check box
Default Selected
Range
Cleared
Do not fail JMS operations if the queue manager is quiescing.
Selected
Fail JMS operations if the queue manager is quiescing.

WebSphere MQ messaging provider connection factory client transport settings:

Use this panel to view or change the client transport settings of a connection factory, queue connection factory, or topic connection factory for use with the WebSphere MQ messaging provider. Client transport properties affect how a client connection is established with a WebSphere MQ queue manager or queue-sharing group. Updates to the settings take effect when the server is restarted.

To view WebSphere MQ connection factory, queue connection factory, or topic connection factory client transport settings, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** > **JMS**.
2. Click **Connection factories**, **Queue connection factories**, or **Topic connection factories** to display existing connection factories, queue connection factories or topic connection factories.
3. Select the name of the connection factory, queue connection factory, or topic connection factory that you want to work with.
4. In the content pane under Additional Properties, click **Client transport properties** to view a list of the client transport settings of the WebSphere MQ connection factory, queue connection factory, or topic connection factory.

Under General Properties there are two groups of properties:
- Additional SSL settings (for more information about setting the SSL properties for WebSphere MQ, see *SSL properties* in the *Using Java* section of the WebSphere MQ information center)
- Channel exits

Make any required changes to these groups and then click **Apply** to return to the connection factory, queue connection factory or topic connection factory.

Note: When specifying WebSphere MQ properties, the following restrictions apply:
- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the *Using Java* section of the WebSphere MQ information center.

A WebSphere MQ connection factory, queue connection factory, or topic connection factory has the following client transport settings properties:

Certificate revocation list:

A list of LDAP URLs pointing to LDAP repositories of SSL certificates that might have been revoked.

Data type String
Default No certificate revocation list
Range The value must be a space-separated list of LDAP URLs.

Peer name:

A name (possibly including wildcards) that must match the distinguished name of the peer SSL certificate for a connection to be established.

Data type	String
Default	Do not check the distinguished name of the peer certificate.
Range	Validated according to the rules for a WebSphere MQ SSLPEER channel parameter.

Reset count:

The total number of bytes to transfer over an SSL connection before renegotiating the symmetric encryption keys used to secure the connection.

Data type	Integer
Default	0 (do not renegotiate)
Range	The value must be in the range 0 through 999,999,999 (inclusive).

Receive exits:

A comma-separated list of Java class names corresponding to receive exits to be loaded.

Data type	String

Receive exit initialization data:

Initialization data to be passed to the receive exit.

Data type	String

Send exits:

A comma-separated list of Java class names corresponding to send exits to be loaded.

Data type	String

Send exit initialization data:

Initialization data to be passed to the send exit.

Data type	String

Security exit:

A Java class name corresponding to the security exit to be loaded.

Data type	String

Security exit initialization data:

Initialization data to be passed to the security exit.

Data type	String

Connection pool settings:

Use this page to configure connection pool settings.

This administrative console page is common to JDBC data sources and JMS connection factories (unified, queue, or topic connection factories). To view this page, the path depends on the type of resource, but generally you select an instance of the resource type then click **Connection Pool**. For example:

- Click **Resources** > **JDBC** > **Data Sources** > ***data_source*** > **[Additional Properties] Connection pool properties**
- Click **Resources** > **JMS->Queue connection factories->*queue_connection_factory*->[Additional Properties] Connection pool**

Note: Connection pooling is not supported in an application client. The application client calls the database directly and does not go through a data source. If you want to use the getConnection() request from the application client, configure the JDBC provider in the application client deployment descriptors, using Rational Application Developer or an assembly tool. The connection is established between application client and the database. Application clients do not have a connection pool, but you can configure JDBC provider settings in the client deployment descriptors.

Connection timeout:

Specifies the interval, in seconds, after which a connection request times out and a ConnectionWaitTimeoutException is thrown.

This value indicates the number of seconds that a connection request waits when there are no connections available in the free pool and no new connections can be created. This usually occurs because the maximum value of connections in the particular connection pool has been reached.

For example, if Connection timeout is set to 300, and the maximum number of connections are all in use, the pool manager waits for 300 seconds for a physical connection to become available. If a physical connection is not available within this time, the pool manager initiates a `ConnectionWaitTimeout` exception. In most cases, you should not retry the getConnection() method; if a longer wait time is required you should increase the Connection timeout setting value. If a `ConnectionWaitTimeout` exception is caught by the application, review the expected connection pool usage of the application and tune the connection pool and database accordingly.

If the Connection timeout is set to 0, the pool manager waits as long as necessary until a connection becomes available. This happens when the application completes a transaction and returns a connection to the pool, or when the number of connections falls below the value of Maximum Connections, and a new physical connection is created.

If Maximum Connections is set to 0, an infinite number of physical connections are enabled, and the Connection timeout value is ignored.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Maximum connections:

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. When this number is reached, no new physical connections are created. The requester waits until a physical connection that is currently in use returns to the pool, or until a ConnectionWaitTimeoutException error displays. For example, if the Max Connections value is set to 5, and there are 5 physical connections in use, the pool manager waits for the amount of time specified in Connection timeout for a physical connection to become free.

Knowing the number of connection pools that can potentially request connections from the backend, such as a DB2 database or a CICS server, helps you determine a value for the Maximum Connections property.

For multiple stand-alone application servers that use the same data source configuration, or J2C connection factory configuration, a separate physical connection pool exists for each server. If you clone these same application servers, WebSphere Application Server (base) implements a separate connection pool for each clone.

All of these connection pools correspond to the same data source or connection factory configuration. Therefore all of these connection pools can potentially request connections from the same backend resource, at the same time. The single Maximum Connections value that you set on this console panel applies to every one of these connection pools. Consequently, setting a high Maximum Connections value can result in a load of connection requests that overwhelms your backend resource.

Data type	Integer
Default	10
Range	0 to maximum integer If Max Connections is set to 0, the Connection timeout value is ignored.

Tip: For better performance, set the value for the connection pool lower than the value for the maximum thread pool connections of the web container. To configure this setting click **Servers** > **Server types** > **WebSphere application servers** > ***server*** > **Thread Pools**, and modify the web container property. Lower settings, such as 10-30 connections, perform better than higher settings, such as 100.

You can use the Tivoli Performance Viewer to find the optimal number of connections in a pool. If the number of concurrent waiters is greater than 0, but the processor load is not close to 100%, consider increasing the connection pool size. If the Percent Used value is consistently low under normal workload, consider decreasing the number of connections in the pool.

Minimum connections:

Specifies the minimum number of physical connections to maintain.

If the size of the connection pool is at or below the minimum connection pool size, the Unused timeout thread does not discard physical connections. However, the pool does not create connections solely to ensure that the minimum connection pool size is maintained. Also, if you set a value for Aged timeout, connections with an expired age are discarded, regardless of the minimum pool size setting.

For example, if the Minimum Connections value is set to 3, and one physical connection is created, the Unused timeout thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the Minimum Connections setting.

Data type	Integer
Default	1
Range	0 to max int

Reap time:

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if Reap Time is set to 60, the pool maintenance thread runs every 60 seconds. The Reap Time interval affects the accuracy of the Unused timeout and Aged timeout settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the Reap Time value less than the values of Unused timeout and Aged timeout. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value specified in Unused timeout, until it reaches the number of connections specified in Minimum Connections. The pool maintenance thread also discards any connections that remain active longer than the time value specified in Aged timeout.

The Reap Time interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread, set Reap Time to `0`, or set both Unused timeout and Aged timeout to `0`. The recommended way to disable the pool maintenance thread is to set Reap Time to `0`, and Unused timeout and Aged timeout are ignored. However, if Unused timeout and Aged timeout are set to `0`, the pool maintenance thread runs, but only physical connections that timeout, because of non-zero timeout values, are discarded.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Unused timeout:

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the Unused timeout value higher than the Reap timeout value for optimal performance. Unused physical connections are only discarded if the current number of connections exceeds the Minimum Connections setting. For example, if the unused timeout value is set to `120`, and the pool maintenance thread is enabled (Reap Time is not `0`), any physical connection that remains unused for 2 minutes is discarded.

The accuracy and performance of this timeout are affected by the Reap Time value. See “Reap time” on page 207 for more information.

Data type	Integer
Units	Seconds
Default	1800
Range	0 to max int

Aged timeout:

Specifies the interval in seconds before a physical connection is discarded.

Setting Aged timeout to 0 supports active physical connections remaining in the pool indefinitely. Set the Aged timeout value higher than the Reap timeout value for optimal performance.

For example, if the Aged timeout value is set to `1200`, and the Reap Time value is not `0`, any physical connection that remains in existence for 1200 seconds (20 minutes) is discarded from the pool. The only

exception is if the connection is involved in a transaction when the aged timeout is reached, the application server will not discard the connection until after the transaction is completed and the connection is closed.

The accuracy and performance of this timeout are affected by the Reap Time value. See “Reap time” on page 207 for more information.

Data type	Integer
Units	Seconds
Default	0
Range	0 to max int

Purge policy:

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**.

Data type	String
Defaults	• EntirePool for J2C connection factories and JMS-related connection factories • EntirePool for WebSphere Version 4.0 data sources • EntirePool for current version data sources that you create through the administrative console • EntirePool for current version data sources that you script through wsadmin AdminConfig commands, starting JDBC templates that are built into WebSphere Application Server. For information about the command createUsingTemplate, see the topic, Commands for the AdminConfig object. • FailingConnectionOnly for data sources that you script in wsadmin tool without starting JDBC templates :

Range

EntirePool
All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and issues a stale connection Exception during the next operation on that connection. Subsequent getConnection() requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this closure is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice.

FailingConnectionOnly
Only the connection that caused the stale connection exception is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a possibility that the next getConnection() request from the application can return a connection from the pool that is also stale. The result is more stale connection exceptions.

The connection pretest function attempts to insulate an application from pooled connections that are not valid. When a backend resource, such as a database, goes down, pooled connections that are not valid might exist in the free pool. This is especially true when the purge policy is failingConnectionOnly; in this case, the failing connection is removed from the pool. Depending on the failure, the remaining connections in the pool might not be valid.

Session pool settings:

Use this page to configure session pool settings.

This administrative console page is common to JMS unified connection factories, queue connection factories and topic connection factories. To view this page, you select an instance of the resource type then click **Session pools**. For example, click **Resources** > **JMS->Queue connection factories->*queue_connection_factory*->[Additional Properties] Session pools**.

Connection Timeout:

Specifies the interval, in seconds, after which a connection request times out and a ConnectionWaitTimeoutException is thrown.

The wait is necessary when the maximum value of connections (**Max Connections**) to a particular connection pool is reached . For example, if *Connection Timeout* is set to 300 and the maximum number of connections is reached, the Pool Manager waits for 300 seconds for an available physical connection. If a physical connection is *not* available within this time, the Pool Manager throws a ConnectionWaitTimeoutException. It usually does not make sense to retry the getConnection() method, because if a longer wait time is required, you should set the **Connection Timeout** setting to a higher

value. Therefore, if this exception is caught by the application, the administrator should review the expected usage of the application and tune the connection pool and the database accordingly.

If Connection Timeout is set to 0, the Pool Manager waits as long as necessary until a connection is allocated (which happens when the number of connections falls below the value of **Max Connections**).

If Max Connections is set to 0, which enables an infinite number of physical connections, then the Connection Timeout value is ignored.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Max Connections:

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. Once this number is reached, no new physical connections are created and the requester waits until a physical connection that is currently in use returns to the pool, or a ConnectionWaitTimeoutException is thrown.

For example, if the Max Connections value is set to 5, and there are five physical connections in use, the pool manager waits for the amount of time specified in Connection Timeout for a physical connection to become free.

If Max Connections is set to 0, the Connection Timeout value is ignored.

For better performance, set the value for the connection pool lower than the value for the Max Connections option in the web container. Lower settings, such as 10-30 connections, perform better than higher settings, such as 100.

If clones are used, one data pool exists for each clone. Knowing the number of data pools is important when configuring the database maximum connections.

You can use the Tivoli Performance Viewer to find the optimal number of connections in a pool. If the number of concurrent waiters is greater than 0, but the CPU load is not close to 100%, consider increasing the connection pool size. If the Percent Used value is consistently low under normal workload, consider decreasing the number of connections in the pool.

Data type	Integer
Default	10
Range	0 to max int

Min Connections:

Specifies the minimum number of physical connections to maintain.

Until this number is reached, the pool maintenance thread does not discard physical connections. However, no attempt is made to bring the number of connections up to this number. If you set a value for Aged Timeout, the minimum is not maintained. All connections with an expired age are discarded.

For example if the **Min Connections** value is set to 3, and one physical connection is created, the Unused Timeout thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the **Min Connections** setting.

Data type	Integer
Default	1
Range	0 to max int

Reap Time:

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if **Reap Time** is set to 60, the pool maintenance thread runs every 60 seconds. The Reap Time interval affects the accuracy of the **Unused Timeout** and **Aged Timeout** settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the Reap Time value less than the values of Unused Timeout and Aged Timeout. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value specified in Unused Timeout, until it reaches the number of connections specified in **Min Connections**. The pool maintenance thread also discards any connections that remain active longer than the time value specified in Aged Timeout.

The Reap Time interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread set Reap Time to 0, or set both Unused Timeout and Aged Timeout to 0. The recommended way to disable the pool maintenance thread is to set Reap Time to 0, in which case Unused Timeout and Aged Timeout are ignored. However, if Unused Timeout and Aged Timeout are set to 0, the pool maintenance thread runs, but only physical connections that timeout due to non-zero timeout values are discarded.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Unused Timeout:

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the Unused Timeout value higher than the Reap Timeout value for optimal performance. Unused physical connections are only discarded if the current number of connections not in use exceeds the **Min Connections** setting. For example, if the unused timeout value is set to 120, and the pool maintenance thread is enabled (Reap Time is not 0), any physical connection that remains unused for two minutes is discarded. Note that accuracy of this timeout, as well as performance, is affected by the **Reap Time** value. For more information, see Reap Time.

Data type	Integer
Units	Seconds
Default	1800
Range	0 to max int

Aged Timeout:

Specifies the interval in seconds before a physical connection is discarded.

Setting **Aged Timeout** to 0 supports active physical connections remaining in the pool indefinitely. Set the Aged Timeout value higher than the **Reap Timeout** value for optimal performance. For example, if the Aged Timeout value is set to 1200, and the Reap Time value is not 0, any physical connection that

remains in existence for 1200 seconds (20 minutes) is discarded from the pool. Note that accuracy of this timeout, as well as performance, are affected by the Reap Time value. For more information, see Reap Time.

Data type	Integer
Units	Seconds
Default	0
Range	0 to max int

Purge Policy:

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**. Java EE Connector Architecture (JCA) data sources can have either option. WebSphere Version 4.0 data sources always have a purge policy of **EntirePool**.

Data type	String
Default	FailingConnectionOnly
Range	**EntirePool** All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and throws a *StaleConnectionException* during the next operation on that connection. Subsequent *getConnection* requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice. **FailingConnectionOnly** Only the connection that caused the *StaleConnectionException* is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a good possibility that the next *getConnection* request from the application can return a connection from the pool that is also stale, resulting in more stale connection exceptions.

Configuring a topic connection factory for the WebSphere MQ messaging provider

Use this task to view or change the configuration of a JMS topic connection factory for publish/subscribe messaging with the WebSphere MQ messaging provider.

About this task

This task applies to topic connection factories. With JMS 1.1, domain-independent (unified) connection factories are preferred to domain-specific queue connection factories and topic connection factories. To view or configure a unified connection factory, see “Configuring a unified connection factory for the WebSphere MQ messaging provider” on page 761.

To view or change the configuration of an existing topic connection factory for use with the WebSphere MQ messaging provider, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click **Resources** > **JMS->Topic connection factories**. A list of existing topic connection factories, with a summary of their properties, is displayed.
2. Select the **Scope** corresponding to the scope at which the topic connection factory is visible to applications.
3. Click the name of the topic connection factory that you want to view or change. Configuration details for the topic connection factory are displayed.
4. Under **General properties** make any required changes.

   For information about each of the available fields, see “WebSphere MQ messaging provider topic connection factory settings.”
5. Click **Apply** to save the configuration.
6. Optional: Click **Advanced properties** to display or change the list of advanced properties of your topic connection factory.
7. Optional: Click **Broker properties** to display or change the list of broker properties of your topic connection factory.
8. Optional: Click **Custom properties** to display or change the list of custom properties of your topic connection factory.
9. Optional: Click **Client transport properties** to display or change the list of client transport properties of your topic connection factory. This link is only appears if, when you created the connection factory, you chose to enter all the information required to connect to WebSphere MQ. This link does not appear if you have chosen to use a client channel definition table (CCDT) to establish a connection to WebSphere MQ
10. Optional: Click **Connection pools** to display or change the connection pools detail of your topic connection factory.
11. Optional: Click **Session pools** to display or change the session pools detail of your topic connection factory.

    There is a mechanism (session.sharing.scope custom property) to make JMS sessions unshareable. This means that whenever an application calls Session.close(), the JMS session is automatically released from any transaction that is associated with and returned to the session pool. This means that sessions can be cleaned up and removed from the session pool even if the servlet or asynchronous bean that created it is still running.
12. Click **OK**.
13. Save your changes to the master configuration.
14. To have the changed configuration take effect, stop then restart the application server.

WebSphere MQ messaging provider topic connection factory settings

Use this panel to view or change the configuration properties of the selected topic connection factory for use with the WebSphere MQ messaging provider. These configuration properties control how connections are created to the associated JMS topic destination.

A WebSphere MQ topic connection factory is used to create JMS connections to topic destinations provided by WebSphere MQ for publish/subscribe messaging.

To view WebSphere MQ topic connection factory settings, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** > **JMS->Topic connection factories** to display existing topic connection factories.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the topic connection factories are defined. This restricts the set of topic connection factories displayed.
3. Select the name of the topic connection factory that you want to work with.

Under General Properties there are four groups of properties:
- "Administration"
- "Connection" on page 816
- "Advanced" on page 822
- "Security settings" on page 823

Make any required changes to the Administration, Connection, Advanced and Security settings groups of properties, and then click **Apply** to save the configuration before, in the content pane under Additional Properties, you click any of the following links:
- **Advanced properties** to display the advanced properties of your WebSphere MQ topic connection factory.
- **Broker properties** to display the broker properties of your WebSphere MQ topic connection factory.
- **Custom properties** to display the custom properties of your WebSphere MQ topic connection factory.
- **Client transport properties** to display or change the client transport properties of your WebSphere MQ topic connection factory. If the selected topic connection factory was not created using a Client Channel Definition Table (CCDT), follow this link to enter all the information required to connect to WebSphere MQ. If the selected topic connection factory was created using a CCDT, you do not need to supply the client transport properties, and so the link is absent.
- **Connection pools** to display the connection pools detail of your WebSphere MQ topic connection factory
- **Session pools** to display the session pools detail of your WebSphere MQ topic connection factory.

Under Related Items, you can click **JAAS - J2C authentication data** to configure authentication information for use with the topic connection factory.

You can specify the following additional properties by using WebSphere MQ administrative commands:
- **-localAddress**
- **-clonedSubs**
- **-componentAuthAlias**

For more information about these properties, refer to the "createWMQConnectionFactory command" on page 888.

Note: When specifying WebSphere MQ properties, the following restrictions apply:
- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when you configured the JMS resources in WebSphere MQ. For more information about configuring JMS resources in WebSphere MQ, see the *Using Java* section of the WebSphere MQ information center.

A WebSphere MQ topic connection factory has the following properties.

Administration:

Scope:

The level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates that are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource at a different scope, change the scope on the WebSphere MQ topic connection factory collection panel, then click **Apply**, before clicking the link for the type of resource.

Data type	String

Provider:

The JMS provider assigned when the topic connection factory is created.

For all topic connection factories created using this panel, the provider is the WebSphere MQ messaging provider.

The provider is displayed for information only.

Data type	String

Name:

The name by which this topic connection factory is known for administrative purposes within WebSphere Application Server.

Data type	String
Range	The name must be unique within the set of JMS topic connection factories defined to the cell.

JNDI name:

The JNDI name that is used to bind the topic connection factory into the JNDI namespace.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

Data type	String

Description:

A description of this topic connection factory for administrative purposes within WebSphere Application Server.

Data type	String
Default	Null

Connection:

The information required to configure a connection depends on whether the selected topic connection factory was created using a Client Channel Definition Table (CCDT).

If the selected topic connection factory was created using a CCDT, only the following properties are displayed:

- Client channel definition table URL
- Queue manager
- SSL configuration

If the selected topic connection factory was not created using a CCDT, the following properties are displayed:

- Queue manager
- Transport
- If **Enter host and port information in the form of separate host and port values** is selected, the connection name list property cannot be used and the following properties can be used:
  - Host name
  - Port
- If **Enter host and port information in the form of a connection name list** is selected, the connection name list property can be used and the following properties cannot be used:
  - Host name
  - Port
- Server connection channel
- If you clear the check box for the **Use SSL to secure communication with Websphere MQ** property, the following properties cannot be used:
  - Centrally managed
  - Specific configuration
  - SSL configuration

For more information about setting the SSL properties for WebSphere MQ, see *SSL properties* in the *Using Java* section of the WebSphere MQ information center.

Client channel definition table URL:

A URL that specifies the location of a WebSphere MQ CCDT.

Data type String

Queue manager:

If the specified topic connection factory is based on a CCDT, this property is used to select an entry in the CCDT. Otherwise, it is the name of the queue manager or queue-sharing group to connect to. A connection is established to this WebSphere MQ resource to send or receive messages.

Data type String

Range

If this topic connection factory is not based on a CCDT, the value must be a valid queue manager name.

If this topic connection factory is based on a CCDT, the value must be one of the following:

- A valid queue manager name
- An asterisk (*) followed by the name of a queue manager group[1]
- An asterisk (*)
- Blank[1]

[1]When you specify the value of the Queue manager property in this form in combination with a CCDT, individual connections established by using the topic connection factory might connect to different queue managers. Selection from multiple queue managers occurs when the CCDT contains multiple client connection channel definitions with a matching queue manager name (QMNAME) parameter, and these connection channel definitions define the network connection details of different queue managers.

If the specified connection factory is based on a CCDT, and the CCDT can select from more than one queue manager, you might not be able to recover global transactions. Therefore, for connection factories that specify a CCDT, you have two alternatives:

- Avoid any ambiguity about the target queue manager when specifying the Queue manager property, which means that the specified value of this property must not include an asterisk (*).
- Avoid using the resources with applications that enlist in global transactions.

Transport:

The WebSphere MQ transport type for the connection. The transport type is used to determine the exact mechanisms used to connect to WebSphere MQ.

Data type Drop-down list
Default **Bindings, then client**

Range

Client Use a TCP/IP-based network connection to communicate with the WebSphere MQ queue manager

Bindings, then client
Attempt a bindings mode connection to the queue manager. If this is not possible, revert to the client transport.

Bindings
Establish a cross-memory connection to a queue manager running on the same node. The following Client Transport Mode properties are disabled:
- Hostname
- Port
- Connection name list
- Server connection channel

For more information about configuring a transport type of *Bindings, then client* or *Bindings*, refer to "Configuring the WebSphere MQ messaging provider with native libraries information" on page 723.

Enter host and port information in the form of separate host and port values:

If this radio button is selected, this means that the connection to the WebSphere MQ queue manager is made using the information supplied by the host name and port properties.

Selecting this option enables the host name and port properties, and disables the connection name list property. To enter connection name list information, click **Enter host and port information in the form of a connection name list**.

This radio button is only available if the scope property specifies a cell, or if the scope property specifies a node or server and that node or server is running WebSphere Application Server Version 8.0.

Data type Radio button

Hostname:

The host name, IPv4, or IPv6 address of the WebSphere MQ queue manager to connect to.

Data type String

Port:

The port number on which WebSphere MQ is listening.

Data type Integer
Default 1414
Range The value must be in the range 1 to 65536 (inclusive).

Enter host and port information in the form of a connection name list:

If this radio button is selected, this means that the connection to the WebSphere MQ queue manager is made using the information supplied by the connection name list property.

Connection name lists can be used to connect to a single queue manager or to a multi-instance queue manager. For more information on using a multi-instance queue manager, see the WebSphere MQ information centre. Selecting this option enables the connection name list property and disables the host name and port properties. To enter separate host and port information, click **Enter host and port information in the form of separate host and port values**.

This radio button is only available if the scope property specifies a cell, or if the scope property specifies a node or server and that node or server is running WebSphere Application Server Version 8.0.

Data type	Radio button

Connection name list:

The connection name list specifying the host name and port details to use when you want the connection factory to connect to a multi-instance queue manager.

This property must only be used to allow connection to a multi-instance queue manager. It must not be used to allow connections to non-multi-instance queue managers as that can result in transaction integrity issues.

Data type	String
Default	Unset
Range	This field must be set to a string in the following form: *host*[(*port*)][,*host*(*port*)] The port information is optional, and if not specified, defaults to 1414. *host* must be a valid TCP/IP host name or IPv4 or IPv6 address. *port* must be an integer value in the range 1 to 65536 (inclusive). For example: `localhost(1234),remotehost1(1234),remotehost2`

When the connection name list property is specified, the host name or port properties are automatically set to the host name and port number of the first entry in the connection name list. So if you specified `localhost(1234),remotehost1(1234),remotehost2`, the host name would be set to localhost and port would be set to 1234.

This property is only available if the scope property specifies a cell, or if the scope property specifies a node or server and that node or server is running WebSphere Application Server Version 8.0.

When used in a mixed cell environment, the information in the connection name list property is not available to versions of WebSphere Application Server earlier than Version 8.0. In this case, the information in the host name and port name fields, based on the first element in the connection name list, is used instead.

Server connection channel:

The WebSphere MQ server connection channel name used when connecting to WebSphere MQ.

Data type	String
Default	SYSTEM.DEF.SVRCONN

Range

The value must be a server connection channel defined to the WebSphere MQ queue manager that is being connected to.

Use SSL to secure communications with WebSphere MQ:

This option determines whether the SSL (Secure Sockets Layer) protocol is used to secure network communications with the WebSphere MQ queue manager or queue-sharing group.

When using a WebSphere MQ messaging provider topic connection factory in the application server environment, the application server manages SSL configuration. To change SSL configuration parameters, use the administrative console to navigate to the **Security** > **SSL certificate and key management** panel.

When using a WebSphere MQ messaging provider topic connection factory in the client environment, the client takes SSL configuration information from the ssl.client.props file. Use of this file is detailed in the related reference information for this topic.

You can only use one cipher suite in the SSL configuration for a WebSphere MQ messaging provider topic connection factory. If you specify more than one cipher suite, only the first one is used.

Data type

Check box. If this check box is cleared, the following SSL properties are disabled:

- Centrally managed
- Specific configuration
- SSL configuration

Centrally managed:

When the SSL protocol is used to communicate with WebSphere MQ, select this radio button to specify that the SSL configuration is taken from the centrally managed WebSphere Application Server SSL configuration.

When you select this radio button, the host name and port attributes from the WebSphere MQ messaging provider connection factory are used to select an appropriate SSL configuration. If host and port information has been supplied by a connection name list this means that the host name and port information of the first element in the list are used to select an appropriate SSL configuration. To provide the SSL configuration which will be matched to the connection factory, see the Dynamic outbound endpoint SSL configuration settings topic listed under related reference.

Data type

Radio button

Specific configuration:

Select this radio button when you want to specify a particular SSL configuration for use when SSL is to be used to secure network communications with the WebSphere MQ queue manager or queue-sharing group.

Data type

Radio button

SSL configuration:

The SSL configuration to use when SSL is to be used to secure network communications with the WebSphere MQ queue manager or queue sharing group.

This property is disabled if the **Centrally managed** radio button is selected and the WebSphere MQ messaging provider resource has been explicitly defined.

This property is always enabled if the WebSphere MQ messaging provider resource is based on a CCDT.

If this WebSphere MQ messaging provider resource is based on a CCDT, this parameter is only used if the relevant entries in the CCDT have been configured to use SSL.

Additionally, if an SSL configuration of `none` is selected, the default centrally managed WebSphere Application Server SSL configuration for the WebSphere MQ messaging provider is used.

Data type Drop-down list

Advanced:

Client ID:

The client identifier to specify when connecting to WebSphere MQ messaging provider.

Data type String

Allow cloned durable subscriptions:

An option that determines whether multiple instances of a durable subscription can be accessed concurrently by different servers.

Data type Check box
Default Cleared
Range
Selected
Multiple instances of a durable subscription can be accessed concurrently by different servers.
Cleared
Multiple instances of a durable subscription cannot be accessed concurrently by different servers.

Provider version:

The WebSphere MQ messaging provider version. This is used to determine whether to connect to a particular version of a queue manager. It is also used to determine the type of functions required by the client.

Data type String
Range
The value entered must either be the empty string or be in one of the following formats:

n.n.n.n

n.n.n

n.n

n

where n is a numeric value greater than or equal to zero.

For example 6.0.0.0.

Support distributed two-phase commit protocol:

An option that specifies whether the topic connection factory supports XA coordination of messaging transactions. Enable this option if multiple resources, including this topic connection factory, are to be used in the same transaction.

If you clear this property, you disable support for distributed two-phase commit protocol. The JMS session can still be enlisted in a transaction, but it uses the resource manager local transaction calls session.commit and session.rollback, instead of XA calls. This can lead to an improvement in performance. However, only a single resource can be enlisted in a transaction in WebSphere Application Server.

Last participant support enables you to enlist one non-XA resource with other XA-capable resources.

Data type Check box
Default Selected
Range
Selected
The connection factory supports the use of distributed two-phase commit protocols for the coordination of transacted work.
Cleared
The connection factory does not support the use of distributed two-phase commit protocols for the coordination of transacted work.

Do not enable XA when the queue manager specified by the topic connection factory is the only resource in the transaction. Enable XA if transactions involve other resources, including other queues or topics.

Security settings:

Authentication alias for XA recovery:

The user name and password to use when connecting to WebSphere MQ during XA recovery.

Data type Drop-down list
Default (none)
Range All authentication aliases defined to the cell and the value "(none)", which specifies that no credentials are passed to WebSphere MQ during XA recovery.

Mapping-configuration alias:

This field is used only in the absence of a login configuration on the component resource reference.

When the resource authority value is "container", the preferred way to define the authentication strategy is by specifying a login configuration and associated properties on the component resource reference.

If the **DefaultPrincipalMapping** login configuration is specified, the associated property will be a JAAS - J2C authentication data entry alias. To configure authentication information for use with the topic connection factory, under Related Items, click **JAAS - J2C authentication data** .

Data type Drop-down list
Default (none)

Range

The following options are available:

ClientContainer
WSLogin
WSKRB5Login
DefaultPrincipalMapping
TrustedConnectionMapping
KerberosMapping

Container-managed authentication alias:

The authentication alias which specifies the user name and password to use when connecting to the WebSphere MQ messaging provider.

Data type Drop-down list
Default (none)
Range All authentication aliases defined to the cell and the value "(none)", which specifies that no credentials are passed to WebSphere MQ.

WebSphere MQ messaging provider topic connection factory advanced properties:

Use this panel to view or change the advanced properties of the selected topic connection factory for use with the WebSphere MQ messaging provider. These advanced properties control the behavior of connections made to WebSphere MQ messaging provider destinations.

To view WebSphere MQ topic connection factory advanced properties, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** > **JMS->Topic connection factories** to display existing topic connection factories.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the topic connection factories are defined. Setting the scope in this way restricts the set of queue connection factories displayed.
3. Select the name of the topic connection factory that you want to work with.
4. In the content pane, under Additional properties, click **Advanced properties** to view a list of the advanced properties of the WebSphere MQ topic connection factory.

Under General Properties there are six groups of advanced properties:

- Client reconnect
- Message compression
- Temporary destinations
- Connection consumer
- Message format
- Additional

Make any required changes to these groups and then click **Apply** to return to the topic connection factory.

Note: When specifying WebSphere MQ properties, the following restrictions apply:

- Names can have a maximum of 48 characters, except for channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring JMS resources for WebSphere MQ. For more information about configuring JMS resources for WebSphere MQ, see the *Using Java* section of the WebSphere MQ information center.

A WebSphere MQ topic connection factory has the following advanced properties.

Client reconnect options:

This property specifies whether a client mode connection reconnects automatically, or not, in the event of a communications or queue manager failure. This parameter is ignored unless the connection factory is being used in a thin or managed client environment.

Data type Drop-down list
Default DISABLED
Range
DISABLED
Client reconnection does not automatically occur.
ASDEF The value from the DefRecon attribute from the channels stanza of the client configuration file is used. If there is no DefRecon value specified in the client configuration file, ASDEF has the same effect as DISABLED.
QMGR Reconnection occurs only to the queue manager to which the connection was originally connected.
RECONNECT
Reconnection occurs to any queue manager that is consistent with the value of the queue manager attribute. This queue manager might be a different queue manager from the one to which the connection was originally connected.

For more information about automatic client reconnection, see the WebSphere MQ information center.

Client reconnect timeout:

The maximum number of seconds that a client mode connection spends attempting to automatically reconnect to a queue manager after a communications or queue manager failure. This parameter is ignored unless the connection factory is being used in a thin or managed client environment. Whether this parameter is used or not depends on the value of the client reconnect options parameter.

Data type Integer
Units Seconds
Default 1800 (30 minutes)
Range A value greater than zero and up to 2147483647

For more information about automatic client reconnection, see the WebSphere MQ information center.

Compress message headers:

An option that enables the compression of message headers.

Data type Check box
Default Cleared
Range
Cleared
Do not compress message headers.
Selected
Compress message headers.

Compression algorithm for message payloads:

The compression algorithm to use to compress message payloads.

Data type Drop-down list
Default NONE
Range
RLE Message data compression is performed using run-length encoding.
ZLIBFAST Message data compression is performed using ZLIB encoding with speed prioritized.
ZLIBHIGH Message data compression is performed using ZLIB encoding with compression prioritized.
NONE No message data compression is performed.

Temporary topic prefix:

The prefix to append to the beginning of the names generated for temporary topics.

Data type String

Polling interval:

This setting is applicable in the client container only. When using a WebSphere MQ Version 6 queue manager (or WebSphere MQ Version 5.3 for z/OS), this setting configures the mechanism used to dispatch messages to JMS asynchronous consumers.

This setting is used when the set of WebSphere MQ queues that is being asynchronously consumed from exceeds the number of threads that are available internally to synchronously get messages from the WebSphere MQ queue. The setting determines how long a thread waits for a message to arrive at a WebSphere MQ queue before polling another WebSphere MQ queue in the set.

Data type Integer
Units Milliseconds
Default 5000
Range A value greater than zero.

Maximum batch size:

The maximum number of messages that can be removed from a queue before at least one must be delivered to an asynchronous consumer.

Data type Integer
Default 10
Range A value greater than zero.

Coded character set identifier:

The character set to use when you are encoding strings in the message.

Data type Integer
Default 819
Range A value greater than zero. The coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *System Administration* and the *Application Programming Reference* sections of the WebSphere MQ information center.

Fail JMS method calls if the WebSphere MQ messaging provider queue manager is quiescing:

An option that enables selected JMS operations to fail when the queue manager is put into a quiescing state. Selecting this option enables the queue manager to quiesce successfully and shut down.

Data type Check box
Default Selected
Range
Cleared
Do not fail JMS operations if the queue manager is quiescing.
Selected
Fail JMS operations if the queue manager is quiescing.

WebSphere MQ messaging provider connection factory broker properties:

Use this panel to view or change the broker settings of the selected connection factory, or topic connection factory, for use with the WebSphere MQ messaging provider. These broker settings determine how the WebSphere MQ messaging provider interacts with a broker for the purposes of publishing messages and subscribing to topics. Updates to the settings take effect when the server is restarted.

To view WebSphere MQ connection factory, or topic connection factory, broker properties use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** > **JMS->Connection factories** to display existing connection factories, or click **Resources** > **JMS->Topic connection factories** to display existing topic connection factories.
2. If appropriate, in the content pane, change the **Scope** setting to the level at which the connection factories are defined. This restricts the set of connection factories displayed.
3. Select the name of the connection factory, or topic connection factory, that you want to work with.
4. In the content pane, under Additional Properties, click **Broker properties** to display the broker properties of the WebSphere MQ connection factory, or topic connection factory.

Under General Properties there are four groups of properties:
- Queues
- Capabilities
- Tuning
- Additional

Make any required changes to these groups and then click **Apply** to return to the connection factory, or topic connection factory.

Note: When specifying WebSphere MQ properties, the following restrictions apply:
- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the WebSphere MQ *Using Java* section of the WebSphere MQ library.

A WebSphere MQ connection factory, or topic connection factory, has the following broker properties:

Broker control queue:

The queue to which broker control messages are sent.

Data type String
Default SYSTEM.BROKER.CONTROL.QUEUE

Broker publication queue:

The queue to which publication messages are sent.

Data type String
Default SYSTEM.BROKER.DEFAULT.STREAM

Broker subscriber queue:

The queue to which subscription messages are sent.

Data type String
Default SYSTEM.JMS.ND.SUBSCRIBER.QUEUE

Broker connection consumer subscription queue:

The queue to which subscription messages that are destined for a connection consumer are sent.

Data type String
Default SYSTEM.JMS.ND.CC.SUBSCRIBER.QUEUE

Version:

The version of the broker that is used. This determines some of the capabilities that the broker is assumed to have. For example, whether to use an RFH version 1 or version 2 header in publications.

Data type Radio button
Default Version 1 broker
Range

Version 1 broker
Message selection cannot be specified.

Version 2 broker
Message selection can be specified. If you select this option, you must also complete **Specify where message selection occurs**.

Specify where message selection occurs:

The process in which message selection is performed. This property is enabled only if **Version 2 broker** was selected.

Data type Drop-down list
Default CLIENT

Range

CLIENT
Message selection is performed in the application server process.

BROKER
Message selection is performed in the broker process.

Subscription store:

The process for tracking subscriptions.

Data type Drop-down list
Default MIGRATE
Range

MIGRATE
Any information that is held on queues is migrated to the broker mechanism for persisting subscription information. If subscription information is already persisted using the broker mechanism then specifying a value of `Migrate` is equivalent to specifying a value of `Broker`.

BROKER
Internal broker mechanisms are used to track subscription information.

QUEUE
A designated WebSphere MQ queue is used to record information about current subscriptions.

Durable subscription state refresh interval:

How often a long running transaction is recreated and used to clean up durable subscriptions, for some versions of the queue manager.

Data type Integer
Default 60000
Range Any positive integer

Subscription cleanup level:

How aggressively messages are cleaned up if the subscriber that is expected to consume the messages terminates unexpectedly.

Data type Drop-down list
Default SAFE

Range

SAFE A conservative algorithm is used to clean up subscriptions.

ASPROP
The cleanup algorithm is determined by a system property.

NONE No cleanup of subscriptions is performed.

STRONG
An aggressive algorithm is used to clean up subscriptions.

Subscription cleanup interval:

How often to check for orphaned subscriptions and clean up messages.

Data type Integer
Default 3600000
Range Any positive integer

Subscription wildcard format:

The wildcard format used for subscribing to more than one topic in a topic hierarchy.

Data type Drop-down list
Default character wildcards
Range

character wildcards
You can use an asterisk (*) or question mark (?) to represent characters, or strings of characters, in a topic name.

* is interpreted as matching many characters.

? is interpreted as matching a single character.

topic level wildcards
You can use a plus sign (+) or number sign (#) to represent topics in a multilevel topic hierarchy.

+ is interpreted as matching a single topic name.

is interpreted as matching many topics in the hierarchy. / is used to delimit topics.

Publish acknowledgement window:

The number of messages to publish before publishing a message that requires broker acknowledgement

Data type Integer
Default 25
Range Any positive integer

Optimize for sparse subscription patterns:

An option to specify whether this connection factory is anticipated to receive a high proportion of messages that match its selection criteria. This information can be used to optimize message delivery.

Data type Check box
Default Cleared
Range
Cleared
Subscriptions frequently receive matching messages.
Selected
Subscriptions do not frequently receive matching messages.

Broker queue manager:

The name of the queue manager that is running the broker, if it is not the same as the queue manager to which the connection factory connects.

Data type String
Default The queue manager name that was specified in the connection factory.

WebSphere MQ messaging provider connection factory client transport settings:

Use this panel to view or change the client transport settings of a connection factory, queue connection factory, or topic connection factory for use with the WebSphere MQ messaging provider. Client transport properties affect how a client connection is established with a WebSphere MQ queue manager or queue-sharing group. Updates to the settings take effect when the server is restarted.

To view WebSphere MQ connection factory, queue connection factory, or topic connection factory client transport settings, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** > **JMS**.
2. Click **Connection factories**, **Queue connection factories**, or **Topic connection factories** to display existing connection factories, queue connection factories or topic connection factories.
3. Select the name of the connection factory, queue connection factory, or topic connection factory that you want to work with.
4. In the content pane under Additional Properties, click **Client transport properties** to view a list of the client transport settings of the WebSphere MQ connection factory, queue connection factory, or topic connection factory.

Under General Properties there are two groups of properties:
- Additional SSL settings (for more information about setting the SSL properties for WebSphere MQ, see *SSL properties* in the *Using Java* section of the WebSphere MQ information center)
- Channel exits

Make any required changes to these groups and then click **Apply** to return to the connection factory, queue connection factory or topic connection factory.

Note: When specifying WebSphere MQ properties, the following restrictions apply:
- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the *Using Java* section of the WebSphere MQ information center.

A WebSphere MQ connection factory, queue connection factory, or topic connection factory has the following client transport settings properties:

Certificate revocation list:

A list of LDAP URLs pointing to LDAP repositories of SSL certificates that might have been revoked.

Data type	String
Default	No certificate revocation list
Range	The value must be a space-separated list of LDAP URLs.

Peer name:

A name (possibly including wildcards) that must match the distinguished name of the peer SSL certificate for a connection to be established.

Data type	String
Default	Do not check the distinguished name of the peer certificate.
Range	Validated according to the rules for a WebSphere MQ SSLPEER channel parameter.

Reset count:

The total number of bytes to transfer over an SSL connection before renegotiating the symmetric encryption keys used to secure the connection.

Data type	Integer
Default	0 (do not renegotiate)
Range	The value must be in the range 0 through 999,999,999 (inclusive).

Receive exits:

A comma-separated list of Java class names corresponding to receive exits to be loaded.

Data type	String

Receive exit initialization data:

Initialization data to be passed to the receive exit.

Data type	String

Send exits:

A comma-separated list of Java class names corresponding to send exits to be loaded.

Data type	String

Send exit initialization data:

Initialization data to be passed to the send exit.

Data type	String

Security exit:

A Java class name corresponding to the security exit to be loaded.

Data type String

Security exit initialization data:

Initialization data to be passed to the security exit.

Data type String

Connection pool settings:

Use this page to configure connection pool settings.

This administrative console page is common to JDBC data sources and JMS connection factories (unified, queue, or topic connection factories). To view this page, the path depends on the type of resource, but generally you select an instance of the resource type then click **Connection Pool**. For example:

- Click **Resources** > **JDBC** > **Data Sources** > ***data_source*** > **[Additional Properties] Connection pool properties**
- Click **Resources** > **JMS->Queue connection factories->*queue_connection_factory*->[Additional Properties] Connection pool**

Note: Connection pooling is not supported in an application client. The application client calls the database directly and does not go through a data source. If you want to use the getConnection() request from the application client, configure the JDBC provider in the application client deployment descriptors, using Rational Application Developer or an assembly tool. The connection is established between application client and the database. Application clients do not have a connection pool, but you can configure JDBC provider settings in the client deployment descriptors.

Connection timeout:

Specifies the interval, in seconds, after which a connection request times out and a ConnectionWaitTimeoutException is thrown.

This value indicates the number of seconds that a connection request waits when there are no connections available in the free pool and no new connections can be created. This usually occurs because the maximum value of connections in the particular connection pool has been reached.

For example, if Connection timeout is set to 300, and the maximum number of connections are all in use, the pool manager waits for 300 seconds for a physical connection to become available. If a physical connection is not available within this time, the pool manager initiates a `ConnectionWaitTimeout` exception. In most cases, you should not retry the getConnection() method; if a longer wait time is required you should increase the Connection timeout setting value. If a `ConnectionWaitTimeout` exception is caught by the application, review the expected connection pool usage of the application and tune the connection pool and database accordingly.

If the Connection timeout is set to 0, the pool manager waits as long as necessary until a connection becomes available. This happens when the application completes a transaction and returns a connection to the pool, or when the number of connections falls below the value of Maximum Connections, and a new physical connection is created.

If Maximum Connections is set to 0, an infinite number of physical connections are enabled, and the Connection timeout value is ignored.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Maximum connections:

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. When this number is reached, no new physical connections are created. The requester waits until a physical connection that is currently in use returns to the pool, or until a ConnectionWaitTimeoutException error displays. For example, if the Max Connections value is set to 5, and there are 5 physical connections in use, the pool manager waits for the amount of time specified in Connection timeout for a physical connection to become free.

Knowing the number of connection pools that can potentially request connections from the backend, such as a DB2 database or a CICS server, helps you determine a value for the Maximum Connections property.

For multiple stand-alone application servers that use the same data source configuration, or J2C connection factory configuration, a separate physical connection pool exists for each server. If you clone these same application servers, WebSphere Application Server (base) implements a separate connection pool for each clone.

All of these connection pools correspond to the same data source or connection factory configuration. Therefore all of these connection pools can potentially request connections from the same backend resource, at the same time. The single Maximum Connections value that you set on this console panel applies to every one of these connection pools. Consequently, setting a high Maximum Connections value can result in a load of connection requests that overwhelms your backend resource.

Data type	Integer
Default	10
Range	0 to maximum integer If Max Connections is set to 0, the Connection timeout value is ignored.

Tip: For better performance, set the value for the connection pool lower than the value for the maximum thread pool connections of the web container. To configure this setting click **Servers** > **Server types** > **WebSphere application servers** > ***server*** > **Thread Pools**, and modify the web container property. Lower settings, such as 10-30 connections, perform better than higher settings, such as 100.

You can use the Tivoli Performance Viewer to find the optimal number of connections in a pool. If the number of concurrent waiters is greater than 0, but the processor load is not close to 100%, consider increasing the connection pool size. If the Percent Used value is consistently low under normal workload, consider decreasing the number of connections in the pool.

Minimum connections:

Specifies the minimum number of physical connections to maintain.

If the size of the connection pool is at or below the minimum connection pool size, the Unused timeout thread does not discard physical connections. However, the pool does not create connections solely to ensure that the minimum connection pool size is maintained. Also, if you set a value for Aged timeout, connections with an expired age are discarded, regardless of the minimum pool size setting.

For example, if the Minimum Connections value is set to 3, and one physical connection is created, the Unused timeout thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the Minimum Connections setting.

Data type	Integer
Default	1
Range	0 to max int

Reap time:

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if Reap Time is set to 60, the pool maintenance thread runs every 60 seconds. The Reap Time interval affects the accuracy of the Unused timeout and Aged timeout settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the Reap Time value less than the values of Unused timeout and Aged timeout. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value specified in Unused timeout, until it reaches the number of connections specified in Minimum Connections. The pool maintenance thread also discards any connections that remain active longer than the time value specified in Aged timeout.

The Reap Time interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread, set Reap Time to `0`, or set both Unused timeout and Aged timeout to `0`. The recommended way to disable the pool maintenance thread is to set Reap Time to `0`, and Unused timeout and Aged timeout are ignored. However, if Unused timeout and Aged timeout are set to `0`, the pool maintenance thread runs, but only physical connections that timeout, because of non-zero timeout values, are discarded.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Unused timeout:

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the Unused timeout value higher than the Reap timeout value for optimal performance. Unused physical connections are only discarded if the current number of connections exceeds the Minimum Connections setting. For example, if the unused timeout value is set to `120`, and the pool maintenance thread is enabled (Reap Time is not `0`), any physical connection that remains unused for 2 minutes is discarded.

The accuracy and performance of this timeout are affected by the Reap Time value. See “Reap time” on page 207 for more information.

Data type	Integer
Units	Seconds
Default	1800
Range	0 to max int

Aged timeout:

Specifies the interval in seconds before a physical connection is discarded.

Setting Aged timeout to 0 supports active physical connections remaining in the pool indefinitely. Set the Aged timeout value higher than the Reap timeout value for optimal performance.

For example, if the Aged timeout value is set to `1200`, and the Reap Time value is not `0`, any physical connection that remains in existence for 1200 seconds (20 minutes) is discarded from the pool. The only exception is if the connection is involved in a transaction when the aged timeout is reached, the application server will not discard the connection until after the transaction is completed and the connection is closed.

The accuracy and performance of this timeout are affected by the Reap Time value. See “Reap time” on page 207 for more information.

Data type	Integer
Units	Seconds
Default	0
Range	0 to max int

Purge policy:

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**.

Data type	String
Defaults	• EntirePool for J2C connection factories and JMS-related connection factories • EntirePool for WebSphere Version 4.0 data sources • EntirePool for current version data sources that you create through the administrative console • EntirePool for current version data sources that you script through wsadmin AdminConfig commands, starting JDBC templates that are built into WebSphere Application Server. For information about the command createUsingTemplate, see the topic, Commands for the AdminConfig object. • FailingConnectionOnly for data sources that you script in wsadmin tool without starting JDBC templates :

Range

EntirePool
All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and issues a stale connection Exception during the next operation on that connection. Subsequent getConnection() requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this closure is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice.

FailingConnectionOnly
Only the connection that caused the stale connection exception is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a possibility that the next getConnection() request from the application can return a connection from the pool that is also stale. The result is more stale connection exceptions.

The connection pretest function attempts to insulate an application from pooled connections that are not valid. When a backend resource, such as a database, goes down, pooled connections that are not valid might exist in the free pool. This is especially true when the purge policy is failingConnectionOnly; in this case, the failing connection is removed from the pool. Depending on the failure, the remaining connections in the pool might not be valid.

Session pool settings:

Use this page to configure session pool settings.

This administrative console page is common to JMS unified connection factories, queue connection factories and topic connection factories. To view this page, you select an instance of the resource type then click **Session pools**. For example, click **Resources** > **JMS->Queue connection factories->*queue_connection_factory*->[Additional Properties] Session pools**.

Connection Timeout:

Specifies the interval, in seconds, after which a connection request times out and a ConnectionWaitTimeoutException is thrown.

The wait is necessary when the maximum value of connections (**Max Connections**) to a particular connection pool is reached . For example, if *Connection Timeout* is set to 300 and the maximum number of connections is reached, the Pool Manager waits for 300 seconds for an available physical connection. If a physical connection is *not* available within this time, the Pool Manager throws a ConnectionWaitTimeoutException. It usually does not make sense to retry the getConnection() method, because if a longer wait time is required, you should set the **Connection Timeout** setting to a higher

value. Therefore, if this exception is caught by the application, the administrator should review the expected usage of the application and tune the connection pool and the database accordingly.

If Connection Timeout is set to 0, the Pool Manager waits as long as necessary until a connection is allocated (which happens when the number of connections falls below the value of **Max Connections**).

If Max Connections is set to 0, which enables an infinite number of physical connections, then the Connection Timeout value is ignored.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Max Connections:

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. Once this number is reached, no new physical connections are created and the requester waits until a physical connection that is currently in use returns to the pool, or a ConnectionWaitTimeoutException is thrown.

For example, if the Max Connections value is set to 5, and there are five physical connections in use, the pool manager waits for the amount of time specified in Connection Timeout for a physical connection to become free.

If Max Connections is set to 0, the Connection Timeout value is ignored.

For better performance, set the value for the connection pool lower than the value for the Max Connections option in the web container. Lower settings, such as 10-30 connections, perform better than higher settings, such as 100.

If clones are used, one data pool exists for each clone. Knowing the number of data pools is important when configuring the database maximum connections.

You can use the Tivoli Performance Viewer to find the optimal number of connections in a pool. If the number of concurrent waiters is greater than 0, but the CPU load is not close to 100%, consider increasing the connection pool size. If the Percent Used value is consistently low under normal workload, consider decreasing the number of connections in the pool.

Data type	Integer
Default	10
Range	0 to max int

Min Connections:

Specifies the minimum number of physical connections to maintain.

Until this number is reached, the pool maintenance thread does not discard physical connections. However, no attempt is made to bring the number of connections up to this number. If you set a value for Aged Timeout, the minimum is not maintained. All connections with an expired age are discarded.

For example if the **Min Connections** value is set to 3, and one physical connection is created, the Unused Timeout thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the **Min Connections** setting.

Data type	Integer
Default	1
Range	0 to max int

Reap Time:

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if **Reap Time** is set to 60, the pool maintenance thread runs every 60 seconds. The Reap Time interval affects the accuracy of the **Unused Timeout** and **Aged Timeout** settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the Reap Time value less than the values of Unused Timeout and Aged Timeout. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value specified in Unused Timeout, until it reaches the number of connections specified in **Min Connections**. The pool maintenance thread also discards any connections that remain active longer than the time value specified in Aged Timeout.

The Reap Time interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread set Reap Time to 0, or set both Unused Timeout and Aged Timeout to 0. The recommended way to disable the pool maintenance thread is to set Reap Time to 0, in which case Unused Timeout and Aged Timeout are ignored. However, if Unused Timeout and Aged Timeout are set to 0, the pool maintenance thread runs, but only physical connections that timeout due to non-zero timeout values are discarded.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Unused Timeout:

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the Unused Timeout value higher than the Reap Timeout value for optimal performance. Unused physical connections are only discarded if the current number of connections not in use exceeds the **Min Connections** setting. For example, if the unused timeout value is set to 120, and the pool maintenance thread is enabled (Reap Time is not 0), any physical connection that remains unused for two minutes is discarded. Note that accuracy of this timeout, as well as performance, is affected by the **Reap Time** value. For more information, see Reap Time.

Data type	Integer
Units	Seconds
Default	1800
Range	0 to max int

Aged Timeout:

Specifies the interval in seconds before a physical connection is discarded.

Setting **Aged Timeout** to 0 supports active physical connections remaining in the pool indefinitely. Set the Aged Timeout value higher than the **Reap Timeout** value for optimal performance. For example, if the Aged Timeout value is set to 1200, and the Reap Time value is not 0, any physical connection that

remains in existence for 1200 seconds (20 minutes) is discarded from the pool. Note that accuracy of this timeout, as well as performance, are affected by the Reap Time value. For more information, see Reap Time.

Data type	Integer
Units	Seconds
Default	0
Range	0 to max int

Purge Policy:

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**. Java EE Connector Architecture (JCA) data sources can have either option. WebSphere Version 4.0 data sources always have a purge policy of **EntirePool**.

Data type	String
Default	FailingConnectionOnly
Range	**EntirePool** All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and throws a *StaleConnectionException* during the next operation on that connection. Subsequent *getConnection* requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice. **FailingConnectionOnly** Only the connection that caused the *StaleConnectionException* is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a good possibility that the next *getConnection* request from the application can return a connection from the pool that is also stale, resulting in more stale connection exceptions.

Configuring a queue for the WebSphere MQ messaging provider

Use this task to view or change the configuration of a JMS queue destination for point-to-point messaging with the WebSphere MQ messaging provider. This task contains an optional step for you to create a new JMS queue destination.

About this task

To view or change the configuration of a queue destination for use with the WebSphere MQ messaging provider, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Resources** > **JMS->Queues** to view existing queue destinations, with a summary of their properties.
2. Select the **Scope** corresponding to the scope of the queue destinations that you want to view or change.
3. To view or change the properties of an existing queue destination, click its name in the list. Otherwise, to create a new queue, complete the following steps:
   a. Click **New** in the content pane. Select **WebSphere MQ messaging provider** then click **OK**.
   b. Specify the following required properties.

      Name The name by which this queue destination is known for administrative purposes within WebSphere Application Server.

      JNDI name
      The JNDI name that is used to bind the queue destination into the namespace.

      Queue name
      The name of the WebSphere MQ queue to which messages are sent.

   c. Click **Apply**. This defines the queue destination to WebSphere Application Server, and enables you to browse or change additional properties.
4. Optional: Change WebSphere MQ queue settings, according to your needs.
5. Click **OK**.
6. Save any changes to the master configuration.
7. To have the changed configuration take effect, stop then restart the application server.

WebSphere MQ messaging provider queue settings

Use this panel to view or change the configuration properties of the selected queue destination for point-to-point messaging with WebSphere MQ as a messaging provider.

A WebSphere MQ queue destination is used to configure the properties of a queue for the WebSphere MQ messaging provider. Connections to the queue are created using an associated WebSphere MQ queue connection factory or connection factory.

To view WebSphere MQ queue settings, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** > **JMS->Queues** to display existing queue destinations.
2. Select the name of the queue destination that you want to work with.
3. Optional: To create a new queue destination, click **New**.
4. Optional: To view or change the queue destination settings, select ts name in the list displayed.

Under General Properties there are two groups of properties:

- Administration
- WebSphere MQ Queue

Make any required changes to the Administration and WebSphere MQ Queue groups of properties and then click **Apply** to save the configuration before, in the content pane under Additional Properties, you click one of the following links:

- **Advanced properties** to display or change the advanced properties of your WebSphere MQ queue destination
- **WebSphere MQ queue connection properties** to display or change the connection properties of your WebSphere MQ queue destination
- **Custom properties** to display or change the custom properties of your WebSphere MQ queue destination

Under Related items, you can click **JAAS - J2C authentication data** to configure authentication information for use with the queue destination.

Note: When specifying WebSphere MQ properties, the following restrictions apply:
- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ JMS resources, see the *Using Java* and *System Administration* sections of the WebSphere MQ information center.

If WebSphere MQ functionality has been disabled at a scope that affects this WebSphere MQ messaging provider resource, then an informational message indicating that WebSphere MQ has been disabled appears. In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

A queue destination for use with the WebSphere MQ messaging provider has the following properties.

Scope:

The scope assigned to the queue when it is created. The scope specifies the level to which this queue definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource at a different scope, change the scope on WebSphere MQ queue destination collection panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Provider:

The JMS provider assigned when the queue is created.

For all queues created using this panel, the provider is the WebSphere MQ messaging provider.

The provider is displayed for information only.

Data type String

Name:

The name by which the queue is known for administrative purposes within WebSphere Application Server.

Data type String

JNDI name:

The name that is used to bind the queue into the JNDI namespace.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

Data type String

Description:

A description of the queue for administrative purposes within WebSphere Application Server.

Data type String
Default Null

Queue name:

The WebSphere MQ name for the queue that holds the messages for the JMS destination.

Data type String

Queue manager or queue-sharing group name:

The name of the WebSphere MQ queue manager or queue-sharing group that hosts the queue.

Data type String

WebSphere MQ queue connection properties:

Use this panel to specify how to connect to the queue manager that hosts the queue.

The system uses these connection properties to retrieve, display and update the queue configuration details that are shown on the **WebSphere MQ queue settings** panel.

To set of change the queue connection properties, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** > **JMS->Queues** to display existing queue destinations.
2. Click the name of the queue destination that you want to work with.
3. To view or change the queue destination settings, click its name in the list displayed.

Under General Properties there are two groups of properties:
- Administration
- WebSphere MQ Queue

Make any required changes to the Administration and WebSphere MQ Queue groups of properties and then click **Apply** before, in the content pane under Additional Properties, you click the **WebSphere MQ queue connection properties** link to display or change the connection properties of your WebSphere MQ queue destination.

Make any required changes to the General properties and then click **Apply** before, in the content pane under Additional Properties, you click **WebSphere MQ configuration** to return to the **WebSphere MQ queue settings** panel.

A queue destination for use with the WebSphere MQ messaging provider has the following WebSphere MQ queue connection properties.

Note:

- The property values that you specify must match the values that you specified when you configured the JMS resources in WebSphere MQ. For more information about configuring JMS resources in WebSphere MQ, see the *Using Java* section of the WebSphere MQ information center.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

Note: You cannot use this panel when WebSphere MQ functionality has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

Queue Manager Host:

The name of host for the queue manager on which the queue destination is created.

Data type	String

Queue Manager Port:

The number of the port used by the queue manager on which this queue is defined.

Data type	Integer
Range	A valid TCP/IP port number. This port must be configured on the WebSphere MQ queue manager.
Default	1414

Server Connection Channel Name:

The name of the channel used for connection to the WebSphere MQ queue manager.

Data type	String
Range	1 through 20 ASCII characters

User ID:

The user ID used, with the **Password** property, for authentication when connecting to the queue manager to define the queue destination.

*If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.*

Data type	String

Password:

The password, used with the **User ID** property, for authentication when connecting to the queue manager to define the queue destination.

*If you specify a value for the **User ID** property, you must also specify a value for the **Password** property.*

Data type	String

WebSphere MQ messaging provider queue and topic advanced properties settings:

Use this panel to view or change the advanced properties for the selected queue or topic destination for use with the WebSphere MQ messaging provider. These advanced properties control the behavior of connections made to WebSphere MQ messaging provider destinations.

To view WebSphere MQ queue or topic advanced properties settings, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** > **JMS**.
2. Click **Queues** or **Topics** to display existing queue or topic destinations.
3. If appropriate, in the content pane, change the **Scope** setting to the level at which the queue or topic destinations are defined. This restricts the set of queue or topic destinations displayed.
4. Click the name of the queue or topic destination that you want to work with.
5. In the content pane, under Additional properties, click **Advanced properties** to display a list of the advanced properties of the WebSphere MQ queue or topic destination.

Under General Properties there are five groups of properties:
- Delivery
- Message format
- Optimizations
- Message descriptor
- Additional

Make any required changes to these groups and then click **Apply** to return to the queue or topic.

Note: When specifying WebSphere MQ properties, the following restrictions apply:
- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring JMS resources for WebSphere MQ. For more information about configuring JMS resources for WebSphere MQ, see *Using Java* section of the WebSphere MQ information center.

A queue or topic for use with the WebSphere MQ messaging provider has the following advanced properties.

Persistence:

The level of persistence used to store messages sent to this destination.

Data type Drop-down list

Default As set by application

Range

As set by application
Messages on the destination have their persistence defined by the application that put them onto the queue.

As per WebSphere MQ queue definition
Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

WebSphere MQ Persistent
Messages on the destination are persistent.

WebSphere MQ Non-persistent
Messages on the destination are not persistent.

WebSphere MQ High
Permit persistent messages to be sent as non-persistent messages when you use an underlying WebSphere MQ queue with a NPMCLASS of 'HIGH'.

Priority:

The priority assigned to messages sent to this destination.

Data type Drop-down list
Default As set by application
Range
As set by application
The priority of messages on this destination is defined by the application that put them onto the destination.
As per WebSphere MQ queue definition
Messages on the destination have their persistence defined by the WebSphere MQ destination definition properties.
Specified
The priority of messages on this destination is defined by the **Specified priority** property. If you select this option, you must define a priority on the **Specified priority** property.

Specified priority:

If the **Priority** property was set to Specified, select the priority assigned to messages sent to this queue type destination.

Data type Drop-down list
Units Message priority level
Default As set by application
Range 0 (lowest priority) through 9 (highest priority)

Expiry:

An option that specifies the expiry timeout for this destination.

Data type Drop-down list
Default As set by application
Range
As set by application
The expiry timeout for messages on this destination is defined by the application that put them onto the destination.
Specified
The expiry timeout for messages on this destination is defined by the **Specified expiry** property. If you select this option, you must define a timeout on the **Specified expiry** property.
Unlimited
Messages on this destination have no expiry timeout, so these messages never expire.

Specified expiry:

If the **Expiry** property is set to Specified, enter the number of milliseconds after which messages expire and are removed from this destination.

Data type Integer
Units Milliseconds
Default 0
Range Greater than or equal to 0
- 0 indicates that messages never timeout
- Other values are an integer number of milliseconds

Coded character set identifier:

The character set to use when encoding strings in the message.

Data type Integer
Default 1208
Range 1 through 65535. The coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ. Blank. Leaving this field empty indicates that the default value must be used.

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *System Administration Guide* and *Application Programming Reference* sections of the WebSphere MQ information center.

Use native encoding:

An option that specifies whether the destination should use native encoding to provide appropriate encoding values for the Java platform.

Data type Check box
Default Selected
Range
Selected
Native encoding is used.
Cleared
Native encoding is not used, so specify the properties for **Integer encoding**, **Decimal encoding**, and **Floating point encoding**.

Integer encoding:

If the **Use native encoding** check box is cleared, select the type of integer encoding to be used.

Data type Drop-down list
Default Normal
Range
Normal
Normal integer encoding is used.
Reversed
Reversed integer encoding is used.

Decimal encoding:

If the **Use native encoding** check box is cleared, select the type of decimal encoding to be used.

Data type Drop-down list
Units Not applicable
Default Normal

Range

Normal
Normal decimal encoding is used.
Reversed
Reversed decimal encoding is used.

Floating point encoding:

If the **Use native encoding** check box is cleared, select the type of floating point encoding to be used.

Data type Drop-down list
Default IEEENORMAL
Range

IEEENORMAL
IEEE normal floating point encoding is used.
IEEEREVERSED
IEEE reversed floating point encoding is used.
z/OS z/OS floating point encoding is used.

Append RFH version 2 headers to messages sent to this destination:

The action to take when replying to a message that is sent to this destination.

Data type Check box
Default Selected
Range

Cleared
Do not append RFH version 2 headers to messages sent to this destination.
Selected
Append RFH version 2 headers to messages sent to this destination.

Message body:

Specifies whether an application processes the RFH version 2 header of a WebSphere MQ message as part of the JMS message body.

Data type Drop-down list
Default UNSPECIFIED

Range

UNSPECIFIED
When sending messages, the WebSphere MQ messaging provider does or does not generate and include an RFH version 2 header, depending on the value of the Append RFH version 2 headers to messages sent to this destination property. When receiving messages, the WebSphere MQ messaging provider acts as if the value is set to JMS.

JMS When sending messages, the WebSphere MQ messaging provider automatically generates an RFH version 2 header and includes it in the WebSphere MQ message. When receiving messages, the WebSphere MQ messaging provider sets the JMS message properties according to values in the RFH version 2 header (if these value are present); it does not present the RFH version 2 header as part of the JMS message body.

MQ When sending messages, the WebSphere MQ messaging provider does not generate an RFH version 2 header. When receiving messages, the WebSphere MQ messaging provider presents the RFH version 2 header as part of the JMS message body.

ReplyTo destination style:

Specifies the format of the JMSReplyTo field.

Data type Drop-down list

Default DEFAULT

Range

DEFAULT
The default value is equivalent to the information in the RFH version 2 header.

MQMD Use the value supplied in the MQMD. This populates the reply to queue manager field with the value from the MQMD, equivalent to the default behaviour of WebSphere MQ Version 6.0.2.4 and 6.0.2.5.

RFH2 Use the value supplied in the RFH version 2 header. If the sending application set a JMSReplyTo value, then that value is used.

Asynchronously send messages to the queue manager:

An option that enables the queue manager to acknowledge receipt of messages sent to it. Asynchronously sending messages to the queue manager is faster, but messages can be lost if the messaging infrastructure fails.

Data type Drop-down list

Default

The default value depends on whether you are working with a queue or topic destination.

As per queue definition
The default value if you are working with a queue destination.

As per topic definition
The default value if you are working with a topic destination.

Range

As per queue definition
Messages are acknowledged according to the WebSphere MQ queue definition properties.

As per topic definition
Messages are acknowledged according to the WebSphere MQ topic definition properties.

Yes The queue manager acknowledges receipt of messages sent to it.

No The queue manager does not acknowledge receipt of messages sent to it.

Read ahead and cache non-persistent messages for consumers:

An option that determines whether messages for non-persistent consumers are sent to the client speculatively. Selecting this option results in faster message delivery but messages can be lost in the event of a failure in the messaging infrastructure.

Data type Drop-down list

Default

The default value depends on whether you are working with a queue or topic destination.

As per queue definition
This is the default value if you are working with a queue destination.

As per topic definition
This is the default value if you are working with a topic destination.

Range

As per queue definition
Messages are sent to the client according to the WebSphere MQ queue definition properties.

As per topic definition
Messages are sent to the client according to the WebSphere MQ topic definition properties.

Yes Messages are sent to the client speculatively.

No Messages are not sent to the client speculatively.

ReplyTo destination style:

Specifies the format of the JMSReplyTo field.

Data type Drop-down list

Default DEFAULT

Range

DEFAULT
The default value is equivalent to the information in the RFH version 2 header.

MQMD Use the value supplied in the MQMD. This populates the reply to queue manager field with the value from the MQMD, equivalent to the default behaviour of WebSphere MQ Version 6.0.2.4 and 6.0.2.5.

RFH2 Use the value supplied in the RFH version 2 header. If the sending application set a JMSReplyTo value, then that value is used.

For more information about automatic client reconnection, see the WebSphere MQ information center.

Read ahead consumer close method:

If **Read ahead and cache non-persistent messages for consumers** is set to `Yes` or `As per queue definition` this property is enabled. This property determines what happens to messages in the internal read ahead buffer when the message consumer is closed.

Data type Drop-down list

Default Close method waits for all cached messages to be delivered

Range

Wait for all cached messages to be delivered
All messages in the internal read ahead buffer are delivered to the application's message listener before returning.

Wait for the current message to be delivered
Only the current message listener invocation completes before returning, potentially leaving messages in the internal read ahead buffer, which are then discarded.

MQMD read enabled:

Specifies whether an application can read the values of MQMD fields from JMS messages that have been sent or received using the WebSphere MQ messaging provider.

Data type Check box

Default Cleared

Range

Cleared
Applications cannot read the values of the MQMD fields.

Selected
Applications can read the values of the MQMD fields.

MQMD write enabled:

Specifies whether an application can write the values of MQMD fields to JMS messages that will be sent or received using the WebSphere MQ messaging provider.

Data type Check box

Default Cleared

Range

Cleared
Applications cannot write the values of the MQMD fields.

Selected
Applications can write the values of the MQMD fields.

MQMD message context:

Defines the message context options specified when sending messages to a destination.

Data type Drop-down list

Default DEFAULT

Range

DEFAULT
The MQOPEN API call and the MQPMO structure specify no explicit message context options.

SET_IDENTITY_CONTEXT
The MQOPEN API call specifies the message context option MQOO_SET_IDENTITY_CONTEXT, and the MQPMO structure specifies MQPMO_SET_IDENTITY_CONTEXT.

SET_ALL_CONTEXT
The MQOPEN API call specifies the message context option MQOO_SET_ALL_CONTEXT, and the MQPMO structure specifies MQPMO_SET_ALL_CONTEXT.

Configuring a topic for the WebSphere MQ messaging provider

Use this task to view or change the configuration of a JMS topic destination for publish/subscribe messaging with the WebSphere MQ messaging provider. This task contains an optional step for you to create a new JMS topic destination.

About this task

To view or change the configuration of a topic destination for use with the WebSphere MQ messaging provider, or to create anew topic destination, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click **Resources** > **JMS->Topics** to view existing topic destinations, with a summary of their properties.
2. Select the **Scope** corresponding to the scope of the topic destinations that you want to view or change.
3. To view or change the properties of an existing topic destination, click its name in the list. Otherwise, to create a new topic destination, complete the following steps:
   a. Click **New** in the content pane. Select **WebSphere MQ messaging provider** then click **OK**.
   b. Specify the following required properties.

      Name The name by which this topic destination is known for administrative purposes within WebSphere Application Server.

JNDI name
The Java Naming and Directory Interface (JNDI) name that is used to bind the topic destination into the namespace.

Topic name
The name of the WebSphere MQtopic to which messages are sent.

c. Click **Apply**. This defines the topic destination to WebSphere Application Server, and enables you to browse or change additional properties.

4. Optional: Change WebSphere MQ topics settings according to your needs.
5. Click **OK**.
6. Save any changes to the master configuration.
7. To have the changed configuration take effect, stop then restart the application server.

WebSphere MQ messaging provider topic settings

Use this panel to view or change the configuration properties of the selected JMS topic destination for publish/subscribe messaging with WebSphere MQ as a messaging provider.

A WebSphere MQ topic destination is used to configure the properties of a topic for the WebSphere MQ messaging provider. Connections to the topic are created using an associated WebSphere MQ topic connection factory or connection factory.

To view WebSphere MQ topic settings, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** > **JMS->Topics** to display existing topic destinations.
2. Select the name of the topic destination that you want to work with.
3. Optional: To create a new topic destination, click **New**.
4. Optional: To view or change the topic destination settings, select its name in the list displayed.

Under General Properties there are two groups of properties:

- Administration
- WebSphere MQ topic

Make any required changes to the Administration and WebSphere MQ topic groups of properties, and then click **Apply** to save the configuration before, in the content pane under Additional Properties, you click either of the following links:

- **Advanced properties** to display or change the advanced properties of your WebSphere MQ topic.
- **Custom properties** to display or change the custom properties of your WebSphere MQ topic.

Under Related items, you can click **JAAS - J2C authentication data** to configure authentication information for use with the topic.

You can specify the following additional properties by using WebSphere MQ administrative commands:

- **wildcardFormat**
- **brokerVersion**

For more information about these properties, refer to the “createWMQTopic command” on page 904.

Note: When specifying WebSphere MQ properties, the following restrictions apply:
- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ JMS resources, see the *Using Java* and *MQ System Administration* sections of the WebSphere MQ information center.

If WebSphere MQ functionality has been disabled at a scope that affects this WebSphere MQ messaging provider resource, then an informational message indicating that WebSphere MQ has been disabled appears. In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

Scope:

The scope assigned to the topic when it is created. The scope specifies the level to which this topic definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates that are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource at a different scope, change the scope on the WebSphere MQ topic destination collection panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Provider:

The JMS provider assigned when the topic is created.

For all topics created using this panel, the provider is the WebSphere MQ messaging provider.

The provider is displayed for information only.

Data type String

Name:

The name by which the topic is known for administrative purposes within WebSphere Application Server.

Data type String

JNDI name:

The name that is used to bind the topic into the JNDI namespace.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

Data type String

Description:

A description of the topic for administrative purposes within WebSphere Application Server.

Data type String

Topic name:

The WebSphere MQ name for the topic.

Data type String

Broker durable subscriber queue:

The queue to use for durable subscribers.

If this property is blank then the default WebSphere MQ value SYSTEM.JMS.D.SUBSCRIBER.QUEUE is used.

Data type String

Broker durable subscription connection consumer queue:

The queue to use for durable subscribers that use a connection consumer.

If this property is blank then the default WebSphere MQ value SYSTEM.JMS.D.CC.SUBSCRIBER.QUEUE is used.

Data type String

Broker publication queue:

The queue to use for publishing messages.

Data type Drop-down list
Default As connection
Range
As connection
The connection factory values are used.
Override connection
Enter the name of a queue in the associated text box.

Broker publication queue manager:

The queue manager that hosts the topic.

Data type String

WebSphere MQ messaging provider queue and topic advanced properties settings:

Use this panel to view or change the advanced properties for the selected queue or topic destination for use with the WebSphere MQ messaging provider. These advanced properties control the behavior of connections made to WebSphere MQ messaging provider destinations.

To view WebSphere MQ queue or topic advanced properties settings, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** > **JMS**.
2. Click **Queues** or **Topics** to display existing queue or topic destinations.
3. If appropriate, in the content pane, change the **Scope** setting to the level at which the queue or topic destinations are defined. This restricts the set of queue or topic destinations displayed.
4. Click the name of the queue or topic destination that you want to work with.

5. In the content pane, under Additional properties, click **Advanced properties** to display a list of the advanced properties of the WebSphere MQ queue or topic destination.

Under General Properties there are five groups of properties:

- Delivery
- Message format
- Optimizations
- Message descriptor
- Additional

Make any required changes to these groups and then click **Apply** to return to the queue or topic.

Note: When specifying WebSphere MQ properties, the following restrictions apply:
- Names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.
- The property values that you specify must match the values that you specified when configuring JMS resources for WebSphere MQ. For more information about configuring JMS resources for WebSphere MQ, see *Using Java* section of the WebSphere MQ information center.

A queue or topic for use with the WebSphere MQ messaging provider has the following advanced properties.

Persistence:

The level of persistence used to store messages sent to this destination.

Data type Drop-down list

Default As set by application

Range

As set by application
Messages on the destination have their persistence defined by the application that put them onto the queue.

As per WebSphere MQ queue definition
Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

WebSphere MQ Persistent
Messages on the destination are persistent.

WebSphere MQ Non-persistent
Messages on the destination are not persistent.

WebSphere MQ High
Permit persistent messages to be sent as non-persistent messages when you use an underlying WebSphere MQ queue with a NPMCLASS of 'HIGH'.

Priority:

The priority assigned to messages sent to this destination.

Data type Drop-down list

Default As set by application

Range

As set by application
The priority of messages on this destination is defined by the application that put them onto the destination.

As per WebSphere MQ queue definition
Messages on the destination have their persistence defined by the WebSphere MQ destination definition properties.

Specified
The priority of messages on this destination is defined by the **Specified priority** property. If you select this option, you must define a priority on the **Specified priority** property.

Specified priority:

If the **Priority** property was set to Specified, select the priority assigned to messages sent to this queue type destination.

Data type Drop-down list
Units Message priority level
Default As set by application
Range 0 (lowest priority) through 9 (highest priority)

Expiry:

An option that specifies the expiry timeout for this destination.

Data type Drop-down list
Default As set by application
Range

As set by application
The expiry timeout for messages on this destination is defined by the application that put them onto the destination.

Specified
The expiry timeout for messages on this destination is defined by the **Specified expiry** property. If you select this option, you must define a timeout on the **Specified expiry** property.

Unlimited
Messages on this destination have no expiry timeout, so these messages never expire.

Specified expiry:

If the **Expiry** property is set to Specified, enter the number of milliseconds after which messages expire and are removed from this destination.

Data type Integer
Units Milliseconds
Default 0
Range Greater than or equal to 0
- 0 indicates that messages never timeout
- Other values are an integer number of milliseconds

Coded character set identifier:

The character set to use when encoding strings in the message.

Data type Integer
Default 1208
Range 1 through 65535. The coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ. Blank. Leaving this field empty indicates that the default value must be used.

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *System Administration Guide* and *Application Programming Reference* sections of the WebSphere MQ information center.

Use native encoding:

An option that specifies whether the destination should use native encoding to provide appropriate encoding values for the Java platform.

Data type Check box
Default Selected
Range
Selected
Native encoding is used.
Cleared
Native encoding is not used, so specify the properties for **Integer encoding**, **Decimal encoding**, and **Floating point encoding**.

Integer encoding:

If the **Use native encoding** check box is cleared, select the type of integer encoding to be used.

Data type Drop-down list
Default Normal
Range
Normal
Normal integer encoding is used.
Reversed
Reversed integer encoding is used.

Decimal encoding:

If the **Use native encoding** check box is cleared, select the type of decimal encoding to be used.

Data type Drop-down list
Units Not applicable
Default Normal
Range
Normal
Normal decimal encoding is used.
Reversed
Reversed decimal encoding is used.

Floating point encoding:

If the **Use native encoding** check box is cleared, select the type of floating point encoding to be used.

Data type Drop-down list
Default IEEENORMAL
Range
IEEENORMAL
IEEE normal floating point encoding is used.
IEEEREVERSED
IEEE reversed floating point encoding is used.
z/OS z/OS floating point encoding is used.

Append RFH version 2 headers to messages sent to this destination:

The action to take when replying to a message that is sent to this destination.

Data type Check box
Default Selected
Range
Cleared
Do not append RFH version 2 headers to messages sent to this destination.
Selected
Append RFH version 2 headers to messages sent to this destination.

Message body:

Specifies whether an application processes the RFH version 2 header of a WebSphere MQ message as part of the JMS message body.

Data type Drop-down list
Default UNSPECIFIED
Range
UNSPECIFIED
When sending messages, the WebSphere MQ messaging provider does or does not generate and include an RFH version 2 header, depending on the value of the Append RFH version 2 headers to messages sent to this destination property. When receiving messages, the WebSphere MQ messaging provider acts as if the value is set to JMS.
JMS When sending messages, the WebSphere MQ messaging provider automatically generates an RFH version 2 header and includes it in the WebSphere MQ message. When receiving messages, the WebSphere MQ messaging provider sets the JMS message properties according to values in the RFH version 2 header (if these value are present); it does not present the RFH version 2 header as part of the JMS message body.
MQ When sending messages, the WebSphere MQ messaging provider does not generate an RFH version 2 header. When receiving messages, the WebSphere MQ messaging provider presents the RFH version 2 header as part of the JMS message body.

ReplyTo destination style:

Specifies the format of the JMSReplyTo field.

Data type Drop-down list

Default DEFAULT

Range

DEFAULT
The default value is equivalent to the information in the RFH version 2 header.

MQMD Use the value supplied in the MQMD. This populates the reply to queue manager field with the value from the MQMD, equivalent to the default behaviour of WebSphere MQ Version 6.0.2.4 and 6.0.2.5.

RFH2 Use the value supplied in the RFH version 2 header. If the sending application set a JMSReplyTo value, then that value is used.

Asynchronously send messages to the queue manager:

An option that enables the queue manager to acknowledge receipt of messages sent to it. Asynchronously sending messages to the queue manager is faster, but messages can be lost if the messaging infrastructure fails.

Data type Drop-down list

Default The default value depends on whether you are working with a queue or topic destination.

As per queue definition
The default value if you are working with a queue destination.

As per topic definition
The default value if you are working with a topic destination.

Range

As per queue definition
Messages are acknowledged according to the WebSphere MQ queue definition properties.

As per topic definition
Messages are acknowledged according to the WebSphere MQ topic definition properties.

Yes The queue manager acknowledges receipt of messages sent to it.

No The queue manager does not acknowledge receipt of messages sent to it.

Read ahead and cache non-persistent messages for consumers:

An option that determines whether messages for non-persistent consumers are sent to the client speculatively. Selecting this option results in faster message delivery but messages can be lost in the event of a failure in the messaging infrastructure.

Data type Drop-down list

Default The default value depends on whether you are working with a queue or topic destination.

As per queue definition
This is the default value if you are working with a queue destination.

As per topic definition
This is the default value if you are working with a topic destination.

Range

As per queue definition
Messages are sent to the client according to the WebSphere MQ queue definition properties.
As per topic definition
Messages are sent to the client according to the WebSphere MQ topic definition properties.
Yes Messages are sent to the client speculatively.
No Messages are not sent to the client speculatively.

ReplyTo destination style:

Specifies the format of the JMSReplyTo field.

Data type Drop-down list
Default DEFAULT
Range

DEFAULT
The default value is equivalent to the information in the RFH version 2 header.
MQMD Use the value supplied in the MQMD. This populates the reply to queue manager field with the value from the MQMD, equivalent to the default behaviour of WebSphere MQ Version 6.0.2.4 and 6.0.2.5.
RFH2 Use the value supplied in the RFH version 2 header. If the sending application set a JMSReplyTo value, then that value is used.

For more information about automatic client reconnection, see the WebSphere MQ information center.

Read ahead consumer close method:

If **Read ahead and cache non-persistent messages for consumers** is set to `Yes` or `As per queue definition` this property is enabled. This property determines what happens to messages in the internal read ahead buffer when the message consumer is closed.

Data type Drop-down list
Default Close method waits for all cached messages to be delivered
Range

Wait for all cached messages to be delivered
All messages in the internal read ahead buffer are delivered to the application's message listener before returning.
Wait for the current message to be delivered
Only the current message listener invocation completes before returning, potentially leaving messages in the internal read ahead buffer, which are then discarded.

MQMD read enabled:

Specifies whether an application can read the values of MQMD fields from JMS messages that have been sent or received using the WebSphere MQ messaging provider.

Data type Check box
Default Cleared

Range

Cleared
Applications cannot read the values of the MQMD fields.

Selected
Applications can read the values of the MQMD fields.

MQMD write enabled:

Specifies whether an application can write the values of MQMD fields to JMS messages that will be sent or received using the WebSphere MQ messaging provider.

Data type Check box
Default Cleared
Range

Cleared
Applications cannot write the values of the MQMD fields.

Selected
Applications can write the values of the MQMD fields.

MQMD message context:

Defines the message context options specified when sending messages to a destination.

Data type Drop-down list
Default DEFAULT
Range

DEFAULT
The MQOPEN API call and the MQPMO structure specify no explicit message context options.

SET_IDENTITY_CONTEXT
The MQOPEN API call specifies the message context option MQOO_SET_IDENTITY_CONTEXT, and the MQPMO structure specifies MQPMO_SET_IDENTITY_CONTEXT.

SET_ALL_CONTEXT
The MQOPEN API call specifies the message context option MQOO_SET_ALL_CONTEXT, and the MQPMO structure specifies MQPMO_SET_ALL_CONTEXT.

Configuring custom properties for WebSphere MQ messaging provider JMS resources

In addition to the standard properties that you can define for WebSphere MQ messaging provider JMS resources, you can configure further WebSphere MQ properties as custom properties. You can configure custom properties for activation specifications, connection factories, and JMS destinations for the WebSphere MQ messaging provider.

About this task

WebSphere Application Server supports the use of custom properties to define WebSphere MQ properties. This is useful because it enables WebSphere Application Server to work with later versions of WebSphere MQ that might have properties that are not exposed in WebSphere Application Server.

You can use this task to set custom properties for JMS destinations, connection factories, and activation specifications for the WebSphere MQ messaging provider. For example, you would use this task to set the custom property WAS_EndpointInitialState for an activation specification. WAS_EndpointInitialState determines whether or not message consumption begins from the JMS destination as soon as the activation specification is used for a message-driven bean to connect with the destination.

To specify custom properties for WebSphere MQ messaging provider JMS resources, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Resources** > **JMS**.
2. Select the type of JMS resource for which you want create custom properties (JMS destinations, connection factories, or activation specifications).
3. Optional: Change the **Scope** setting to the level at which the resource definition is visible to applications.
4. In the contents pane, select the specific WebSphere MQ messaging provider JMS resource name for which you want to specify the custom property. This displays information about the resource.
5. To create a custom property, select **[Additional Properties] Custom properties**.
6. Click **New** in the content pane.
7. Specify the following attributes for the new custom property:

   Name
   The name of the custom property. A property name is required.

   Value The value for the custom property.

   Type The type of the custom property. Select the custom property type from the list.
8. Click **Apply**. This defines the custom property to WebSphere Application Server, and enables you to browse or change additional properties.
9. Save any changes to the master configuration.
10. To have the changed configuration take effect, stop then restart the application server.

Example

To set the custom property WAS_EndpointInitialState for an activation specification, specify the following attributes:

- For **Name**, specify `WAS_EndpointInitialState`.
- For **Value**, specify one of the following options:

  `ACTIVE` Specify a value of `ACTIVE` if message consumption is to begin as soon as the message-driven bean connects with the JMS destination.

  `INACTIVE`
  Specify a value of `INACTIVE` if message consumption is not to begin until you use the wsadmin tool or the administrative console to activate message consumption for the message-driven bean.
- For **Type**, select String.

WebSphere MQ messaging provider custom properties

WebSphere MQ messaging provider custom properties can be specified in the administrative console. Click **Resources** > **JMS**. Select the type of JMS resource for which you want create custom properties (JMS destinations, connection factories, or activation specifications). In the contents pane, select the specific WebSphere MQ messaging provider JMS resource name. Information about the resource is displayed. To create custom properties, select **[Additional Properties] Custom properties**.

You can define the following WebSphere MQ messaging provider custom properties:

- "WAS_EndpointInitialState"

WAS_EndpointInitialState

This custom property is for use with activation specifications.

This parameter determines whether the endpoint is activated when the endpoint is registered.

This parameter should be ignored for subsequent activation or deactivation via the J2CMessageEndpoint.

Table 61. WAS_EndpointInitialState custom property. The table includes the data type and acceptable values for the property.

Data type	String
Acceptable values	ACTIVE, INACTIVE

Configuring custom properties for WebSphere MQ messaging provider JMS resources

In addition to the standard properties that you can define for WebSphere MQ messaging provider JMS resources, you can configure further WebSphere MQ properties as custom properties. You can configure custom properties for activation specifications, connection factories, and JMS destinations for the WebSphere MQ messaging provider.

About this task

WebSphere Application Server supports the use of custom properties to define WebSphere MQ properties. This is useful because it enables WebSphere Application Server to work with later versions of WebSphere MQ that might have properties that are not exposed in WebSphere Application Server.

You can use this task to set custom properties for JMS destinations, connection factories, and activation specifications for the WebSphere MQ messaging provider. For example, you would use this task to set the custom property WAS_EndpointInitialState for an activation specification. WAS_EndpointInitialState determines whether or not message consumption begins from the JMS destination as soon as the activation specification is used for a message-driven bean to connect with the destination.

To specify custom properties for WebSphere MQ messaging provider JMS resources, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Resources** > **JMS**.
2. Select the type of JMS resource for which you want create custom properties (JMS destinations, connection factories, or activation specifications).
3. Optional: Change the **Scope** setting to the level at which the resource definition is visible to applications.
4. In the contents pane, select the specific WebSphere MQ messaging provider JMS resource name for which you want to specify the custom property. This displays information about the resource.
5. To create a custom property, select **[Additional Properties] Custom properties**.
6. Click **New** in the content pane.
7. Specify the following attributes for the new custom property:

   Name

   The name of the custom property. A property name is required.

Value The value for the custom property.

Type The type of the custom property. Select the custom property type from the list.

8. Click **Apply**. This defines the custom property to WebSphere Application Server, and enables you to browse or change additional properties.
9. Save any changes to the master configuration.
10. To have the changed configuration take effect, stop then restart the application server.

Example

To set the custom property WAS_EndpointInitialState for an activation specification, specify the following attributes:

- For **Name**, specify `WAS_EndpointInitialState`.
- For **Value**, specify one of the following options:

  `ACTIVE` Specify a value of `ACTIVE` if message consumption is to begin as soon as the message-driven bean connects with the JMS destination.

  `INACTIVE`
  Specify a value of `INACTIVE` if message consumption is not to begin until you use the wsadmin tool or the administrative console to activate message consumption for the message-driven bean.
- For **Type**, select String.

WebSphere MQ resource custom properties settings

Use this page to specify custom properties that your enterprise information system (EIS) requires for the resource providers and resource factories that you configure. For example, most database vendors require additional custom properties for data sources that access the database.

To view this administrative console page, complete the following steps:

1. In the navigation pane, click **Resources** > **JMS->JMS providers**.
2. If appropriate, in the content pane, change the scope of the WebSphere MQ messaging provider.
3. In the content pane, click the **WebSphere MQ messaging provider** that you want to support the JMS destination.
4. In the content pane, under Additional Properties, click the type of resource that you want to change, for example **Queues**.
5. Click the name of the resource that you want to work with.
6. In the content pane, under General Properties, complete the groups of fields, for example **Administration** and **WebSphere MQ Queue**.
7. In the content pane, under Additional Properties, click **Custom properties** to display a list of the custom properties of a WebSphere MQ resource.

A resource for use with the WebSphere MQ messaging provider has the following custom properties.

Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ for JMS resources, see the *Using Java* section of the WebSphere MQ information center.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels, which have a maximum of 20 characters.

Name:

The name by which the resource is known for administrative purposes within WebSphere Application Server.

Data type String

Value:

The value of the resource.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of the resource, for administrative purposes within WebSphere Application Server.

Data type String
Default Null

Required:

Whether the resource is required, for administrative purposes within WebSphere Application Server.

Data type String
Default Null

Configuring properties for the WebSphere MQ resource adapter

You can configure the WebSphere MQ resource adapter properties that affect the connection pool, which is used by WebSphere MQ messaging provider activation specifications.

About this task

There are four properties that are used to configure the WebSphere MQ resource adapter used by the WebSphere MQ messaging provider:

- **maxConnections**
- **connectionConcurrency**
- **reconnectionRetryCount**
- **reconnectionRetryInterval**

These four properties affect the connection pool, which is used by the WebSphere MQ messaging provider activation specifications. They do not affect the WebSphere MQ messaging provider queues, topics, or connection factories.

For further information about these properties, see Configuration of the ResourceAdapter object in the WebSphere MQ information center.

To configure the WebSphere MQ resource adapter properties, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Resources** > **JMS->JMS providers** to display a list of JMS providers in the content pane.
2. If you want to manage JMS resources that are defined at a different scope setting, change the **Scope** setting to the required level.

   Note: These properties only have an effect on the WebSphere MQ messaging provider objects that are defined at the same scope as the messaging provider and resource adapter on which they are set. So, for example, if you set the **max connections** property to a particular setting at the server scope, only the server scoped WebSphere MQ messaging provider activation specifications are affected by this setting.
3. In the Providers column of the displayed list of JMS providers, click the name of the WebSphere MQ messaging provider that you want to work with.
4. In the content pane under Additional properties, click **Resource adapter properties** to view the configuration page for the properties.
5. Specify the required values for the properties:

   Max connections
   The maximum number of connections to a WebSphere MQ queue manager.

   Connection concurrency
   The maximum number of message-driven beans that can be supplied by each connection.

   Reconnection retry count
   The maximum number of attempts made by a WebSphere MQ messaging provider activation specification to reconnect to a WebSphere MQ queue manager if a connection fails.

   Reconnection retry interval
   The time, in milliseconds, that a WebSphere MQ messaging provider activation specification waits before making another attempt to reconnect to a WebSphere MQ queue manager.
6. Click **Apply**. This defines the property to WebSphere Application Server, and enables you to browse or change additional properties.
7. Save any changes to the master configuration.
8. To have the changed configuration take effect, stop then restart the application server.

Configuring custom properties for the WebSphere MQ resource adapter

In addition to the standard properties that you can specify for the WebSphere MQ resource adapter, you can configure custom properties for WebSphere MQ resource adapter.

About this task

WebSphere Application Server supports the definition of custom properties for the WebSphere MQ resource adapter. This is useful because it enables WebSphere Application Server to work with later versions of WebSphere MQ that might have properties that are not exposed in WebSphere Application Server.

To specify custom properties for the WebSphere MQ resource adapter, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click **Resources** > **JMS->JMS providers** to display a list of JMS providers in the content pane.
2. If you want to manage JMS resources that are defined at a different scope setting, change the **Scope** setting to the required level.

3. In the Providers column of the displayed list of JMS providers, click the name of the WebSphere MQ messaging provider that you want to work with.
4. In the content pane under Additional properties, click **Resource adapter properties** to view the configuration page for the properties.
5. In the content pane under Additional properties, click **Custom properties** to view the configuration page for the properties.
6. Click the name of the property that you want to configure then make any required changes.
7. Click **Apply**. This defines the custom property to WebSphere Application Server, and enables you to browse or change additional properties.
8. Save any changes to the master configuration.
9. To have the changed configuration take effect, stop then restart the application server.

Disabling WebSphere MQ functionality in WebSphere Application Server

If you do not need to use WebSphere MQ functionality in an application server you can disable it by using either the administrative console or an administrative command. You can also disable WebSphere MQ functionality in a client process by specifying a custom property.

About this task

Note: When a WebSphere Application Server process or an application client process starts, and while this process is running, an amount of processing is performed to allow it to support WebSphere MQ-related functionality such as the WebSphere MQ messaging provider. By default this processing is performed regardless of whether any WebSphere MQ-related functionality is ever used. If you do not need to take advantage of any WebSphere MQ functionality, it is possible to disable all WebSphere MQ functionality in an application server or client process to give increased performance.

Disabling WebSphere MQ functionality in a WebSphere Application Server process has the following effects:

- No WebSphere MQ messaging provider functionality is available on that particular server:
  - Any defined WebSphere MQ messaging provider resources are not bound into JNDI, and so are unavailable to look up from inside the affected application server process, from other application server processes or application clients.
  - It is still possible to define WebSphere MQ messaging provider resources. However the **test connection** button on either the create connection factory or create activation specification wizard, depending on the scope at which WebSphere MQ has been disabled, does not work.
  - Any message driven beans that use message listener ports configured with WebSphere MQ messaging provider resources do not start.
  - Any message driven beans that use WebSphere MQ messaging provider activation specifications do not start.
  - It is not possible to recover any indoubt XA transactions involving WebSphere MQ messaging provider resources.
  - Any attempt to look up a WebSphere MQ messaging provider resource from a remote server that does not have WebSphere MQ functionality disabled fails.
  - It is not possible to use the WebSphere MQ queue connection properties function.
- No WebSphere MQ link functionality is available on that particular server:
  - It is not possible to stop or start any WebSphere MQ links.
  - It is not possible to stop or start any WebSphere MQ receiver channels.
  - It is not possible to stop, start, or reset any WebSphere MQ sender channels.

  - It is not possible to send messages to a WebSphere MQ queue manager. Any messages that are sent to a foreign bus based on a WebSphere MQ link remain on the transmission item stream for that WebSphere MQ link.
  - It is not possible to receive messages from a WebSphere MQ queue manager.
  - The inbound channel chains used by the WebSphere MQ link do not start.
  - It is not possible to resolve indoubt sender channels.
  - Attempts to use the **Test connection** functionality of the foreign bus connection that uses the WebSphere MQ link fail.
  - It is not possible to fully delete a WebSphere MQ link, as any stored state about indoubt messages cannot be processed.
- No WebSphere MQ server functionality is available on that particular server:
  - It is not possible to send messages to WebSphere MQ.
  - It is not possible to receive messages from WebSphere MQ.
  - The **Test connection** button does not work.
- No WebSphere MQ client link functionality works:
  - It is not possible to stop or start any WebSphere MQ client links.
  - It is not possible to send messages using a WebSphere MQ client link.
  - It is not possible to receive messages using a WebSphere MQ client link.
  - The inbound channel chains used by the WebSphere MQ link do not start.
- WebSphere MQ resource adapters do not start.
- WebSphere MQ Base Java functionality is unavailable.
- Any attempt to use any classes provided by WebSphere MQ fails.

Disabling WebSphere MQ functionality in a WebSphere Application Server client process has the following effects:

- Any attempt to look up a WebSphere MQ messaging provider resource from a remote server that does not have WebSphere MQ functionality disabled fails.
- WebSphere MQ Base Java functionality is not available.
- Any attempt to make use of any classes provided by WebSphere MQ fails.

Procedure

- To disable WebSphere MQ functionality in a WebSphere Application Server process, complete one of the following steps:
  - Using the administrative console, select the **Disable WebSphere MQ** check box on the required WebSphere MQ messaging provider panel.
  - Use the manageWMQ administrative command with the disableWMQ flag.

  In a single server environment, you can only disable WebSphere MQ at the server scope. When you have saved your changes and restarted the application server, all WebSphere MQ functionality is disabled on that server.

  In a network deployment environment, you can disable WebSphere MQ at all scopes in order to give fine grained configuration flexibility:
  - At the cell scope, all WebSphere MQ functionality is disabled on all application servers in the cell.
  - At the node scope, all WebSphere MQ functionality is disabled on all application servers that are part of that node.
  - At the cluster scope, all WebSphere MQ functionality is disabled on all application servers in that cluster.
  - At the server scope, all WebSphere MQ functionality is disabled in that particular application server.

The value of the **Disable WebSphere MQ** check box at a higher scope takes precedence over the value at a lower scope. For example, if you do not select the check box at the server scope but do select it for a higher (for example, cell) scoped WebSphere MQ messaging provider, the value at the cell scope takes precedence and WebSphere MQ functionality is therefore disabled in all application servers in the cell, regardless of whether the check box is selected at the server scope. The changes take effect when you have saved them and restarted all affected processes in the cell.

- To disable WebSphere MQ functionality in a WebSphere Application Server client process, specify the custom property com.ibm.ejs.jms.disableWMQSupport=true.

Example

Consider the following example: A network deployment configuration with two nodes: node1 and node2. Node1 has two servers on it, server1 and server2. Node2 has a single server on it, server3. Server3 and server1 are part of a cluster, cluster1. The WebSphere MQ messaging provider panel at cluster1 scope has the **WebSphere MQ disabled** check box selected and the changes saved. When cluster1 has been restarted, all WebSphere MQ functionality is disabled on server3 and server1.

It is worth noting that it is possible to have WebSphere MQ functionality disabled on all processes in a network deployment configuration without all scopes having WebSphere MQ functionality disabled. Using the scenario in the previous example, if all nodes in the topology (deployment manager node, node1 and node2) have WebSphere MQ functionality disabled, then all the processes in the topology also have WebSphere MQ functionality disabled.

What to do next

When the server starts, it is possible to detect whether WebSphere MQ functionality has been disabled on that server because messages with the following ids are output:

- `WMSG2016I` is output when the server starts if WebSphere MQ has been disabled.
- `CWSIC3650I` is output once for any configured WebSphere MQ links that are running on the server.
- `CWSIC3713I` is output once for any configured WebSphere MQ client links that are running on the server.

WMQAdminCommands command group for the AdminTask object

You can use the WebSphere MQ administrative commands to manage JMS resources for the WebSphere MQ messaging provider.

You can configure JMS resources for the WebSphere MQ messaging provider through the WebSphere MQ administrative commands, or you can configure JMS resources for the WebSphere MQ messaging provider through the administrative console.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

These commands are valid only when they are used with WebSphere Application Server Version 7 and later application servers. Do not use them with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using these commands, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

The following commands are available for the WMQAdminCommands group of the AdminTask object:

- createWMQActivationSpec command
- deleteWMQActivationSpec command
- listWMQActivationSpec command
- modifyWMQActivationSpec command
- showWMQActivationSpec command
- createWMQConnectionFactory command
- deleteWMQConnectionFactory command
- listWMQConnectionFactory command
- modifyWMQConnectionFactory command
- showWMQConnectionFactory command
- createWMQTopic command
- deleteWMQTopic command
- listWMQTopic command
- modifyWMQTopic command
- showWMQTopic command
- manageWMQ command
- migrateWMQMLP command
- createWMQQueue command
- deleteWMQQueue command
- listWMQQueue command
- modifyWMQQueue command
- showWMQQueue command

createWMQActivationSpec command

Use the createWMQActivationSpec command to create an activation specification for the WebSphere MQ messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the createWMQActivationSpec command to create a WebSphere MQ messaging provider activation specification at a specific scope.

You cannot create a WebSphere MQ messaging provider activation specification under either of the following conditions:

- A WebSphere MQ messaging provider activation specification already exists with the same name, at the same scope.
- The JNDI name clashes with another entry in WebSphere Application Server JNDI.

You create a CCDT based activation specification by specifying any of the following parameters:

- **-ccdtUrl**
- **-ccdtQmgrName**

If you do not specify any of the following parameters, you create a generic activation specification :

- **-ccdtUrl**
- **-ccdtQmgrName**

Target object

The scope of the WebSphere MQ messaging provider at which the WebSphere MQ messaging provider activation specification is to be created.

Required parameters

-name
The administrative name assigned to this WebSphere MQ messaging provider activation specification.

-jndiName
The name and location used to bind this object into WebSphere Application Server JNDI.

-destinationJndiName
The JNDI name of a WebSphere MQ messaging provider queue or topic type destination. When an MDB is deployed with this activation specification, messages for the MDB are consumed from this destination.

-destinationType
The type of the destination specified by using the **-destinationJndiName** parameter.

Enter one of the following values:

- javax.jms.Queue
- javax.jms.Topic

There is no default value.

Optional parameters

-description
An administrative description assigned to the activation specification.

-ccdtUrl
A URL to a client channel definition table to use, for this activation specification, when contacting WebSphere MQ.

Use this parameter to create ccdtURL activation specifications

Do not specify this parameter in conjunction with the following parameters: **-qmgrName**, **-qmgrType**, **-qmgrHostname**, **-qmgrPortNumber**, **-qmgrSvrconnChannel**, or **-localAddress**.

-ccdtQmgrName
A queue manager name, used to select one or more entries from a client channel definition table.

You must specify this parameter if the **-transportType** has been specified as client or bindingsThenClient.

Do not specify this parameter in conjunction with the following parameters: **-qmgrName**, **-qmgrType**, **-qmgrHostname**, **-qmgrPortNumber**, **-qmgrSvrconnChannel**, or **-localAddress**.

-qmgrName
The name of the queue manager to use, for this activation specification, when contacting WebSphere MQ.

Use this parameter to create generic activation specifications.

Do not specify this parameter in conjunction with the following parameters: **-ccdtUrl** or **-ccdtQmgrName**.

-wmqTransportType
This parameter determines the way in which a connection is established to WebSphere MQ for this activation specification.

Use this parameter to create generic activation specifications.

Enter one of the following case-sensitive values:

- BINDINGS
- BINDINGS_THEN_CLIENT
- CLIENT

BINDINGS_THEN_CLIENT is the default value.

Do not specify this parameter in conjunction with the following parameters: **-ccdtUrl** or **-ccdtQmgrName**.

For more information about configuring a transport type of bindings then client or bindings, refer to “Configuring the WebSphere MQ messaging provider with native libraries information” on page 723.

-qmgrHostname
The host name to use, for this activation specification, when attempting a client mode connection to WebSphere MQ. It must be a valid TCP/IP host name or IPv4 or IPv6 address.

The default value is the local host.

Do not specify this parameter in conjunction with the following parameters: **-ccdtUrl** or **-ccdtQmgrName**.

For information on setting the **-qmgrHostname** parameter in conjunction with the **-connectionNameList** parameter, see the description of the **-connectionNameList** parameter.

-qmgrPortNumber
The port number to use, for this activation specification, when attempting a client mode connection to WebSphere MQ.

Enter an integer value in the range 1 - 65536 (inclusive).

The default value is 1414.

Do not specify this parameter in conjunction with the following parameters: **-ccdtUrl** or **-ccdtQmgrName**.

For information on setting the **-qmgrPortNumber** parameter in conjunction with the **-connectionNameList** parameter, see the description of the **-connectionNameList** parameter.

-connectionNameList

The connection name list specifying the host name and port details to use when you want the activation specification to connect to a multi-instance queue manager.

Note: You must only use the **-connectionNameList** parameter to allow a connection to a multi-instance queue manager. Using the **-connectionNameList** parameter to connect to a non-multi-instance queue manager can jeopardize transaction integrity.

The **-connectionNameList** parameter must be entered as a comma separated list of host names and ports in the following format:

host(*port*),*host*(*port*)

For *host* enter a valid TCP/IP host name, IPv4 or IPv6 address.

For *port* enter an integer value between 1 and 65536 (inclusive). Specifying a value for *port* is optional. When you do not specify a value, *port* defaults to 1414.

For example: `localhost(1234),remotehost(1234),remotehost2`

When you specify the **-connectionNameList** parameter, the **-qmgrHostname** and **-qmgrPortNumber** parameters are automatically set to the host name and port number of the first entry in the connection name list. This overrides any values that you previously specified in the **-qmgrHostname** and **-qmgrPortNumber** parameters.

In the preceding example this would mean that **-qmgrHostname** would be `localhost` and **-qmgrPortNumber** would be `1234`.

The **-connectionNameList** parameter is only valid for use in WebSphere Application Server Version 8.0.

Attempting to specify the **-connectionNameList** parameter on a WebSphere MQ messaging provider activation specification which is defined at a server or node scope that is running on a version of WebSphere Application Server earlier than Version 8.0 results in an error message when you run the following commands:

- createWMQActivationSpec
- modifyWMQActivationSpec

If you specify the **-connectionNameList** parameter on a cell or cluster-scoped WebSphere MQ activation specification, you can use it for nodes that are running WebSphere Application Server Version 7.0. The exact behaviour is determined by the fix pack level of the node:

- For nodes running at WebSphere Application Server Version 7.0 Fix Pack 7 or later, the activation specification uses the **-connectionNameList** parameter to connect to a multi-instance queue manager.
- For nodes running at a fix pack level earlier than WebSphere Application Server Version 7.0 Fix Pack 7, a warning message similar to the one in the following example is output:

```
[29/09/10 12:15:27:468 BST] 00000018 J2CUtilityCla W
J2CA0008W: Class com.ibm.mq.connector.inbound.ActivationSpecImpl used by resource
cells/L3A3316Node01Cell/resources.xml#J2CResourceAdapter_1284547647859 did not contain
method setConnectionNameList. Processing continued.
```

You can ignore this message.

You must not specify the **-connectionNameList** parameter in conjunction with the **-ccdtUrl** or **-ccdtQmgrName** parameters.

Note: If you use the**-connectionNameList** parameter with a centrally managed SSL configuration the host name and port number information used to select the appropriate SSL configuration is based on the first entry in the **-connectionNameList**, regardless of which entry in the list is actually used to connect to the queue manager. This is because each instance of a multi-instance queue manager should be using the same SSL configuration, for a given server connection channel, regardless of which instance is actually running.

For more information on using multi-instance queue managers, see the WebSphere MQ information center.

-authAlias
The authentication alias used to obtain the credentials specified when this activation specification needs to establish a connection to WebSphere MQ.

-clientId
The client identifier used for connections started by using this activation specification.

-providerVersion
This parameter determines the minimum version, and capabilities of the queue manager.

Enter values in one of the following formats:

- *n*
- *n.n*
- *n.n.n*
- *n.n.n.n*

where *n* is an integer greater than or equal to zero.

For example 6.0.0.0

-sslCrl
This parameter specifies a list of LDAP servers that are used to provide certificate revocation information if this activation specification establishes an SSL based connection to WebSphere MQ.

-sslResetCount
This parameter is used when the activation specification establishes an SSL connection to the queue manager. This parameter determines how many bytes to transfer before resetting the symmetric encryption key that is used for the SSL session.

Enter a value in the range 0 through 999,999,999.

The default value is 0.

-sslPeerName
This parameter is used when the activation specification establishes an SSL connection to the queue manager. The value is compared with the distinguished name present in the peer's certificate.

-rcvExit
A comma-separated list of receive exit class names.

-rcvExitInitData
Initialization data to pass to the receive exit.

Do not specify this parameter unless you specify the **-rcvExit** parameter.

-sendExit
A comma-separated list of send exit class names.

-sendExitInitData
Initialization data to pass to the send exit.

Do not specify this parameter unless you specify the **-sendExit** parameter.

-secExit
A security exit class name.

-secExitInitData
Initialization data to pass to the security exit.

Do not specify this parameter unless you specify the **-secExit** parameter.

-compressHeaders
This parameter determines if message headers are compressed.

Enter one of the following values:

- NONE
- SYSTEM

The default value is NONE.

-compressPayload
This parameter determines if message payloads are compressed.

Enter one of the following values:

- NONE
- RLE
- ZLIBFAST
- ZLIBHIGH

The default value is NONE.

-msgRetention
This parameter determines if the connection consumer keeps unwanted messages on the input queue.

Enter one of the following values:

- YES
- NO

where YES specifies that the connection consumer keeps unwanted messages on the input queue, and NO specifies that the messages are disposed of according to their disposition options.

The default value is YES.

-rescanInterval
When a message consumer in the point-to-point domain uses a message selector to select which messages it is to receive, the JMS client searches the WebSphere MQ queue for suitable messages in the sequence determined by the MsgDeliverySequence attribute of the queue. When the client finds a suitable message and delivers it to the consumer, the client resumes the search for the next suitable message from its current position in the queue. The client continues to search the queue in this way until it reaches the end of the queue, or until the interval of time in milliseconds, as determined by the value of this **-rescanInterval** parameter has expired. In each case, the client returns to the beginning of the queue to continue its search, and a new time interval commences.

This parameter must be a positive integer value.

The default value is 5000.

-ccsid
The coded character set identifier (CCSID) to be used on connections.

The value of this parameter must be a positive integer and must be one of the CCSIDs supported by WebSphere MQ. See the “WebSphere MQ messaging provider activation specification advanced properties” on page 749 for more details.

The default value is 819.

-failIfQuiescing
This parameter determines the behavior of certain calls to the queue manager when the queue manager is put into quiescing state.

The value of this parameter must be true or false.

true specifies that calls to certain methods fail if the queue manager is in a quiescing state. If an application detects that the queue manager is quiescing, the application can complete its immediate task and close the connection, allowing the queue manager to stop.

false specifies that no methods fail if the queue manager is in a quiescing state. If you specify this value, an application cannot detect that the queue manager is quiescing. The application might continue to perform operations against the queue manager, and therefore prevent the queue manager from stopping.

The default value is true.

-brokerCtrlQueue
The name of the broker control queue to use if this activation specification is to subscribe to a topic.

The default value is SYSTEM.BROKER.CONTROL.QUEUE.

-brokerSubQueue
The name of the queue to use for obtaining subscription messages if this activation specification is to subscribe to a topic.

The default value is SYSTEM.JMS.ND.SUBSCRIBER.QUEUE.

-brokerCCSubQueue
The name of the queue from which non-durable subscription messages are retrieved for a ConnectionConsumer.

The default value is SYSTEM.JMS.ND.CC.SUBSCRIBER.QUEUE.

-brokerVersion
The value of this parameter determines the level of functionality required for publish/subscribe operations.

Valid values are 1 and 2.

The default value is 1.

-msgSelection
This parameter determines where message selection occurs.

Valid values are CLIENT and BROKER.

The default value is CLIENT.

-subStore
This parameter determines where WebSphere MQ messaging provider stores persistent data relating to active subscriptions.

Valid values are MIGRATE, QUEUE and BROKER.

The default value is MIGRATE.

-stateRefreshInt
The interval, in milliseconds, between refreshes of the long running transaction that detects when a subscriber loses its connection to the queue manager. This parameter is relevant only if **-subStore** parameter has the value QUEUE.

The value of this parameter must be a positive integer.

The default value is 60,000.

-cleanupLevel
The cleanup level for BROKER or MIGRATE subscription stores.

Valid values are SAFE, NONE, ASPROP, and STRONG.

The default value is SAFE.

-cleanupInterval
The interval between background executions of the publish/subscribe cleanup utility.

The value of this parameter must be a positive integer.

The default value is 3,600,000.

-wildcardFormat
This parameter determines which sets of characters are interpreted as topic wildcards.

Valid values are Topic or Char.

The default value is Char.

-sparseSubs
This parameter controls the message retrieval policy of a TopicSubscriber object.

The value of this parameter must be true or false

The default value is false.

-brokerQmgr
The name of the queue manager on which the broker is running.

-clonedSubs
This parameter determines whether two or more instances of the same durable topic subscriber can run simultaneously.

The value of this parameter must be ENABLED or DISABLED

The default value is DISABLED.

-qmgrSvrconnChannel
The SVRCONN channel to use when connecting to WebSphere MQ.

Use this parameter to create **explicitly defined** activation specifications.

The default value is SYSTEM.DEF.SVRCONN.

Do not specify this parameter in conjunction with the following parameters: **-ccdtUrl** or **-ccdtQmgrName**.

-brokerCCDurSubQueue
The name of the queue from which a connection consumer receives durable subscription messages.

The default value is SYSTEM.JMS.D.CC.SUBSCRIBER.QUEUE.

-maxPoolSize
The maximum number of server sessions in the server session pool used by the connection consumer.

The value of this parameter must be a positive integer.

The default value is 10.

-messageSelector
A message selector expression specifying which messages are to be delivered.

The value of this parameter must be either the empty string or a valid SQL 92 statement.

-poolTimeout
The period of time, in milliseconds, that an unused server session is held open in the server session pool before being closed due to inactivity.

The value of this parameter must be a positive integer.

The default value is 300,000.

-startTimeout
The period of time, in milliseconds, within which delivery of a message to an MDB must start after the work to deliver the message has been scheduled. If this period of time elapses, the message is rolled back onto the queue.

The value of this parameter must be a positive integer.

The default value is 10,000.

-subscriptionDurability
This parameter determines whether a durable or nondurable subscription is used to deliver messages to an MDB that is subscribing to the topic.

The value of this parameter must be Durable or Nondurable

The default value is Nondurable.

-subscriptionName
The name of the durable subscription.

-customProperties
This parameter specifies custom properties to be passed to the WebSphere MQ messaging provider activation specification implementation. Typically, custom properties are used to set attributes of the activation specification which are not directly supported through the WebSphere administration interfaces.

Each custom property is specified using name and value table step parameters. Since these are table steps, the order of the two parameters is fixed, so you must always specify the name first and the value second:
- In Jython: [*name value*]
- In Jacl: {*name value*}

For example, **-WAS_EndpointInitialState** is a custom property that can be used with the **-customProperties** parameter. The value of **-WAS_EndpointInitialState** must be ACTIVE or INACTIVE. **-WAS_EndpointInitialState** determines whether the endpoint is activated when the endpoint is registered. If the parameter is set to active, message consumption begins from the JMS destination as soon as the activation specification is used for a message-driven bean to connect with the destination.

This parameter should be ignored for subsequent activation or deactivation via the J2CMessageEndpoint MBean.

-localAddress
This parameter specifies either or both of the following:
- the local network interface
- the local port, or range of local ports

Do not specify this parameter in conjunction with the following parameters: **-ccdtUrl** or **-ccdtQmgrName**.

-sslType
This parameter determines the configuration, if any, to use when applying SSL encryption to the network connection to the queue manager.

The value of this parameter must be CENTRAL, SPECIFIC or NONE

The **-sslConfiguration** parameter is not valid unless this parameter is set to SPECIFIC.

The default value is NONE.

-sslConfiguration
The name of the SSL configuration to use when using SSL to secure network connections to the queue manager.

Do not specify this parameter unless the parameter **-sslType** is assigned the value SPECIFIC.

The value of this parameter must correspond to an SSL configuration.

There is no default value.

-stopEndpointIfDeliveryFails
This parameter indicates whether the endpoint should be stopped if message delivery fails the number of times specified by the **failureDeliveryCount** property.

The value of this parameter must be true or false.

The default value is true.

-failureDeliveryCount
This parameter specifies the number of sequential delivery failures that are allowed before the endpoint is suspended. This value is only used if **stopEndpointIfDeliveryFails** is true.

The value of this parameter must be a non-negative integer.

The default value is 0, which means that the endpoint is stopped the first time it fails.

Minimal activation specification definition

The following example creates an activation specification, specifying the minimum number of parameters. Due to the default values assumed for the unspecified parameters, MDBs deployed by using this activation specification are co-located with a generic queue manager installed on the same node.

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01")
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>AdminTask.createWMQActivationSpec("9994GKCNode01(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|node.xml#Node_1)", ["-name spec1 -jndiName jms/as/spec1
 -destinationJndiName jms/queues/q1 -destinationType javax.jms.Queue"])
spec1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098737234986)
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask createWMQActivationSpec
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
{-name spec1 -jndiName jms/as/spec1 -destinationJndiName jms/queues/q1
-destinationType javax.jms.Queue}
spec1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098737234986)
```

Explicit activation specification definition

The following example creates an activation specification for which the user must specify and maintain all the parameters used for establishing a connection to WebSphere MQ.

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01")
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>AdminTask.createWMQActivationSpec("9994GKCNode01(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|node.xml#Node_1)", ["-name spec2 -jndiName 'jms/as/spec2'
 -destinationJndiName 'jms/topics/t2' -destinationType javax.jms.Topic
 -description 'Must remember to keep each of these activation specifications in
 sync with the WebSphere MQ queue manager to which they refer' -qmgrName QM1
 -qmgrHostname 192.168.0.22 -qmgrPort 1415 -qmgrSvrconnChannel QM1.SVRCONN"])
spec2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098737234987)
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask createWMQActivationSpec
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
{-name spec2 -jndiName "jms/as/spec2" -destinationJndiName "jms/topics/t2"
-destinationType javax.jms.Topic -description "Must remember to keep each
of these activation specifications in sync with the WebSphere MQ queue manager
to which they refer" -qmgrName QM1 -qmgrHostname 192.168.0.22 -qmgrPort 1415
-qmgrSvrconnChannel QM1.SVRCONN}
spec2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098737234987)
```

Activation specification definition specifying a CCDT

The following example creates an activation specification that uses a CCDT to locate the queue manager to connect to.

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode019994GKCNode01(cells/
9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)")

wsadmin>AdminTask.createWMQActivationSpec("9994GKCNode01(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|node.xml#Node_1)", ["-name spec3 -jndiName 'jms/as/spec3'
 -destinationJndiName 'jms/queue/q3' -destinationType javax.jms.Queue
 -ccdtUrl 'http://gorillaaction:9080/ccdt/amqclchl.tab' -ccdtQmgrName QM3"])
spec3(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098737234988)
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask createWMQActivationSpec
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
{-name spec3 -jndiName "jms/as/spec3" -destinationJndiName "jms/queue/q3"
-destinationType javax.jms.Queue -ccdtUrl "http://gorillaaction:9080/ccdt/
amqclchl.tab" -ccdtQmgrName QM3}
spec3(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098737234988)
```

Creating an activation specification with the -WAS_EndpointInitialState custom property set to ACTIVE

- The following example creates an activation specification with the WAS_EndpointInitialState custom property activated, using Jython:

```
wsadmin>attrs = '[[name "WAS_EndpointInitialState"] [required "false"] [type "java.lang.String"] [value "ACTIVE"]]
wsadmin>AdminConfig.getid("/Node:myNode01")
myNode01(cells/myCell01/nodes/myNode01|node.xml#Node_1)'
```

```
wsadmin>theActSpec = AdminTask.createWMQActivationSpec("myNode01(cells/myCell01/nodes/myNode01|node.xml#Node_1)",
'-name testas -jndiName testas -destinationJndiName testq -destinationType javax.jms.Queue
-customProperties [[WAS_EndpointInitialState Active]]')
```

deleteWMQActivationSpec command

Use this command to delete a WebSphere MQ messaging provider activation specification at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the deleteWMQActivationSpec command to delete a WebSphere MQ messaging provider activation specification defined at the scope at which the command is issued.

Target object

A WebSphere MQ messaging provider activation specification at the specific scope.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01")
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>AdminTask.listWMQActivationSpecs("9994GKCNode01(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|node.xml#Node_1)")
unwantedSpec(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098737234986)
```

```
wsadmin>AdminTask.deleteWMQActivationSpec("unwantedSpec(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|resources.xml#J2CActivationSpec_1098737234986)")
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask listWMQActivationSpecs
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
unwantedSpec(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098737234986)

wsadmin>$AdminTask deleteWMQActivationSpec
unwantedSpec(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098737234986)
```

listWMQActivationSpecs command

Use the listWMQActivationSpecs command to list WebSphere MQ messaging provider activation specifications.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

Use the listWMQActivationSpecs command to list all of the WebSphere MQ messaging provider activation specifications defined at the scope at which the command is issued.

Target object

WebSphere MQ messaging provider activation specifications at the specific scope.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01")
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>AdminTask.listWMQActivationSpecs("9994GKCNode01(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|node.xml#Node_1)")
spec1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098737234986)
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask listWMQActivationSpecs
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
spec1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098737234986)
```

modifyWMQActivationSpec command

Use the modifyWMQActivationSpec command to change certain parameters of a WebSphere MQ messaging provider activation specification.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the modifyWMQActivationSpec command to modify a WebSphere MQ messaging provider activation specification defined at the scope at which the command is issued.

Note: You cannot change the type of an activation specification. For example, you cannot create an activation specification where you enter all the configuration information manually and then modify it to use a CCDT.

For a CCDT-based activation specification, you cannot modify of the following parameters:

- **qmgrName**
- **qmgrHostname**
- **qmgrPortNumber**
- **qmgrSrvconnChannel**

- **transportChain**
- **wmqTransportType**

For a generic activation specification, you cannot modify any of the following parameters:

- **ccdtUrl**
- **ccdtQmgrName**

Target object

A WebSphere MQ messaging provider activation specification at the specific scope.

Required parameters

The parameters for this command are identical to those used to create a WebSphere MQ messaging provider activation specification.

Optional parameters

The parameters for this command are identical to those used to create a WebSphere MQ messaging provider activation specification.

Note: If either the **-qmgrHostname** or **-qmgrPortNumber** parameters are specified without the **-connectionNameList** parameter being specified, then it is assumed that a connection name list should no longer be used to connect to WebSphere MQ and that the specified host name and port number information should be used instead. As a result of this the **-connectionNameList** parameter is set to blank.

Note the behavior of this command on the **-customProperties** parameter.

-customProperties

This parameter specifies custom properties to be passed to the WebSphere MQ messaging provider activation specification implementation. Typically, custom properties are used to set attributes of the activation specification which are not directly supported through the WebSphere administration interfaces.

Each custom property is specified using name and value table step parameters. Since these are table steps, the order of the two parameters is fixed, so you must always specify the name first and the value second:

- In Jython: [*name value*]
- In Jacl: {*name value*}

For example, **-WAS_EndpointInitialState** is a custom property that can be used with the **-customProperties** parameter. The value of **-WAS_EndpointInitialState** must be ACTIVE or INACTIVE. **-WAS_EndpointInitialState** determines whether the endpoint is activated when the endpoint is registered. If the parameter is set to active, message consumption begins from the JMS destination as soon as the activation specification is used for a message-driven bean to connect with the destination.

This parameter should be ignored for subsequent activation or deactivation via the J2CMessageEndpoint MBean.

New name/value pairs are added to the existing set of custom properties using the following rules:

- If the existing set of properties does not contain a property with the same name as that supplied as part of a modify command, the supplied property is added to the set of custom properties, unless the custom property has no value specified, when it is disregarded.

- If the existing set of properties contains a property with the same name as that supplied as part of a modify command, and the modify command also specifies a value for the property, the existing value is replaced by the supplied value.
- If the existing set of properties contains a property with the same name as that supplied as part of a modify command, but the modify command does not specify a value for the property, the property with the same name is deleted from the existing set of custom properties.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01")
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>AdminTask.listWMQActivationSpecs("9994GKCNode01(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|node.xml#Node_1)")
spec1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098737234986)

wsadmin>AdminTask.modifyWMQActivationSpec("spec1(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|resources.xml#J2CActivationSpec_1098737234986)",
["-destinationJndiName jms/topics/t5 -destinationType javax.jms.Topic"])
spec1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098737234986)
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask listWMQActivationSpecs
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
spec1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098737234986)

wsadmin>$AdminTask modifyWMQActivationSpec
spec1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098737234986)
{-destinationJndiName jms/topics/t5 -destinationType javax.jms.Topic}
spec1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098737234986)
```

- The following example modifies an activation specification by activating the WAS_EndpointInitialState custom property, using Jython:

```
wsadmin>AdminConfig.getid("/Node:myNode01")
'myNode01(cells/myCell01/nodes/myNode01|node.xml#Node_1)'
wsadmin>wsadmin>AdminTask.listWMQActivationSpecs("myNode01(cells/myCell01/nodes/myNode01|node.xml#Node_1)")
'newas(cells/myCell01/nodes/myNode01|resources.xml#J2CActivationSpec_1298546034140)'
wsadmin>AdminTask.modifyWMQActivationSpec("newas(cells/myCell01/nodes/myNode01|resources.xml
#J2CActivationSpec_1298546034140)", '-customProperties [[WAS_EndpointInitialState ACTIVE]]')
```

showWMQActivationSpec command

Use the showWMQActivationSpec command to display information about a specific WebSphere MQ messaging provider activation specification.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

Use the showWMQActivationSpec command to display all the parameters, and their values, associated with a particular WebSphere MQ messaging provider activation specification.

Target object

A WebSphere MQ messaging provider activation specification at the specific scope.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01")
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>AdminTask.listWMQActivationSpecs("9994GKCNode01(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|node.xml#Node_1)")
spec1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098737234986)

wsadmin>AdminTask.showWMQActivationSpec("spec1(cells/9994GKCNode01Cell/nodes/
9994GKCNode01|resources.xml#J2CActivationSpec_1098737234986)")
{cleanupLevel=SAFE, useConnectionPooling=true, port=1414, maxPoolDepth=10,
channel=channel1, transportType=CLIENT, subscriptionStore=MIGRATE,
messageSelection=CLIENT, cleanupInterval=3600000,
brokerCCSubQueue=SYSTEM.JMS.ND.CC.SUBSCRIBER.QUEUE, name=spec1, CCSID=819,
useJNDI=true, hostName=localhost, rescanInterval=5000, headerCompression=NONE,
brokerCCDurSubQueue=SYSTEM.JMS.D.CC.SUBSCRIBER.QUEUE, queueManager=QMGR1,
messageCompression=NONE, startTimeout=10000,  destinationJndiName=jms/q1,
poolTimeout=300000, sslType=NONE,
destinationType=javax.jms.Queue, brokerSubQueue=SYSTEM.JMS.ND.SUBSCRIBER.QUEUE,
sslResetCount=0, brokerControlQueue=SYSTEM.BROKER.CONTROL.QUEUE,
stateRefreshInt=60000, cloneSupport=DISABLED, jndiName=jms/as1,
sparseSubscriptions=false, authenticationAlias=null, failIfQuiesce=true,
description=, brokerVersion=1}
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
```

```
wsadmin>$AdminTask listWMQActivationSpecs
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
spec1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098737234986)

wsadmin>$AdminTask showWMQActivationSpec
spec1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
J2CActivationSpec_1098737234986)
{cleanupLevel=SAFE, useConnectionPooling=true, port=1414, maxPoolDepth=10,
channel=channel1, transportType=CLIENT, subscriptionStore=MIGRATE,
messageSelection=CLIENT, cleanupInterval=3600000,
brokerCCSubQueue=SYSTEM.JMS.ND.CC.SUBSCRIBER.QUEUE, name=spec1, CCSID=819,

```

createWMQConnectionFactory command

Use the createWMQConnectionFactory command to create a connection factory for the WebSphere MQ messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the createWMQConnectionFactory command to create a WebSphere MQ messaging provider connection factory at a specific scope.

You cannot create a WebSphere MQ messaging provider connection factory under either of the following conditions:

- A WebSphere MQ messaging provider connection factory already exists with the same name, at the same scope.
- The JNDI name clashes with another entry in WebSphere Application Server JNDI.

Target object

The scope of the WebSphere MQ messaging provider at which the WebSphere MQ messaging provider connection factory is to be created.

Required parameters

-name
The administrative name assigned to this WebSphere MQ messaging provider connection factory.

-jndiName
The name and location used to bind this object into WebSphere Application Server JNDI.

-type
Use this parameter to determine whether a unified connection factory, a queue connection factory or a topic connection factory is to be created.

Enter one of the following values:

- CF
- QCF
- TCF

CF is the default value.

If you specify QCF, you cannot specify any of the following parameters:

- **-brokerCtrlQueue**
- **-brokerSubQueue**
- **-brokerCCSubQueue**
- **-brokerVersion**
- **-brokerPubQueue**
- **-tempTopicPrefix**
- **-pubAckWindow**
- **-subStore**
- **-stateRefreshInt**
- **-cleanupLevel**
- **-sparesSubs**
- **-wildcardFormat**
- **-brokerQmgr**
- **-clonedSubs**
- **-msgSelection**

If you specify TCF, you cannot specify any of the following parameters:

- **-msgRetention**
- **-rescanInterval**
- **-tempQueuePrefix**
- **-modelQueue**
- **-replyWithRFH2**

Optional parameters

-description
An administrative description assigned to the connection factory.

-ccdtUrl
A URL to a client channel definition table to use, for this connection factory, when contacting WebSphere MQ.

Use this parameter to create a ccdtURL connection factory

Do not specify this parameter in conjunction with the following parameters: **-qmgrName**, **-qmgrHostname**, **-qmgrPortNumber**, **-qmgrSvrconnChannel**, **–wmqTransportType** or **-localAddress**.

-ccdtQmgrName
A queue manager name, used to select one or more entries from a client channel definition table.

Do not specify this parameter in conjunction with the following parameters: **-qmgrName**, **-qmgrHostname**, **-qmgrPortNumber**, **-qmgrSvrconnChannel**, **–wmqTransportType**, or **-localAddress**.

-qmgrName
The name of the queue manager to use, for this connection factory, when contacting WebSphere MQ.

Use this parameter to create a generic connection factory.

Do not specify this parameter in conjunction with the following parameters: **-ccdtUrl** or **-ccdtQmgrName**.

-wmqTransportType
This parameter determines the way in which a connection is established to WebSphere MQ for this connection factory.

Use this parameter to create a generic connection factory.

Enter one of the following values:

- BINDINGS
- BINDINGS_THEN_CLIENT
- CLIENT

The default value is BINDINGS_THEN_CLIENT.

Do not specify this parameter in conjunction with the following parameters: **-ccdtUrl** or **-ccdtQmgrName**.

For more information about configuring a transport type of BINDINGS_THEN_CLIENT or BINDINGS, refer to “Configuring the WebSphere MQ messaging provider with native libraries information” on page 723.

-qmgrHostname
The host name to use, for this connection factory, when attempting a client mode connection to WebSphere MQ. It must be a valid TCP/IP host name or IPv4 or IPv6 address.

The default value is the local host.

Do not specify this parameter in conjunction with the following parameters: **-ccdtUrl** or **-ccdtQmgrName**.

For information on setting the **-qmgrHostname** parameter in conjunction with the **-connectionNameList** parameter, see the description of the **-connectionNameList** parameter.

-qmgrPortNumber
The port number to use, for this connection factory, when attempting a client mode connection to WebSphere MQ.

Enter an integer value in the range 1 - 65536 (inclusive).

The default value is 1414.

Do not specify this parameter in conjunction with the following parameters: **-ccdtUrl** or **-ccdtQmgrName**.

For information on setting the **-qmgrPortNumber** parameter in conjunction with the **-connectionNameList** parameter, see the description of the **-connectionNameList** parameter.

-connectionNameList

The connection name list specifying the host name and port details to use when you want the connection factory to connect to a multi-instance queue manager.

Note: You must only use the **-connectionNameList** parameter to allow a connection to a multi-instance queue manager. Using the **-connectionNameList** parameter to connect to a non-multi-instance queue manager can jeopardize transaction integrity.

The **-connectionNameList** parameter must be entered as a comma separated list of host names and ports in the following format:

host(*port*),*host*(*port*)

For *host* enter a valid TCP/IP host name, IPv4 or IPv6 address.

For *port* enter an integer value between 1 and 65536 (inclusive). Specifying a value for *port* is optional. When you do not specify a value, *port* defaults to 1414.

For example: `localhost(1234),remotehost1(1234),remotehost2`

When you specify the **-connectionNameList** parameter, the **-qmgrHostname** and **-qmgrPortNumber** parameters are automatically set to the host name and port number of the first entry in the connection name list. This overrides any values that you previously specified in the **-qmgrHostname** and **-qmgrPortNumber** parameters.

In the preceding example this would mean that **-qmgrHostname** would be `localhost` and **-qmgrPortNumber** would be `1234`.

The **-connectionNameList** parameter is only valid for use in WebSphere Application Server Version 8.0. Attempting to specify the **-connectionNameList** parameter on a WebSphere MQ messaging provider connection factory which is defined at a server or node scope that is running on a version of WebSphere Application Server earlier than Version 8.0 results in an error message when you run the following commands:

- createWMQConnectionFactory
- modifyWMQConnectionFactory

If a WebSphere MQ messaging provider connection factory that is based on a connection name list is used by an application client or server that is running a version of WebSphere Application Server earlier than Version 8.0, the **-connectionNameList** information is not used. Instead, the values specified in the **-qmgrHostname** and **–qmgrPortNumber** are used, and are set to the relevant values from the first entry in the **connectionNameList** parameter.

You must not specify the **connectionNameList** parameter in conjunction with the **-ccdtUrl** or **-ccdtQmgrName** parameters.

Note: If you use the**-connectionNameList** parameter with a centrally managed SSL configuration, the host name and port number information used to select the appropriate SSL configuration is based on the first entry in the connection name list, regardless of which entry in the list is actually used to connect to the queue manager. This is because each instance of a multi-instance queue manager should be using the same SSL configuration, for a given server connection channel, regardless of which instance is actually running.

For more information on using multi-instance queue managers see the WebSphere MQ information center.

-containerAuthAlias
The container-managed authentication alias, defined to the cell, from which security credentials are used to establish a connection to WebSphere MQ.

-componentAuthAlias
The component-managed authentication alias, defined to the cell, from which security credentials are used to establish a connection to WebSphere MQ.

-clientId
The client identifier used for connections started by using this connection factory.

-providerVersion
This parameter determines the minimum version, and capabilities of the queue manager.

Enter values in one of the following formats:

- *n*
- *n.n*
- *n.n.n*
- *n.n.n.n*

where *n* is an integer greater than or equal to zero.

For example 6.0.0.0

-sslCrl
This parameter specifies a list of LDAP servers that are used to provide certificate revocation information if this connection factory establishes an SSL based connection to WebSphere MQ.

-sslResetCount
This parameter is used when the connection factory establishes an SSL connection to the queue manager. This parameter determines how many bytes to transfer before resetting the symmetric encryption key that is used for the SSL session.

Enter a value in the range 0 through 999,999,999.

The default value is 0.

-sslPeerName
This parameter is used when the connection factory establishes an SSL connection to the queue manager. The value is compared with the distinguished name present in the peer's certificate.

-rcvExit
A comma-separated list of receive exit class names.

-rcvExitInitData
Initialization data to pass to the receive exit.

Do not specify this parameter unless you specify the **-rcvExit** parameter.

-sendExit
A comma-separated list of send exit class names.

-sendExitInitData
Initialization data to pass to the send exit.

Do not specify this parameter unless you specify the **-sendExit** parameter.

-secExit
A security exit class name.

-secExitInitData
Initialization data to pass to the security exit.

Do not specify this parameter unless you specify the **-secExit** parameter.

-compressHeaders
This parameter determines if message headers are compressed.

Enter one of the following values:

- NONE
- SYSTEM

The default value is NONE.

-compressPayload
This parameter determines if message payloads are compressed.

Enter one of the following values:

- NONE
- RLE
- ZLIBFAST
- ZLIBHIGH

The default value is NONE.

-msgRetention
This parameter determines if the connection consumer keeps unwanted messages on the input queue.

Enter one of the following values:

- YES
- NO

where YES specifies that the connection consumer keeps unwanted messages on the input queue, and NO specifies that the messages are disposed of according to their disposition options.

The default value is YES.

-pollingInterval
This property is applicable in the client container only.

If each message listener within a session has no suitable message on its queue, this parameter is the maximum interval, in milliseconds, that elapses before each message listener tries again to get a message from its queue. If it frequently happens that no suitable message is available for any of the message listeners in a session, consider increasing the value of this parameter.
The default value is 5000.

-rescanInterval
When a message consumer in the point-to-point domain uses a message selector to select which messages it is to receive, the JMS client searches the WebSphere MQ queue for suitable messages in the sequence determined by the MsgDeliverySequence attribute of the queue. When the client finds a suitable message and delivers it to the consumer, the client resumes the search for the next suitable message from its current position in the queue. The client continues to search the queue in this way until it reaches the end of the queue, or until the interval of time in milliseconds, as determined by the value of this **-rescanInterval** parameter has expired. In each case, the client returns to the beginning of the queue to continue its search, and a new time interval commences

This parameter must be a positive integer value.

The default value is 5000.

-ccsid
The coded character set identifier (CCSID) to be used on connections.

The value of this parameter must be a positive integer. See the “WebSphere MQ messaging provider connection factory advanced properties” on page 772 for more details.

The default value is 819.

-failIfQuiescing
This parameter determines the behavior of certain calls to the queue manager when the queue manager is put into quiescing state.

The value of this parameter must be true or false.

true specifies that calls to certain methods fail if the queue manager is in a quiescing state. If an application detects that the queue manager is quiescing, the application can complete its immediate task and close the connection, allowing the queue manager to stop.

false specifies that no methods fail if the queue manager is in a quiescing state. If you specify this value, an application cannot detect that the queue manager is quiescing. The application might continue to perform operations against the queue manager, and therefore prevent the queue manager from stopping.

The default value is true.

-brokerCtrlQueue
The name of the broker control queue to use if this connection factory is to subscribe to a topic.

The default value is SYSTEM.BROKER.CONTROL.QUEUE.

-brokerSubQueue
The name of the queue to use for obtaining subscription messages if this connection factory is to subscribe to a topic.

The default value is SYSTEM.JMS.ND.SUBSCRIBER.QUEUE.

-brokerCCSubQueue
The name of the queue from which non-durable subscription messages are retrieved for a ConnectionConsumer.

The default value is SYSTEM.JMS.ND.CC.SUBSCRIBER.QUEUE.

-brokerVersion
The value of this parameter determines the level of functionality required for publish/subscribe operations.

Valid values are 1 and 2.

The default value is 1.

-msgSelection
This parameter determines where message selection occurs.

Valid values are CLIENT and BROKER.

The default value is CLIENT.

-subStore
This parameter determines where WebSphere MQ messaging provider stores persistent data relating to active subscriptions.

Valid values are MIGRATE, QUEUE and BROKER.

The default value is MIGRATE.

-stateRefreshInt
The interval, in milliseconds, between refreshes of the long running transaction that detects when a subscriber loses its connection to the queue manager. This parameter is relevant only if **-subStore** parameter has the value QUEUE.

The value of this parameter must be a positive integer.

The default value is 60,000.

-cleanupLevel
The cleanup level for BROKER or MIGRATE subscription stores

Valid values are SAFE, NONE, ASPROP, and STRONG.

The default value is SAFE.

-cleanupInterval
The interval between background executions of the publish/subscribe cleanup utility.

The value of this parameter must be a positive integer.

The default value is 3,600,000.

-wildcardFormat
This parameter determines which sets of characters are interpreted as topic wildcards.

Valid values are Topic or Char.

The default value is Topic.

-sparseSubs
This parameter controls the message retrieval policy of a TopicSubscriber object.

The value of this parameter must be true or false

The default value is false.

-brokerQmgr
The name of the queue manager that is running the broker, if it is not the same as the queue manager to which the connection factory connects.

There is no default value.

-clonedSubs
This parameter determines whether two or more instances of the same durable topic subscriber can run simultaneously

The value of this parameter must be ENABLED or DISABLED

The default value is DISABLED.

-customProperties
This parameter specifies custom properties to be passed to the WebSphere MQ messaging provider connection factory implementation. Typically, custom properties are used to set attributes of the connection factory that are not directly supported through the WebSphere administration interfaces.

Each custom property is specified using name and value table step parameters. Since these are table steps, the order of the two parameters is fixed, so you must always specify the name first and the value second:
- In Jython: [*name value*]
- In Jacl: {*name value*}

-qmgrSvrconnChannel
The SVRCONN channel to use when connecting to WebSphere MQ.

Use this parameter to create an **explicitly defined** connection factory.

The default value is SYSTEM.DEF.SVRCONN.

Do not specify this parameter in conjunction with the following parameters: **-ccdtUrl** or **-ccdtQmgrName**.

-support2PCProtocol
This parameter determines if the connection factory acts as a resource that is capable of participation in distributed two-phase commit processing.

The value of this parameter must be True or False.

The default value True specifies that the connection factory acts as a resource that is capable of participation in distributed two-phase commit processing.

-modelQueue
The name of the WebSphere MQ model queue whose definition is used as a basis when creating JMS temporary destinations.

The default value is SYSTEM.DEFAULT.MODEL.QUEUE.

-tempQueuePrefix
The prefix to apply to WebSphere MQ temporary queues that are used to represent JMS temporary queue type destinations.

There is no default value.

-tempTopicPrefix
The prefix to apply to the names generated for temporary topics. This parameter is only valid for connection factories or topic connection factories.

There is no default value.

-replyWithRFH2
This parameter determines whether, when sending a reply message to the reply-to queue obtained from a message that does not include an RFH version 2 header, a RFH version 2 header is included in the reply message.

The value of this parameter must be ALWAYS or AS_REPLY_DEST

The default value is AS_REPLY_DEST.

-brokerPubQueue
The name of the queue to which to send publication messages when using queue based brokering.

The default value is SYSTEM.BROKER.DEFAULT.STREAM.

-pubAckInterval
The number of publications to send to a queue based broker before sending a publication that solicits an acknowledgement.

The value of this parameter must be a positive integer greater than zero.

The default value is 25.

-sslType
This parameter determines the configuration, if any, to use when applying SSL encryption to the network connection to the queue manager.

The value of this parameter must be CENTRAL, SPECIFIC or NONE

The default value is NONE.

The **sslConfiguration** parameter is not valid unless this parameter is set to the value SPECIFIC.

-sslConfiguration
The name of the SSL configuration to use when using SSL to secure network connections to the queue manager.

The value of this parameter must correspond to an SSL configuration.

Do not specify this parameter unless the parameter **-sslType** is assigned the value SPECIFIC.

-localAddress
This parameter specifies either or both of the following:

- the local network interface
- the local port, or range of local ports

Do not specify this parameter in conjunction with the following parameters: **-ccdtUrl** or **-ccdtQmgrName**.

-mappingAlias
The JAAS mapping alias used when determining which security credentials to use when establishing a connection to WebSphere MQ.

The default value is DefaultPrincipleMapping.

-xaRecoveryAuthAlias
The authentication alias from which credentials are taken and used to connect to WebSphere MQ for XA recovery.

There is no default value.

Minimal connection factory definition

The following example creates an connection factory, specifying the minimum number of parameters. Due to the default values assumed for the unspecified parameters, applications using this connection factory expect to be co-located with a queue manager installed on the same node.

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask createWMQConnectionFactory
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
{-name cf1 -jndiName "jms/cf/cf1" -type CF}
cf1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQConnectionFactory_1205322636000)
```

Explicitly defined connection factory

The following example creates an connection factory for which the user must specify and maintain all the parameters used for establishing a connection to WebSphere MQ.

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01")
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>AdminTask.createWMQConnectionFactory("9994GKCNode01(cells/
9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)", ["-name cf2
 -jndiName 'jms/cf/cf2' -type CF -description 'Must remember to keep each
of these connection factories in sync with the WebSphere MQ queue manager
to which they refer' -qmgrName QM1 -qmgrHostname 192.168.0.22 -qmgrPort 1415
 -qmgrSvrconnChannel QM1.SVRCONN"])
cf2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQConnectionFactory_120532263601)
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask createWMQConnectionFactory
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
{-name cf2 -jndiName "jms/cf/cf2" -type CF -description "Must remember to
keep each of these connection factories in sync with the WebSphere MQ queue
manager to which they refer" -qmgrName QM1 -qmgrHostname 192.168.0.22
-qmgrPort 1415 -qmgrSvrconnChannel QM1.SVRCONN}
cf2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQConnectionFactory_120532263601)
```

Connection factory definition specifying a CCDT

The following example creates an connection factory that uses a CCDT to locate the queue manager to connect to.

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01")
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>AdminTask.createWMQConnectionFactory("9994GKCNode01(cells/
9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)", ["-name cf3 -jndiName
 'jms/cf/cf3' -type CF -ccdtUrl 'http://gorillaaction:9080/ccdt/amqclchl.tab'
 -ccdtQmgrName QM3"])
cf3(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQConnectionFactory_120532263606)
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask createWMQConnectionFactory
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
{-name cf3 -jndiName "jms/cf/cf3" -type CF -ccdtUrl
"http://gorillaaction:9080/ccdt/amqclchl.tab" -ccdtQmgrName QM3}
cf3(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQConnectionFactory_120532263606)
```

deleteWMQConnectionFactory command

Use the deleteWMQConnectionFactory command to delete a WebSphere MQ messaging provider connection factory at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the deleteWMQConnectionFactory command to delete a WebSphere MQ messaging provider connection factory defined at the scope at which the command is issued.

Target object

A WebSphere MQ messaging provider connection factory at the specific scope.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01")
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>AdminTask.listWMQConnectionFactories("9994GKCNode01(cells/
9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)")
unwantedCF(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQConnectionFactory_1098737234986)

wsadmin>AdminTask.deleteWMQConnectionFactory("unwantedCF(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|resources.xml#MQConnectionFactory_1098737234986)")
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask listWMQConnectionFactories
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
unwantedCF(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQConnectionFactory_1098737234986)

wsadmin>$AdminTask deleteWMQConnectionFactory
unwantedCF(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQConnectionFactory_1098737234986)
```

listWMQConnectionFactories command

Use the listWMQConnectionFactories command to list WebSphere MQ messaging provider connection factories.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

Use the listWMQConnectionFactories command to list all of the WebSphere MQ messaging provider connection factories defined at the scope at which the command is issued.

Target object

WebSphere MQ messaging provider connection factories at the specific scope.

Required parameters

None.

Optional parameters

-type
Use this parameter to determine which type of connection factory is listed. If it is omitted all connection factories are shown at the appropriate scope.

Valid values are:

- CF to list only common connection factories
- QCF to list only queue connection factories
- TCF to list only topic connection factories

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01")
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>AdminTask.listWMQConnectionFactories("9994GKCNode01(cells/
9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)")
cf2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQConnectionFactory_1098737234986)
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask listWMQConnectionFactories
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
cf2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQConnectionFactory_1098737234986)
```

modifyWMQConnectionFactory command

Use the modifyWMQConnectionFactory command to change certain parameters of a WebSphere MQ messaging provider connection factory.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the modifyWMQConnectionFactory command to modify a WebSphere MQ messaging provider connection factory defined at the scope at which the command is issued.

Note: When modifying a WebSphere MQ messaging provider connection factory, there is an interaction between the **mappingAlias** and **containerAuthAlias** parameters. This interaction occurs if the **containerAuthAlias** parameter is specified but the **mappingAlias** is not specified. In this situation, the **mappingAlias** parameter is automatically set to the value DefaultPrincipleMapping.

Target object

A WebSphere MQ messaging provider connection factory at the specific scope.

Required parameters

The parameters for this command are identical to those used to create a WebSphere MQ messaging provider connection factory.

Optional parameters

The parameters for this command are identical to those used to create a WebSphere MQ messaging provider connection factory.

Note: If either the **-qmgrHostname** or **-qmgrPortNumber** parameters are specified without the **-connectionNameList** parameter being specified, then it is assumed that a connection name list should no longer be used to connect to WebSphere MQ and that the specified host name and port number information should be used instead. As a result of this the **-connectionNameList** parameter is set to blank.

Note the behavior of this command on the **-customProperties** parameter.

-customProperties
This parameter specifies custom properties to be passed to the WebSphere MQ messaging provider connection factory implementation. Typically, custom properties are used to set attributes of the connection factory that are not directly supported through the WebSphere administration interfaces.

Each custom property is specified using name and value table step parameters. Since these are table steps, the order of the two parameters is fixed, so you must always specify the name first and the value second:
- In Jython: [*name value*]
- In Jacl: {*name value*}

New name/value pairs are added to the existing set of custom properties using the following rules:

- If the existing set of properties does not contain a property with the same name as that supplied as part of a modify command, the supplied property is added to the set of custom properties, unless the custom property has no value specified, when it is disregarded.
- If the existing set of properties contains a property with the same name as that supplied as part of a modify command, and the modify command also specifies a value for the property, the existing value is replaced by the supplied value.
- If the existing set of properties contains a property with the same name as that supplied as part of a modify command but the modify command does not specify a value for the property, the property with the same name is deleted from the existing set of custom properties.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01")
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>AdminTask.listWMQConnectionFactories("9994GKCNode01(cells/
9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)")
cf1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQConnectionFactory_1098737234986)

wsadmin>AdminTask.modifyWMQConnectionFactory("cf1(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|resources.xml#MQConnectionFactory_1098737234986)", ["-description
 'My new description'"])
cf1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQConnectionFactory_1098737234986)
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask listWMQConnectionFactories
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
cf1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQConnectionFactory_1098737234986)

wsadmin>$AdminTask modifyWMQConnectionFactory
cf1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQConnectionFactory_1098737234986) {-description "My new description"}
cf1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQConnectionFactory_1098737234986)
```

showWMQConnectionFactory command

Use the showWMQConnectionFactory command to display information about a specific WebSphere MQ messaging provider connection factory.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

Use the showWMQConnectionFactory command to display all the parameters, and their values, associated with a particular WebSphere MQ messaging provider connection factory.

Target object

A WebSphere MQ messaging provider connection factory at the specific scope.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01")
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>AdminTask.listWMQConnectionFactories("9994GKCNode01(cells/
9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)")
cf1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQConnectionFactory_1098737234986)

wsadmin>AdminTask.showWMQConnectionFactory("cf1(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|resources.xml#MQConnectionFactory_1098737234986)")

```

createWMQTopic command

Use the createWMQTopic command to create a JMS topic destination for the WebSphere MQ messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the createWMQTopic command to create a WebSphere MQ messaging provider topic type destination at a specific scope.

You cannot create a WebSphere MQ messaging provider topic type destination under either of the following conditions:

- A WebSphere MQ messaging provider topic type destination already exists with the same name, at the same scope.
- The JNDI name clashes with another entry in WebSphere Application Server JNDI.

Target object

The scope of the WebSphere MQ messaging provider at which the WebSphere MQ messaging provider topic type destination is to be created.

Required parameters

-name
The administrative name assigned to this WebSphere MQ messaging provider topic type destination.

-jndiName
The name used to bind this object into WebSphere Application Server JNDI.

-topicName
The name of the WebSphere MQ topic where publications are received from, or sent to, when this destination definition is used.

Optional parameters

-description
An administrative description assigned to the topic type destination.

-persistence
This parameter determines the level of persistence used to store messages sent to this destination.

Enter one of the following case-sensitive values:

- APP
- TDEF
- PERS
- NON
- HIGHT

APP is the default value.

-priority
The priority level to assign to messages sent to this destination.

Enter one of the following case-sensitive values:

- APP
- TDEF

or enter a positive integer in the range 0 to 9 (inclusive).

The default value is APP .

-expiry
The length of time after which messages that are sent to this destination expire and are dealt with according to their disposition options.

Enter one of the following case-sensitive values:

- APP
- UNLIM

or enter any positive integer.

The default value is APP.

-ccsid
The coded character set identifier (CCSID).

The value of this parameter must be a positive integer or blank. See the “WebSphere MQ messaging provider queue and topic advanced properties settings” on page 844 for more details.

The default value is 1208.

Leaving this field empty indicates that the default value must be used.

-useNativeEncoding
This parameter specifies whether to use native encoding or not. It can take a value true or false.

If it is set to true, the values of the **-integerEncoding**, **-decimalEncoding** and **-floatingPointEncoding** attributes are ignored.

If it is set to false, the encoding is specified by the **-integerEncoding**, **-decimalEncoding** and **-floatingPointEncoding** attributes.

-integerEncoding
The integer encoding setting for this queue.

Enter one of the following case-sensitive values: Normal, Reversed.

Normal is the default value.

-decimalEncoding
The decimal encoding setting for this queue.

Enter one of the following case-sensitive values: Normal, Reversed.

The default value is Normal.

-floatingPointEncoding
The floating point encoding setting for this queue.

Enter one of the following case-sensitive values: IEEENormal, IEEEReversed, z/OS

The default value is IEEENormal.

-useRFH2
This parameter determines whether an RFH version 2 header is appended to messages sent to this destination.

Enter one of the following case-sensitive values: true or false.

The default value is true.

-sendAsync
This parameter determines whether messages can be sent to this destination without queue manager acknowledging that they have arrived.

Enter one of the following case-sensitive values: YES, NO or TDEF.

The default value is YES.

-readAhead
This parameter determines whether messages for non-persistent consumers can be read ahead and cached.

Enter one of the following case-sensitive values: YES, NO or TDEF.

The default value is YES.

-readAheadClose
This property determines the behavior that occurs when closing a message consumer that is receiving messages asynchronously by using a message listener from a destination that has the **readAhead** parameter set to True.

When a value of deliverAll is specified, all read-ahead messages are delivered before closing the consumer.

When a value of deliverCurrent is specified, only in-progress messages are delivered before closing the consumer.

The default value is deliverCurrent.

-wildcardFormat
This parameter determines which sets of characters are interpreted as topic wildcards.

Valid values are Topic or Char.

The default value is Topic.

-brokerDurSubQueue
The name of the queue, defined to the queue manager, from which a connection consumer receives non-durable subscription messages.

The value of this parameter must be a valid queue name or left blank

The default value is SYSTEM.JMS.D.SUBSCRIBER.QUEUE.

-brokerCCDurSubQueue
The name of the queue, defined to the queue manager, from which a connection consumer receives durable subscription messages.

The value of this parameter must be a valid queue name or left blank

The default value is SYSTEM.JMS.D.CC.SUBSCRIBER.QUEUE.

-brokerPubQueue
The name of the queue, defined to the queue manager, to which publication messages are sent.

The value of this parameter must be a valid queue name or left blank

The default value is SYSTEM.BROKER.DEFAULT.STREAM.

-brokerPubQmgr
The name of the queue manager on which the broker is running.

The value of this parameter must be a valid queue manager name or left blank

There is no default value.

-brokerVersion
This parameter determines the level of functionality required for publish/subscribe operations.

The value of this parameter must be V1 or V2.

The default value is V1.

-customProperties
This parameter specifies custom properties to be passed to the WebSphere MQ messaging provider topic type destination implementation. Typically, custom properties are used to set attributes of the topic type destination that are not directly supported through the WebSphere administration interfaces.

Each custom property is specified using name and value table step parameters. Since these are table steps, the order of the two parameters is fixed, so you must always specify the name first and the value second:
- In Jython: [*name value*]
- In Jacl: {*name value*}

The following example creates a topic definition by specifying the minimum number of parameters.

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01")
 9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>AdminTask.createWMQTopic("9994GKCNode01(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|node.xml#Node_1)", ["-name T1 -jndiName jms/topic/t1
 -topicName woodland/creatures/badger"])
T1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQTopic_1098737234986)
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
 9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask createWMQTopic
```

```
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
{-name T1 -jndiName jms/topic/t1 -topicName woodland/creatures/badger}
T1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQTopic_1098737234986)
```

deleteWMQTopic command

Use this command to delete a WebSphere MQ messaging provider topic at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the deleteWMQTopic command to delete a WebSphere MQ messaging provider topic defined at the scope at which the command is issued.

Target object

A WebSphere MQ messaging provider topic at the specific scope.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01")
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>AdminTask.listWMQTopics("9994GKCNode01(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|node.xml#Node_1)")
unwantedTopic(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQTopic_1098737234986)
```

```
wsadmin>$AdminTask deleteWMQTopic
unwantedTopic(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQTopic_1098737234986)
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask listWMQTopics
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
unwantedTopic(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQTopic_1098737234986)

wsadmin>$AdminTask deleteWMQTopic
unwantedTopic(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQTopic_1098737234986)
```

listWMQTopics command

Use the listWMQTopics command to list WebSphere MQ messaging provider topics.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

Use the listWMQTopics command to list all of the WebSphere MQ messaging provider topics defined at the scope at which the command is issued.

Target object

WebSphere MQ messaging provider topics at the specific scope.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01")
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>AdminTask.listWMQTopics("9994GKCNode01(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|node.xml#Node_1)")
aaaTopic(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQTopic_1098737234986)
bbbTopic(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQTopic_1098737234987)
cccTopic(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQTopic_1098737234988)
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask listWMQTopics
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
aaaTopic(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQTopic_1098737234986)
bbbTopic(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQTopic_1098737234987)
cccTopic(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQTopic_1098737234988)
```

modifyWMQTopic command

Use the modifyWMQTopic command to change certain parameters of a WebSphere MQ messaging provider topic.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the modifyWMQTopic command to modify a WebSphere MQ messaging provider topic defined at the scope at which the command is issued.

Note: You cannot change the name of an topic.

Target object

A WebSphere MQ messaging provider topic at the specific scope.

Required parameters

The parameters for this command are identical to those used to create a WebSphere MQ messaging provider topic.

Optional parameters

The parameters for this command are identical to those used to create a WebSphere MQ messaging provider topic.

Note the behavior of this command on the **-customProperties** parameter.

-customProperties
This parameter specifies custom properties to be passed to the WebSphere MQ messaging provider topic implementation. Typically, custom properties are used to set attributes of the topic that are not directly supported through the WebSphere administration interfaces.

Each custom property is specified using name and value table step parameters. Since these are table steps, the order of the two parameters is fixed, so you must always specify the name first and the value second:
- In Jython: [*name value*]
- In Jacl: {*name value*}

New name/value pairs are added to the existing set of custom properties using the following rules:
- If the existing set of properties does not contain a property with the same name as that supplied as part of a modify command, the supplied property is added to the set of custom properties, unless the custom property has no value specified, when it is disregarded.
- If the existing set of properties contains a property with the same name as that supplied as part of a modify command, and the modify command also specifies a value for the property, the existing value is replaced by the supplied value.
- If the existing set of properties contains a property with the same name as that supplied as part of a modify command, but the modify command does not specify a value for the property, the property with the same name is deleted from the existing set of custom properties.

Example

- Using Jython:

```
wsadmin>AdminTask.modifyWMQTopic("t1(cells/L3A3316Node04Cell/
nodes/L3A3316Node05|resources.xml#MQTopic_1204538835312)", ["-priority 7"])
t1(cells/L3A3316Node04Cell/nodes/L3A3316Node05|resources.xml#
MQTopic_1204538835312)
```

- Using Jacl:

```
wsadmin>$AdminTask modifyWMQTopic
t1(cells/L3A3316Node04Cell/nodes/L3A3316Node05|resources.xml#
MQTopic_1204538835312) {-priority 7}
t1(cells/L3A3316Node04Cell/nodes/L3A3316Node05|resources.xml#
MQTopic_1204538835312)
```

showWMQTopic command

Use the showWMQTopic command to display information about a specific WebSphere MQ messaging provider topic.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

Use the showWMQTopic command to display all the parameters, and their values, associated with a particular WebSphere MQ messaging provider topic.

Target object

A WebSphere MQ messaging provider topic at the specific scope.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01")
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>AdminTask.listWMQTopics("9994GKCNode01(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|node.xml#Node_1)")
topic1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQTopic_1098737234986)

wsadmin>AdminTask.showWMQTopic("topic1(cells/9994GKCNode01Cell/nodes/
9994GKCNode01|resources.xml#MQTopic_1098737234986)")
{specifiedExpiry=0, priority=APPLICATION_DEFINED, decimalEncoding=Normal,
baseTopicName=topic1, name=topic1, readAhead=NO, brokerPubQmgr=null,
readAheadClose=DELIVERCURRENT, brokerPubQueue=SYSTEM.BROKER.DEFAULT.STREAM,
ccsid=1208, integerEncoding=Normal, useNativeEncoding=true,
wildcardFormat=charWildcards, expiry=APP, specifiedPriority=0,
jndiName=jms/t1, sendAsync=NO,
brokerDurSubQueue=SYSTEM.JMS.D.SUBSCRIBER.QUEUE, brokerCCDurSubQueue=null,
description=null, targetClient=JMS, floatingPointEncoding=IEEENormal,
persistence=APP, brokerVersion=V1}
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask listWMQTopics
```

```
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
topic1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQTopic_1098737234986)

wsadmin>$AdminTask showWMQTopic
topic1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQTopic_1098737234986)
{specifiedExpiry=0, priority=APPLICATION_DEFINED, decimalEncoding=Normal,
baseTopicName=topic1, name=topic1, readAhead=NO, brokerPubQmgr=null,
readAheadClose=DELIVERCURRENT, brokerPubQueue=SYSTEM.BROKER.DEFAULT.STREAM,
ccsid=1208, integerEncoding=Normal, useNativeEncoding=true,
wildcardFormat=charWildcards, expiry=APP, specifiedPriority=0,
jndiName=jms/t1, sendAsync=NO,
brokerDurSubQueue=SYSTEM.JMS.D.SUBSCRIBER.QUEUE, brokerCCDurSubQueue=null,
description=null, targetClient=JMS, floatingPointEncoding=IEEENormal,
persistence=APP, brokerVersion=V1}
```

manageWMQ command

Use the manageWMQ command to manage the settings of the WebSphere MQ resource adapter that is installed at a particular scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the manageWMQ command to manage the settings associated with the WebSphere MQ resource adapter that is installed at a particular scope.

You can use the manageWMQ command to manage the native library path and query the metadata of the specified WebSphere MQ resource adapter.

Target object

A WebSphere MQ resource adapter.

Required parameters

None.

Optional parameters

-nativePath
This parameter specifies the path to the WebSphere MQ messaging provider native libraries that are used by the WebSphere MQ resource adapter to establish a bindings mode connection to the queue manager. This parameter can be specified on a WebSphere MQ adapter at any scope.

-query
This parameter provides information about the level of WebSphere MQ resource adapter that is used by the WebSphere MQ messaging provider. This parameter can be specified on a WebSphere MQ resource adapter at any scope.

-disableWMQ
This parameter specifies whether or not to disable WebSphere MQ functionality at the scope of the specified resource adapter, and at all scopes beneath it.

The value of this parameter must be true or false.

The default value is false.

In a single server environment this parameter is valid only at the server scope. In a network deployment environment this parameter is valid at all scopes. The affect of setting this parameter to true depends on the scope at which you set it:

- For a cell scoped WebSphere MQ resource adapter, all WebSphere MQ functionality on all application servers in the cell is disabled.
- For a node scoped WebSphere MQ resource adapter, all WebSphere MQ functionality on all application servers that are part of that node is disabled.
- For a cluster scoped WebSphere MQ resource adapter, all WebSphere MQ functionality on all application servers in that cluster are disabled.
- For a server scoped WebSphere MQ resource adapter, all WebSphere MQ functionality in that particular application server is disabled.

In all cases, all affected processes must be restarted for the changes to take effect.

The value of the parameter at a higher scope takes precedence over the value at a lower scope. For example, if you set the parameter to false at the server scope but a higher (for example, cell) scoped WebSphere MQ messaging provider has the parameter set to true, the value at the cell scope takes precedence and WebSphere MQ functionality is therefore disabled in all application servers in the cell, regardless of the parameter value at the server scope.

-maxConnections
This parameter specifies the maximum number of connections to a WebSphere MQ queue manager.

The default value is 10.

For further information, see Configuration of the ResourceAdapter object in the WebSphere MQ information center.

-connectionConcurrency
This parameter specifies the maximum number of message-driven beans that can be supplied by each connection.

The default value is 5.

For further information, see Configuration of the ResourceAdapter object in the WebSphere MQ information center.

-reconnectionRetryCount
This parameter specifies the maximum number of attempts made by a WebSphere MQ messaging provider activation specification to reconnect to a WebSphere MQ queue manager if a connection fails.

The default value is 5.

For further information, see Configuration of the ResourceAdapter object in the WebSphere MQ information center.

-reconnectionRetryInterval
This parameter specifies the time, in milliseconds, that a WebSphere MQ messaging provider activation specification waits before making another attempt to reconnect to a WebSphere MQ queue manager.

The default value is 300000.

For further information, see Configuration of the ResourceAdapter object in the WebSphere MQ information center.

-customProperties
This parameter specifies custom properties to be passed to the WebSphere MQ resource adapter. Typically, custom properties are used to set attributes of the WebSphere MQ resource adapter that are not directly supported through the WebSphere Application Server administration interfaces.

Each custom property is specified using name and value table step parameters. Since these are table steps, the order of the two parameters is fixed, so you must always specify the name first and the value second:
- In Jython: [*name value*]
- In Jacl: {*name value*}

New name/value pairs are added to the existing set of custom properties using the following rules:
- If the existing set of properties does not contain a property with the same name as that which is supplied, the supplied property is added to the set of custom properties, unless the custom property has no value specified, when it is disregarded.
- If the existing set of properties contains a property with the same name as that supplied as part of a modify command, and the modify command also specifies a value for the property, the existing value is replaced by the supplied value.
- If the existing set of properties contains a property with the same name as that supplied as part of a modify command, but the modify command does not specify a value for the property, the property with the same name is deleted from the existing set of custom properties.

Examples

The following example shows how to enable inbound JCA message delivery on the z/OS platform.

- Using Jython:

```
wsadmin>AdminTask.manageWMQ("WebSphere MQ Resource Adapter
(cells/L3A3316Node04Cell/nodes/L3A3316Node05/servers/server1|resources.xml#
J2CResourceAdapter_1201601803796)", ["-enableInbound true"])
```

- Using Jacl:

```
wsadmin>$AdminTask manageWMQ "WebSphere MQ Resource Adapter
(cells/L3A3316Node04Cell/nodes/L3A3316Node05/servers/server1|resources.xml#
J2CResourceAdapter_1201601803796)" {-enableInbound true}
```

The following example sets the value of **-maxConnections** to 100 and adds a custom property with name `name1` and value `value1`.

- Using Jython:

```
AdminTask.manageWMQ("WebSphere MQ Resource Adapter(
cells/L3A3316Node01Cell|resources.xml#J2CResourceAdapter_1284547647859)",
["-maxConnections 100 -customProperties [[name1 value1]]"])
```

- Using Jacl:

```
wsadmin>$AdminTask manageWMQ "WebSphere MQ Resource Adapter(
cells/L3A3316Node01Cell|resources.xml#J2CResourceAdapter_1284547647859)"
{-maxConnections 100 -customProperties {{name1 value1}}}
```

showWMQ command

Use the showWMQ command to show the settings which can be set by the manageWMQ command.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the showWMQ command to display all the parameters, and their values that can be set by the manageWMQ command. These settings are either related to the WebSphere MQ resource adapter or the WebSphere MQ messaging provider. The command also shows custom properties which are set on the WebSphere MQ resource adapter.

The following settings are expected:

- maxConnections
- connectionConcurrency
- reconnectionRetryCount
- reconnectionRetryInterval
- nativePath
- enableInbound
- disableWMQ (this parameter is only visible when setting it is valid, see the description of the manageWMQ command for more information)

For a description of these settings, see “manageWMQ command” on page 913.

Any other setting that is shown is either a custom property or a property that is not appropriate in WebSphere Application Server.

Target object

A WebSphere MQ resource adapter.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminTask.showWMQ("WebSphere MQ Resource Adapter
(cells/L3A3316Node01Cell|resources.xml#J2CResourceAdapter_1284547647859)")
'{name1=value1, logWriterEnabled=true, maxConnections=100, startupReconnectionRetryCount=500,
connectionConcurrency=123, reconnectionRetryCount=3, traceEnabled=false,
reconnectionRetryInterval=4, nativePath=[], startupReconnectionRetryInterval=600, traceLevel=3}'
```

- Using Jacl:

```
wsadmin>$AdminTask showWMQ "WebSphere MQ Resource Adapter(
cells/L3A3316Node01Cell|resources.xml#J2CResourceAdapter_1284547647859)"
{name1=value1, logWriterEnabled=true, maxConnections=100, startupReconnectionRetryCount=500,
connectionConcurrency=123, reconnectionRetryCount=3, traceEnabled=false,
reconnectionRetryInterval=4, nativePath=[], startupReconnectionRetryInterval=600, traceLevel=3}
```

migrateWMQMLP command

Use the migrateWMQMLP command to migrate a WebSphere MQ message listener port definition to an activation specification definition.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the migrateWMQMLP command to migrate a WebSphere MQ message listener port definition to an activation specification definition. After the activation specification has been created, you can delete the listener port.

Note that the **Maximum retries** listener port setting is not migrated to the new activation specification as there is no exact equivalent.

When you are migrating a listener port associated with a message-driven bean (MDB) that has the subscriptionDurability activation configuration property set to Durable, and that MDB already has an active durable subscription, the durable subscription is not migrated. This is because listener ports and WebSphere MQ activation specifications use incompatible forms of subscription name. As a result there can be two active durable subscriptions subscribed to the relevant topic for the same MDB. As part of the migration process, you must delete the old durable subscription that was associated with the listener port and manually clean up any messages associated with it. For information on how do to this see the WebSphere MQ and WebSphere Message Broker information centres.

Target object

The message listener port to be migrated.

Required parameters

-asName
The name of the activation specification to be created.

-asJNDIName
The JNDI name of the activation specification to be created.

-asScope
The type of scope at which to create the activation specification (server, node, cluster or cell). Note that the cluster option is only supported when the server that contains the message listener port is part of a cluster. If not specified this defaults to server. The scopes specified are relative to the message listener port, so node is the node of the server that contains the message listener port.

Optional parameters

None.

The following example shows how to migrate a message listener port to an activation specification.

- Using Jython:

```
wsadmin>AdminConfig.list("ListenerPort")
lp1(cells/L3A3316Node09Cell/nodes/L3A3316Node10/servers/server1|
server.xml#ListenerPort_1211265363796)

wsadmin>AdminTask.migrateWMQMLP("lp1(cells/L3A3316Node09Cell/nodes/
L3A3316Node10/servers/server1|server.xml#ListenerPort_1211265363796)",
 ["-asName migratedFromLP -asJNDIName jms/as1 -asScope node"])
migratedFromLP(cells/L3A3316Node09Cell/nodes/L3A3316Node10|
resources.xml#J2CActivationSpec_1211265679078)
```

- Using Jacl:

```
wsadmin>$AdminConfig list ListenerPort
lp1(cells/L3A3316Node09Cell/nodes/L3A3316Node10/servers/server1|
server.xml#ListenerPort_1211265363796)

wsadmin>$AdminTask migrateWMQMLP
lp1(cells/L3A3316Node09Cell/nodes/L3A3316Node10/servers/server1|
```

```
server.xml#ListenerPort_1211265363796)
{-asName migratedFromLP -asJNDIName jms/as1 -asScope node}
migratedFromLP(cells/L3A3316Node09Cell/nodes/L3A3316Node10|
resources.xml#J2CActivationSpec_1211265679078)
```

createWMQQueue command

Use the createWMQQueue command to create a queue type destination for the WebSphere MQ messaging provider at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the createWMQQueue command to create a WebSphere MQ messaging provider queue type destination at a specific scope.

You cannot create a WebSphere MQ messaging provider queue type destination under either of the following conditions:

- A WebSphere MQ messaging provider queue type destination already exists with the same name, at the same scope.
- The JNDI name clashes with another entry in WebSphere Application Server JNDI.

Target object

The scope of the WebSphere MQ messaging provider at which the WebSphere MQ messaging provider queue type destination is to be created.

Required parameters

-name
The administrative name assigned to this WebSphere MQ messaging provider queue type destination.

-jndiName
The name used to bind this object into WebSphere Application Server JNDI.

Optional parameters

-description
An administrative description assigned to the queue type destination.

-queueName
The name of the WebSphere MQ queue to use to store messages for the WebSphere MQ messaging provider queue type destination definition.

-qmgr
The queue manager that hosts the WebSphere MQ queue.

-persistence
This parameter determines the level of persistence used to store messages sent to this destination.

Enter one of the following case-sensitive values:

- APP
- QDEF
- PERS
- NON
- HIGH

The default value is APP.

-priority
The priority level to assign to messages sent to this destination.

Enter one of the following case-sensitive values:

- APP
- QDEF

or enter a positive integer in the range 0 to 9 (inclusive).

The default value is APP.

-expiry
The length of time after which messages sent to this destination expire and are dealt with according to their disposition options.

Enter one of the following case-sensitive values:

- APP
- UNLIM

or enter any positive integer.

The default value is APP.

-ccsid
The coded character set identifier (CCSID).

The value of this parameter must be a positive integer or blank. See the “WebSphere MQ messaging provider queue and topic advanced properties settings” on page 844 for more details.

The default value is 1208.

Leaving this field empty indicates that the default value must be used.

-useNativeEncoding
This parameter specifies whether to use native encoding or not. It can take a value true or false.

If it is set to true, the values of the **-integerEncoding**, **-decimalEncoding** and **-floatingPointEncoding** attributes are ignored.

If it is set to false, the encoding is specified by the **-integerEncoding**, **-decimalEncoding** and **-floatingPointEncoding** attributes.

-integerEncoding
The integer encoding setting for this queue.

Enter one of the following case-sensitive values: Normal or Reversed.

The default value is Normal.

-decimalEncoding
The decimal encoding setting for this queue.

Enter one of the following case-sensitive values: Normal or Reversed.

The default value is Normal.

-floatingPointEncoding
The floating point encoding setting for this queue.

Enter one of the following case-sensitive values: IEEENormal, IEEEReversed, z/OS

The default value is IEEENormal.

-useRFH2
This parameter determines whether an RFH version 2 header is appended to messages sent to this destination.

Enter one of the following case-sensitive values: true or false.

The default value is true.

-sendAsync
This parameter determines whether messages can be sent to this destination without queue manager acknowledging that they have arrived.

Enter one of the following case-sensitive values: YES, NO or QDEF.

The default value is YES.

-readAhead
This parameter determines whether messages for non-persistent consumers can be read ahead and cached.

Enter one of the following case-sensitive values: YES, NO or QDEF.

The default value is YES.

-readAheadClose

Enter one of the following case-sensitive values: YES, NO or QDEF.

The default value is YES.

-customProperties
This parameter specifies custom properties to be passed to the WebSphere MQ messaging provider queue type destination implementation. Typically, custom properties are used to set attributes of the queue type destination that are not directly supported through the WebSphere administration interfaces.

Each custom property is specified using name and value table step parameters. Since these are table steps, the order of the two parameters is fixed, so you must always specify the name first and the value second:
- In Jython: [*name value*]
- In Jacl: {*name value*}

The following example creates a WebSphere MQ messaging provider queue type destination.

- Using Jython:

```
wsadmin>AdminTask.createWMQQueue("9994GKCNode01(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|node.xml#Node_1)", ["-name queue1 -jndiName jms/queues/Q1
 -queueName APP1.QUEUE1"])
queue1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQQueue_1098737234986)
```

- Using Jacl:

```
wsadmin>$AdminTask createWMQQueue
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
{-name queue1 -jndiName jms/queues/Q1 -queueName APP1.QUEUE1}
queue1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQQueue_1098737234986)
```

deleteWMQQueue command

Use this command to delete a WebSphere MQ messaging provider queue type destination at a specific scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the deleteWMQQueue command to delete a WebSphere MQ messaging provider queue type destination defined at the scope at which the command is issued.

Note: The WebSphere MQ messaging provider queue type destination definition is deleted from WebSphere Application Server JNDI at the specific scope. Any messages present on the underlying WebSphere MQ queue are not affected.

Target object

A WebSphere MQ messaging provider queue type destination at the specific scope.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01")
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>AdminTask.listWMQQueues("9994GKCNode01(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|node.xml#Node_1)")
unwantedQueue(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQQueue_1098737234986)

wsadmin>AdminTask.deleteWMQQueue("unwantedQueue(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|resources.xml#MQQueue_1098737234986)")
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask listWMQQueues
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
unwantedQueue(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQQueue_1098737234986)

wsadmin>$AdminTask deleteWMQQueue
unwantedQueue(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQQueue_1098737234986)
```

listWMQQueues command

Use the listWMQQueues command to list WebSphere MQ messaging provider queue type destinations.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

Use the listWMQQueues command to list all of the WebSphere MQ messaging provider queue type destinations defined at the scope at which the command is issued.

Target object

WebSphere MQ messaging provider queue type destinations at the specific scope.

Required parameters

None.

Optional parameters

-type
If this parameter it is omitted all connection factories are shown at the appropriate scope.

Enter one of the following case-sensitive values: CF, QCF or TCF.Enter CF to list only common connection factories, QCF to list only queue connection factories or **TCF** to list only topic connection factories.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01")
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>AdminTask.listWMQQueues("9994GKCNode01(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|node.xml#Node_1)")
jmsq2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask listWMQQueues
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
jmsq2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.
```

modifyWMQQueue command

Use the modifyWMQQueue command to change certain parameters of a WebSphere MQ messaging provider queue type destination.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

After using the command, save your changes to the master configuration. For example, use the following command:

```
AdminConfig.save()
```

Purpose

Use the modifyWMQQueue command to modify a WebSphere MQ messaging provider queue type destination defined at the scope at which the command is issued.

Target object

A WebSphere MQ messaging provider queue type destination at the specific scope.

Required parameters

The parameters for this command are identical to those used to create a WebSphere MQ messaging provider queue type destination.

Optional parameters

The parameters for this command are identical to those used to create a WebSphere MQ messaging provider queue type destination.

Note the behavior of this command on the **-customProperties** parameter.

-customProperties

This parameter specifies custom properties to be passed to the WebSphere MQ messaging provider queue type destination implementation. Typically, custom properties are used to set attributes of the queue type destination which are not directly supported through the WebSphere administration interfaces.

Each custom property is specified using name and value table step parameters. Since these are table steps, the order of the two parameters is fixed, so you must always specify the name first and the value second:

- In Jython: [*name value*]
- In Jacl: {*name value*}

New name/value pairs are added to the existing set of custom properties using the following rules:

- If the existing set of properties does not contain a property with the same name as that supplied as part of a modify command, the supplied property is added to the set of custom properties, unless the custom property has no value specified, when it is disregarded.
- If the existing set of properties contains a property with the same name as that supplied as part of a modify command, and the modify command also specifies a value for the property, the existing value is replaced by the supplied value.
- If the existing set of properties contains a property with the same name as that supplied as part of a modify command, but the modify command does not specify a value for the property, the property with the same name is deleted from the existing set of custom properties.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01")
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>AdminTask.listWMQQueues("9994GKCNode01(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|node.xml#Node_1)")
jmsq2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQQueue_1098737234986)

wsadmin>AdminTask.modifyWMQQueue("jmsq2(cells/9994GKCNode01Cell/nodes/
9994GKCNode01|resources.xml#
MQQueue_1098737234986)", ["-ccsid 500"])
jmsq2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask listWMQQueues
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
jmsq2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQQueue_1098737234986)

wsadmin>$AdminTask modifyWMQQueue
jmsq2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQQueue_1098737234986) {-ccsid 500}
jmsq2(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.
```

showWMQQueue command

Use the showWMQQueue command to display information about a specific WebSphere MQ messaging provider queue type destination.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see the topic “Configure Qshell to run WebSphere Application Server scripts”.

This command is valid only when it is used with WebSphere Application Server Version 7 and later application servers. Do not use it with earlier versions.

For a list of the available WebSphere MQ messaging provider administrative commands, plus a brief description of each command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('WMQAdminCommands')
```

For overview help on a given command, enter the following command at the wsadmin prompt:

```
print AdminTask.help('command_name')
```

Purpose

Use the showWMQQueue command to display all the parameters, and their values, associated with a particular WebSphere MQ messaging provider queue type destination.

Target object

A WebSphere MQ messaging provider queue type destination at the specific scope.

Required parameters

None.

Optional parameters

None.

Example

- Using Jython:

```
wsadmin>AdminConfig.getid("/Node:9994GKCNode01")
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
```

```
wsadmin>AdminTask.listWMQQueues("9994GKCNode01(cells/9994GKCNode01Cell/
nodes/9994GKCNode01|node.xml#Node_1)")
ncq1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQQueue_1098737234986)

wsadmin>AdminTask.showWMQQueue("ncq1(cells/9994GKCNode01Cell/nodes/
9994GKCNode01|resources.xml#MQQueue_1098737234986)")
{expiry=0, priority=9, decimalEncoding=Normal, queueName=TARGETQ, name=q1,
readAhead=YES, readAheadClose=DELIVERALL,  ccsid=1208,
useNativeEncoding=true, integerEncoding=Normal, specifiedPriority=0,
jndiName=jms/q1, sendAsync=YES,  qmgr=null, description=null,
targetClient=JMS, floatingPointEncoding=IEEENormal, persistence=APP}
```

- Using Jacl:

```
wsadmin>$AdminConfig getid /Node:9994GKCNode01
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)

wsadmin>$AdminTask listWMQQueues
9994GKCNode01(cells/9994GKCNode01Cell/nodes/9994GKCNode01|node.xml#Node_1)
ncq1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQQueue_1098737234986)

wsadmin>$AdminTask showWMQQueue
ncq1(cells/9994GKCNode01Cell/nodes/9994GKCNode01|resources.xml#
MQQueue_1098737234986)
{expiry=0, priority=9, decimalEncoding=Normal, queueName=TARGETQ, name=q1,
readAhead=YES, readAheadClose=DELIVERALL,  ccsid=1208,
useNativeEncoding=true, integerEncoding=Normal, specifiedPriority=0,
jndiName=jms/q1, sendAsync=YES,  qmgr=null, description=null,
targetClient=JMS, floatingPointEncoding=IEEENormal, persistence=APP}
```

Mapping of administrative console panel names to command names and WebSphere MQ names

Use these tables to relate the names used in the administrative console panels to the names in the commands and the names used by WebSphere MQ.

The following tables list property mappings. Use these tables in conjunction with the WebSphere MQ information center to get more information on a particular property.

Note that not every WebSphere Application Server panel or command property maps to a WebSphere MQ property.

Table 62. WebSphere MQ Activation Specification property mappings. The first column of this table shows the property names that appear on a WebSphere Application Server administrative console panel, and the second column shows the corresponding WebSphere Application Server command names. The third column shows the WebSphere MQ activation specification properties that the administrative console panel names and command names map on to.

Name on WebSphere Application Server administrative console panel	WebSphere Application Server command name	WebSphere MQ activation specification property
Basic panel		
Queue manager	qmgrName	queueManager
Queue manager (when used with CCDT)	ccdtQmgrName	queueManager
Transport	wmqTransportType	transportType
Host name	qmgrHostname	hostName
Port	qmgrPortNumber	port
Server connection channel	qmgrSvrconnChannel	channel
Destination JNDI name	destinationJndiName	destination

Table 62. WebSphere MQ Activation Specification property mappings (continued). The first column of this table shows the property names that appear on a WebSphere Application Server administrative console panel, and the second column shows the corresponding WebSphere Application Server command names. The third column shows the WebSphere MQ activation specification properties that the administrative console panel names and command names map on to.

Name on WebSphere Application Server administrative console panel	WebSphere Application Server command name	WebSphere MQ activation specification property
Message selector	messageSelector	messageSelector
Destination type	destinationType	destinationType
Durable subscription	subscriptionDurability	subscriptionDurability

Chapter 14. Managing messaging with a third-party or (deprecated) V5 default messaging provider

For messaging between application servers, most requirements are best met by either the default messaging provider or the WebSphere MQ messaging provider. However, you can instead use a third-party messaging provider (that is, use another company's product as the provider). You might want to do this, for example, if you have existing investments. For backwards compatibility with earlier releases, there is also support for the V5 default messaging provider.

Before you begin

If you are not sure which provider combination is best suited to your needs, see Types of messaging providers.

About this task

Enterprise applications in WebSphere Application Server can use asynchronous messaging through services based on Java Message Service (JMS) messaging providers and their related messaging systems. These messaging providers conform to the JMS Version 1.1 specification.

The choice of provider depends on what your JMS application needs to do, and on other factors relating to your business environment and planned changes to that environment.

Procedure

- Choose a third-party messaging provider.

  To administer a third-party messaging provider, you use either the resource adaptor (for a Java EE Connector Architecture (JCA) 1.5-compliant messaging provider) or the client (for a non-JCA messaging provider) that is supplied by the third party. You use the WebSphere Application Server administrative console to administer the activation specifications, connection factories and destinations that are within WebSphere Application Server, but you cannot use the administrative console to administer the JMS provider itself, or any of its resources that are outside of WebSphere Application Server.

  To use message-driven beans, third-party messaging providers must either provide an inbound JCA 1.5-compliant resource adapter, or (for non-JCA messaging providers) include Application Server Facility (ASF), an optional feature that is part of the JMS Version 1.1 specification.

  To work with a third-party provider, choose one of the following options:

  1. Manage messaging with a third-party JCA 1.5-compliant messaging provider.
  2. Manage messaging with a third-party non-JCA messaging provider.

- Choose the (deprecated) V5 default messaging provider.

  This deprecated provider is identical to the WebSphere Application Server Version 5 default provider. Only the name has changed. It provides backwards compatibility that enables WebSphere Application Server Version 6 or later applications to connect to WebSphere Application Server Version 5 resources in a mixed cell. It also allows WebSphere Application Server Version 5 applications to connect to WebSphere Application Server Version 6 or later resources in a mixed cell. To configure and manage messaging to interoperate with WebSphere Application Server Version 5, see “Maintaining (deprecated) Version 5 default messaging resources” on page 959.

Managing messaging with a third-party JCA 1.5-compliant messaging provider

You can configure WebSphere Application Server to use a third-party JCA 1.5-compliant messaging provider. You might want to do this, for example, if you have existing investments.

Before you begin

For messaging between application servers, perhaps with some interaction with a WebSphere MQ system, you can use the default messaging provider. To integrate WebSphere Application Server messaging into a predominately WebSphere MQ network, you can use the WebSphere MQ messaging provider. You can also use a third-party messaging provider as described in this topic. To choose the provider that is best suited to your needs, see Choosing a messaging provider.

About this task

A third-party JCA 1.5-compliant messaging provider takes the form of a resource adapter that you install in WebSphere Application Server. You use the administrative console to administer the activation specifications (for message-driven beans) and other J2C administered objects for the provider.

Procedure

- Install the third-party JCA 1.5-compliant messaging provider.

  Install the resource adapter for the third-party provider, as described in “Installing a resource adapter archive” on page 180.
- Configure an activation specification for a third-party JCA resource adapter.
- Configure an administered object for a third-party JCA resource adapter.

Configuring an activation specification for a third-party JCA resource adapter

You can configure an activation specification that is used to deploy message-driven beans with a Java™ Connector Architecture (JCA), also called J2EE Connector (J2C), resource adapter that is not included as part of the WebSphere Application Server.

Before you begin

For guidance about when to configure your message-driven beans to work with listener ports rather than activation specifications. see Message-driven beans, activation specifications, and listener ports.

This task assumes that you have installed the resource adapter for the third-party provider, as described in “Installing a resource adapter archive” on page 180.

About this task

Use this task if you want to use a message-driven bean as a listener on a JCA resource adapter other than the default messaging provider or the WebSphere MQ messaging provider.

Procedure

1. Start the administrative console.
2. Display the resource adapter. In the navigation pane, click **Resources** > **Resource Adapters** > *adapter_name*. This displays in the content pane a table of properties for the resource adapter, including links to the types of JCA resource that it provides.
3. Optional: Change the **Scope** setting to the scope level at which the activation specification is to be visible to applications, according to your needs.
4. In the content pane, under the Activation specifications heading, click **J2C Activation Specifications**. This lists any existing activation specifications for the resource adapter.
5. Display the properties of the activation specification.

   If you want to display an existing activation specification, click one of the names listed.

Alternatively, if you want to create a new activation specification, click **New**, then specify the following required properties:

Name Type the name by which the activation specification is known for administrative purposes. The JNDI name is automatically generated based on the value for the Name property.

Message listener type
Select the message listener type that this activation specification instance should support. This list is based on the deployment descriptor of the resource adapter.

Depending on the resource adapter, there can be additional required properties that you must supply. To provide values for these properties, click **Custom properties**. When creating a new activation specification, you might have to click **Apply** before this custom property selection is available.

6. Specify properties for the activation specification, according to your needs.
7. Click **OK**.
8. Save your changes to the master configuration.

J2C Activation Specifications collection

This page contains a list of Java 2 Connector (J2C) activation specifications for a resource adapter configuration and is used to create new J2C activation specifications, to select J2C activation specifications for configuration changes, or to delete J2C activation specifications.

Activation specification definitions and classes are provided by a resource adapter when it is installed. Using this information, the administrator can create and configure J2C activation specifications with JNDI names that are then available for applications to use. The resource adapter uses a J2C activation specification to configure a specific endpoint instance. Each application configuring one or more endpoints must specify the resource adapter that sends messages to the endpoint. The application must use the activation specification to provide the configuration properties related to the processing of the inbound messages.

The following guidelines show which scenarios use activation specifications or listener ports:

- If you are using Java 2 Platform, Enterprise Edition (J2EE) 1.2 and EJB 1.1 with WebSphere Application Server v4, message driven beans (MDB) are not used so you do not need listener ports or activation specifications. WebSphere Application Server v4 uses message beans, but these are not MDBs or Enterprise JavaBeans (EJB).
- If you are using J2EE 1.3 and EJB 2.0 with WebSphere Application Server v5, you must use listener ports. The MDBs are JMS MDBs that implement MessageListener, and there is no JCA support. WebSphere Application Server v5 uses listener ports to associate MDB classes with their JMS destinations.
- If you are using J2EE 1.4 and EJB 2.1 with WebSphere Application Server v6, the decision depends on whether your JMS provider API is implemented with JCA. In J2EE 1.4, the JMS 1.1 API can now be implemented with the JCA 1.5 API. If so, your MDB is a JMS MDB that is implemented as a connector MDB, and must therefore be configured with an activation specification. If not, this is the same JMS situation as for J2EE 1.3, and you must configure this EJB 2.1 MDB in the same way as you would configure an EJB 2.0 MDB, which in WebSphere Application Server is to use a listener port.

You can access this administrative console page in one of two ways:

- **Resources** > **Resource Adapters** > **Resource adapters** > ***resource_adapter*** > **J2C activation specifications**.
- **Resources** > **Resource Adapters** > **J2C activation specifications**.

Name:

Specifies the display name of the J2C activation specification instance.

A string with no spaces meant to be a meaningful text identifier for the J2C activation specification.

Data type String

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name for the J2C activation specification instance.

Data type String

Scope:

Specifies the scope of the resource adapter that supports this activation specification. Only applications that are installed within this scope can use this activation specification.

Provider:

Specifies the resource adapter that encapsulates the appropriate classes for this activation specification.

Description:

A free-form text string to describe the J2C activation specification instance.

Data type String

Message Listener Type:

The Message Listener Type that is used by this activation specification.

The list of available classes is provided by the resource adapter.

Data type String

J2C Activation Specifications settings:

Use this page to specify the settings for a Java 2 Connector (J2C) activation specification.

The resource adapter uses a J2C activation specification to configure a specific endpoint instance. Each application configuring one or more endpoints must specify the resource adapter that sends messages to the endpoint. The application must use the activation specification to provide the configuration properties related to the processing of the inbound messages.

You can access this administrative console page in one of two ways:

- **Resources** > **Resource Adapters** > **Resource adapters** > ***resource_adapter*** > **J2C activation specifications** > ***activation_specification***.
- **Resources** > **Resource Adapters** > **J2C activation specifications** > ***activation_specification***.

Scope:

Specifies the scope of the resource adapter that supports this activation specification. Only applications that are installed within this scope can use this activation specification.

Provider:

Specifies the resource adapter that encapsulates the appropriate classes for this activation specification.

For new objects, available resource adapters are listed in a drop-down list. After you create the activation specification, the field is a read only text field.

Data type Drop-down list or text

Name:

Specifies the display name of the J2C activation specification instance.

A string with no spaces meant to be a meaningful text identifier for the J2C activation specification. Name is required

Data type String

JNDI name:

Specifies the Java Naming and Directory Interface (JNDI) name for the J2C activation specification instance.

The JNDI name is required. If you do not specify one, it is created from the Name field. If not specified, the JNDI name defaults to *eis/[name]*

Data type String

Description:

A free-form text string to describe the J2C activation specification instance.

Data type String

Authentication alias:

This optional field is used to bind the J2C activation specification to an authentication alias (configured through the security JAAS screens).

This alias is used to access a user name and password that are set on the configured J2C activation specification. This field is meaningful only if the J2C activation specification that you are configuring has a UserName and Password field.

If you have defined security domains in the application server, you can click **Browse...** to select a J2C authentication alias for the resource that you are configuring. Security domains allow you to isolate J2C authentication aliases between servers. The tree view is useful in determining the security domain to which an alias belongs, and the tree view can help you determine the servers that is able to access each authentication alias. The tree view is tailored for each resource, so domains and aliases are hidden when you cannot use them.

The Browse button is only accessible if at least one security domain is defined and assigned a scope that is applicable to the resource that is being edited. Additionally, that security domain must contain at least one JAAS J2C Authentication alias.

Data type Drop-down list

Message Listener Type:

The Message Listener Type used by this activation specification.

For new objects, the list of available classes is provided by the resource adapter in a drop-down list. After you create the activation specification, the field is a read only text field.

Data type Drop-down list or text

Destination JNDIName:

The destination JNDIName field appears only when a message of type javax.jms.Destination with name *Destination* is received.

Configuring an administered object for a third-party JCA resource adapter

You can configure an administered object for a Java™ Connector Architecture (JCA), also called J2EE Connector (J2C), resource adapter that is not included as part of the WebSphere Application Server.

Before you begin

This task assumes that you have installed the resource adapter for the third-party provider, as described in “Installing a resource adapter archive” on page 180.

About this task

Use this task if you want to configure a JCA administered object for a JCA resource adapter other than the default messaging provider or the WebSphere MQ messaging provider.

Procedure

1. Start the administrative console.
2. Display the resource adapter. In the navigation pane, click **Resources** > **Resource Adapters** > *adapter_name*. This displays in the content pane a table of properties for the resource adapter, including links to the types of JCA resource that it provides.
3. Optional: Change the **Scope** setting to the scope level at which the administered object is to be visible to applications, according to your needs.
4. In the content pane, under the Additional Properties heading, click **J2C Administered Objects**. This lists any existing administered objects for the resource adapter.
5. Display the properties of the administered object.

   If you want to display an existing administered object, click one of the names listed.

   Alternatively, if you want to create a new administered object, click **New**, then specify the following required properties:

   Name Type the name by which the administered object is known for administrative purposes. The JNDI name is automatically generated based on the value for the Name property.

   Administered object class
   Select the administered object class that this instance should support. This list is based on the deployment descriptor of the resource adapter.

   Depending on the resource adapter, there can be additional required properties that you must supply. To provide values for these properties, click **Custom properties**. When creating a new administered object, you might have to click **Apply** before this custom property selection is available.
6. Specify properties for the administered object, according to your needs.

7. Click **OK**.
8. Save your changes to the master configuration.

J2C Administered Objects collection

This page contains a list of Java 2 Connector Architecture (JCA) administered objects for a resource adapter configuration. This page is also used to create JCA administered objects, select J2C administered objects for configuration changes, or to delete J2C administered objects.

Administered object definitions and classes are provided by a resource adapter when you install it. Using this information, the administrator can create and configure J2C administered objects with JNDI names that are then available for applications to use. Some messaging styles might need applications to use special administered objects for sending and synchronously receiving messages through connection objects with messaging style-specific APIs. Administered objects can also be used to perform transformations on an asynchronously received message in a message provider-specific way. Administered objects can be accessed by a component by using either a resource environment reference or a message destination reference (preferred).

You can access this administrative console page in one of two ways:

- **Resources** > **Resource Adapters** > **Resource adapters** > ***resource_adapter*** > **J2C administered objects**
- **Resources** > **Resource Adapters** > **Resource adapters** > **J2C administered objects**

Name:

Specifies display name assigned to this administered object.

Data type String

JNDI Name:

Specifies the JNDI name of the administered object.

Data type String

Scope:

Specifies the scope of the resource adapter that supports this administered object. Only applications that are installed within this scope can use this object.

Provider:

Specifies the resource adapter that encapsulates the appropriate classes for this administrative object.

For new objects, available resource adapters are listed in a drop-down list. After you create the administered object, the field is a read only text field.

Data type Drop-down list or text

Description:

Specifies a description for the administered object.

Data type String

Administered object class:

Specifies the Administered Object class that is associated with this J2C administered object. This class must be one that is provided by the resource adapter.

Data type String

J2C Administered Object settings:

Use this page to specify the settings for a Java 2 Connector (J2C) administered object.

Administered object definitions and classes are provided by a resource adapter when you install it. Using this information, the administrator can create and configure J2C administered objects with Java Naming and Directory Interface (JNDI) names that are then available for applications to use. Some messaging styles may need applications to use special administered objects for sending and synchronously receiving messages (through connection objects using messaging style specific APIs). It is also possible that administered objects may be used to perform transformations on an asynchronously received message in a message provider-specific way. Administered objects can be accessed by a component by using either a resource environment reference or a message destination reference (preferred).

You can access this administrative console page in one of two ways:

- **Resources** > **Resource Adapters** > **Resource adapters** > ***resource_adapter*** > **J2C administered objects** > ***J2C_administered_object***
- **Resources** > **Resource Adapters** > **Resource adapters** > **J2C administered objects** > ***J2C_administered_object***

Scope:

Specifies the scope of the resource adapter that supports this administered object. Only applications that are installed within this scope can use this object.

Provider:

Specifies the resource adapter that encapsulates the appropriate classes for this administrative object.

For new objects, a list of available resource adapters appears in a drop-down list. After you create the administered object, the field is a read only text field.

Data type Drop-down list or text

Name:

Specifies the name of the J2C administered object instance.

A string with no spaces meant to be a meaningful text identifier for the administered object. This name is required.

Data type String

JNDI name:

Specifies the JNDI name that this administered object is bound under.

The JNDI name is required. If you do not specify one, it is created from the Name field. If not specified, the JNDI name defaults to *eis/[name]*

Data type String

Description:

Specifies a text description of the J2C administered object instance.

Data type String

Administered object class:

For new objects, the list of available classes is provided by the resource adapter in a drop-down list. You can only select classes from this list.

After you create the administered object, you cannot modify the administered object class; it is read only.

Data type Class name

Managing messaging with a third-party non-JCA messaging provider

You can configure WebSphere Application Server to use a third-party non-JCA messaging provider. You might want to do this, for example, if you have existing investments. You can configure any third-party non-JCA messaging provider that supports the JMS Version 1.1 unified connection factory.

Before you begin

For messaging between application servers, perhaps with some interaction with a WebSphere MQ system, you can use the default messaging provider. To integrate WebSphere Application Server messaging into a predominately WebSphere MQ network, you can use the WebSphere MQ messaging provider. You can also use a third-party messaging provider as described in this topic. To choose the provider that is best suited to your needs, see Choosing a messaging provider.

To work with message-driven beans, the third-party non-JCA messaging provider must include Application Server Facility (ASF), an optional feature that is part of the JMS Version 1.1 specification.

About this task

To administer a third-party non-JCA messaging provider, you use the client that is supplied by the third party. You use the administrative console to administer the connection factories and destinations that are within WebSphere Application Server, but you cannot use the administrative console to administer the JMS provider itself, or any of its resources that are outside of WebSphere Application Server.

Procedure

- Define a third-party non-JCA messaging provider.
- List JMS resources for a third-party non-JCA messaging provider.
- Configure JMS resources for a third-party non-JCA messaging provider.

Defining a third-party non-JCA messaging provider

Use this task to define a third-party non-JCA messaging provider to WebSphere Application Server. You might want to do this, for example, if you have existing investments.

Before you begin

Before you define a third-party non-JCA messaging provider, you might want to check whether your requirement can be met by the default messaging provider or the WebSphere MQ messaging provider that are supplied with WebSphere Application Server. To choose the provider that is best suited to your needs, see Choosing a messaging provider.

To work with message-driven beans, the third-party non-JCA messaging provider must include Application Server Facility (ASF), an optional feature that is part of the JMS Version 1.1 specification.

About this task

You can configure any third-party non-JCA messaging provider that supports the JMS Version 1.1 unified connection factory.

To administer a third-party non-JCA messaging provider, you use the client that is supplied by the third party. You use the administrative console to administer the connection factories and destinations that are within WebSphere Application Server, but you cannot use the administrative console to administer the JMS provider itself, or any of its resources that are outside of WebSphere Application Server.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Resources** > **JMS->JMS providers**. The existing messaging providers are displayed, including the default messaging provider and the WebSphere MQ messaging provider.
3. To define a new third-party non-JCA messaging provider, click **New** in the content pane. Otherwise, to change the definition of an existing messaging provider, click the name of the provider.
4. Specify the following required properties. You can specify other properties, as described in a later step.

   Name The name by which this messaging provider is known for administrative purposes within WebSphere Application Server.

   External initial context factory
   The Java classname of the initial context factory for the JMS provider.

   External provider URL
   The JMS provider URL for external JNDI lookups.
5. Optional: Click **Apply**. This enables you to specify additional properties.
6. Optional: Specify other properties for the messaging provider.

   Under Additional Properties, you can use the **Custom Properties** link to specify custom properties for your initial context factory, in the form of standard **javax.naming** properties.
7. Click **OK**.
8. Save the changes to the master configuration.
9. To have the changed configuration take effect, stop then restart the application server.

What to do next

You can now configure JMS resources for your messaging provider, as described in “Configuring JMS resources for a third-party non-JCA messaging provider” on page 952.

JMS provider settings

Use this panel to view the configuration properties of a selected JMS provider.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** > **JMS->JMS providers**. This displays a list of JMS providers in the content pane. For each JMS provider in the list, the entry indicates the *scope* level at which JMS

resource definitions are visible to applications. You can create the same type of JMS provider at different Scope settings, to offer JMS resources at different levels of visibility to applications.

2. (optional) If you want to manage JMS resources that are defined at a different scope setting, change the **Scope** setting to the required level.
3. In the Providers column of the list displayed, click the name of a JMS provider.

If you want to browse or change JMS resources of the JMS provider, click the link for the type of resource under Additional Properties. For more information about the administrative console panels for the types of JMS resources, see the related topics.

For the default messaging provider (which is based on service integration technologies) and the WebSphere MQ messaging provider, the scope, name, and description properties are displayed for information only. You cannot change these properties.

For a third-party non-JCA provider that you have defined yourself, the properties of that provider are displayed.

Scope:

The level (cell, node, or server level) at which this resource definition is available.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates that are defined at more general scopes. For more information about the scope setting, see Scope settings.

Name:

The name by which the JMS provider is known for administrative purposes.

Data type

String

Default

- Default messaging provider.

  For JMS resources to be provided by a service integration bus, as part of WebSphere Application Server.
- *My JMSprovider*

  For JMS resources to be provided by a third-party JMS provider that you specify, rather than by the default messaging provider or the WebSphere MQ messaging provider that are available as part of WebSphere Application Server. You assign the name, for example “My JMSprovider”, when you define the third-party JMS provider to WebSphere Application Server. You must also have installed and configured the third-party JMS provider before applications can use its JMS resources.
- WebSphere MQ messaging provider

  For JMS resources to be provided by WebSphere MQ. You must have installed and configured WebSphere MQ before applications can use its JMS resources.
- V5 default messaging provider.

  For JMS resources to be provided by a WebSphere Application Server Version 5 node.

Description:

A description of the JMS provider, for administrative purposes within WebSphere Application Server.

Data type String

Classpath:

A list of paths or JAR file names that together form the location for the JMS provider classes. Each class path entry is on a separate line (separated by using the Enter key) and must not contain path separator characters (such as ';' or ': '). Class paths can contain variable (symbolic) names to be substituted by using a variable map. Check your driver installation notes for specific JAR file names that are required.

Note: This property is only available for third-party messaging providers.

Data type String

Native library path:

An optional path to any native libraries (*.dll, *.so). Each native path entry is on a separate line (separated by using the Enter key) and must not contain path separator characters (such as ';' or ': '). Native paths can contain variable (symbolic) names to be substituted by using a variable map.

Note: This property is only available for the WebSphere MQ messaging provider and third-party messaging providers.

Data type String

Update resource adapter:

This button can be used to update the WebSphere MQ resource adapter that provides the function made available by the WebSphere MQ messaging provider. This button must only be used as directed by a member of IBM service, otherwise it may result in the use of an unsupported level of the WebSphere MQ resource adapter.

Normally the WebSphere MQ resource adapter is automatically updated by applying WebSphere Application Server fix packs. It is important to note that use of the **Update resource adapter** button prevents these automatic updates from happening for future fix packs for any node on which the button is used. If, in the future, you require the WebSphere MQ resource adapter used by the node to receive updates when a fix pack is applied then you must re-establish the recommended resource adapter configuration. For more information see “Maintaining the WebSphere MQ resource adapter” on page 724.

Note: This property is only available for the WebSphere MQ messaging provider.

Data type Button

External initial context factory:

The Java classname of the initial context factory for the JMS provider.

For example, for an LDAP service provider the value has the form: com.sun.jndi.ldap.LdapCtxFactory.

Note: This property is only available for third-party messaging providers.

Data type String
Default Null

External provider URL:

The JMS provider URL for external JNDI lookups.

For example, an LDAP URL for a messaging provider has the form: `ldap://hostname.company.com/contextName`.

Note: This property is only available for third-party messaging providers.

Data type	String
Default	Null

Disable WebSphere MQ:

This check box is only valid for the WebSphere MQ messaging provider. When selected, this check box disables all WebSphere MQ functionality on affected application servers. Note that you must restart the affected application server processes for this change to take effect.

In a single server environment this check box is only available on the WebSphere MQ messaging provider panel where the scope is set to server, and has the effect of disabling all WebSphere MQ functionality in that application server.

In a network deployment environment this check box is available on all WebSphere MQ messaging provider panels. The effect of selecting the check box depends on the scope at which you select it:

- At the cell scope, all WebSphere MQ functionality is disabled on all application servers in the cell.
- At the node scope, all WebSphere MQ functionality is disabled on all application servers that are part of that node.
- At the cluster scope, all WebSphere MQ functionality is disabled on all application servers in that cluster.
- At the server scope, all WebSphere MQ functionality is disabled in that particular application server.

The value of the check box at a higher scope takes precedence over the value at a lower scope. For example, if you do not select the check box for a WebSphere MQ messaging provider at the server scope, but do select it for a WebSphere MQ messaging provider at a higher scope (such as the cell scope), the value of the check box at the cell scope takes precedence and WebSphere MQ functionality is therefore disabled in all application servers in the cell, regardless of whether the check box is selected at the server scope.

An informational message indicating that WebSphere MQ has been disabled is added to all WebSphere MQ messaging provider panels that are at affected scopes, but this message does not appear on those panels where the check box is selected. In a single server environment this informational message is only displayed after a server restart is performed. In a network deployment environment the informational message is displayed immediately.

For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

Data type	Check box
Default	Not selected

Additional properties:

Connection factories

A connection factory is used to create connections to the associated JMS provider. These connection factories can be used for accessing JMS Queue and JMS Topic destinations.

Queue connection factories
A queue connection factory is used to create connections to the associated JMS provider of the JMS queue destinations, for point-to-point messaging.

Topic connection factories
A topic connection factory is used to create connections to the associated JMS provider of JMS topic destinations, for publish and subscribe messaging.

Queues
A JMS queue is used as a destination for point-to-point messaging.

Topics
A JMS topic is used as a destination for publish/subscribe messaging.

Activation specifications
A JMS activation specification is associated with one or more message-driven beans and provides configuration necessary for them to receive messages.

Resource adapter properties
These properties are used to configure the WebSphere MQ resource adapter, which is used by the WebSphere MQ messaging provider. In particular most of these settings affect the behavior of WebSphere MQ messaging provider activation specifications.

Listing JMS resources for a third-party non-JCA messaging provider

Use the WebSphere Application Server administrative console to list JMS resources for a third party non-JCA messaging provider.

Before you begin

This topic assumes that you have defined a third-party non-JCA messaging provider.

About this task

You use the WebSphere Application Server administrative console to list JMS resources, if you want to view, modify or delete any of the following resources:

- Unified connection factories
- Queue connection factories
- Topic connection factories
- Queues
- Topics

When you use the administrative console to locate these resources, two different navigation pathways are available:

- **Provider-centric navigation** lets you view all providers, or just those for a specified scope, then navigate to a specific resource for a specific provider. This is the traditional way of navigating to a resource when you know which provider supports it. Any navigation that starts with **Resources** > **JMS->JMS providers** is provider-centric.
- **Resource-centric navigation** lets you view all resources of a specified type, then navigate to a resource. This is useful if you want to find a resource, but you do not know which provider supports it (you can list all resources of a given type across all scopes, for all providers, in a single panel). Any navigation that follows the pattern **Resources** > **JMS** > ***resource_type*** is resource-centric, where *resource_type* is one of the resource types previously listed.

You can use either of these navigation pathways to locate JMS resources of any type.

Procedure

- Use provider-centric navigation, for example to navigate to a specified queue connection factory.
  1. Start the administrative console.
  2. In the navigation pane, click **Resources** > **JMS->JMS providers**.

     The JMS providers collection panel is displayed. This lists all currently configured messaging providers across all scopes (you can modify the scope if required).
  3. Select the required JMS provider.

     The settings panel for this provider is displayed. The configuration tab contains a set of links to all the JMS resources owned by this provider.
  4. Click the link for a JMS resource type. For example, click **Queue connection factories**.

     The queue connection factories collection panel is displayed. This panel lists all the queue connection factories for this provider.
  5. Select the required queue connection factory.
- Use resource-centric navigation, for example to navigate to a specified queue connection factory.
  1. Start the administrative console..
  2. In the navigation pane, click **Resources** > **JMS->Queue connection factories**.

     The queue connection factories collection panel is displayed. This panel lists all the queue connection factories across all messaging providers.
  3. Select the required queue connection factory.

Results

You can now view and work with the resource properties.

JMS providers collection

Use this panel to list JMS providers, or to select a JMS provider to view or change its configuration properties.

To view this administrative console page, click **Resources** > **JMS->JMS providers**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS providers that are available to WebSphere applications. For each JMS provider in the list, the entry indicates the *scope* level at which JMS resource definitions are visible to applications. You can create the same type of JMS provider at different Scope settings, to offer JMS resources at different levels of visibility to applications.

If you want to manage existing JMS resource definitions, or create a new JMS resource definition, you can select the name of one of the JMS providers in the list.

If you want to define a new third-party JMS provider (that is, a provider other than the default messaging provider or the WebSphere MQ messaging provider), select the Scope setting at which JMS resource definitions are to be visible for that provider, then click **New**.

Name The name by which this JMS provider is known for administrative purposes.

Description
A description of this JMS provider for administrative purposes.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Connection factory collection

A JMS connection factory is used to create connections to the associated messaging provider of JMS destinations, for both point-to-point and publish/subscribe messaging. Use connection factory administrative objects to manage JMS connection factories for the default messaging provider, the WebSphere MQ messaging provider or a third-party messaging provider.

In the administrative console, to view this page click **Resources** > **JMS->Connection factories**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS connection factories that are available to WebSphere Application Server applications at the scope indicated by the **Scope** field.

A JMS connection factory is used to create connections to JMS destinations. When an application needs a JMS connection, an instance can be created by the factory of the messaging provider named in the **Provider** column of the list.

This type of connection factory is for applications that use the JMS 1.1 domain-independent interfaces (referred to as the “common interfaces” in the JMS specification).

This type of JMS connection factory can also be used by the domain-specific (queue and topic) interfaces, as used in JMS 1.0.2, so applications can still use those interfaces without the need for you to create a domain-specific connection factory, such as a queue connection factory.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

Name The display name of each connection factory instance.

JNDI name
The Java Naming and Directory Interface (JNDI) name of each connection factory instance.

Provider
The messaging provider that supports each connection factory instance. This is the default messaging provider (service integration), the WebSphere MQ messaging provider or a third-party messaging provider.

Description
An optional description of each connection factory instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Queue connection factory collection

A queue connection factory is used to create connections to the associated JMS provider of the JMS queue destinations, for point-to-point messaging.

In the administrative console, to view this page click **Resources** > **JMS->Queue connection factories**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS queue connection factories that are available to WebSphere Application Server applications at the scope indicated by the **Scope** field.

A JMS queue connection factory is used to create connections to JMS destinations. When an application needs a JMS queue connection, an instance can be created by the factory for the JMS provider that is named in the **Provider** column of the list.

This type of connection factory is for applications that use the JMS 1.0.2 queue-specific interfaces.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

Name The display name of each queue connection factory instance.

JNDI name
The Java Naming and Directory Interface (JNDI) name of each queue connection factory instance.

Provider
The messaging provider that supports each queue connection factory instance.

Description
An optional description of each queue connection factory instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Topic connection factory collection

A JMS topic connection factory is used to create connections to the associated messaging provider of JMS topic destinations, for publish and subscribe messaging.

In the administrative console, to view this page click **Resources** > **JMS->Topic connection factories**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS topic connection factories that are available to WebSphere Application Server applications at the scope indicated by the **Scope** field.

A JMS connection factory is used to create connections to JMS destinations. When an application needs a JMS connection, an instance can be created by the factory for the JMS provider that is named in the Provider column of the list.

This type of connection factory is for applications that use the JMS 1.0.2 topic-specific interfaces.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

General properties

Name The display name of each topic connection factory instance.

JNDI name
The Java Naming and Directory Interface (JNDI) name of each topic connection factory instance.

Provider
The messaging provider that supports each topic connection factory instance.

Description
An optional description of each topic connection factory instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Queue collection

A JMS queue destination is used for point-to-point messaging. Use this panel to create or delete queue destinations, or to select a queue destination to view or change its configuration properties.

In the administrative console, to view this page click **Resources** > **JMS->Queues**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS queue destinations that are available to WebSphere Application Server applications at the scope indicated by the **Scope** field.

Use a queue destination to manage JMS queues for the JMS provider that is named in the **Provider** column of the list. Connections to the queue are created by a unified connection factory or queue connection factory for that JMS provider.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

General properties

Name The display name of each queue destination instance.

JNDI name
The Java Naming and Directory Interface (JNDI) name of each queue destination instance.

Provider
The messaging provider that supports each queue destination instance.

Description
An optional description of each queue destination instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Topic collection

A JMS topic destination is used for publish and subscribe messaging. Use this panel to create or delete topic destinations, or to select a topic destination to view or change its configuration properties.

In the administrative console, to view this page click **Resources** > **JMS->Topics**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS topic destinations that are available to WebSphere Application Server applications at the scope indicated by the **Scope** field.

Use a topic destination to manage JMS topics for the JMS provider that is named in the **Provider** column of the list. Connections to the topic are created by a unified connection factory or topic connection factory for that JMS provider.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

General properties

Name The display name of each topic destination instance.

JNDI name
The Java Naming and Directory Interface (JNDI) name of each topic destination instance.

Provider
The messaging provider that supports each topic destination instance.

Description
An optional description of each topic destination instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Configuring JMS resources for a third-party non-JCA messaging provider

Use this task to configure the JMS connection factories and destinations for a third-party non-JCA messaging provider.

Before you begin

You only have to complete these tasks if your WebSphere Application Server environment uses a third-party non-JCA messaging provider to support enterprise applications that use JMS.

Before you can configure resources for your third-party non-JCA messaging provider, you must have defined your messaging provider.

About this task

To configure JMS resources for a third-party non-JCA messaging provider, complete the following tasks:

Procedure

- Configure a JMS connection factory for a third-party non-JCA messaging provider.
- Configure a JMS destination for a third-party non-JCA messaging provider.

Configuring a JMS connection factory for a third-party non-JCA messaging provider

Use this task to view or change the properties of a JMS connection factory for use with a third-party non-JCA messaging provider.

About this task

To view or change the configuration of a JMS connection factory for use with a third-party non-JCA messaging provider, use the administrative console to complete the following steps:

Procedure

1. Display the third-party non-JCA messaging provider. In the navigation pane, click **Resources** > **JMS->JMS providers**.
2. Select the third-party non-JCA messaging provider for which you want to configure a connection factory.
3. Optional: Select the **Scope** setting corresponding to the scope of the connection factories that you want to view or change.
4. In the content pane, under Additional Properties, click **Connection factories** This displays a table listing any existing JMS connection factories, with a summary of their properties.
5. To browse or change an existing JMS connection factory, click its name in the list. Otherwise, to create a new connection factory, complete the following steps:
   a. Click **New** in the content pane.
   b. Specify the following required properties. You can specify other properties, as described in a later step.

      Name The name by which this JMS connection factory is known for administrative purposes within IBM WebSphere Application Server.

      Type Select whether the connection factory is for JMS queues (QUEUE) or JMS topics (TOPIC).

      JNDI Name
      The JNDI name that is used to bind the JMS connection factory into the WebSphere Application Server namespace.

      External JNDI Name
      The JNDI name that is used to bind the JMS connection factory into the namespace of the messaging provider.

   c. Click **Apply**. This defines the JMS connection factory to WebSphere Application Server, and enables you to browse or change additional properties.
6. Optional: Change properties for the JMS connection factory, according to your needs.
7. Click **OK**.
8. Save any changes to the master configuration.
9. To have the changed configuration take effect, stop then restart the application server.

Third-party JMS connection factory settings:

Use this panel to browse or change the configuration properties of a JMS connection factory configured for use with a third-party non-JCA messaging provider. These configuration properties control how connections are created to the JMS destinations on the provider.

A JMS connection factory is used to create connections to JMS destinations. The JMS connection factory is created by the associated JMS provider.

To view this page, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** > **JMS->JMS providers**. The JMS providers collection panel is displayed. This lists all currently configured messaging providers across all scopes (you can modify the scope if required).
2. Click the name of the third-party non-JCA messaging provider.
3. Under Additional Properties, click **Connection factories**.
4. Click the name of the JMS connection factory that you want to work with.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates that are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Name:

The name by which this JMS connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the associated messaging provider.

Data type String

Type:

Whether this connection factory is for creating JMS queue destinations or JMS topic destinations.

Select one of the following options:

QUEUE
A JMS queue connection factory for point-to-point messaging.

TOPIC
A JMS topic connection factory for publish/subscribe messaging.

JNDI name:

The JNDI name that is used to bind the connection factory into the WebSphere Application Server namespace.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

Category:

A category used to classify or group this connection factory, for your IBM WebSphere Application Server administrative records.

Data type String

External JNDI name:

The JNDI name that is used to bind the connection factory into the namespace of the third-party messaging provider.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Component-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled administrative security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of the deployment descriptors for an application component.

Container-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for container-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled administrative security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of the deployment descriptors for an application component.

Mapping-Configuration Alias:

The module used to map authentication aliases.

This field provides a list of the modules that have been configured on the **Global Security** > **JAAS Configuration** > **Application Logins Configuration** property. For more information about the mapping configurations, see Java Authentication and Authorization service configuration entry settings.

Data type Enum

Default Null

Range

ClientContainer
The client container maps authentication aliases.

WSLogin
The WSLogin module maps authentication aliases.

DefaultPrincipalMapping
The JAAS configuration maps an authentication alias to its userid and password.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the messaging provider to improve performance. You have to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Session pool:

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the messaging provider to improve performance. You have to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Custom properties:

An optional set of name and value pairs for custom properties passed to the messaging provider.

Configuring a JMS destination for a third-party non-JCA messaging provider

Use this task to browse or change the properties of a JMS destination for use with a third-party non-JCA messaging provider.

Before you begin

Before starting this task, you should have defined the messaging provider to WebSphere Application Server.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Resources** > **JMS->JMS providers**.
3. Click the name of the third-party non-JCA messaging provider.
4. In the content pane, under Additional Properties, click **Queues** for point-to-point messaging or **Topics** for publish/subscribe messaging. This displays a table listing any existing JMS destinations, with a summary of their properties.
5. To browse or change an existing JMS destination, click its name in the list. Otherwise, to create a new destination, complete the following steps:
   a. Click **New** in the content pane.
   b. Specify the following required properties. You can specify other properties, as described in a later step.

      Name The name by which this JMS destination is known for administrative purposes within WebSphere Application Server.

      Type Select whether the destination is for JMS queues (QUEUE) or JMS topics (TOPIC).

      JNDI Name
      The JNDI name that is used to bind the JMS destination into the WebSphere Application Server namespace.

      External JNDI Name
      The JNDI name that is used to bind the JMS destination into the namespace of the messaging provider.

   c. Click **Apply**. This defines the JMS destination to WebSphere Application Server, and enables you to browse or change additional properties.
6. Optional: Change properties for the JMS destination, according to your needs.
7. Click **OK**.
8. Save any changes to the master configuration.
9. To have the changed configuration take effect, stop then restart the application server.

Third-party JMS destination settings:

Use this panel to browse or change the configuration properties of the selected JMS destination for use with an associated third-party non-JCA messaging provider.

A JMS destination is used to configure the properties of a JMS destination for the associated third-party non-JCA messaging provider. Connections to the JMS destination are created by the associated JMS connection factory.

To navigate to this panel, complete the following steps:
1. In the navigation pane, click **Resources** > **JMS->JMS providers**. The JMS providers collection panel is displayed. This lists all currently configured messaging providers across all scopes (you can modify the scope if required).
2. Click the name of the third-party non-JCA messaging provider.

3. Under Additional Properties, click **Queues** for point-to-point messaging or **Topics** for publish/subscribe messaging.
4. Click the name of the JMS destination that you want to work with.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates that are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Name:

The name by which the queue is known for administrative purposes within WebSphere Application Server.

Data type String

Type:

Whether this JMS destination is a queue (for point-to-point) or topic (for publish/subscribe).

Select one of the following options:
Queue
A JMS queue destination for point-to-point messaging.
Topic A JMS topic destination for publish/subscribe messaging.

JNDI name:

The JNDI name that is used to bind the queue into the application server namespace.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of the queue, for administrative purposes

Data type String

Category:

A category used to classify or group this queue, for your WebSphere Application Server administrative records.

Data type String

External JNDI name:

The JNDI name that is used to bind the queue into the application server namespace.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Maintaining (deprecated) Version 5 default messaging resources

You can use the WebSphere Application Server administrative console to manage the JMS connection factories and destinations for WebSphere Application Server Version 5.1 applications. JMS connection factories and destinations for the WebSphere Application Server Version 5.1 default messaging provider are not the same as those for the default messaging provider in WebSphere Application Server Version 6 and later. Such JMS resources are maintained as *V5 default messaging* resources.

About this task

V5 default messaging provides a JMS transport to a messaging engine of a service integration bus that supports the default messaging provider in later versions of the product. The messaging engine emulates the service of a JMS server running on WebSphere Application Server Version 5.1.

Procedure

- List Version 5 default messaging resources.
- Configure Version 5 default messaging resources.

JMS provider settings

Use this panel to view the configuration properties of a selected JMS provider.

To view this page, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources** > **JMS->JMS providers**. This displays a list of JMS providers in the content pane. For each JMS provider in the list, the entry indicates the *scope* level at which JMS resource definitions are visible to applications. You can create the same type of JMS provider at different Scope settings, to offer JMS resources at different levels of visibility to applications.
2. (optional) If you want to manage JMS resources that are defined at a different scope setting, change the **Scope** setting to the required level.
3. In the Providers column of the list displayed, click the name of a JMS provider.

If you want to browse or change JMS resources of the JMS provider, click the link for the type of resource under Additional Properties. For more information about the administrative console panels for the types of JMS resources, see the related topics.

For the default messaging provider (which is based on service integration technologies) and the WebSphere MQ messaging provider, the scope, name, and description properties are displayed for information only. You cannot change these properties.

For a third-party non-JCA provider that you have defined yourself, the properties of that provider are displayed.

Scope
The level (cell, node, or server level) at which this resource definition is available.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates that are defined at more general scopes. For more information about the scope setting, see Scope settings.

Name
The name by which the JMS provider is known for administrative purposes.

Data type String

Default

- Default messaging provider.

  For JMS resources to be provided by a service integration bus, as part of WebSphere Application Server.
- *My JMSprovider*

  For JMS resources to be provided by a third-party JMS provider that you specify, rather than by the default messaging provider or the WebSphere MQ messaging provider that are available as part of WebSphere Application Server. You assign the name, for example “My JMSprovider”, when you define the third-party JMS provider to WebSphere Application Server. You must also have installed and configured the third-party JMS provider before applications can use its JMS resources.
- WebSphere MQ messaging provider

  For JMS resources to be provided by WebSphere MQ. You must have installed and configured WebSphere MQ before applications can use its JMS resources.
- V5 default messaging provider.

  For JMS resources to be provided by a WebSphere Application Server Version 5 node.

Description
A description of the JMS provider, for administrative purposes within WebSphere Application Server.

Data type String

Classpath
A list of paths or JAR file names that together form the location for the JMS provider classes. Each class path entry is on a separate line (separated by using the Enter key) and must not contain path separator characters (such as ';' or ': '). Class paths can contain variable (symbolic) names to be substituted by using a variable map. Check your driver installation notes for specific JAR file names that are required.

Note: This property is only available for third-party messaging providers.

Data type String

Native library path

An optional path to any native libraries (*.dll, *.so). Each native path entry is on a separate line (separated by using the Enter key) and must not contain path separator characters (such as ';' or ': '). Native paths can contain variable (symbolic) names to be substituted by using a variable map.

Note: This property is only available for the WebSphere MQ messaging provider and third-party messaging providers.

Data type String

Update resource adapter

This button can be used to update the WebSphere MQ resource adapter that provides the function made available by the WebSphere MQ messaging provider. This button must only be used as directed by a member of IBM service, otherwise it may result in the use of an unsupported level of the WebSphere MQ resource adapter.

Normally the WebSphere MQ resource adapter is automatically updated by applying WebSphere Application Server fix packs. It is important to note that use of the **Update resource adapter** button prevents these automatic updates from happening for future fix packs for any node on which the button is used. If, in the future, you require the WebSphere MQ resource adapter used by the node to receive updates when a fix pack is applied then you must re-establish the recommended resource adapter configuration. For more information see “Maintaining the WebSphere MQ resource adapter” on page 724.

Note: This property is only available for the WebSphere MQ messaging provider.

Data type Button

External initial context factory

The Java classname of the initial context factory for the JMS provider.

For example, for an LDAP service provider the value has the form: com.sun.jndi.ldap.LdapCtxFactory.

Note: This property is only available for third-party messaging providers.

Data type String
Default Null

External provider URL

The JMS provider URL for external JNDI lookups.

For example, an LDAP URL for a messaging provider has the form: `ldap://hostname.company.com/contextName`.

Note: This property is only available for third-party messaging providers.

Data type String
Default Null

Disable WebSphere MQ

This check box is only valid for the WebSphere MQ messaging provider. When selected, this check box disables all WebSphere MQ functionality on affected application servers. Note that you must restart the affected application server processes for this change to take effect.

In a single server environment this check box is only available on the WebSphere MQ messaging provider panel where the scope is set to server, and has the effect of disabling all WebSphere MQ functionality in that application server.

In a network deployment environment this check box is available on all WebSphere MQ messaging provider panels. The effect of selecting the check box depends on the scope at which you select it:

- At the cell scope, all WebSphere MQ functionality is disabled on all application servers in the cell.
- At the node scope, all WebSphere MQ functionality is disabled on all application servers that are part of that node.
- At the cluster scope, all WebSphere MQ functionality is disabled on all application servers in that cluster.
- At the server scope, all WebSphere MQ functionality is disabled in that particular application server.

The value of the check box at a higher scope takes precedence over the value at a lower scope. For example, if you do not select the check box for a WebSphere MQ messaging provider at the server scope, but do select it for a WebSphere MQ messaging provider at a higher scope (such as the cell scope), the value of the check box at the cell scope takes precedence and WebSphere MQ functionality is therefore disabled in all application servers in the cell, regardless of whether the check box is selected at the server scope.

An informational message indicating that WebSphere MQ has been disabled is added to all WebSphere MQ messaging provider panels that are at affected scopes, but this message does not appear on those panels where the check box is selected. In a single server environment this informational message is only displayed after a server restart is performed. In a network deployment environment the informational message is displayed immediately.

For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

Data type	Check box
Default	Not selected

Additional properties

Connection factories
A connection factory is used to create connections to the associated JMS provider. These connection factories can be used for accessing JMS Queue and JMS Topic destinations.

Queue connection factories
A queue connection factory is used to create connections to the associated JMS provider of the JMS queue destinations, for point-to-point messaging.

Topic connection factories
A topic connection factory is used to create connections to the associated JMS provider of JMS topic destinations, for publish and subscribe messaging.

Queues
A JMS queue is used as a destination for point-to-point messaging.

Topics
A JMS topic is used as a destination for publish/subscribe messaging.

Activation specifications
A JMS activation specification is associated with one or more message-driven beans and provides configuration necessary for them to receive messages.

Resource adapter properties
These properties are used to configure the WebSphere MQ resource adapter, which is used by

the WebSphere MQ messaging provider. In particular most of these settings affect the behavior of WebSphere MQ messaging provider activation specifications.

Listing Version 5 default messaging resources

Use the WebSphere Application Server administrative console to list JMS resources for the V5 default messaging provider, for administrative purposes.

About this task

You use the WebSphere Application Server administrative console to list JMS resources, if you want to view, modify or delete any of the following resources:

- Queue connection factories
- Topic connection factories
- Queues
- Topics

When you use the administrative console to locate these resources, two different navigation pathways are available:

- **Provider-centric navigation** lets you view all providers, or just those for a specified scope, then navigate to a specific resource for a specific provider. This is the traditional way of navigating to a resource when you know which provider supports it. Any navigation that starts with **Resources** > **JMS->JMS providers** is provider-centric.
- **Resource-centric navigation** lets you view all resources of a specified type, then navigate to a resource. This is useful if you want to find a resource, but you do not know which provider supports it (you can list all resources of a given type across all scopes, for all providers, in a single panel). Any navigation that follows the pattern **Resources** > **JMS** > ***resource_type*** is resource-centric, where *resource_type* is one of the resource types previously listed.

You can use either of these navigation pathways to locate JMS resources of any type.

Procedure

- Use provider-centric navigation, for example to navigate to a specified queue connection factory.
  1. Start the administrative console.
  2. In the navigation pane, click **Resources** > **JMS->JMS providers**.

     The JMS providers collection panel is displayed. This lists all currently configured messaging providers across all scopes (you can modify the scope if required).
  3. Select the required JMS provider.

     The settings panel for this provider is displayed. The configuration tab contains a set of links to all the JMS resources owned by this provider.
  4. Click the link for a JMS resource type. For example, click **Queue connection factories**.

     The queue connection factories collection panel is displayed. This panel lists all the queue connection factories for this provider.
  5. Select the required queue connection factory.
- Use resource-centric navigation, for example to navigate to a specified queue connection factory.
  1. Start the administrative console..
  2. In the navigation pane, click **Resources** > **JMS->Queue connection factories**.

     The queue connection factories collection panel is displayed. This panel lists all the queue connection factories across all messaging providers.
  3. Select the required queue connection factory.

Results

You can now view and work with the resource properties.

JMS providers collection

Use this panel to list JMS providers, or to select a JMS provider to view or change its configuration properties.

To view this administrative console page, click **Resources** > **JMS->JMS providers**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS providers that are available to WebSphere applications. For each JMS provider in the list, the entry indicates the *scope* level at which JMS resource definitions are visible to applications. You can create the same type of JMS provider at different Scope settings, to offer JMS resources at different levels of visibility to applications.

If you want to manage existing JMS resource definitions, or create a new JMS resource definition, you can select the name of one of the JMS providers in the list.

If you want to define a new third-party JMS provider (that is, a provider other than the default messaging provider or the WebSphere MQ messaging provider), select the Scope setting at which JMS resource definitions are to be visible for that provider, then click **New**.

Name The name by which this JMS provider is known for administrative purposes.

Description
A description of this JMS provider for administrative purposes.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Queue connection factory collection

A queue connection factory is used to create connections to the associated JMS provider of the JMS queue destinations, for point-to-point messaging.

In the administrative console, to view this page click **Resources** > **JMS->Queue connection factories**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS queue connection factories that are available to WebSphere Application Server applications at the scope indicated by the **Scope** field.

A JMS queue connection factory is used to create connections to JMS destinations. When an application needs a JMS queue connection, an instance can be created by the factory for the JMS provider that is named in the **Provider** column of the list.

This type of connection factory is for applications that use the JMS 1.0.2 queue-specific interfaces.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

Name The display name of each queue connection factory instance.

JNDI name
The Java Naming and Directory Interface (JNDI) name of each queue connection factory instance.

Provider
The messaging provider that supports each queue connection factory instance.

Description
An optional description of each queue connection factory instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Topic connection factory collection

A JMS topic connection factory is used to create connections to the associated messaging provider of JMS topic destinations, for publish and subscribe messaging.

In the administrative console, to view this page click **Resources** > **JMS->Topic connection factories**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS topic connection factories that are available to WebSphere Application Server applications at the scope indicated by the **Scope** field.

A JMS connection factory is used to create connections to JMS destinations. When an application needs a JMS connection, an instance can be created by the factory for the JMS provider that is named in the Provider column of the list.

This type of connection factory is for applications that use the JMS 1.0.2 topic-specific interfaces.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

General properties

Name The display name of each topic connection factory instance.

JNDI name
The Java Naming and Directory Interface (JNDI) name of each topic connection factory instance.

Provider
The messaging provider that supports each topic connection factory instance.

Description
An optional description of each topic connection factory instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Queue collection

A JMS queue destination is used for point-to-point messaging. Use this panel to create or delete queue destinations, or to select a queue destination to view or change its configuration properties.

In the administrative console, to view this page click **Resources** > **JMS->Queues**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS queue destinations that are available to WebSphere Application Server applications at the scope indicated by the **Scope** field.

Use a queue destination to manage JMS queues for the JMS provider that is named in the **Provider** column of the list. Connections to the queue are created by a unified connection factory or queue connection factory for that JMS provider.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server

environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

General properties

Name The display name of each queue destination instance.

JNDI name
The Java Naming and Directory Interface (JNDI) name of each queue destination instance.

Provider
The messaging provider that supports each queue destination instance.

Description
An optional description of each queue destination instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Topic collection

A JMS topic destination is used for publish and subscribe messaging. Use this panel to create or delete topic destinations, or to select a topic destination to view or change its configuration properties.

In the administrative console, to view this page click **Resources** > **JMS->Topics**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

This page lists the JMS topic destinations that are available to WebSphere Application Server applications at the scope indicated by the **Scope** field.

Use a topic destination to manage JMS topics for the JMS provider that is named in the **Provider** column of the list. Connections to the topic are created by a unified connection factory or topic connection factory for that JMS provider.

If WebSphere MQ functionality has been disabled, an informational message indicating that WebSphere MQ has been disabled appears when the scope field is set to a scope which is the same as, or above, the scope at which WebSphere MQ has been disabled, or when the scope field is set to display all scopes. Note that this informational message is not displayed if you are viewing a provider specific collection that is not for WebSphere MQ (for example, the default messaging provider collection). In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

General properties

Name The display name of each topic destination instance.

JNDI name
The Java Naming and Directory Interface (JNDI) name of each topic destination instance.

Provider
The messaging provider that supports each topic destination instance.

Description
An optional description of each topic destination instance.

Scope The level to which this resource definition is visible; for example, the cell, node, cluster, or server level.

Buttons

New	Create a new JMS resource of this type.
Delete	Delete the selected items.

Configuring Version 5 default messaging resources

Use the following tasks to configure the JMS connection factories and destinations for WebSphere Application Server Version 5 applications.

About this task

You only have to complete these tasks if you have WebSphere Application Server Version 5 applications that use JMS resources provided by the default messaging provider. Such JMS resources are maintained as *V5 default messaging* resources.

Procedure

- Configure a connection for Version 5 default messaging
- Configure a queue connection factory for Version 5 default messaging
- Configure a topic connection factory for Version 5 default messaging
- Configure a queue for Version 5 default messaging
- Configure a topic for Version 5 default messaging

Configuring a connection for V5 default messaging

Use this task to configure a connection to V5 default messaging. This task is provided to help you manually migrate nodes from Version 5 to Version 6. If you use the supplied tools to migrate existing Version 5 nodes to Version 6, the jmsserver, application server and port that you create with this task are defined automatically.

About this task

To configure a connection for V5 default messaging, use the administrative console to complete the following steps:

Procedure

1. Create an application server with the name jmsserver (only one of these can exist on each node). In the navigation pane, expand **Servers** > **Server Types** > **WebSphere application servers**.
2. On the new server, define a new JMSSERVER_QUEUED_ADDRESS port with the host set to the Version 6 server host, and the port set to the same as the SIB_MQ_ENDPOINT_ADDRESS of the server that is a member of your bus. The appserver called jmsserver does not have to be started; it is only used for looking up the port address.
3. Define a queue connection factory and queue at the Node or Cell scope. In the navigation pane, click **Resources** > **JMS->JMS providers**.

4. In the content pane, click the name of the V5 default messaging provider.
5. Define a queue destination on your bus with the same name as your queue defined for the V5 default messaging provider.
6. Define an alias destination on your bus with the same name as your queue defined for the V5 default messaging provider but with WQ_ appended to the front the name. For example, if your queue has the name MyV5Queue, your alias should have the name WQ_MyV5Queue.
7. Point the alias at your queue destination with the correct name. The migration process targets the queue with the WQ_ prefix; defining the alias to point to the real queue helps migration.
8. Define the WebSphere MQ Client Link on your messaging engine on the bus. Keep the WebSphere MQ channel name WAS.JMS.SVRCONN and set the queue manager name so that it contains your node name. For example, if your node name is MyNode, you would set the queue manager name to WAS_<MyNode>_jmsserver. Now set the queue manager name to the same; in this example it would be WAS_MyNode_jmsserver. The WebSphere MQ Client Link will show a status of inactive, this is normal.
9. Restart your server so that the new JNDI definitions bind correctly. Your Version 5 client should now be able to connect to Version 6 by using the host and bootstrap address of the Version 6 system in the provider URL component of the initial context. Your client should now also be able to send messages to the destination on the bus.
10. If you open the Client connections view and click the refresh icon, the host name of the connecting system is visible when the client is connected. In the navigation pane, expand**Buses** > **[bus name]** > **Messaging engines** > **[messaging engine name]** > **WebSphere MQ client links** > **[client link name]** > **Runtime** > **Client connections view**.
11. Click **OK**.
12. Save any changes to the master configuration.
13. To have the changed configuration take effect, stop then restart the application server.

Configuring a queue connection factory for Version 5 default messaging

Use this task to browse or change the properties of a JMS queue connection factory for point-to-point messaging with the default messaging provider on a Version 5 node. This task contains an optional step for you to create a new JMS queue connection factory.

About this task

To configure a JMS queue connection factory for use by WebSphere Application Server Version 5 applications, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Resources** > **JMS->JMS providers**.
2. Select the V5 default messaging provider for which you want to configure a queue connection factory.
3. In the content pane, under Additional Properties, click **Queue connection factories** This displays any existing JMS queue connection factories for the Version 5 messaging provider in the content pane.
4. To browse or change an existing JMS queue connection factory, click its name in the list. Otherwise, to create a new connection factory, complete the following steps:
   a. Click **New** in the content pane.
   b. Specify the following required properties. You can specify other properties, as described in a later step.

      Name The name by which this JMS queue connection factory is known for administrative purposes within WebSphere Application Server.

      JNDI Name
      The JNDI name that is used to bind the JMS queue connection factory into the namespace.

c. Click **Apply**. This defines the JMS queue connection factory to WebSphere Application Server, and enables you to browse or change additional properties.

5. Optional: Change properties for the queue connection factory, according to your needs.
6. Click **OK**.
7. Save any changes to the master configuration.
8. To have the changed configuration take effect, stop then restart the application server.

Version 5 default messaging queue connection factory settings:

Use this panel to browse or change the configuration properties of the selected JMS queue connection factory for point-to-point messaging for use by WebSphere Application Server Version 5 applications.

A WebSphere queue connection factory is used to create JMS connections to the default messaging provider for use by WebSphere Application Server Version 5 applications.

To view this page, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** > **JMS->JMS providers**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
3. In the content pane, click the name of the V5 default messaging provider that you want to support the JMS destination.
4. Under Additional Resources, click **Queue connection factories**. This displays a list of any existing JMS queue connection factories.
5. Click the name of the JMS queue connection factory that you want to work with.

A queue connection factory for the embedded WebSphere JMS provider has the following properties:

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates that are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Name:

The name by which this JMS queue connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type String
Default Null

JNDI name:

The JNDI name that is used to bind the JMS connection factory into the namespace.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

Category:

A category used to classify or group this connection factory, for your IBM WebSphere Application Server administrative records.

Data type String

Node:

The WebSphere node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

Data type Enum
Default Null
Range Drop-down list of Version 5 nodes in the WebSphere administrative domain.

Component-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to the messaging provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled administrative security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the messaging provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of the deployment descriptors for an application component.

Note: User IDs longer than 12 characters cannot be used for authentication with the V5 default messaging provider. For example, the default Windows NT user ID, **Administrator**, is not valid because it contains 13 characters. Therefore, an authentication alias for a WebSphere queue connection factory must specify a user ID no longer than 12 characters.

Container-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to the messaging provider for container-managed authentication.

The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container. If the 'DefaultPrincipalMapping' login configuration is used, the associated property is a container-managed authentication alias. This field is used only in the absence of a loginConfiguration on the component resource reference. To define a new alias, see the related item J2EE Connector Architecture (J2C) authentication data entries.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled administrative security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the messaging provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of the deployment descriptors for an application component.

Note: User IDs longer than 12 characters cannot be used for authentication with the V5 default messaging provider. For example, the default Windows NT user ID, **Administrator**, is not valid because it contains 13 characters. Therefore, an authentication alias for a WebSphere topic connection factory must specify a user ID no longer than 12 characters.

Mapping-Configuration Alias:

The module used to map authentication aliases.

This field is deprecated in 6.0. The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container. This field is used only in the absence of a loginConfiguration on the component resource reference.

This field provides a list of the modules that have been configured on the **Security** > **JAAS Configuration** > **Application Logins Configuration** property. For more information about the mapping configurations, see Java Authentication and Authorization service configuration entry settings.

Data type Enum

Default Null

Range

ClientContainer
The client container maps authentication aliases.

WSLogin
The WSLogin module maps authentication aliases.

DefaultPrincipalMapping
The JAAS configuration maps an authentication alias to its userid and password.

XA Enabled:

Specifies whether the connection factory is for XA or non-XA coordination of messages and controls if the application server uses XA QCF/TCF. Enable XA if multiple resources are used in the same transaction.

If you clear this check box property (for non-XA coordination), the JMS session is still enlisted in a transaction, but uses the resource manager local transaction calls (session.commit and session.rollback) instead of XA calls. This can lead to an improvement in performance. However, this means that only a single resource can be enlisted in a transaction in WebSphere Application Server.

Last participant support enables you to enlist one non-XA resource with other XA-capable resources.

For a WebSphere Topic Connection Factory with the **Port** property set to DIRECT this property does not apply, and always adopts non-XA coordination.

Data type	check box
Default	Selected (enabled for XA coordination)
Range	**Selected** The connection factory is enabled for XA-coordination of messages **Cleared** The connection factory is not enabled for XA coordination of messages
Recommended	Do not enable XA coordination when the message queue or topic received is the only resource in the transaction. Enable XA coordination when other resources, including other queues or topics, are involved.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the messaging provider to improve performance. You have to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Session pool:

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the messaging provider to improve performance. You have to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Session pool settings:

Use this page to configure session pool settings.

This administrative console page is common to JMS unified connection factories, queue connection factories and topic connection factories. To view this page, you select an instance of the resource type then click **Session pools**. For example, click **Resources** > **JMS->Queue connection factories->*queue_connection_factory*->[Additional Properties] Session pools**.

Connection Timeout:

Specifies the interval, in seconds, after which a connection request times out and a ConnectionWaitTimeoutException is thrown.

The wait is necessary when the maximum value of connections (**Max Connections**) to a particular connection pool is reached . For example, if *Connection Timeout* is set to 300 and the maximum number of connections is reached, the Pool Manager waits for 300 seconds for an available physical connection. If a physical connection is *not* available within this time, the Pool Manager throws a ConnectionWaitTimeoutException. It usually does not make sense to retry the getConnection() method, because if a longer wait time is required, you should set the **Connection Timeout** setting to a higher value. Therefore, if this exception is caught by the application, the administrator should review the expected usage of the application and tune the connection pool and the database accordingly.

If Connection Timeout is set to 0, the Pool Manager waits as long as necessary until a connection is allocated (which happens when the number of connections falls below the value of **Max Connections**).

If Max Connections is set to 0, which enables an infinite number of physical connections, then the Connection Timeout value is ignored.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Max Connections:

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. Once this number is reached, no new physical connections are created and the requester waits until a physical connection that is currently in use returns to the pool, or a ConnectionWaitTimeoutException is thrown.

For example, if the Max Connections value is set to 5, and there are five physical connections in use, the pool manager waits for the amount of time specified in Connection Timeout for a physical connection to become free.

If Max Connections is set to 0, the Connection Timeout value is ignored.

For better performance, set the value for the connection pool lower than the value for the Max Connections option in the web container. Lower settings, such as 10-30 connections, perform better than higher settings, such as 100.

If clones are used, one data pool exists for each clone. Knowing the number of data pools is important when configuring the database maximum connections.

You can use the Tivoli Performance Viewer to find the optimal number of connections in a pool. If the number of concurrent waiters is greater than 0, but the CPU load is not close to 100%, consider increasing the connection pool size. If the Percent Used value is consistently low under normal workload, consider decreasing the number of connections in the pool.

Data type	Integer
Default	10
Range	0 to max int

Min Connections:

Specifies the minimum number of physical connections to maintain.

Until this number is reached, the pool maintenance thread does not discard physical connections. However, no attempt is made to bring the number of connections up to this number. If you set a value for Aged Timeout, the minimum is not maintained. All connections with an expired age are discarded.

For example if the **Min Connections** value is set to 3, and one physical connection is created, the Unused Timeout thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the **Min Connections** setting.

Data type	Integer
Default	1
Range	0 to max int

Reap Time:

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if **Reap Time** is set to 60, the pool maintenance thread runs every 60 seconds. The Reap Time interval affects the accuracy of the **Unused Timeout** and **Aged Timeout** settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the Reap Time value less than the values of Unused Timeout and Aged Timeout. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value specified in Unused Timeout, until it reaches the number of connections specified in **Min Connections**. The pool maintenance thread also discards any connections that remain active longer than the time value specified in Aged Timeout.

The Reap Time interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread set Reap Time to 0, or set both Unused Timeout and Aged Timeout to 0. The recommended way to disable the pool maintenance thread is to set Reap Time to 0, in which case Unused Timeout and Aged Timeout are ignored. However, if Unused Timeout and Aged Timeout are set to 0, the pool maintenance thread runs, but only physical connections that timeout due to non-zero timeout values are discarded.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Unused Timeout:

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the Unused Timeout value higher than the Reap Timeout value for optimal performance. Unused physical connections are only discarded if the current number of connections not in use exceeds the **Min Connections** setting. For example, if the unused timeout value is set to 120, and the pool maintenance thread is enabled (Reap Time is not 0), any physical connection that remains unused for two minutes is discarded. Note that accuracy of this timeout, as well as performance, is affected by the **Reap Time** value. For more information, see Reap Time.

Data type	Integer
Units	Seconds
Default	1800
Range	0 to max int

Aged Timeout:

Specifies the interval in seconds before a physical connection is discarded.

Setting **Aged Timeout** to 0 supports active physical connections remaining in the pool indefinitely. Set the Aged Timeout value higher than the **Reap Timeout** value for optimal performance. For example, if the Aged Timeout value is set to 1200, and the Reap Time value is not 0, any physical connection that remains in existence for 1200 seconds (20 minutes) is discarded from the pool. Note that accuracy of this timeout, as well as performance, are affected by the Reap Time value. For more information, see Reap Time.

Data type	Integer
Units	Seconds
Default	0
Range	0 to max int

Purge Policy:

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**. Java EE Connector Architecture (JCA) data sources can have either option. WebSphere Version 4.0 data sources always have a purge policy of **EntirePool**.

Data type	String
Default	FailingConnectionOnly
Range	**EntirePool** All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and throws a *StaleConnectionException* during the next operation on that connection. Subsequent *getConnection* requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice. **FailingConnectionOnly** Only the connection that caused the *StaleConnectionException* is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a good possibility that the next *getConnection* request from the application can return a connection from the pool that is also stale, resulting in more stale connection exceptions.

Configuring a topic connection factory for Version 5 default messaging

Use this task to browse or change a JMS topic connection factory for publish/subscribe messaging by WebSphere Application Server Version 5 applications.

About this task

To configure a JMS topic connection factory for use by WebSphere Application Server Version 5 applications, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Resources** > **JMS->JMS providers**.
2. Select the V5 default messaging provider for which you want to configure a topic connection factory.
3. Optional: Change the **Scope** setting to the level at which the JMS topic connection factory is visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
4. In the content pane, under Additional Properties, click **Topic connection factories** This displays any existing JMS topic connection factories for the Version 5 messaging provider in the content pane.
5. To browse or change an existing JMS topic connection factory, click its name in the list. Otherwise, to create a new connection factory, complete the following steps:
   a. Click **New** in the content pane.
   b. Specify the following required properties. You can specify other properties, as described in a later step.

      Name The name by which this JMS topic connection factory is known for administrative purposes within IBM WebSphere Application Server.

      JNDI Name
      The JNDI name that is used to bind the JMS topic connection factory into the namespace.
   c. Click **Apply**. This defines the JMS topic connection factory to WebSphere Application Server, and enables you to browse or change additional properties.
6. Optional: Change properties for the topic connection factory, according to your needs.
7. Click **OK**.
8. Save any changes to the master configuration.
9. To have the changed configuration take effect, stop then restart the application server.

Version 5 default messaging topic connection factory settings:

Use this panel to browse or change the configuration properties of the selected JMS topic connection factory for publish/subscribe messaging by WebSphere Application Server Version 5 applications.

A WebSphere topic connection factory is used to create JMS connections to the default messaging provider for use by WebSphere Application Server Version 5 applications.

To view this page, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** > **JMS->JMS providers**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
3. In the content pane, click the name of the V5 default messaging provider that you want to support the JMS destination.
4. Under Additional Resources, click **Topic connection factories**. This displays a list of any existing JMS topic connection factories.
5. Click the name of the JMS topic connection factory that you want to work with.

A JMS topic connection factory for use with the V5 default messaging provider has the following properties.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates that are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Name:

The name by which this JMS topic connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

Data type String
Default Null

JNDI name:

The JNDI name that is used to bind the topic connection factory into the namespace.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of this topic connection factory for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

Category:

A category used to classify or group this topic connection factory, for your IBM WebSphere Application Server administrative records.

Data type String

Node:

The WebSphere node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

Data type Enum
Default Null
Range Drop-down list of nodes in the WebSphere administrative domain.

Port:

Which of the two ports that connections use to connect to the JMS server. The QUEUED port is for full-function JMS publish/subscribe support, the DIRECT port is for non-persistent, non-transactional, non-durable subscriptions only.

Note: Message-driven beans cannot use the direct listener port for publish/subscribe support. Therefore, any topic connection factory configured with **Port** set to Direct cannot be used with message-driven beans.

Data type Enum
Units Not applicable
Default QUEUED
Range
QUEUED
The listener port used for full-function JMS-compliant, publish/subscribe support.
DIRECT
The listener port used for direct TCP/IP connection (non-transactional, non-persistent, and non-durable subscriptions only) for publish/subscribe support.

Component-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to the messaging provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled administrative security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the messaging provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of the deployment descriptors for an application component.

Note: User IDs longer than 12 characters cannot be used for authentication with the V5 default messaging provider. For example, the default Windows NT user ID, **Administrator**, is not valid because it contains 13 characters. Therefore, an authentication alias for a WebSphere topic connection factory must specify a user ID no longer than 12 characters.

Container-managed Authentication Alias:

This alias specifies a user ID and password to be used to authenticate connection to the messaging provider for container-managed authentication.

The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container. If the 'DefaultPrincipalMapping' login configuration is used, the associated property is a container-managed authentication alias. This field is used only in the absence of a loginConfiguration on the component resource reference. To define a new alias, see the related item J2EE Connector Architecture (J2C) authentication data entries.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled administrative security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of the deployment descriptors for an application component.

Note: User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, **Administrator**, is not valid for use with embedded WebSphere messaging, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider connection factory must specify a user ID no longer than 12 characters.

Mapping-Configuration Alias:

The module used to map authentication aliases.

The specification of a login configuration and associated properties on the component resource reference determines the container-managed authentication strategy when the res-auth value is Container. This field is used only in the absence of a loginConfiguration on the component resource reference.

This field provides a list of the modules that have been configured on the **Security** > **JAAS Configuration** > **Application Logins Configuration** property. For more information about the mapping configurations, see Java Authentication and Authorization service configuration entry settings.

Data type Enum
Default Null
Range
ClientContainer
The client container maps authentication aliases.
WSLogin
The WSLogin module maps authentication aliases.
DefaultPrincipalMapping
The JAAS configuration maps an authentication alias to its userid and password.

Clone Support:

Select this check box to enable clone support to allow the same durable subscription across topic clones.

Data type Enum
Default Cleared
Range
Selected
Clone support is enabled.
Cleared
Clone support is disabled.

If you select this property, you must also specify a value for the **Client ID** property.

Client ID:

The JMS client identifier used for connections to the queue manager.

Data type	String
Range	A valid JMS client ID

XA Enabled:

Specifies whether the connection factory is for XA or non-XA coordination of messages and controls if the application server uses XA QCF/TCF. Enable XA if multiple resources are used in the same transaction.

If you clear this check box property (for non-XA coordination), the JMS session is still enlisted in a transaction, but uses the resource manager local transaction calls (session.commit and session.rollback) instead of XA calls. This can lead to an improvement in performance. However, this means that only a single resource can be enlisted in a transaction in WebSphere Application Server.

Last participant support enables you to enlist one non-XA resource with other XA-capable resources.

For a WebSphere Topic Connection Factory with the **Port** property set to DIRECT this property does not apply, and always adopts non-XA coordination.

Data type	check box
Default	Selected (enabled for XA coordination)
Range	**Selected** The connection factory is enabled for XA-coordination of messages **Cleared** The connection factory is not enabled for XA coordination of messages
Recommended	Do not enable XA coordination when the message queue or topic received is the only resource in the transaction. Enable XA coordination when other resources, including other queues or topics, are involved.

Connection pool:

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the messaging provider to improve performance. You have to configure the connection and session pool properties appropriately for your applications, otherwise you might not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis.

Session pool:

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. You have to configure the connection and session pool properties appropriately for your applications, otherwise you might not get the connection and session behavior that you want.

Session pool settings:

Use this page to configure session pool settings.

This administrative console page is common to JMS unified connection factories, queue connection factories and topic connection factories. To view this page, you select an instance of the resource type then click **Session pools**. For example, click **Resources** > **JMS->Queue connection factories->*queue_connection_factory*->[Additional Properties] Session pools**.

Connection Timeout:

Specifies the interval, in seconds, after which a connection request times out and a ConnectionWaitTimeoutException is thrown.

The wait is necessary when the maximum value of connections (**Max Connections**) to a particular connection pool is reached . For example, if *Connection Timeout* is set to 300 and the maximum number of connections is reached, the Pool Manager waits for 300 seconds for an available physical connection. If a physical connection is *not* available within this time, the Pool Manager throws a ConnectionWaitTimeoutException. It usually does not make sense to retry the getConnection() method, because if a longer wait time is required, you should set the **Connection Timeout** setting to a higher value. Therefore, if this exception is caught by the application, the administrator should review the expected usage of the application and tune the connection pool and the database accordingly.

If Connection Timeout is set to 0, the Pool Manager waits as long as necessary until a connection is allocated (which happens when the number of connections falls below the value of **Max Connections**).

If Max Connections is set to 0, which enables an infinite number of physical connections, then the Connection Timeout value is ignored.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Max Connections:

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. Once this number is reached, no new physical connections are created and the requester waits until a physical connection that is currently in use returns to the pool, or a ConnectionWaitTimeoutException is thrown.

For example, if the Max Connections value is set to 5, and there are five physical connections in use, the pool manager waits for the amount of time specified in Connection Timeout for a physical connection to become free.

If Max Connections is set to 0, the Connection Timeout value is ignored.

For better performance, set the value for the connection pool lower than the value for the Max Connections option in the web container. Lower settings, such as 10-30 connections, perform better than higher settings, such as 100.

If clones are used, one data pool exists for each clone. Knowing the number of data pools is important when configuring the database maximum connections.

You can use the Tivoli Performance Viewer to find the optimal number of connections in a pool. If the number of concurrent waiters is greater than 0, but the CPU load is not close to 100%, consider increasing the connection pool size. If the Percent Used value is consistently low under normal workload, consider decreasing the number of connections in the pool.

Data type	Integer
Default	10
Range	0 to max int

Min Connections:

Specifies the minimum number of physical connections to maintain.

Until this number is reached, the pool maintenance thread does not discard physical connections. However, no attempt is made to bring the number of connections up to this number. If you set a value for Aged Timeout, the minimum is not maintained. All connections with an expired age are discarded.

For example if the **Min Connections** value is set to 3, and one physical connection is created, the Unused Timeout thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the **Min Connections** setting.

Data type	Integer
Default	1
Range	0 to max int

Reap Time:

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if **Reap Time** is set to 60, the pool maintenance thread runs every 60 seconds. The Reap Time interval affects the accuracy of the **Unused Timeout** and **Aged Timeout** settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the Reap Time value less than the values of Unused Timeout and Aged Timeout. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value specified in Unused Timeout, until it reaches the number of connections specified in **Min Connections**. The pool maintenance thread also discards any connections that remain active longer than the time value specified in Aged Timeout.

The Reap Time interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread set Reap Time to 0, or set both Unused Timeout and Aged Timeout to 0. The recommended way to disable the pool maintenance thread is to set Reap Time to 0, in which case Unused Timeout and Aged Timeout are ignored. However, if Unused Timeout and Aged Timeout are set to 0, the pool maintenance thread runs, but only physical connections that timeout due to non-zero timeout values are discarded.

Data type	Integer
Units	Seconds
Default	180
Range	0 to max int

Unused Timeout:

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the Unused Timeout value higher than the Reap Timeout value for optimal performance. Unused physical connections are only discarded if the current number of connections not in use exceeds the **Min Connections** setting. For example, if the unused timeout value is set to 120, and the pool maintenance thread is enabled (Reap Time is not 0), any physical connection that remains unused for two minutes is discarded. Note that accuracy of this timeout, as well as performance, is affected by the **Reap Time** value. For more information, see Reap Time.

Data type	Integer
Units	Seconds
Default	1800
Range	0 to max int

Aged Timeout:

Specifies the interval in seconds before a physical connection is discarded.

Setting **Aged Timeout** to 0 supports active physical connections remaining in the pool indefinitely. Set the Aged Timeout value higher than the **Reap Timeout** value for optimal performance. For example, if the Aged Timeout value is set to 1200, and the Reap Time value is not 0, any physical connection that remains in existence for 1200 seconds (20 minutes) is discarded from the pool. Note that accuracy of this timeout, as well as performance, are affected by the Reap Time value. For more information, see Reap Time.

Data type	Integer
Units	Seconds
Default	0
Range	0 to max int

Purge Policy:

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**. Java EE Connector Architecture (JCA) data sources can have either option. WebSphere Version 4.0 data sources always have a purge policy of **EntirePool**.

Data type	String
Default	FailingConnectionOnly

Range

EntirePool
All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and throws a *StaleConnectionException* during the next operation on that connection. Subsequent *getConnection* requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice.

FailingConnectionOnly
Only the connection that caused the *StaleConnectionException* is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a good possibility that the next *getConnection* request from the application can return a connection from the pool that is also stale, resulting in more stale connection exceptions.

Configuring a queue for Version 5 default messaging

Use this task to browse or change the properties of a JMS queue destination for point-to-point messaging by WebSphere Application Server Version 5 applications. This task contains an optional step for you to create a new topic destination.

About this task

To configure a JMS queue destination for use by WebSphere Application Server Version 5 applications, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Resources** > **JMS->JMS providers**.
2. Select the V5 default messaging provider for which you want to configure a queue destination.
3. Optional: Change the **Scope** setting to the level at which the JMS destination is visible to applications.
4. In the content pane, under Additional Properties, click **Queues** This displays any existing queue destinations for the Version 5 default messaging provider in the content pane.
5. To browse or change an existing JMS queue destination, click its name in the list. Otherwise, to create a new queue destination, complete the following steps:
   a. Click **New** in the content pane.
   b. Specify the following required properties. You can specify other properties, as described in a later step.

      Name The name by which this queue destination is known for administrative purposes within IBM WebSphere Application Server.

      JNDI Name
      The JNDI name that is used to bind the queue destination into the namespace.

c. Click **Apply**. This defines the queue destination to WebSphere Application Server, and enables you to browse or change additional properties.

6. Optional: Change properties for the queue destination, according to your needs.
7. Click **OK**.
8. Save any changes to the master configuration.
9. To make a queue destination available to applications, host the queue on a JMS server. To add a new queue to a JMS server or to change an existing queue on a JMS server, you define the administrative name of the queue to the JMS server.
10. To have the changed configuration take effect, stop then restart the application server.

Version 5 default messaging queue settings:

Use this page to view or change the configuration properties of the selected JMS queue destination for point-to-point messaging by WebSphere Application Server Version 5 applications.

A queue destination is used to configure a JMS queue of the default messaging provider for use by WebSphere Application Server Version 5 applications. Connections to the queue are created by the associated V5 default messaging WebSphere queue connection factory.

To view this page, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** > **JMS->JMS providers**.
2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource. However, the JMS resource has only the subset of properties that apply to WebSphere Application Server Version 5. If you want to define a JMS resource at Cell level for use on non-Version 5 nodes, you should define the JMS resource for the Version 6 default messaging provider.
3. In the content pane, click the name of the V5 default messaging provider that you want to support the JMS destination.
4. Under Additional Resources, click **Queues**. This displays a list of any existing JMS queue destinations.
5. Click the name of the JMS queue destination that you want to work with.

A JMS queue for use with the internal WebSphere JMS provider has the following properties.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates that are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this page. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the JMS provider settings page, then click **Apply**, before clicking the link for the type of resource.

Data type String

Name:

The name by which the queue is known for administrative purposes within WebSphere Application Server.

To enable applications to use this queue, you must add the queue name to the **Queue Names** field on the Version 5 JMS server settings page for the JMS server that hosts the queue.

Data type String

JNDI name:

The JNDI name that is used to bind the queue into the application server namespace.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of the queue, for administrative purposes.

Data type String
Default Null

Category:

A category used to classify or group this queue, for your WebSphere Application Server administrative records.

Data type String

Persistence:

Whether all messages sent to the destination are persistent, non-persistent, or have their persistence defined by the application.

Data type Enum
Default APPLICATION DEFINED
Range

APPLICATION DEFINED
Messages on the destination have their persistence defined by the application that put them onto the queue.

NON PERSISTENT
Messages on the destination are not persistent.

PERSISTENT
Messages on the destination are persistent. When a persistent message is put to a queue, all of the message data is written to the messaging log (under the *embedded_messaging_install*\log directory) to make recovery of the message possible.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property

Data type Enum
Default APPLICATION DEFINED
Range
APPLICATION DEFINED
The priority of messages on this destination is defined by the application that put them onto the destination.
QUEUE DEFINED
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
SPECIFIED
The priority of messages on this destination is defined by the **Specified priority** property.
Note: If you select this option, you must define a priority on the **Specified priority** property.

Specified priority:

If the **Priority** property is set to Specified, type here the message priority for this queue, in the range 0 (lowest) through 9 (highest)

If the **Priority** property is set to Specified, messages sent to this queue have the priority value specified by this property.

Data type Integer
Units Message priority level
Default 0
Range 0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or messages on the queue never expire (have an unlimited expiry timeout)

Data type Enum
Default APPLICATION DEFINED
Range
APPLICATION DEFINED
The expiry timeout for messages on this queue is defined by the application that put them onto the queue.
UNLIMITED
Messages on this queue have no expiry timeout, so those messages never expire.
SPECIFIED
The expiry timeout for messages on this queue is defined by the **Specified expiry** property.
Note: If you select this option, you must define a timeout on the **Specified expiry** property.

Specified expiry:

If the **Expiry timeout** property is set to Specified, type here the number of milliseconds (greater than 0) after which messages on this queue expire

Data type Integer
Units Milliseconds

Default 0

Range Greater than or equal to 0
- 0 indicates that messages never timeout
- Other values are an integer number of milliseconds

Configuring a topic for Version 5 default messaging

Use this task to browse or change the properties of a JMS topic destination for publish/subscribe messaging by WebSphere Application Server Version 5 applications. This task contains an optional step for you to create a new topic destination.

About this task

To configure a JMS topic destination for use WebSphere Application Server Version 5 applications, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Resources** > **JMS->JMS providers**.
2. Select the V5 default messaging provider for which you want to configure a topic destination.
3. Optional: Change the **Scope** setting to the level at which the JMS destination is visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource.
4. In the content pane, under Additional Properties, click **Topics** This displays any existing JMS topic destinations for the Version 5 default messaging provider in the content pane.
5. To browse or change an existing JMS topic destination, click its name in the list. Otherwise, to create a new topic destination, complete the following steps:
   a. Click **New** in the content pane.
   b. Specify the following required properties. You can specify other properties, as described in a later step.

      Name The name by which this topic destination is known for administrative purposes within IBM WebSphere Application Server.

      JNDI Name
      The JNDI name that is used to bind the topic destination into the namespace.

      Topic The name of the topic in the default messaging provider, to which messages are sent.
   c. Click **Apply**. This defines the topic destination to WebSphere Application Server, and enables you to browse or change additional properties.
6. Optional: Change properties for the topic destination, according to your needs.
7. Click **OK**.
8. Save any changes to the master configuration.
9. To have the changed configuration take effect, stop then restart the application server.

Version 5 default messaging topic settings:

Use this panel to browse or change the configuration properties of the selected JMS topic destination for publish/subscribe messaging by WebSphere Application Server Version 5 applications.

A WebSphere topic destination is used to configure the properties of a JMS topic for the default messaging provider on a Version 5 node. Connections to the topic are created by the associated topic connection factory.

To view this page, use the administrative console to complete the following steps:
1. In the navigation pane, click **Resources** > **JMS->JMS providers**.

2. **(Optional)** In the content pane, change the **Scope** setting to the level at which JMS resources are visible to applications. If you define a Version 5 JMS resource at the Cell scope level, all users in the cell can look up and use that JMS resource. However, the JMS resource has only the subset of properties that apply to WebSphere Application Server Version 5. If you want to define a JMS resource at Cell level for use on non-Version 5 nodes, you should define the JMS resource for the Version 6 default messaging provider.
3. In the content pane, click the name of the V5 default messaging provider that you want to support the JMS destination.
4. Under Additional Resources, click **Topics**. This displays a list of any existing JMS topic destinations.
5. Click the name of the JMS topic destination that you want to work with.

A JMS topic destination for use with the V5 default messaging provider has the following properties.

Scope:

Specifies the level to which this resource definition is visible to applications.

Resources such as messaging providers, namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates that are defined at more general scopes.

The scope displayed is for information only, and cannot be changed on this panel. If you want to browse or change this resource (or other resources) at a different scope, change the scope on the messaging provider settings panel, then click **Apply**, before clicking the link for the type of resource.

Data type String

Name:

The name by which the topic is known for administrative purposes within IBM WebSphere Application Server.

Data type String

JNDI name:

The JNDI name that is used to bind the topic into the application server namespace.

As a convention, use the fully qualified JNDI name; for example, in the form jms/*Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

Data type String

Description:

A description of the topic, for administrative purposes within IBM WebSphere Application Server.

Data type String
Default Null

Category:

A category used to classify or group this topic, for your IBM WebSphere Application Server administrative records.

Data type String

Topic:

The name of the topic as defined to the JMS provider.

Data type String
Default Null
Range The topic value can be dot notation and include wildcard characters.

Persistence:

Whether all messages sent to the destination are persistent, non-persistent, or have their persistence defined by the application

Data type Enum
Default APPLICATION DEFINED
Range
APPLICATION DEFINED
Messages on the destination have their persistence defined by the application that put them onto the queue.
NON-PERSISTENT
Messages on the destination are not persistent.
PERSISTENT
Messages on the destination are persistent.

Priority:

Whether the message priority for this destination is defined by the application or the **Specified priority** property

Data type Enum
Units Not applicable
Default APPLICATION DEFINED
Range
APPLICATION DEFINED
The priority of messages on this destination is defined by the application that put them onto the destination.
QUEUE DEFINED
[WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.
SPECIFIED
The priority of messages on this destination is defined by the **Specified priority** property. *If you select this option, you must define a priority on the **Specified priority** property.*

Specified priority:

If the **Priority** property is set to Specified, type here the message priority for this queue, in the range 0 (lowest) through 9 (highest)

If the **Priority** property is set to Specified, messages sent to this queue have the priority value specified by this property.

Data type Integer
Units Message priority level
Default 0
Range 0 (lowest priority) through 9 (highest priority)

Expiry:

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or messages on the queue never expire (have an unlimited expiry timeout)

Data type Enum
Units Not applicable
Default APPLICATION DEFINED
Range

APPLICATION DEFINED
The expiry timeout for messages on this queue is defined by the application that put them onto the queue.

UNLIMITED
Messages on this queue have no expiry timeout, so those messages never expire.

SPECIFIED
The expiry timeout for messages on this queue is defined by the **Specified expiry** property. *If you select this option, you must define a timeout on the **Specified expiry** property.*

Specified expiry:

If the **Expiry timeout** property is set to Specified, type here the number of milliseconds (greater than 0) after which messages on this queue expire

Data type Integer
Units Milliseconds
Default 0
Range Greater than or equal to 0

- 0 indicates that messages never timeout
- Other values are an integer number of milliseconds

Chapter 15. Managing message-driven beans

You can manage the Java EE Connector Architecture (JCA) Version 1.5-compliant message-driven beans that you deploy as message endpoints, and you can manage the message listener resources for non-JCA message-driven beans that you deploy against listener ports.

Before you begin

For WebSphere Application Server Version 7 and later, listener ports are stabilized. For more information, read the article on stabilized features. You should plan to migrate your WebSphere MQ message-driven bean deployment configurations from using listener ports to using activation specifications. However, you should not begin this migration until you are sure the application does not have to work on application servers earlier than WebSphere Application Server Version 7. For example, if you have an application server cluster with some members at Version 6.1 and some at Version 7, you should not migrate applications on that cluster to use activation specifications until after you migrate all the application servers in the cluster to Version 7.

If you want to use message-driven beans with a messaging provider that does not have a JCA 1.5 resource adapter, you cannot use activation specifications and therefore you must configure your beans against a listener port. There are also a few scenarios in which, although you could use activation specifications, you might still choose to use listener ports. For example, for compatability with existing message-driven bean applications.

For more information about when to use listener ports rather than activation specifications, see Message-driven beans, activation specifications, and listener ports.

About this task

You can manage the following resources for message-driven beans:

- JCA 1.5-compliant message-driven beans that you deploy as message endpoints, and the associated activation specifications.
- The message listener service, listener ports, and listeners for non-JCA message-driven beans that you deploy against listener ports.

Procedure

- Manage JCA 1.5-compliant message-driven beans that are used as message endpoints.

  JCA 1.5-compliant message-driven beans, deployed by using activation specifications, can be used as message endpoints. You can start and stop specific endpoints within your applications to ensure that messages are delivered only to listening message-driven beans that are interacting with healthy resources.
- Manage message listener resources for message-driven beans.

  The message listener service supports message-driven beans that are used with a non-JCA messaging provider. A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. When you deploy a message-driven bean, you associate the bean with a listener port. When a message arrives on the destination, the listener passes the message to a new instance of a message-driven bean for processing. You can manage the resources used by the message listener service, including being able to start and stop specific listener ports manually.

Managing messages with message endpoints

Manage message delivery for message-driven beans (MDB) that are deployed as message endpoints. The message endpoints are managed beans (MBeans) for inbound resource adapters that are compliant with Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) Version 1.5.

About this task

The application server provides message endpoint MBeans to assist you in managing the delivery of a message to your message-driven beans that are acting as listeners on specific endpoints, which are destinations, and in managing the enterprise information system (EIS) resources that are utilized by these message-driven beans. Message-driven beans that are deployed as message endpoints are not the same as message-driven beans that are configured against a listener port. Message-driven beans that are used as message endpoints must be deployed using an ActivationSpecification that is defined within a resource adapter configuration for JCA Version 1.5.

With message endpoint MBeans, you can activate and deactivate specific endpoints within your applications to ensure that messages are delivered only to listening message-driven beans that are interacting with healthy EIS resources. This capability allows you to optimize the performance of your JMS applications in situations where an EIS resource is not behaving as expected. Message delivery to an endpoint typically fails when the message driven bean that is listening invokes an operation against a resource that is not healthy. For example, a messaging provider, which is an inbound resource adapter that is JCA Version 1.5 compliant, might fail to deliver messages to an endpoint when its underlying message-driven bean attempts to commit transactions against a database server that is not responding.

Note: Design your message-driven beans to delegate business processing to other enterprise beans. Do not access the EIS resources directly in the message-driven bean, but do so indirectly through a delegate bean.

Message endpoint MBeans alleviate two problems that are inherent to applications that provide message endpoints that access resources:

- Failed messages require additional processing, such as delivering them to the listening endpoint again or redirecting them to alternate destinations that process failed messages. In addition, a resource adapter might redeliver a message to an endpoint an infinite number of times.
- Message redirection requires the implementation of specialized destinations (queues and listeners) to process failed messages, as well as the logic to detect message failures. Message redirection is potentially error prone and computationally expensive due to its complexity.

The capability to deactivate (pause) and reactivate (resume) a specific message endpoint alleviates these problems by enabling the administrator to deactivate the endpoint from processing messages that are destined to fail. When the message endpoint is deactivated, you can repair the resource that is causing the problems and reactivate the endpoint to resume handling message requests. In the course of troubleshooting, you will not affect the resource adapter or the application that is hosting the endpoint.

If you are connecting to WebSphere MQ, you can also use the WAS_EndpointInitialState custom property in the activation specification to make the message endpoint start out in a deactivated state. When you set this property to Inactive, the message-driven bean connects with the destination, but does not start receiving messages. Use this setting to automatically deactivate a message endpoint when you know that certain tasks must be completed, services must be started, or checks must be carried out, before message handling begins. You activate the message endpoint in the same way as you would reactivate a message endpoint that you paused during its operation.

Procedure

1. Using the administrative console, navigate to the Message Endpoints panel for the application that is hosting the message endpoint.
   a. Select the **Applications** > **Application Types** > **Websphere enterprise applications** > ***application_name***.
   b. Select the **Runtime** panel.
   c. Select **Message Endpoints**. The panel lists the set of message endpoints that are hosted by the application.

2. Optional: Temporarily disable a message endpoint from handling messages and troubleshoot the problem.
   a. Deactivate the message endpoint by selecting the appropriate endpoint and clicking **Pause**.
   b. When the message endpoint is inactive, diagnose and repair the underlying cause of the delivery failures.
   c. Reactivate the message endpoint by selecting the appropriate endpoint and clicking **Resume**.
3. Optional: Activate a message endpoint that started out in a deactivated state. Select the appropriate endpoint and click **Resume**.

Results

The behavior you will observe when you deactivate (pause) a message endpoint using the message endpoint MBean is dependent upon a variety of factors, including the resource adapter that manages the message endpoint, the configuration of the message endpoint and the application server topology. Some specific examples of interest are as follows:

- **MDB listening on a non-durable topic (dependent on configuration):** The behavior that is implied by the deactivation (pause) of a message endpoint is often dependent upon the function that it is fulfilling. For example, if you have configured a message-driven bean to listen on a non-durable topic on the service integration bus, deactivating the message endpoint is analogous to stopping the application and will cause the subscription to be closed. This means that any messages that are published during the time that the message endpoint is paused will not be received by the message-driven bean.
- **Clustered message-driven bean (dependent on topology):** In this scenario a message-driven bean application has been deployed to a cluster of servers. A given message endpoint MBean controls only the behavior of the MDB in one server from the cluster, so will cause only one server to stop processing messages. Depending upon the messaging configuration and the specific resource adapter in use the messages that would have been consumed by the paused message endpoint may be consumed by the active message endpoints in the cluster, or they may remain unconsumed until the paused message endpoint is resumed.
- **Clustered message-driven bean, a non-clustered queue:** In this scenario, you have a cluster of servers with the same message-driven bean deployed to them. This is similar to the case, in which you have different message-driven beans with the same message selection criteria, except that in this case the message-driven beans are logically the same message-driven bean. Pausing the endpoint will cause only one of the servers to stop receiving messages, and the other message-driven beans will receive all the messages; none of the messages will be orphaned. To stop all of the endpoints, you must direct each server in the cluster to stop the local message endpoint.
- **Clustered message-driven bean, clustered queue:** In this scenario, each message-driven bean is pulling messages from a different partition of the queue. Messaging through WebSphere MQ and the Service Integration Bus have similar, but different, capabilities. If you are using WebSphere MQ, then pausing one endpoint will not allow the other instances of the message-driven bean to receive the messages. In the Service Integration Bus, messages from a paused endpoint will be redirected to the other message-driven beans.

Managing message listener resources for message-driven beans

Manage the resources used by the message listener service to support message-driven beans, typically for use with a messaging provider that does not have a Java EE Connector Architecture (JCA) 1.5 resource adapter.

Before you begin

For WebSphere Application Server Version 7 and later, listener ports are stabilized. For more information, read the article on stabilized features. You should plan to migrate your WebSphere MQ message-driven bean deployment configurations from using listener ports to using activation specifications. However, you should not begin this migration until you are sure the application does not have to work on application

servers earlier than WebSphere Application Server Version 7. For example, if you have an application server cluster with some members at Version 6.1 and some at Version 7, you should not migrate applications on that cluster to use activation specifications until after you migrate all the application servers in the cluster to Version 7.

If you want to use message-driven beans with a messaging provider that does not have a JCA 1.5 resource adapter, you cannot use activation specifications and therefore you must configure your beans against a listener port. There are also a few scenarios in which, although you could use activation specifications, you might still choose to use listener ports. For example, for compatability with existing message-driven bean applications.

If you have existing message-driven beans that use the WebSphere MQ messaging provider (or a compliant third-party JMS provider) with listener ports, and instead you want to use EJB 3 message-driven beans with listener ports, these new beans can continue to use the same messaging provider.

For more information about when to use listener ports rather than activation specifications, see Message-driven beans, activation specifications, and listener ports.

About this task

The message listener service is an extension to the JMS functions of the JMS provider and provides a listener manager, which controls and monitors one or more JMS listeners. Each listener monitors either a JMS queue destination (for point-to-point messaging) or a JMS topic destination (for publish/subscribe messaging). A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. When you deploy a message-driven bean, you associate the bean with a listener port. When a message arrives on the destination, the listener passes the message to a new instance of a message-driven bean for processing. For more information, see Message-driven beans - listener port components.

Procedure

1. Configure the message listener service.
2. Administer listener ports.

   You can complete any of the following administrative tasks:
   - Create or configure a listener port.
   - Start or stop a listener port.
   - Delete a listener port.
3. Configure security for message-driven beans that use listener ports.

Results

You have configured the resources needed by the message listener service to support message-driven beans.

Configuring the message listener service

To support message-driven beans deployed against listener ports, you configure the properties of the message listener service for an application server.

Before you begin

If you want to use message-driven beans with a messaging provider that does not have a JCA 1.5 resource adapter, you cannot use activation specifications and therefore you must configure your beans against a listener port. There are also a few scenarios in which, although you could use activation specifications, you might still choose to use listener ports. For example, for compatability with existing message-driven bean applications.

If you have existing message-driven beans that use the WebSphere MQ messaging provider (or a compliant third-party JMS provider) with listener ports, and instead you want to use EJB 3 message-driven beans with listener ports, these new beans can continue to use the same messaging provider.

For more information about when to use listener ports rather than activation specifications, see Message-driven beans, activation specifications, and listener ports.

About this task

The message listener service is an extension to the JMS functions of the JMS provider and provides a listener manager, which controls and monitors one or more JMS listeners. Each listener monitors either a JMS queue destination (for point-to-point messaging) or a JMS topic destination (for publish/subscribe messaging). For more information, see Message-driven beans - listener port components.

When you deploy an enterprise application to use message-driven beans with listener ports, you can browse or change the configuration of the message listener service for a given application server.

If your messaging system is running in non-ASF mode, to avoid unwanted transaction timeouts, you must make sure that the time that you specify for the **NON.ASF.RECEIVE.TIMEOUT** message listener service custom property is smaller than the sum of the maximum amount of time that the `onMessage()` method of the message-driven bean (MDB) takes to process the message, plus the time you specify for the **Total transaction lifetime timeout** transaction service property.

Procedure

1. Display the listener service settings page:
   a. In the navigation pane, select **Servers** > **Server Types** > **WebSphere application servers**.
   b. In the content pane, click the name of the application server.
   c. Under Communications, click **Messaging** > **Message Listener Service**.
2. Optional: Browse or change the value of properties for the message-driven bean thread pool.
   a. Click **Thread Pool**.
   b. Change the following properties, as required:

      Minimum size
      The minimum number of threads to allow in the pool.

      Maximum size
      The maximum number of threads to allow in the pool.

      Thread inactivity timeout
      The number of milliseconds of inactivity that should elapse before a thread is reclaimed. A value of 0 indicates not to wait and a negative value (less than 0) means to wait forever.

      Note: The administrative console does not allow you to set the inactivity timeout to a negative number. To do this you must modify the value directly in the config.xml file.

      Allow thread allocation beyond maximum thread size
      Select this check box to enable the number of threads to increase beyond the maximum size configured for the thread pool.

   c. Click **OK**.
3. Optional: Specify any message listener service custom properties that you need, as **Custom properties** of the message listener service.
   a. Click **Custom properties**
   b. For each custom property, specify the name and value you require.

      If you have not specified a property before:

      1) Click **New**.

2) Type the name of the property.
3) Type the value of the property.
4) Click **OK**.

For more information about these custom properties, see “Message listener service custom properties” on page 419.

4. Save your changes to the master configuration.
5. To activate the changed configuration, stop then restart the application server.

Results

You have configured the properties of the message listener service for a given application server.

Avoiding transaction timeouts in non-ASF mode

If your messaging system runs in non-Application Server Facilities (non-ASF) mode, you must configure the **Total transaction lifetime timeout** transaction service property and the **NON.ASF.RECEIVE.TIMEOUT** message listener service custom property correctly, to avoid unwanted transaction timeouts.

Before you begin

To carry out the steps in this task, your messaging system must be running in non-ASF mode. To change from ASF mode to non-ASF mode, add the **NON.ASF.RECEIVE.TIMEOUT** custom property to the message listener service as described in “Configuring the message listener service” on page 415.

About this task

For WebSphere Application Server Version 7 and later, listener ports are stabilized. For more information, read the article on stabilized features. You should plan to migrate your WebSphere MQ message-driven bean deployment configurations from using listener ports to using activation specifications. However, you should not begin this migration until you are sure the application does not have to work on application servers earlier than WebSphere Application Server Version 7. For example, if you have an application server cluster with some members at Version 6.1 and some at Version 7, you should not migrate applications on that cluster to use activation specifications until after you migrate all the application servers in the cluster to Version 7.

If your messaging system is running in non-ASF mode, to avoid unwanted transaction timeouts, you must make sure that the time that you specify for the **NON.ASF.RECEIVE.TIMEOUT** message listener service custom property is smaller than the sum of the maximum amount of time that the `onMessage()` method of the message-driven bean (MDB) takes to process the message, plus the time you specify for the **Total transaction lifetime timeout** transaction service property.

Procedure

1. To configure the **Total transaction lifetime timeout** transaction service property, complete step 8 in “Configuring transaction properties for an application server” on page 2491.
2. To configure the **NON.ASF.RECEIVE.TIMEOUT** message listener service custom property, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Communications] Messaging** > **Message Listener Service** > **Custom Properties**.
3. Click **NON.ASF.RECEIVE.TIMEOUT**. The General Properties page is displayed.
4. Modify the **Value** field. The value for **NON.ASF.RECEIVE.TIMEOUT** must be specified in milliseconds. Make sure that the value you specify, when converted into seconds (by dividing by 1000) , is less than the value you have specified for **Total transaction lifetime timeout** combined with the maximum number of seconds the onMessage() method of your MDB takes to process a message.
5. Click **OK**.

6. Stop and restart the application server.

Example

If **Total transaction lifetime timeout** and **NON.ASF.RECEIVE.TIMEOUT** are not correctly configured, transactions can time out before they are completed. This is because the thread begins calling the `receive()` method as soon as the transaction is created. In the following example, **NON.ASF.RECEIVE.TIMEOUT** is set to `110000` milliseconds (110 seconds), **Total transaction lifetime timeout** is set to `120` seconds and the onMessage () method of the MDB takes 15 seconds to process a message. The example supposes that a message does not appear at the destination until the `receive()` method has almost timed out:

1. The listener port starts and allocates a thread from the thread pool and creates a transaction on the thread.
2. The thread calls the `receive()` method to listen for messages.
3. After 110 seconds a message appears at the destination.
4. The thread removes the message from the destination and calls the `onMessage()` method of the MDB to begin processing the message.
5. Ten seconds later, the transaction timeout is reached. The application server marks the transaction for rollback.
6. Five seconds later, the `onMessage()` method finishes processing the message and tries to commit the transaction.
7. The total amount of time that has elapsed since the transaction was started is 125 seconds (110 seconds waiting for a message, plus 15 seconds to process the message). As this time is longer than the transaction timeout, the application server prevents the transaction from being committed, and it is rolled back.

Message listener service

The message listener service is an extension to the JMS functions of the JMS provider. It provides a listener manager that controls and monitors one or more JMS listeners, which each monitor a JMS destination on behalf of a deployed message-driven bean.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Communications] Messaging** > **Message Listener Service**

Custom Properties

You can use the Custom properties page to define the following properties for use by the message listener service.

- "DYNAMIC.CONFIGURATION.ENABLED" on page 419
- "MAX.RECOVERY.RETRIES" on page 419
- "MQJMS.POOLING.THRESHOLD" on page 419
- "MQJMS.POOLING.TIMEOUT" on page 420
- "NON.ASF.RECEIVE.TIMEOUT" on page 420
- "NON.ASF.BMT.ROLLBACK.ENABLED" on page 421
- "RECOVERY.RETRY.INTERVAL" on page 421
- "SERVER.SESSION.POOL.REAP.TIME" on page 421
- "SERVER.SESSION.POOL.UNUSED.TIMEOUT" on page 422
- "SERVER.SESSION.POOL.UNUSED.TIMEOUT.*lpname*" on page 422

Listener Ports

You can use the Listener Ports page to create and modify listener ports by specifying the following properties:

- Name
- Initial State
- Description
- Connection factory JNDI name
- Destination JNDI name
- Maximum sessions
- Maximum retries
- Maximum messages

Thread pool

You can use the Thread pool page to change the following properties for the message-driven bean thread pool:

- Minimum size
- Maximum size
- Thread inactivity timeout

Message listener service custom properties:

Use this panel to view or change custom properties of the message listener service.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Communications] Messaging** > **Message Listener Service** > **Custom Properties**.

You can use the Custom properties page to define the following properties for use by the message listener service.

- "DYNAMIC.CONFIGURATION.ENABLED" on page 419
- "MAX.RECOVERY.RETRIES" on page 419
- "MQJMS.POOLING.THRESHOLD" on page 419
- "MQJMS.POOLING.TIMEOUT" on page 420
- "NON.ASF.RECEIVE.TIMEOUT" on page 420
- "NON.ASF.BMT.ROLLBACK.ENABLED" on page 421
- "RECOVERY.RETRY.INTERVAL" on page 421
- "SERVER.SESSION.POOL.REAP.TIME" on page 421
- "SERVER.SESSION.POOL.UNUSED.TIMEOUT" on page 422
- "SERVER.SESSION.POOL.UNUSED.TIMEOUT.*lpname*" on page 422

DYNAMIC.CONFIGURATION.ENABLED:

This property controls whether the application server on which a listener port is created requires to be restarted. Set this property to true to enable dynamic configuration.

Data type	Boolean
Default	False (not selected)

MAX.RECOVERY.RETRIES:

The maximum number of times that a listener port managed by this service tries to recover from a failure before giving up and stopping. When stopped the associated listener port is changed to the stop state. The interval between retry attempts is defined by the **RECOVERY.RETRY.INTERVAL** property.

A failure can be caused by either of the following conditions:

- An unexpected error has occurred when a listener port tries to get a message from the JMS provider.
- The connection between the application server and the JMS provider has been lost, usually due to a network error.

Data type	Integer
Units	Retry attempts
Default	5
Range	0 (no retries) through 2147483647

MQJMS.POOLING.THRESHOLD:

The maximum number of unused connections in the pool.

An MQSimpleConnectionManager allocates connections on a most-recently-used basis, and destroys connections on a least-recently-used basis. By default, a connection is destroyed if there are more than ten unused connections in the pool.

Data type	Integer
Units	Number of connections
Default	10

MQJMS.POOLING.TIMEOUT:

The number of milliseconds after which a connection in the pool is destroyed if it has not been used.

An MQSimpleConnectionManager allocates connections on a most-recently-used basis, and destroys connections on a least-recently-used basis. By default, a connection is destroyed if it has not been used for five minutes.

Data type	Integer
Units	Milliseconds
Default	5 minutes

NON.ASF.RECEIVE.TIMEOUT:

The timeout in milliseconds for synchronous message receives performed by message-driven bean listener sessions in the non-ASF mode of operation.

Note: The message listener service has two modes of operation, Application Server Facilities (ASF) and non-Application Server Facilities (non-ASF):

- ASF mode provides concurrency and transactional support for applications. For publish/subscribe message-drive beans, ASF mode provides better throughput and concurrency, because in the non-ASF mode the listener is single-threaded.

- Non-ASF mode is mainly for use with third-party messaging providers that do not support JMS ASF, which is an optional extension to the JMS specification. Non-ASF mode is also transactional but, because the path length is shorter than for ASF mode, usually provides improved performance.

To enable the non-ASF mode of operation for all message-driven bean listeners on the application server, set this property to a non-zero value.

If your messaging system is running in non-ASF mode, to avoid unwanted transaction timeouts, you must make sure that the time that you specify for the **NON.ASF.RECEIVE.TIMEOUT** message listener service custom property is smaller than the sum of the maximum amount of time that the `onMessage()` method of the message-driven bean (MDB) takes to process the message, plus the time you specify for the **Total transaction lifetime timeout** transaction service property.

Data type	Integer
Units	Milliseconds
Default	ASF mode (custom property not created)
Range	0 or greater milliseconds **0** Non-ASF mode is disabled **1 or more** The timeout in milliseconds for non-ASF message-driven bean listener synchronous session receives
Recommended	If a transaction timeout occurs, the message must recycle causing extra work. If you want to use the non-ASF mode, set this property to less than the transaction timeout, but greater than or equal to the maximum duration of your message-driven bean onMessage() method. For example, if your message-driven bean onMessage() method typically takes a maximum of 10 seconds, and the transaction timeout is set to 120 seconds, you might set the **NON.ASF.RECEIVE.TIMEOUT** property to no more than 110000 milliseconds (that is, 110 seconds).

NON.ASF.BMT.ROLLBACK.ENABLED:

When the non-Application Server Facilities (non-ASF) mode of operation is in use (because you have set the **NON.ASF.RECEIVE.TIMEOUT** property to a non-zero value), and a message-driven bean that uses bean-managed transactions generates a runtime exception, the **NON.ASF.BMT.ROLLBACK.ENABLED** property determines whether messages are returned to the destination.

Note: The message listener service has two modes of operation, Application Server Facilities (ASF) and non-Application Server Facilities (non-ASF):

- ASF mode provides concurrency and transactional support for applications. For publish/subscribe message-drive beans, ASF mode provides better throughput and concurrency, because in the non-ASF mode the listener is single-threaded.
- Non-ASF mode is mainly for use with third-party messaging providers that do not support JMS ASF, which is an optional extension to the JMS specification. Non-ASF mode is also transactional but, because the path length is shorter than for ASF mode, usually provides improved performance.

When this property is set to false (default), the message is automatically acknowledged before it is passed to the message-driven bean.

When this property is set to true, the message listener service sends a message acknowledgement to the client after the message is successfully processed by the message-driven bean, and the message listener service requests recovery of any message for which the bean generates an exception.

Data type	Boolean
Default	False

RECOVERY.RETRY.INTERVAL:

The time in seconds between retry attempts by a listener port to recover from a failure. The maximum number of retry attempts is defined by the **MAX.RECOVERY.RETRIES** property.

A failure can be caused by either of the following conditions:

- An unexpected error has occurred when a listener port tries to get a message from the JMS provider.
- The connection between the application server and the JMS provider has been lost, usually due to a network error.

Data type	Integer
Units	Seconds
Default	60
Range	1 through 2147483647

SERVER.SESSION.POOL.REAP.TIME:

The time in seconds between checks on server session pools. To enable server session pool monitoring, set this property to a non-negative value.

The **SERVER.SESSION.POOL.REAP.TIME** custom property is not applicable if your messaging system is running in non-ASF mode.

Data type	Integer
Units	Seconds
Default	-1 (disabled)
Range	-2147483648 through 2147483647

SERVER.SESSION.POOL.UNUSED.TIMEOUT:

The default server session pool timeout in seconds.

When this property is set to a non-negative value, it is compared to the time that has elapsed since a server session was used. If the timeout value is less than the elapsed time, the server session is removed from the server session pool and its JMS session is returned to the JMS session pool. For example, if the timeout value is one second and the time that has elapsed since a particular server session was used is two seconds, that server session is removed from the server session pool and its JMS session is returned to the JMS session pool.

The **SERVER.SESSION.POOL.UNUSED.TIMEOUT** custom property is not applicable if your messaging system is running in non-ASF mode.

Data type	Integer
Units	Seconds
Default	-1 (disabled)
Range	-2147483648 through 2147483647

SERVER.SESSION.POOL.UNUSED.TIMEOUT.lpname:

This property overrides the default **SERVER.SESSION.POOL.UNUSED.TIMEOUT** value for the listener port with the name defined for *lpname*. This value applies to all message-driven beans that use the specified listener port.

If this override is set to a non-negative value, it overrides the **SERVER.SESSION.POOL.UNUSED.TIMEOUT** property, even if the **SERVER.SESSION.POOL.UNUSED.TIMEOUT** property has a negative value.

If this override is set to a negative value, it disables server session pool monitoring for the specified listener port.

The **SERVER.SESSION.POOL.UNUSED.TIMEOUT.lpname** custom property is not applicable if your messaging system is running in non-ASF mode.

Data type	Integer
Units	Seconds
Default	Not set
Range	-2147483648 through 2147483647

Administering listener ports

You can use the WebSphere Application Server administrative console to administer listener ports, which each define the association between a connection factory, a destination, and a message-driven bean.

Before you begin

If you want to use message-driven beans with a messaging provider that does not have a JCA 1.5 resource adapter, you cannot use activation specifications and therefore you must configure your beans against a listener port. There are also a few scenarios in which, although you could use activation specifications, you might still choose to use listener ports. For example, for compatability with existing message-driven bean applications.

If you have existing message-driven beans that use the WebSphere MQ messaging provider (or a compliant third-party JMS provider) with listener ports, and instead you want to use EJB 3 message-driven beans with listener ports, these new beans can continue to use the same messaging provider.

For more information about when to use listener ports rather than activation specifications, see Message-driven beans, activation specifications, and listener ports.

About this task

A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. If you set the initial state of a listener port to Started, the listener port is started automatically when a message-driven bean associated with that port is installed.

Listener ports can be manually started and stopped. If a message-driven bean fails to process a message several times, the listener port is automatically stopped by the application server. When a listener port is stopped, the listener manager stops the listeners for all message-driven beans associated with the port. Consequently, the associated message-driven beans can no longer process messages.

Note: You do not usually need to start or stop a listener port manually.

Procedure

- Create a new listener port.

Create a new listener port, to specify a new association between a connection factory, a destination, and a message-driven bean. This association enables deployed message-driven beans associated with the port to retrieve messages from the destination.

- Configure a listener port.

  Browse or change the configuration properties of a listener port.
- Start a listener port.
- Stop a listener port.
- Delete a listener port.

Creating a new listener port

You create a new listener port for the message listener service to define the association between a connection factory, a destination, and a deployed message-driven bean. This association enables the message-driven bean to retrieve messages from the associated destination.

Before you begin

If you want to use message-driven beans with a messaging provider that does not have a JCA 1.5 resource adapter, you cannot use activation specifications and therefore you must configure your beans against a listener port. There are also a few scenarios in which, although you could use activation specifications, you might still choose to use listener ports. For example, for compatability with existing message-driven bean applications.

If you have existing message-driven beans that use the WebSphere MQ messaging provider (or a compliant third-party JMS provider) with listener ports, and instead you want to use EJB 3 message-driven beans with listener ports, these new beans can continue to use the same messaging provider.

For more information about when to use listener ports rather than activation specifications, see Message-driven beans, activation specifications, and listener ports.

About this task

A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. This association enables deployed message-driven beans associated with the port to retrieve messages from the destination. For more information, see Message-driven beans - listener port components.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Servers** > **Server Types** > **WebSphere application servers->*server_name*** > **[Communications] Messaging** > **Message listener service** > **[Additional Properties] Listener Ports**. The “Message listener port collection” on page 425 panel is displayed.
3. Click **New**.
4. Specify the following required properties:

   Name The name by which the listener port is known for administrative purposes.

   Connection factory JNDI name
   The JNDI name for the JMS connection factory to be used by the listener port; for example, `jms/connFactory1`.

   Destination JNDI name
   The JNDI name for the destination to be used by the listener port; for example, `jms/destn1`.
5. Optional: Change other properties for the listener port, as required.
6. Click **OK**.
7. Save your changes to the master configuration.

8. To have the changed configuration take effect, stop then restart the application server.

Results

If you set the initial state of a listener port to Started, the listener port is started automatically when a message-driven bean associated with that port is installed.

Configuring a listener port

Use this task to browse or change the properties of an existing listener port, which is used by message-driven beans associated with the port to retrieve messages.

Before you begin

If you want to use message-driven beans with a messaging provider that does not have a JCA 1.5 resource adapter, you cannot use activation specifications and therefore you must configure your beans against a listener port. There are also a few scenarios in which, although you could use activation specifications, you might still choose to use listener ports. For example, for compatability with existing message-driven bean applications. For more information about when to use listener ports rather than activation specifications, see Message-driven beans, activation specifications, and listener ports.

About this task

A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. This association enables deployed message-driven beans associated with the port to retrieve messages from the destination. For more information, see Message-driven beans - listener port components.

When you deploy an enterprise application to use message-driven beans with listener ports, you can browse or change the configuration of a listener port.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Servers** > **Server Types** > **WebSphere application servers->*server_name*** > **[Communications] Messaging** > **Message listener service** > **[Additional Properties] Listener Ports**

   The “Message listener port collection” on page 425 panel is displayed.
3. Select the name of the listener port that you want to work with. This displays the properties of the listener port in the content pane.
4. Optional: Change properties for the listener port, according to your needs.
5. Click **OK**.
6. Save your changes to the master configuration.
7. To have a changed configuration take effect, stop then restart the application server.

Message listener port collection:

The message listener ports configured in the administrative domain

A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. This association enables deployed message-driven beans associated with the port to retrieve messages from the destination.

This panel displays a list of the message listener ports configured in the administrative domain. You can use this panel to add new listener ports or to change the properties of existing listener ports.

To view this administrative console panel, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Messaging] Message Listener Service** > **Listener Ports**

To manage a listener port, select the check box beside the listener port name in the list and click a button:

Button	Resulting action
Convert to activation specification	Opens a wizard that helps you convert the selected listener port to an activation specification.
New	Accesses the panel to configure a new listener port.
Delete	Deletes the selected listener port or ports.
Start	Starts the selected listener port or ports.
Stop	Stops the selected listener port or ports.

Listener port settings:

A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. This association enables deployed message-driven beans associated with the port to retrieve messages from the destination.

Use this panel to view or change the configuration properties of the selected listener port.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **[Communications] Messaging** > **Message Listener Service** > **Listener Ports** > ***listener_port***.

Name:

The name by which the listener port is known for administrative purposes.

Data type String
Default Null

Initial state:

The state that you want the listener port to have when the application server is next restarted

Data type Enum
Units Not applicable
Default Started
Range

Started
When the application server is next started, the listener port is started automatically.

Stopped
When the application server is next started, the listener port is not started automatically. If message-driven beans are to use this listener port on the application server, the system administrator must start the port manually or select the Started value of this property then restart the application server.

Description:

A description of the listener port, for administrative purposes within IBM WebSphere Application Server.

Data type	String
Default	Null

Connection factory JNDI name:

The JNDI name for the JMS connection factory to be used by the listener port; for example, jms/connFactory1.

Data type	String
Default	Null

Destination JNDI name:

The JNDI name for the destination to be used by the listener port; for example, jms/destn1.

You cannot use a temporary destination for late responses.

Data type	String
Default	Null

Maximum sessions:

The maximum number of concurrent sessions that a listener can have with the JMS server to process messages.

Each session corresponds to a separate listener thread and therefore controls the number of concurrently processed messages. Adjust this parameter when the server does not fully use the available capacity of the machine.

Data type	Integer
Units	Sessions
Default	1
Range	1 through 2147483647
Recommended	• For message concurrency, that is to process multiple messages simultaneously, set this property to a value greater than 1. Keep this value as low as possible to prevent overloading client applications. A good starting point for a 100% JMS workload with short transaction times is 2 to 4 sessions per processor. If longer running transactions exist, you might need more sessions, which should be determined by experimentation. The total number of sessions specified in the Maximum Sessions property of all configured listener ports must be less than or equal to the number of threads specified for the Maximum Size property of the message listener service thread pool.

Maximum retries:

The maximum number of times that the listener tries to deliver a message to a message-driven bean instance before the listener is stopped, in the range 0 through 2147483647.

Note: A WebSphere MQ queue has a similar property called the **BackoutThreshold** property. If your listener port is reading from a WebSphere MQ queue, then the retry limit and the behavior when the limit is reached is determined by whichever of these two properties is set to the lower limit:

- If you exceed the WebSphere MQ queue **BackoutThreshold** limit, the message that cannot be delivered is moved to somewhere else by WebSphere MQ (for example, to the WebSphere MQ backout requeue queue or the WebSphere MQ dead letter queue) and the listener port services the next message on the queue. In this case, WebSphere Application Server might not know that the message has not been delivered successfully.
- If you exceed the listener port **maximum retries** limit, the listener port stops. You then manually intervene to investigate the problem, possibly to remove the message from the WebSphere MQ queue then restart the listener port.

Data type	Integer
Units	Retry attempts
Default	0 (no retries)
Range	0 (no retries) through 2147483647

Maximum messages:

The maximum number of messages that the listener can process in one transaction.

If the queue is empty, the listener processes each message when it arrives. Each message is processed within a separate transaction.

For the WebSphere V5 default messaging provider or WebSphere MQ as the JMS provider, if messages start accumulating on the queue then the listener can start processing messages in batches. For third-party messaging providers, this property value is passed to the JMS provider but the effect depends on the JMS provider.

Data type	Integer
Units	Number of messages
Default	1
Range	1 through 2147483647
Recommended	For the WebSphere default messaging providers or WebSphere MQ as the JMS provider, to process multiple messages in a single transaction, set this value to more than 1. If messages start accumulating on the queue, a value greater than 1 enables multiple messages to be batch-processed into a single transaction, and eliminates much of the transaction processing costs for JMS messages. **CAUTION:** • If one message in the batch fails processing with an exception, the entire batch of messages is put back on the queue for processing. • Any resource lock held by any of the interactions for the individual messages are held for the duration of the entire batch. • Depending on the amount of processing that messages need, and if XA transactions are being used, setting a value greater than 1 can cause the transaction to time out. If an XA transaction does time out routinely because processing multiple messages exceeds the transaction timeout, reduce this property to 1 (to limit processing to one message per transaction) or increase your transaction timeout.

Starting a listener port

Use this task to start a listener port on an application server, to enable the listeners for message-driven beans associated with the port to retrieve messages.

About this task

A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. For more information, see Message-driven beans - listener port components.

A listener is active, that is able to receive messages from a destination, if the deployed message-driven bean, listener port, and message listener service are all started. Although you can start these components in any order, they must all be in a started state before the listener can retrieve messages.

If you set the initial state of a listener port to Started, the listener port is started automatically when a message-driven bean associated with that port is installed. You can also start a listener port manually.

When a listener port is started, the listener manager tries to start the listeners for each message-driven bean associated with the port. If a message-driven bean is stopped, the port is started but the listener is not started, and remains stopped. If you start a message-driven bean, the related listener is started.

Procedure

1. Start the administrative console.
2. If you want the listener for a deployed message-driven bean to be able to receive messages at the port, check that the message-driven bean has been started.
3. In the navigation pane, click **Servers** > **Server Types** > **WebSphere application servers->*server_name*** > **[Communications] Messaging** > **Message listener service** > **[Additional Properties] Listener Ports**

   The “Message listener port collection” on page 425 panel is displayed.
4. Select the check box for the listener port that you want to start.
5. Click **Start**.
6. Save your changes to the master configuration.

Stopping a listener port

Use this task to stop a listener port on an application server, to prevent the listeners for message-driven beans associated with the port from retrieving messages.

About this task

A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. For more information, see Message-driven beans - listener port components.

If a message-driven bean fails to process a message several times, the listener port is automatically stopped by the application server. You can also stop a listener port manually. When a listener port is stopped, the listener manager stops the listeners for all message-driven beans associated with the port. Consequently, the associated message-driven beans can no longer process messages.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Servers** > **Server Types** > **WebSphere application servers->*server_name*** > **[Communications] Messaging** > **Message listener service** > **[Additional Properties] Listener Ports**

   The “Message listener port collection” on page 425 panel is displayed.

3. Select the check box for the listener port that you want to stop.
4. Click **Stop**.
5. Save your changes to the master configuration.
6. To have the changed configuration take effect, stop then restart the application server.

Deleting a listener port

Use this task to delete a listener port from the message listener service, to prevent message-driven beans associated with the port from retrieving messages.

About this task

A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. For more information, see Message-driven beans - listener port components.

To delete a listener port, use the administrative console to complete the following steps:

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Servers** > **Server Types** > **WebSphere application servers->*server_name*** > **[Communications] Messaging** > **Message listener service** > **[Additional Properties] Listener Ports**

   The “Message listener port collection” on page 425 panel is displayed.
3. Select the check box for the listener port that you want to delete.
4. Click **Delete**.

   This action stops the port (needed to allow the port to be deleted) then deletes the port.
5. Save your changes to the master configuration.
6. To have the changed configuration take effect, stop then restart the application server.

Monitoring server session pools for listener ports

You can minimize the number of resources that server sessions use by enabling server session pool monitoring and defining the timeout value to be applied to a server session.

About this task

Each listener port uses one or more server sessions, which are held in a server session pool. Each server session is associated with a JMS session, which is taken from the JMS session pool that is associated with the JMS connection factory that the listener port is configured to use.

By default, server session pool monitoring is disabled. When a listener port uses a server session the listener port does not release the server session from the server session pool until the listener port is shut down. This means that the associated JMS session is not released into the JMS session pool until the listener port is shut down, even if the listener port is not processing any messages. Consequently the resources that the JMS session uses, for example TCP/IP connections, can be held for a long time, and this can cause problems for resource-constrained systems.

To minimize the number of resources that server sessions use, you must monitor the server session pools. When you enable server session pool monitoring each server session in each server session pool that a listener port uses is monitored to determine how much time has elapsed since the server session was last used. If the elapsed time is greater than the timeout value that you have configured, the server session is removed from the server session pool and its associated JMS session is returned to the JMS session pool. The returned JMS session can be either reused by another application or closed, depending on your JMS session pool settings. You can also configure additional pooling mechanisms, depending on your JMS provider.

Note: Server session pool monitoring cannot be used if the message listener service is operating in non-Application Server Facilities (non-ASF) mode, that is if the NON.ASF.RECEIVE.TIMEOUT message listener service custom property is set to a non-zero value.

Procedure

To enable server session pool monitoring, configure the following message listener service custom properties on each application server as required.

SERVER.SESSION.POOL.REAP.TIME
To enable server session pool monitoring, set this property to the time in seconds between checks on server session pools (this must be a non-negative value).

SERVER.SESSION.POOL.UNUSED.TIMEOUT
To specify the default server session pool timeout, set this property to the required number of seconds for the timeout. When this property is set to a non-negative value, it is compared with the time that has elapsed since a server session was used. If the timeout value is less than the elapsed time, the server session is removed from the server session pool and its JMS session is returned to the JMS session pool. For example, if the timeout value is one second and the time that has elapsed since a particular server session was used is two seconds, that server session is removed from the server session pool and its JMS session is returned to the JMS session pool.

SERVER.SESSION.POOL.UNUSED.TIMEOUT.*lpname*
To override the default SERVER.SESSION.POOL.UNUSED.TIMEOUT value for the listener port with the name *lpname*, set this property to the appropriate value:

- To override the SERVER.SESSION.POOL.UNUSED.TIMEOUT for the specified listener port, set this property to a non-negative value defining the required number of seconds for the server session timeout for this listener port.
- To disable server session pool monitoring for the specified listener port, set this property to a negative value.

The value that you set for this property applies to all message-driven beans that are using the specified listener port.

Example

For example, consider an application server that is configured with listener ports lp1, and lp2.

The following rules apply:

No properties set
If none of the properties are set, server session pool monitoring is disabled and JMS sessions used by server sessions are not returned to the JMS session pool until the listener port (lp1 or lp2), or its associated message-driven bean, is shut down.

SERVER.SESSION.POOL.REAP.TIME and SERVER.SESSION.POOL.UNUSED.TIMEOUT set
Consider, for example, the following settings:

SERVER.SESSION.POOL.REAP.TIME=60

SERVER.SESSION.POOL.UNUSED.TIMEOUT=120

The server session pool of both listener ports (lp1 and lp2) is checked for inactive server sessions every 60 seconds. If a server session is detected as being inactive for more than 120 seconds, it is removed from the server session pool and its JMS session is returned to the JMS session pool. Taking into account the SERVER.SESSION.POOL.REAP.TIME value, the server session pool could be removed from the session pool between two and three minutes after the server session was last used.

SERVER.SESSION.POOL.REAP.TIME and SERVER.SESSION.POOL.UNUSED.TIMEOUT set, and overrides set for SERVER.SESSION.POOL.UNUSED.TIMEOUT.*lpname*

Consider, for example, the following settings:

```
SERVER.SESSION.POOL.REAP.TIME=60
SERVER.SESSION.POOL.UNUSED.TIMEOUT=120
SERVER.SESSION.POOL.UNUSED.TIMEOUT.lp2=-1
SERVER.SESSION.POOL.UNUSED.TIMEOUT.lp1=60
```

The server session pool for listener port lp2 is not checked because it has a negative timeout value. In the server session pool for listener port lp1, any server sessions that are inactive for more than 60 seconds are removed from the server session pool.

Chapter 16. Administering Naming and directory

This page provides a starting point for finding information about naming support. Naming includes both server-side and client-side components. The server-side component is a Common Object Request Broker Architecture (CORBA) naming service (CosNaming). The client-side component is a Java™ Naming and Directory Interface (JNDI) service provider. JNDI is a core component in the Java Platform, Enterprise Edition (Java EE) programming model.

The WebSphere® JNDI service provider can be used to interoperate with any CosNaming name server implementation. Yet WebSphere name servers implement an extension to CosNaming, and the JNDI service provider uses those WebSphere extensions to provide greater capability than CosNaming alone. Some added capabilities are binding and looking up of non-CORBA objects.

Java EE applications use the JNDI service provider supported by WebSphere Application Server to obtain references to objects related to server applications, such as enterprise bean (EJB) homes, which have been bound into a CosNaming name space.

Configuring namespace bindings

Instead of creating namespace bindings from a program, you can configure namespace bindings using the administrative console. Name servers add these configured bindings to the namespace view by reading the configuration data for the bindings. Configured bindings are created each time a server starts, even when the binding is created in a transient partition of the namespace. One major use of configured bindings is to provide fixed qualified names for server application objects.

Before you begin

Assemble and deploy your application onto an application server. If the application is a client to an application running in another server process, specify qualified jndiName values for the server objects of the other application during assembly or deployment. For more information on qualified names, refer to the topic on lookup names support in deployment descriptors and thin clients.

About this task

A deployed application requires qualified fixed names if the application is accessed by thin client applications or by Java Platform, Enterprise Edition (Java EE) client applications or server applications running in another server process.

When you configure a namespace binding, you create a qualified fixed name for a server object. A fixed name does not change if the object is moved to another server. A qualified fixed name with a cell scope has the following form:

`cell/persistent/`*`fixedName`*

The *fixedName* is an arbitrary fixed name.

You can configure namespace bindings, and thus qualified fixed names, for the following objects:
- A string constant value
- An enterprise bean (EJB) home installed on a server in the cell
- A CORBA object available from a CosNaming name server
- An object bound in a WebSphere Application Server namespace that is accessible using a Java Naming and Directory Interface (JNDI) indirect lookup

To view or configure a namespace binding for an object of a deployed application, complete the following:

Procedure

1. Go to the Name space bindings page.

   In the administrative console, click **Environment** > **Naming** > **Name space bindings**.

2. Select the desired scope.

   The scope determines where in the namespace binding is created. It also affects which name servers contain the binding in the namespace that they manage. Regardless of the scope, a namespace binding is accessible from all name servers in the cell. However, the scope can affect whether the lookup can be resolved locally by a name server or whether the name server must make a remote call to another name server to resolve the binding.

   Only namespace bindings created with the selected scope are visible in the collection table on the page. By changing the scope, you can see and create bindings in other scopes.

   a. Select a scope.

      If you are creating a new namespace binding, refer to the table below as a guide in selecting a scope:

Table 66. Namespace binding scope descriptions. The scope can be a cell, node, server, or cluster.

Scope	Description
Cell	Cell-scoped bindings are created under the cell persistent root context. Select **Cell** if the namespace binding is not specific to any particular node or server, or if you do not want the binding to be associated with any specific node or server. For example, you can use cell-scoped bindings to create fixed qualified names for enterprise beans. Fixed qualified names do not have any node or server names embedded within them.
Node	Node-scoped bindings are created under the node persistent root context for the selected node. Select **Node** if the namespace binding is specific to a particular node, or if you want the binding to be associated with a specific node.
Server	Server-scoped bindings are created under the server root context for the selected server. Select **Server** if a binding is to be used only by clients of an application running on a particular server, or if you want to configure a binding with the same name on different servers which resolve to different objects. Note that two servers can have configured bindings with the same name but resolve to different objects. Server-scoped bindings are created in the process of the selected application server. Therefore, the name server running in the selected application server can resolve those bindings locally. No remote invocations to other name servers are necessary to resolve the bindings. However, all other name servers in the cell must make remote calls to the selected server in order to resolve the bindings. For example, in order for the name server running in *server1* in node *node1* to resolve the name `cell/nodes/node1/servers/server2/serverScopedConfiguredBinding`, it must make a remote call to *server2* in *node1*. Only the name server in *server2* in *node1* can resolve that name without invoking any other name servers.

   b. Click **Apply**.

3. Create a new namespace binding.

   a. Open the New Name Space Binding wizard.

      On the Name space bindings page, click **New**.

   b. On the **Specify binding type** page, select the binding type.

      The namespace binding can be for a constant string value, an EJB home, a CORBA CosNaming NamingContext or CORBA leaf node object, or an object that you can look up indirectly using JNDI.

   c. On the **Specify basic properties** page, specify the binding identifier and other properties for the binding.

      For property descriptions, refer to the following:
      - "String binding settings" on page 1019
      - "EJB binding settings" on page 1020
      - "CORBA object binding settings" on page 1021
      - "Indirect lookup binding settings" on page 1022

d. On the **Summary** page, verify the settings and click **Finish**.

The name of the new binding is displayed in the collection table on the Name space bindings page.

4. Optional: Edit a previously created binding.
   a. From the collection table on the Name space bindings page, click the name of the binding that you want to edit.
   b. Edit the binding properties as desired. Step 3(c) provides links to property descriptions.
   c. Click **OK**.

Results

Cell-scoped bindings are created under the cell persistent root context. Node-scoped bindings are created under the node persistent root context for the specified node. Server-scoped bindings are created under the server root context for the selected server.

Name space binding collection

Use this page to configure a name binding of an EJB, a CORBA CosNaming NamingContext, a CORBA leaf node object, an object that you can look up using Java Naming and Directory Interface (JNDI), or a constant string value.

Binding information for configured bindings is stored in the configuration and applied upon startup of the name server for each server within the scope of the binding.

To view the Name space bindings page, click **Environment** > **Naming** > **Name space bindings**.

Click the check boxes to select one or more of the bindings in your collection. Use the buttons to control the selected bindings.

When creating a new binding, select a scope before clicking **New**. The **Scope** setting filters what bindings are listed in the collection as well as sets the scope of the new binding.

Name

Shows the names given to uniquely identify these configured bindings.

Scope

Shows the scope of the configured binding. This value indicates the configuration location for the `namebindings.xml` file. This field is for information purposes only and cannot be updated.

If the configured binding is cell-scoped, the starting context is the cell persistent root context. If the configured binding is node-scoped, the starting context is the node persistent root context. If the configured binding is server-scoped, the starting context is the server's server root context.

Binding type

Shows the type of binding configured. Valid values are String, EJB, CORBA, and Indirect. This field is for information purposes only and cannot be updated.

Specify binding type settings

Use this page to select the type of namespace binding that you want.

To view this administrative console page, click **Environment** > **Naming** > **Name space bindings** > **New**.

You can configure a namespace binding for any of the following objects:

- A string constant value
- An enterprise bean (EJB) home installed on a server in the cell

- A CORBA object available from a CosNaming name server
- An object bound in a WebSphere Application Server namespace that is accessible using a Java Naming and Directory Interface (JNDI) indirect lookup

On this page, select a binding type and then click **Next**.

Binding type

Specifies the type of binding configured.

Table 67. Namespace binding types. Available types include String, EJB, CORBA, or Indirect.

String	Select **String** to configure a namespace binding for a string constant value. To configure a String binding, you need the following information: • The string constant value • The target root context for the configured binding (scope) • The name of the configured binding, relative to the target root context You can create a file that maps multiple variable names to values and specify the file name for the **String** value. By default, a name server performs variable substitution on the string value of a String namespace binding. Thus, by default, the com.ibm.websphere.naming.expandStringBindings property is set to `true` and a name server expands the value of String bindings. **Tip:** Variable substitution can result in errors or unexpected changes to a string. For example, with variable substitution, a `$$` string is expanded as `$`. You can disable variable substitution and cause the name server to treat the **String** value as a literal or constant. Create a custom property with **Name** set to `com.ibm.websphere.naming.expandStringBindings` and **Value** set to `false`. You can define a custom property at the cell, node, server, or name server scope. Create the custom property on a console page for the appropriate scope: **Cell scope** Click **System administration** > **Cell** > **Custom properties** > **New**. **Node scope** Click **System administration** > **Nodes** > ***node_name*** > **Custom properties** > **New**. **Server scope** Click **Application servers** > ***server_name*** > **Administration** > **Custom properties** > **New**. **Name server scope** Click **Application servers** > ***server_name*** > **Administration** > **Server components** > **Name server** > **Custom properties** > **New**. All name servers within the specified custom property scope apply the setting. Settings at a narrower scope override settings at a wider scope. For example, on multiple-server products, settings at the node scope override settings at the cell scope. Select a custom property scope that is at least as wide as the namespace binding scope. Thus, to prevent variable expansion in a cell-scoped String namespace binding, define the custom property at the cell scope. If the custom property has a scope narrower than the namespace binding, only name servers within the scope prevent variable expansion in the String namespace binding. Name servers outside of the scope expand the variable reference and handle the reference differently.
EJB	Select **EJB** to configure a namespace binding for an EJB home installed on a server in the cell. Use a cell-scoped EJB binding to create a fixed qualified lookup name for an enterprise bean. A fixed qualified lookup name is not dependent on the cell topology. To configure an EJB home binding, you need the following information: • The JNDI name of the EJB server or server cluster where the enterprise bean is deployed • The target root context for the configured binding (scope) • The name of the configured binding, relative to the target root context On stand-alone servers, do not configure an EJB binding that resolves to another server. The name server cannot read configuration data for other servers. That data is required to construct the binding.

Table 67. Namespace binding types (continued). Available types include String, EJB, CORBA, or Indirect.

CORBA	Select **CORBA** to configure a namespace binding for a Common Object Request Broker: Architecture and Specification (CORBA) object available from a Object Management Group (OMG) Interoperable Naming (CosNaming) name server. Identify a CORBA object bound into an INS compliant CosNaming server with a corbaname URL. The referenced object does not have to be available until the binding is actually referenced by an application. To configure a CORBA binding, you need the following information: • The corbaname URL of the CORBA object • An indicator if the bound object is a context or leaf node object (to set the correct CORBA binding type of context or object) • The target root context for the configured binding • The name of the configured binding, relative to the target root context
Indirect	Select **Indirect** to configure a namespace binding for an object bound in a WebSphere Application Server namespace that is accessible using a JNDI indirect lookup. You can select **Indirect** for CORBA objects as well as for javax.naming.Referenceable, javax.naming.Reference, and java.io.Serializable objects. The target object itself is not bound to the namespace. Only the information required to look up the object is bound. Therefore, the referenced name server does not have to be running until the binding is actually referenced by some application. To configure an indirect JNDI lookup binding, you need the following information: • The JNDI provider URL of the name server where the object resides • The JNDI lookup name of the object • The target root context for the configured binding (scope) • The name of the configured binding, relative to the target root context The following information is optional: • The JNDI initial context factory class name. The default is the WebSphere Application Server initial context factory, com.ibm.websphere.naming.WsnInitialContextFactory. • Additional properties to pass to the javax.naming.InitialContext constructor. A cell-scoped indirect binding is useful when creating a fixed qualified lookup name for a bound object so that the qualified lookup name is not dependent on the cell topology.

String binding settings

Use this page to view or configure a string binding.

To view this administrative console page, click **Environment** > **Naming** > **Name space bindings** > ***string_namespace_binding***. The settings on this page are similar to those on the **Specify basic properties** panel of the New name space binding wizard.

Scope

Shows the scope of the configured binding. This value indicates the configuration location for the `namebindings.xml` file.

The **Scope** setting is shown only when you edit an existing binding on the console page, and is not shown when you create a new binding on the wizard panel. This setting is for information purposes and cannot be updated.

If the configured binding is cell-scoped, the starting context is the cell persistent root context. If the configured binding is node-scoped, the starting context is the node persistent root context. If the configured binding is server-scoped, the starting context is the server's server root context.

Binding type
Shows the type of binding configured. Possible choices are String, EJB, CORBA, and Indirect. This setting is for information purposes only and cannot be updated.

Binding identifier
Specifies the name that uniquely identifies this configured binding.

Name in name space
Specifies the name used for this binding in the namespace. This name can be a simple or compound name depending on the portion of the namespace where this binding is configured.

String value
Specifies the string to be bound into the namespace.

You can create a file that maps multiple variable names to values and specify the file name for the **String** value. By default, a name server performs variable substitution on the string value of a String namespace binding. Thus, by default, the com.ibm.websphere.naming.expandStringBindings property is set to `true` and a name server expands the value of String bindings.

Tip: Variable substitution can result in errors or unexpected changes to a string. For example, with variable substitution, a `$$` string is expanded as `$`. You can disable variable substitution and cause the name server to treat the **String** value as a literal or constant. Create a custom property with **Name** set to `com.ibm.websphere.naming.expandStringBindings` and **Value** set to `false`. You can define a custom property at the cell, node, server, or name server scope. Create the custom property on a console page for the appropriate scope:

Cell scope
Click **System administration** > **Cell** > **Custom properties** > **New**.

Node scope
Click **System administration** > **Nodes** > ***node_name*** > **Custom properties** > **New**.

Server scope
Click **Application servers** > ***server_name*** > **Administration** > **Custom properties** > **New**.

Name server scope
Click **Application servers** > ***server_name*** > **Administration** > **Server components** > **Name server** > **Custom properties** > **New**.

All name servers within the specified custom property scope apply the setting. Settings at a narrower scope override settings at a wider scope. For example, on multiple-server products, settings at the node scope override settings at the cell scope. Select a custom property scope that is at least as wide as the namespace binding scope. Thus, to prevent variable expansion in a cell-scoped String namespace binding, define the custom property at the cell scope. If the custom property has a scope narrower than the namespace binding, only name servers within the scope prevent variable expansion in the String namespace binding. Name servers outside of the scope expand the variable reference and handle the reference differently.

EJB binding settings
Use this page to configure a new enterprise bean (EJB) binding, or to view or edit an existing EJB binding.

To view this console page, click **Environment** > **Naming** > **Name space bindings** > ***EJB_namespace_binding***. The settings on this page are similar to those on the **Specify basic properties** panel of the New name space binding wizard.

Scope
Shows the scope of the configured binding. This value indicates the configuration location for the `namebindings.xml` file.

The **Scope** setting is shown only when you edit an existing binding on the console page, and is not shown when you create a new binding on the wizard panel. This setting is for information purposes and cannot be updated.

If the configured binding is cell-scoped, the starting context is the cell persistent root context. If the configured binding is node-scoped, the starting context is the node persistent root context. If the configured binding is server-scoped, the starting context is the server's server root context.

Binding type
Shows the type of binding configured. Possible choices are String, EJB, CORBA, and Indirect. This setting is for information purposes only and cannot be updated.

Binding identifier
Specifies the name that uniquely identifies this configured binding.

Name in name space
Specifies the name used for this binding in the namespace. This name can be a simple or compound name depending on the portion of the namespace where this binding is configured.

Enterprise bean location
Specifies whether the enterprise bean is running in a single server. If `Single server` is specified, type the node name.

Server
Specifies the name of the server in which the enterprise bean is configured.

JNDI name
Specifies the Java Naming and Directory Interface (JNDI) name of the deployed enterprise bean. It is the bean's JNDI name that is in the enterprise bean bindings, not the java:comp name.

CORBA object binding settings
Use this page to configure a new name binding of a CORBA object binding, or to view or edit an existing CORBA object binding.

To view this console page, click **Environment** > **Naming** > **Name space bindings** > ***CORBA_namespace_binding***. The settings on this page are similar to those on the **Specify basic properties** panel of the New name space binding wizard.

Scope
Shows the scope of the configured binding. This value indicates the configuration location for the `namebindings.xml` file.

The **Scope** setting is for information purposes and cannot be updated.

If the configured binding is cell-scoped, the starting context is the cell persistent root context. If the configured binding is node-scoped, the starting context is the node persistent root context. If the configured binding is server-scoped, the starting context is the server's server root context.

Binding type
Shows the type of binding configured. Possible choices are String, EJB, CORBA, and Indirect. This setting is for information purposes and cannot be updated.

Binding identifier
Specifies the name that uniquely identifies this configured binding.

Name in name space
Specifies the name used for this binding in the namespace. This name can be a simple or compound name depending on the portion of the namespace where this binding is configured.

Corbaname URL
Specifies the CORBA name URL string identifying where the object is bound in a CosNaming server.

Federated context
Specifies whether the target is a CosNaming context (true) or a leaf node object (false).

true	The target object is bound with a context CORBA binding type. If the corbaname URL does not resolve to a NamingContext, an error occurs when the binding is first used (which is when the URL is first resolved).
false	The target object is bound with an object CORBA binding type.

Indirect lookup binding settings
Use this page to configure a new indirect lookup name binding, or to view or edit an existing indirect lookup binding.

To view this console page, click **Environment** > **Naming** > **Name space bindings** > ***indirect_lookup_namespace_binding***. The settings on this page are similar to those on the **Specify basic properties** panel of the New name space binding wizard.

Scope
Shows the scope of the configured binding. This value indicates the configuration location for the `namebindings.xml` file.

The **Scope** setting is shown only when you edit an existing binding on the console page, and is not shown when you create a new binding on the wizard panel. This setting is for information purposes and cannot be updated.

If the configured binding is cell-scoped, the starting context is the cell persistent root context. If the configured binding is node-scoped, the starting context is the node persistent root context. If the configured binding is server-scoped, the starting context is the server's server root context.

Binding type
Shows the type of binding configured. Possible choices are String, EJB, CORBA, and Indirect. This setting is for information purposes only and cannot be updated.

Binding identifier
Specifies the name that uniquely identifies this configured binding.

Name in name space
Specifies the name used for this binding in the namespace. This name can be a simple or compound name depending on the portion of the namespace where this binding is configured.

Provider URL
Specifies the provider URL string needed to obtain a Java Naming and Directory Interface (JNDI) initial context.

JNDI name
Specifies the name used to look up the target object from the initial context.

Initial context factory name
Specifies the class name of the initial context factory used to obtain a JNDI initial context.

This field is optional. If no factory is specified, the WebSphere Application Server initial context factory is used.

If the scope of the indirect lookup binding includes servers or nodes previous to Version 6.1, the initial context factory name and other context factory properties are not shown on the console page.

Configuring name servers

Name servers add configured name space bindings to the name space view by reading the configuration data for the bindings. If you use configured bindings, you do not need to create name space bindings from a program.

About this task

You can configure a name server to provide a display name and initial state for an application server, as well as specify custom properties for the name server. Configure a name server using the administrative console.

Procedure
1. In the administrative console, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **Administration** > **Server components** > **Name server**.
2. Edit the fields as needed.
   All of the fields are mandatory.
3. To make other changes, click **Custom properties** and configure a custom property.
4. Click **OK** to register your changes.

What to do next

Examine and start the name server.

Name server settings
Use this page to configure Naming Service Provider settings for the application server.

To view this administrative console page, click one of the following paths:
- **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **Administration** > **Server components** > **Name server**
- **Servers** > **Server Types** > **Version 5 JMS servers** > ***server_name*** > **Administration** > **Server components** > **Name server**

Name
Specifies the display name for the server component.

Data type String

Initial state
Specifies the execution state. The options are: *Started* and *Stopped*.

Data type String
Default Started

Chapter 17. Administering Object pools

This page provides a starting point for finding information about object pools.

Object pools provide an effective means of improving application performance at run time, by supporting the reuse of multiple instances of objects.

Using object pools

An object pool helps an application avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused.

About this task

Object pools are not meant to be used for pooling JDBC connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To use an object pool, the product administrator must define an *object pool manager* using the administrative console. Multiple object pool managers can be created in an Application Server cell.

Note: The Object pool manager service is only supported from within the EJB container or Web container. Looking up and using a configured object pool manager from a Java 2 Platform Enterprise Edition (J2EE) application client container is not supported.

Procedure

1. Start the administrative console.
2. Click **Resources > Object pool managers**.
3. Specify a **Scope** value and click **New**.
4. Specify the required properties for work manager settings.
   Scope The scope of the configured resource. This value indicates the location for the configuration file.
   Name The name of the object pool manager. This name can be up to 30 ASCII characters long.
   JNDI Name
   The Java Naming and Directory Interface (JNDI) name for the pool manager.
5. [Optional] Specify a **Description** and a **Category** for the object pool manager.

Results

After you have completed these steps, applications can find the object pool manager by doing a JNDI lookup using the specified JNDI name.

Example

The following code illustrates how an application can find an object pool manager object:

```
InitialContext ic = new InitialContext();
ObjectPoolManager opm = (ObjectPoolManager)ic.lookup("java:comp/env/pool");
```

When the application has an ObjectPoolManager, it can cache an object pool for classes of the types it wants to use. The following is an example:

```
ObjectPool arrayListPool = null;
ObjectPool vectorPool = null;
try
```

```
{
 arrayListPool = opm.getPool(ArrayList.class);
 vectorPool = opm.getPool(Vector.class);
}
catch(InstantiationException e)
{
 // problem creating pool
}
catch(IllegalAccessException e)
{
 // problem creating pool
}
```

When the application has the pools, the application can use them as in the following example:

```
ArrayList list = null;
try
{
 list = (ArrayList)arrayListPool.getObject();
 list.clear(); // just in case
 for(int i = 0; i < 10; ++i)
 {
  list.add("" + i);
 }
 // do what ever we need with the ArrayList
}
finally
{
 if(list != null) arrayListPool.returnObject(list);
}
```

This example presents the basic pattern for using object pooling. If the application does not return the object, then the only adverse effect is that the object cannot be reused.

Object pool managers

Object pool managers control the reuse of application objects and Developer Kit objects, such as Vectors and HashMaps.

Multiple object pool managers can be created in an Application Server cell. Each object pool manager has a unique cell-wide Java Naming and Directory Interface (JNDI) name. Applications can find a specific object pool manager by doing a JNDI lookup using the specific JNDI name.

The object pool manager and its associated objects implement the following interfaces:

```
public interface ObjectPoolManager
{
 ObjectPool getPool(Class aClass)
  throws InstantiationException, IllegalAccessException;
 ObjectPool createFastPool(Class aClass)
  throws InstantiationException, IllegalAccessException;

}

public interface ObjectPool
{
 Object getObject();
 void returnObject(Object o);

}
```

The getObject() method removes the object from the object pool. If a getObject() call is made and the pool is empty, then an object of the same type is created. A returnObject( ) call puts the object back into the object pool. If returnObject() is not called, then the object is no longer allocatable from the object pool. If the object is not returned to the object pool, then it can be garbage collected.

Each object pool manager can be used to pool any Java object with the following characteristics:
- The object must be a public class with a public default constructor.
- If the object implements the java.util.Collection interface, it must support the optional clear() method.

Each pooled object class must have its own object pool. In addition, an application gets an object pool for a specific object using either the ObjectPoolManager.getPool() method or the ObjectPoolManager.createFastPool() method. The difference between these methods is that the getPool() method returns a pool that can be shared across multiple threads. The createFastPool() method returns a pool that can only be used by a single thread.

If in a Java virtual machine (JVM), the getPool() method is called multiple times for a single class, the same pool is returned. A new pool is returned for each call when the createFastPool() method is called. Basically, the getPool() method returns a pool that is thread-synchronized.

The pool for use by multiple threads is slightly slower than a fast pool because of the need to handle thread synchronization. However, extreme care must be taken when using a fast pool.

Consider the following interface:

```
public interface PoolableObject
{
 void init();
 void returned();
}
```

If the objects placed in the pool implement this interface and the ObjectPool.getObject() method is called, the object that the pool distributes has the init() method called on it. When the ObjectPool.returnObject() method is called, the PoolableObject.returned() method is called on the object before it is returned to the object pool. Using this method objects can be pre-initialized or cleaned up.

It is not always possible for an object to implement PoolableObject. For example, an application might want to pool ArrayList objects. The ArrayList object needs clearing each time the application reuses it. The application might extend the ArrayList object and have the ArrayList object implement a poolable object. For example, consider the following:

```
public class PooledArrayList extends ArrayList implements PoolableObject
{
 public PooledArrayList()
 {
 }

 public void init() {
 }

 public void returned()
 {
  clear();
 }
}
```

If the application uses this object, in place of a true ArrayList object, the ArrayList object is cleared automatically when it is returned to the pool.

Clearing an ArrayList object simply marks it as empty and the array backing the ArrayList object is not freed. Therefore, as the application reuses the ArrayList, the backing array expands until it is big enough for all of the application requirements. When this point is reached, the application stops allocating and copying new backing arrays and achieves the best performance.

It might not be possible or desirable to use the previous procedure. An alternative is to implement a custom object pool and register this pool with the object pool manager as the pool to use for classes of

that type. The class is registered by the WebSphere administrator when the object pool manager is defined in the cell. Take care that these classes are packaged in Java Archive (JAR) files available on all of the nodes in the cell where they might be used.

Object pool managers collection

An object pool manages a pool of arbitrary objects and helps applications avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused. These object pools are not meant to be used for pooling Java Database Connectivity connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To view this administrative console page, click **Resources > Object pool managers**.

To use an object pool, the product administrator must define an object pool manager using the administrative console. Multiple object pool managers can be created in an Application Server cell.

Name

Specifies the name by which the object pool manager is known for administrative purposes.

Data type String
Range 1 through 30 ASCII characters

JNDI name

Specifies the Java Naming and Directory Interface (JNDI) name for the object pool manager.

Data type String

Scope

Specifies the scope of the configured resource. This value indicates the location for the configuration file.

Description

Specifies the description of the object pool manager.

Data type String

Category

Specifies the category name used to classify or group this object pool manager.

Data type String

Object pool managers settings

An object pool manages a pool of arbitrary objects and helps applications avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused. These object pools are not meant to be used for pooling Java Database Connectivity connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To view this administrative console page, click **Resources > Object pool managers >** *objectpoolmanager_name*

To use an object pool, the product administrator must define an object pool manager using the administrative console. Multiple object pool managers can be created in an Application Server cell.

Scope:

Specifies the scope of the configured resource. This value indicates the location for the configuration file.

Name:

The name by which the object pool manager is known for administrative purposes.

Data type	String
Range	1 through 30 ASCII characters

JNDI Name:

The Java Naming and Directory Interface (JNDI) name for the object pool manager.

Data type	String

Description:

A description of the object pool manager.

Data type	String

Category:

A category name used to classify or to group this object pool manager.

Data type	String

Custom object pool collection:

An object pool manages a pool of arbitrary objects and helps applications avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused. These object pools are not meant to be used for pooling Java Database Connectivity connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To view this administrative console page, click **Resources > Object pool managers >** *objectpoolmanager_name* **> Custom object pools**.

Use custom object pools to insert additional logic around the following mechanisms:

- Constructing an object pool (A list of properties can be set)
- Flushing the object pool
- Getting objects from the pool
- Returning objects from the pool

These features allow for actions such as, clearing the state of an object when returning it to the pool, configuring the state of an object when retrieving it from the pool, or configuring generic pools and sending instructions on how to behave using custom properties.

To use an object pool the product administrator must define an object pool manager using the administrative console. You can create multiple object pool managers in an Application Server cell.

Pool class name:

Specifies the fully qualified class name of the objects that are stored in the custom object pool.

Data type String

Pool implementation class name:

Specifies the fully qualified class name of the implementation class for the custom object pool.

Data type String

Custom object pool settings:

An object pool manages a pool of arbitrary objects and helps applications avoid creating new Java objects repeatedly. Most objects can be created once, used and then reused. An object pool supports the pooling of objects waiting to be reused. These object pools are not meant to be used for pooling Java Database Connectivity connections or Java Message Service (JMS) connections and sessions. WebSphere Application Server provides specialized mechanisms for dealing with those types of objects. These object pools are intended for pooling application-defined objects or basic Developer Kit types.

To view this administrative console page, click **Resources > Object pool managers >** *objectpoolmanager_name* **> Custom object pools >** *objectpool_name*.

Use custom object pools to insert additional logic around the following mechanisms:

- Constructing an object pool (A list of properties can be set)
- Flushing the object pool
- Getting objects from the pool
- Returning objects from the pool

These features allow for actions such as, clearing the state of an object when returning it to the pool, configuring the state of an object when retrieving it from the pool, or configuring generic pools and sending instructions on how to behave using custom properties.

To use an object pool, the product administrator must define an object pool manager using the administrative console. Multiple object pool managers can be created in an Application Server cell.

Pool Class Name:

The fully qualified class name of the objects that are stored in the object pool.

Data type String

Pool Impl Class Name:

The fully qualified class name of the CustomObjectPool implementation class for this object pool.

Data type String

Object pool service settings

Use this page to enable or disable the object pool service, which manages object pool resources used by the server.

To view this administrative console page, click **Servers > Server Types > WebSphere application servers >** *server_name* > Container Services > **Object pool service**.

Enable service at server startup

Specifies whether the server attempts to start the object pool service.

Default
Cleared

Range

Selected
When the application server starts, it attempts to start the object pool service automatically.

Cleared
The server does not try to start the object pool service. If object pool resources are used on this server, then the system administrator must start the object pool service manually or select this property, and then restart the server.

Object pools: Resources for learning

This topic provides links to find relevant supplemental information about object pools.

Use the following links to find relevant supplemental information about object pools. The information resides on IBM and non-IBM Internet sites, whose sponsors control the technical accuracy of the information.

These links are provided for convenience. Often, the information is not specific to the IBM WebSphere Application Server product, but is useful all or in part for understanding the product. When possible, links are provided to technical papers and Redbooks that supplement the broad coverage of the release documentation with in-depth examinations of particular product areas.

Furthermore, these links provide guidance on using object pools. Since object pooling is a general topic and the WebSphere Application Server product implementation is only one way to use it, you must understand when object pooling is necessary. These articles help you make that decision.

Programming model and decisions

- Build your own ObjectPool in Java to boost application speed
- Improve the robustness and performance of your ObjectPool
- Recycle broken objects in resource pools

MBeans for object pool managers and object pools

Legacy MBean names for object pool managers and object pools are deprecated. The legacy names are based on the object pool manager name (which is not required to be unique) rather than the object pool manager JNDI name.

About this task

For object pools, the legacy name is also lacking any identifier of the version of the pooled class. Additionally, object pool Performance Monitoring Instrumentation (PMI) statistics are aggregated for object pools with the same legacy object pool MBean name.

For example, if the object pool manager and pooled class are as follows:

```
object pool manager name:               My ObjectPool
object pool manager JNDI name:          op/MyObjectPool
pooled class name:                      java.util.ArrayList
hash code of java.util.ArrayList.class: 1111eb3f (hexadecimal)
```

the legacy object pool manager MBean name will be:

```
ObjectPoolManager_My ObjectPool
```

and the legacy object pool MBean name will be:

```
ObjectPool_My ObjectPool_java.util.ArrayList
```

Instead of using the deprecated legacy MBean names, use the MBean names that are based on the JNDI name of the object pool manager.

For the example above, the JNDI name-based object pool manager MBean name is:

```
ObjectPoolManager_op/MyObjectPool
```

and the JNDI name-based object pool MBean name is:

```
ObjectPool_op/MyObjectPool_java.util.ArrayList.class@1111eb3f
```

Formats for MBean names

Type	Name format
Deprecated legacy object pool manager MBean name:	ObjectPoolManager_[object pool manager name]
JNDI name-based object pool manager MBean name:	ObjectPoolManager_[object pool manager JNDI name]
Deprecated legacy object pool MBean name:	ObjectPool_[object pool manager name]_[pooled class name]
JNDI name-based object pool MBean name:	ObjectPool_[object pool manager JNDI name]_[pooled class name].class@[hexadecimal representation of the hash code of the pooled class' java.lang.Class reference]

In all of the above formats, characters that are not valid for MBean names are replaced with the '.' character.

Chapter 18. Administering Object Request Broker (ORB)

This page provides a starting point for finding information about the Object Request Broker (ORB). The product uses an ORB to manage communication between client applications and server applications as well as among product components. These Java Platform, Enterprise Edition (Java EE) standard services are relevant to the ORB: Remote Method Invocation/Internet Inter-ORB Protocol (RMI/IIOP) and Java Interface Definition Language (Java IDL).

The ORB provides a framework for clients to locate objects in the network and call operations on those objects as though the remote objects were located in the same running process as the client, providing location transparency.

Administering Object Request Brokers

Object Request Broker service settings

Use this page to configure the Java Object Request Broker (ORB) service.

To view this administrative console page:

- For an application server, click **Servers > Server Types > WebSphere application servers >** *server_name* **> Container services > ORB service**.
- For a deployment manager, click **System administration > Deployment manager > ORB service**.

Several settings are available for controlling internal Object Request Broker (ORB) processing. You can use these settings to improve application performance in the case of applications that contain enterprise beans. You can make changes to these settings for the default server or any application server that is configured in the administrative domain.

Request timeout

Specifies the number of seconds to wait before timing out on a request message.

If you use command-line scripting, the full name of this system property is com.ibm.CORBA.RequestTimeout.

Data type	int
Units	Seconds
Default	180
Range	0 - largest integer recognized by Java

Request retries count

Specifies the number of times that the ORB attempts to send a request if a server fails. Retrying sometimes enables recovery from transient network failures. This field is ignored for z/OS.

If you use command-line scripting, the full name of this system property is com.ibm.CORBA.requestRetriesCount.

Data type	int
Default	1
Range	1 to 10

Request retries delay

Specifies the number of milliseconds between request retries. This field is ignored for z/OS.

If you use command-line scripting, the full name of this system property is com.ibm.CORBA.requestRetriesDelay.

Data type	int
Units	Milliseconds
Default	0
Range	0 to 60,000

Connection cache maximum

Specifies the maximum number of entries that can occupy the ORB connection cache before the ORB starts to remove inactive connections from the cache. This field is ignored for z/OS.

It is possible that the number of active connections in the cache will temporarily exceed this threshold value. If necessary, the ORB will continue to add connections as long as resources are available.

For use in command-line scripting, the full name of this system property is com.ibm.CORBA.MaxOpenConnections.

Data type	Integer
Units	Connections
Default	240
Range	10 - largest integer recognized by Java

Connection cache minimum

Specifies the minimum number of entries in the ORB connection cache. This field is ignored for z/OS.

The ORB will not remove inactive connections when the number of entries is below this value.

For use in command-line scripting, the full name of this system property is com.ibm.CORBA.MinOpenConnections.

Data type	Integer
Units	Connections
Default	100
Range	Any integer that is at least 5 less than the value specified for the Connection cache maximum property.

ORB tracing

Enables the tracing of ORB General Inter-ORB Protocol (GIOP) messages.

This setting affects two system properties: com.ibm.CORBA.Debug and com.ibm.CORBA.CommTrace. If you set these properties through command-line scripting, you must set both properties to `true` to enable the tracing of GIOP messages.

Data type	Boolean
Default	Not enabled (false)

Locate request timeout

Specifies the number of seconds to wait before timing out on a LocateRequest message. This field is ignored for z/OS.

If you use command-line scripting, the full name of this system property is com.ibm.CORBA.LocateRequestTimeout.

Data type	int
Units	Seconds
Default	180
Range	0 to 300

Force tunneling

Controls how the client ORB attempts to use HTTP tunneling. This field is ignored for z/OS.

If you use command-line scripting, the full name of this system property is com.ibm.CORBA.ForceTunnel.

Data type	String
Default	`NEVER`
Range	Valid values are `ALWAYS`, `NEVER`, or `WHENREQUIRED`.

Considering the following information when choosing the valid value:

ALWAYS
Use HTTP tunneling immediately, without trying TCP connections first.

NEVER
Disable HTTP tunneling. If a TCP connection fails, a CORBA system exception (COMM_FAILURE) occurs.

WHENREQUIRED
Use HTTP tunneling if TCP connections fail.

Tunnel agent URL

Specifies the web address of the servlet to use in support of HTTP tunneling. This field is ignored on the z/OS platform.

This web address must be a proper format:

```
http://w3.mycorp.com:81/servlet/com.ibm.CORBA.services.IIOPTunnelServlet
```

For applets: `http://applethost:port/servlet/com.ibm.CORBA.services.IIOPTunnelServlet`.

This field is required if HTTP tunneling is set. If you use command-line scripting, the full name of this system property is com.ibm.CORBA.TunnelAgentURL.

Pass by reference

Specifies how the ORB passes parameters. If enabled, the ORB passes parameters by reference instead of by value, to avoid making an object copy. If you do not enable the pass by reference option, a copy of the parameter passes rather than the parameter object itself. This can be expensive because the ORB must first make a copy of each parameter object.

You can use this option only when the Enterprise JavaBeans (EJB) client and the EJB are on the same classloader. This requirement means that the EJB client and the EJB must be deployed in the same EAR file.

If the Enterprise JavaBeans (EJB) client and server are installed in the same instance or the product, and the client and server use remote interfaces, enabling the pass by reference option can improve performance up to 50%. The pass by reference option helps performance only where non-primitive object types are passed as parameters. Therefore, int and floats are always copied, regardless of the call model.

gotcha: Enable this property with caution because unexpected behavior can occur. If an object reference is modified by the callee, the caller's object is modified as well, since they are the same object.

If you use command-line scripting, the full name of this system property is com.ibm.CORBA.iiop.noLocalCopies.

Data type	Boolean
Default	Not enabled (false)

The use of this option for enterprise beans with remote interfaces violates Enterprise JavaBeans (EJB) Specification, Version 2.0 (see section 5.4). Object references passed to Enterprise JavaBeans (EJB) methods or to EJB home methods are not copied and can be subject to corruption.

Consider the following example:

```
Iterator iterator = collection.iterator();
MyPrimaryKey pk = new MyPrimaryKey();
while (iterator.hasNext()) {
   pk.id = (String) iterator.next();
   MyEJB myEJB = myEJBHome.findByPrimaryKey(pk);
}
```

In this example, a reference to the same MyPrimaryKey object passes into the product with a different ID value each time. Running this code with pass by reference enabled causes a problem within the application server because multiple enterprise beans are referencing the same MyPrimaryKey object. To avoid this problem, set the com.ibm.websphere.ejbcontainer.allowPrimaryKeyMutation system property to `true` when the pass by reference option is enabled. Setting the pass by reference option to `true` causes the EJB container to make a local copy of the PrimaryKey object. As a result, however, a small portion of the performance advantage of setting the pass by reference option is lost.

As a general rule, any application code that passes an object reference as a parameter to an enterprise bean method or to an EJB home method must be scrutinized to determine if passing that object reference results in loss of data integrity or in other problems.

After examining your code, you can enable the pass by reference option by setting the com.ibm.CORBA.iiop.noLocalCopies system property to `true`. You can also enable the pass by reference option in the administrative console. Click **Servers > Server Types > Application servers >** *server_name* **> Container services > ORB Service** and select **Pass by reference**.

Object Request Broker custom properties

There are several ways to configure an Object Request Broker (ORB). For example, you can use ORB custom property settings, or system property settings to configure an ORB, or you can provide objects during ORB initialization. If you use the following ORB custom properties to configure an ORB, remember that two types of default values exist for some of these properties: the Java SE Development Kit (JDK) default values and the WebSphere Application Server default values.

The JDK default is the value that the ORB uses for a property if the property is not specified in any way. The WebSphere Application Server default is the value that the WebSphere Application Server sets for a property in one of the following files:

- The orb.properties file when an application server is installed.
- The server.xml file when an application server is configured.

Because WebSphere Application Server explicitly sets its default value, if both a WebSphere Application Server and a JDK default value are defined for a property, the WebSphere Application Server default takes precedence over the JDK default.

For more information about the different ways to specify ORB properties and the precedence order, read the JDK Diagnostic Guide for the version of the JDK that you are using.

The orb.properties file, that is located in the *was_home*/properties directory, contains ORB custom properties that are initially set to the WebSphere Application Server default values during the product installation process. These values are passed to the ORB in a properties object and take precedence over Java virtual machine (JVM) arguments and other orb.properties files in either the *java_home*/lib or *user_home* directories.

You can use the administrative console to specify new values for these ORB custom properties. Any value that you specify takes precedence over any JDK or WebSphere Application Server default values for these properties, including JVM arguments. The ORB custom properties settings that you specify in the administrative console are stored in the server.xml system file and are passed to an ORB in a properties object whenever an ORB is initialized.

To use the administrative console to set ORB custom properties, click **Servers > Server Types > Application servers >** *server_name* **> Container services > ORB service > Custom properties**. You can then change the setting of one of the listed custom properties or click **New** to add a new property to the list. Then, click **Apply** to save your change. When you finish the changes, click **OK** and then click **Save** to save your changes.

To use the java command on a command line, use the -D option; for example:

```
java -Dcom.ibm.CORBA.propname1=value1 -Dcom.ibm.CORBA.propname2=value2 ... application name
```

To use the launchclient command on a command line, prefix the property with -CC; for example:

```
launchclient yourapp.ear -CCDcom.ibm.CORBA.propname1=value1 -CCDcom.ibm.CORBA.propname2=value2
   ... optional application arguments
```

The Custom properties page might already include Secure Sockets Layer (SSL) properties that were added during product installation. A list of the additional properties that are associated with the ORB service follows. Unless otherwise indicated, the default values that are provided in the descriptions of these properties are the JDK default values.

You can use the custom properties page to define the following properties for use by the ORB.

- “com.ibm.CORBA.BootstrapHost” on page 1038
- “com.ibm.CORBA.BootstrapPort” on page 1038
- “com.ibm.CORBA.ConnectTimeout” on page 1038
- “com.ibm.CORBA.ConnectionInterceptorName” on page 1039
- “com.ibm.CORBA.enableLocateRequest” on page 1039
- “com.ibm.CORBA.FragmentSize” on page 1039
- “com.ibm.CORBA.ListenerPort” on page 1039
- “com.ibm.CORBA.LocalHost” on page 1039
- “com.ibm.CORBA.numJNIReaders” on page 1040
- “com.ibm.CORBA.ORBPluginClass.com.ibm.ws.orbimpl.transport.JNIReaderPoolImpl” on page 1040
- “com.ibm.CORBA.RasManager” on page 1040
- “com.ibm.CORBA.ServerSocketQueueDepth” on page 1041
- “com.ibm.CORBA.ShortExceptionDetails” on page 1041
- “com.ibm.CORBA.WSSSLClientSocketFactoryName” on page 1041
- “com.ibm.CORBA.WSSSLServerSocketFactoryName” on page 1041
- “com.ibm.websphere.orb.threadPoolTimeout” on page 1041
- “com.ibm.websphere.threadpool.strategy.implementation” on page 1042
- “com.ibm.websphere.threadpool.strategy.LogicalPoolDistribution.calcinterval” on page 1042
- “com.ibm.websphere.threadpool.strategy.LogicalPoolDistribution.lruinterval” on page 1042
- “com.ibm.websphere.threadpool.strategy.LogicalPoolDistribution.outqueues” on page 1042

- “com.ibm.websphere.threadpool.strategy.LogicalPoolDistribution.statsinterval” on page 1043
- “com.ibm.websphere.threadpool.strategy.LogicalPoolDistribution.workqueue” on page 1043
- “com.ibm.ws.orb.services.redirector.MaxOpenSocketsPerEndpoint” on page 1043
- “com.ibm.ws.orb.services.redirector.RequestTimeout” on page 1043
- “com.ibm.ws.orb.transport.SSLHandshakeTimeout” on page 1044
- “com.ibm.ws.orb.transport.useMultiHome” on page 1044
- “javax.rmi.CORBA.UtilClass” on page 1044

com.ibm.CORBA.BootstrapHost

Specifies the domain name service (DNS) host name or IP address of the machine on which initial server contact for this client resides.

depfeat: This setting is deprecated.

For a command-line or programmatic alternative, read the topic *Client-side programming tips for the Object Request Broker service*.

com.ibm.CORBA.BootstrapPort

Specifies the port that the ORB uses to bootstrap to the machine on which the initial server contact for this client listens.

depfeat: This setting is deprecated.

For a command line or programmatic alternative, read the topic *Client-side programming tips for the Object Request Broker service*.

Default	2809

com.ibm.CORBA.ConnectTimeout

The com.ibm.CORBA.ConnectTimeout property specifies the maximum time, in seconds, that the client ORB waits before timing out when attempting to establish an IIOP connection with a remote server ORB. Typically, client applications use this property. You can specify the property for each individual application server through the administrative console.

Client applications can specify the com.ibm.CORBA.ConnectTimeout property in one of two ways:
- By including it in the orb.properties file
- By using the -CCD option to set the property with the launchclient script. The following example specifies a maximum timeout value of 10 seconds:

```
launchclient clientapp.ear -CCDcom.ibm.com.CORBA.ConnectTimeout=10...
```

Begin with the default timeout value, but consider factors such as network congestion and application server load and capacity. Lower values provide better failover performance in the case of extended problems with the remote server, such as downtime. Higher values are better for slow network or remote server performance. However, exceptions can occur if the remote server does not have enough time to complete the subsequent request. A value of `0` means that the ORB relies on the timeout set by the operating system TCP/IP layer. For most operating systems, the timeout is set to 75 seconds.

Note: The default for the com.ibm.CORBA.ConnectTimeout property for Version 8 is 10. Before Version 8, the default is 0.

Valid Range	0-300
Default	10

com.ibm.CORBA.ConnectionInterceptorName

Specifies the connection interceptor class that is used to determine the type of outbound IIOP connection to use for a request, and if secure, the quality of protection characteristics associated with the request.

WebSphere Application Server default	com.ibm.ISecurityLocalObjectBaseL13Impl.SecurityConnectionInterceptor
JDK default	None

com.ibm.CORBA.enableLocateRequest

Specifies whether the ORB uses the locate request mechanism to find objects in a WebSphere Application Server cell. Use this property for performance tuning.

When this property is set to `true`, the ORB first sends a short message to the server to find the object that it needs to access. This first contact is called the *locate request*. If most of your initial method invocations are small, setting this property to `false` might improve performance because this setting change can reduce the GIOP traffic by as much as one-half. If most of your initial method invocations are large, you should set this property to `true`. When the property is set to `true`, the small locate request message is sent instead of the large locate request message. The large message is then sent to the target after the desired object is found.

WebSphere Application Server default	true
JDK default	false

com.ibm.CORBA.FragmentSize

Specifies the size of GIOP fragments that the ORB uses when it sends requests. If the total size of a request exceeds the set value, the ORB breaks the request into fragments, and sends each fragment separately until the entire request is sent. Set this property on the client side with a -D system property if you use a stand-alone Java application.

Adjust the value specified for the com.ibm.CORBA.FragmentSize property if the amount of data that is sent over IIOP in most GIOP requests exceeds 1 KB, or if thread dumps show that most client-side threads are waiting while sending or receiving data. Most messages should have few or no fragments.

If you want to instruct the ORB not to chunk any of the requests or replies it sends, set this property to `0`. However, setting the value to zero does not prevent the ORB from receiving GIOP fragments in requests or replies sent by another ORB.

Units	Bytes.
Default	1024
Range	From 64 to the largest value of a Java integer type that is divisible by 8

com.ibm.CORBA.ListenerPort

Specifies the port on which this server listens for incoming requests. This setting only applies for client-side ORBs.

Default	Next available system-assigned port number
Range	0 - 2147483647

com.ibm.CORBA.LocalHost

Specifies the host name or IP address of the system on which the application server or client application ORB is running.

For application servers, this property is automatically set to the host name of the ORB_LISTENER_ADDRESS endpoint. Any value specified by the user will be overwritten by the ORB_LISTENER_ADDRESS host name.

- If the ORB_LISTENER_ADDRESS host name is "*", then the property is set to the local host name by using the InetAddress.getLocalHost().getCanonicalHostName() method.
- For client applications, if no value is specified for this property, the ORB obtains a value at run time by calling the InetAddress.getLocalHost().getHostAddress() method.

Note: Do not set this property to the "localhost" string or "127.0.0.1" value as these values can result in unpredictable behavior for both clients and servers. Those values might impact callback behavior, the use of server IORs, and the creation of ORB connections.

com.ibm.CORBA.numJNIReaders

Specifies the number of JNI reader threads to be allocated in the JNI reader thread pool that is used by the ORB. Each thread can handle up to 1024 connections.

gotcha: Before you specify this property, verify that a JSSE provider is selected as the provider for the SSL repertoire that is associated with the port on which the ORB service listens for incoming requests. You can specify either `IBMJSSE2 SSL` or `IBMJSSE SSL`. `IBMJSSE2 SSL` is the default provider setting for SSL repertoires.

Valid Range	1 - 2147483647
Default	4

com.ibm.CORBA.ORBPluginClass.com.ibm.ws.orbimpl.transport.JNIReaderPoolImpl

Specifies that JNI reader threads are used. The property name specifies the class name of the ORB component that manages the pool of JNI reader threads and interacts with the native OS library used to process multiple connections simultaneously.

gotcha:

- Verify that the library is located in the bin directory for the product.

  For an Intel operating system, the name of the file that contains the library name is `Selector.dll`

  For a UNIX-based operating system, the name of the file that contains the library is either `libSelector.a` or `libSelector.so`. If the lib prefix is missing from the file name, rename the file such that the name includes the lib prefix.
- When you specify this property using the administrative console, enter `com.ibm.CORBA.ORBPluginClass.com.ibm.ws.orbimpl.transport.JNIReaderPoolImpl` for the property name and an empty string ("") for the value.

  When you specify this property on the java command, do not include a value:

  `-Dcom.ibm.CORBA.ORBPluginClass.com.ibm.ws.orbimpl.transport.JNIReaderPoolImpl`

Valid Range	Not applicable
Default	None

com.ibm.CORBA.RasManager

Specifies an alternative to the default RAS manager of the ORB. This property must be set to com.ibm.websphere.ras.WsOrbRasManager before the ORB can be integrated with the rest of the RAS processing for the product.

WebSphere Application Server default	com.ibm.websphere.ras.WsOrbRasManager
JDK default	None

com.ibm.CORBA.ServerSocketQueueDepth

Specifies the maximum number of connection requests that can be waiting to be handled by the Server ORB before the product starts to reject new incoming connection requests. This property corresponds to the `backlog` argument to a ServerSocket constructor and is handled directly by TCP/IP.

If you see a "connection refused" message in a trace log, typically, either the port on the target machine is not open, or the server is overloaded with queued-up connection requests. Increasing the value specified for this property can help alleviate this problem if there does not appear to be any other problem in the system.

Default	50
Range	From 50 to the largest value of the Java int type

com.ibm.CORBA.ShortExceptionDetails

Specifies that the exception detail message that is returned whenever the server ORB encounters a CORBA system exception contains a short description of the exception as returned by the toString method of java.lang.Throwable class. Otherwise, the message contains the complete stack trace as returned by the printStackTrace method of java.lang.Throwable class.

com.ibm.CORBA.WSSSLClientSocketFactoryName

Specifies the class that the ORB uses to create SSL sockets for secure outbound IIOP connections.

WebSphere Application Server default	com.ibm.ws.security.orbssl.WSSSLClientSocketFactoryImpl
JDK default	None

com.ibm.CORBA.WSSSLServerSocketFactoryName

Specifies the class that the ORB uses to create SSL sockets for inbound IIOP connections.

WebSphere Application Server default	com.ibm.ws.security.orbssl.WSSSLServerSocketFactoryImpl
JDK default	None

com.ibm.websphere.orb.threadPoolTimeout

Use this custom property to specify the length of time in which the object request broker (ORB) waits for an available thread from the ORB thread pool before rejecting a request.

When the ORB receives an incoming request, the request is read by an ORB reader thread. The ORB reader thread attempts to hand off the request for processing by a worker thread in the ORB thread pool. When all the worker threads are handling other requests, the reader thread waits until a worker thread becomes available. While the reader thread is waiting, new requests are not processed by that particular reader thread. This situation can lead to deadlocks between the ORB thread pools on two different Java virtual machine (JVM) processes. The deadlocks are prominent when the ORB in one JVM process must call back to the ORB in the other JVM process to complete its request. Therefore, it is highly advisable to set this property to a positive non-zero value, which configures a finite wait period and can limit deadlock situations. However, configure the value for this custom property based on its effect on the average request processing time, the ORB request timeout value, and whether servers are making additional circular or backend calls.

Data type	Integer
Units	Milliseconds
Default	0
Range	0 - largest integer that is recognized by the Java run time

com.ibm.websphere.threadpool.strategy.implementation

Specifies the logical pool distribution (LPD) thread pool strategy that takes effect the next time you start the application server, and is enabled if set to com.ibm.ws.threadpool.strategy.LogicalPoolDistribution.

depfeat: The logical pool distribution function is deprecated. Do not configure logical pool distribution unless you have already configured it for a previous release of the product.

Some requests have shorter start times than others. LPD is a mechanism for providing these shorter requests more access to start threads. For more information, read the topic *Logical pool distribution*, that is included in the product information center.

com.ibm.websphere.threadpool.strategy.LogicalPoolDistribution.calcinterval

Specifies how often the logical pool distribution (LPD) mechanism readjusts the pool start target times. This property cannot be turned off after this support is installed.

depfeat: The logical pool distribution function is deprecated. Do not configure logical pool distribution unless you have already configured it with a previous release of the product.

If you use this property, LPD must be enabled. Read the description of the com.ibm.websphere.threadpool.strategy.implementation property for more information.

Data type	Integer
Units	Milliseconds
Default	30
Range	20,000 milliseconds minimum

com.ibm.websphere.threadpool.strategy.LogicalPoolDistribution.lruinterval

Specifies, in milliseconds, how long the logical pool distribution internal data is kept for inactive requests. This mechanism tracks several statistics for each request type that is received. Consider removing requests that have been inactive for an unusually long length of time.

depfeat: This function is deprecated. Do not configure logical pool distribution unless you have already configured it with a previous release of the product.

If you use this property, LPD must be enabled. Read the description of the com.ibm.websphere.threadpool.strategy.implementation property for more information.

Data type	Integer
Units	Milliseconds
Default	300000 (5 minutes)
Range	60000 (1 minute) minimum

com.ibm.websphere.threadpool.strategy.LogicalPoolDistribution.outqueues

Specifies how many pools are created and how many threads are allocated to each pool in the logical pool distribution mechanism.

depfeat: The logical pool distribution function is deprecated. Do not configure logical pool distribution unless you have already configured it with a previous release of the product.

The ORB parameter for specifying the maximum number of threads controls the total number of threads. The outqueues parameter is specified as a comma-separated list of percentages that add up to 100. For example, the list 25,25,25,25 sets up 4 pools, each allocated 25 percent of the available ORB thread pool. The pools are indexed left to right from 0 to n-1. The calculation mechanism dynamically assigns each outqueue a target start time. Target start times are assigned to outqueues in increasing order. Therefore, pool 0 gets the requests with the least start time, and pool n-1 gets requests with the highest start times.

If you specify this property, LPD must be enabled. Read the description of the com.ibm.websphere.threadpool.strategy.implementation property for more information.

Data type	Integers in comma-separated list
Default	25,25,25,25
Range	Percentages in list must total 100 percent

com.ibm.websphere.threadpool.strategy.LogicalPoolDistribution.statsinterval

Specifies that statistics are dumped to stdout after this interval expires, but only if requests are processed. This process keeps the mechanism from filling the log files with redundant information. These statistics are beneficial for tuning the logical pool distribution mechanism.

depfeat: The logical pool distribution function is deprecated. Do not configure logical pool distribution unless you have already configured it with a previous release of the product.

If you use this property, LPD must be enabled. Read the description of the com.ibm.websphere.threadpool.strategy.implementation property for more information.

Data type	Integer
Units	Milliseconds
Default	0 (off)
Range	30,000 (30 seconds) minimum

com.ibm.websphere.threadpool.strategy.LogicalPoolDistribution.workqueue

Specifies the size of a new queue where incoming requests wait for dispatch. Pertains to the logical pool distribution mechanism.

depfeat: The logical pool distribution function is deprecated. Do not configure logical pool distribution unless you have already configured it with a previous release of the product.

If you use this property, LPD must be enabled. Read the description of the com.ibm.websphere.threadpool.strategy.implementation property for more information.

Data type	Integer
Default	96
Range	10 minimum

com.ibm.ws.orb.services.redirector.MaxOpenSocketsPerEndpoint

Specifies the maximum number of connections that the IIOP Tunnel Servlet maintains in its connection cache for each target host and port. If the number of concurrent client requests to a single host and port exceeds the setting for this property, the IIOP Tunnel Servlet opens a temporary connection to the target server for each extra client request, and then closes the connection after it receives the reply. Connections that are opened, but not used within 5 minutes, are removed from the cache for the IIOP Tunnel Servlet.

WebSphere Application Server default	3
JDK default	Not applicable
Range	0 - largest integer recognized by Java

com.ibm.ws.orb.services.redirector.RequestTimeout

Specifies the number of seconds that the IIOP Tunnel Servlet waits for a reply from the target server on behalf of a client before timing out. If a value is not specified for this property, or is incorrectly specified, the com.ibm.CORBA.RequestTimeout property setting for the application server, on which the IIOP Tunnel Servlet is installed, is used as the setting for the com.ibm.ws.orb.services.redirector.RequestTimeout property.

The value you specify for this property must be at least as high as the highest client setting for the com.ibm.CORBA.RequestTimeout property; otherwise the IIOP Tunnel Servlet might timeout more quickly than the client typically times out while waiting for a reply. If this property is set to zero, the IIOP Tunnel Servlet does not timeout.

WebSphere Application Server default	com.ibm.CORBA.RequestTimeout property setting for the application server on which the IIOP Tunnel Servlet is installed. The request_timeout request-level Reliability Availability and Serviceability (RAS) attribute overrides the com.ibm.CORBA.RequestTimeout property for IIOP requests. You define the request-level RAS attributes in the workload classification file.
JDK default	Not applicable
Range	0 - largest integer recognized by Java

com.ibm.ws.orb.transport.SSLHandshakeTimeout

This custom property specifies a timeout value for reading Secure Sockets Layer (SSL) handshake-related messages.

When you set the com.ibm.ws.orb.transport.SSLHandshakeTimeout custom property to a positive integer value, the listener thread does not hang if a message is received after the specified timeout period. If you do not set this custom property or do not set it to a positive integer value, the timeout value defaults to zero (0), a timeout period is not added, and the listener thread can hang.

Data type	Integer
Default	Zero (0)
Units	Milliseconds

com.ibm.ws.orb.transport.useMultiHome

Specifies whether the server ORB binds to all network interfaces in the system. If you specify `true`, the ORB binds to all network interfaces that are available to it. If you specify `false`, the ORB only binds to the network interface that is specified for the com.ibm.CORBA.LocalHost system property.

WebSphere Application Server default	true
JDK default	true

javax.rmi.CORBA.UtilClass

Specifies the name of the Java class that the product uses to implement the javax.rmi.CORBA.UtilDelegate interface.

This property supports delegation for method implementations in the javax.rmi.CORBA.Util class. The javax.rmi.CORBA.Util class provides utility methods that can be used by stubs and ties to perform common operations. The delegate is a singleton instance of a class that implements this interface and provides a replacement implementation for all of the methods of javax.rmi.CORBA.Util. To enable a delegate, provide the class name of the delegate as the value of the javax.rmi.CORBA.UtilClass system property. The default value provides support for the com.ibm.CORBA.iiop.noLocalCopies property.

WebSphere Application Server default	com.ibm.ws.orb.WSUtilDelegateImpl
JDK default	None

Character code set conversion support for the Java Object Request Broker service

The CORBA/IIOP specification defines a framework for negotiation and conversion of character code sets used by the Java Object Request Broker (ORB) service.

This product supports the framework and provides the following system properties for modifying the default settings:

com.ibm.CORBA.ORBCharEncoding

Specifies the name of the native code set that the ORB uses for character data (referred to as *NCS-C* in the CORBA/IIOP specification). By default, the ORB uses `UTF8`. Valid code set values for this property are shown in the table that follows this list; values that are valid only for ORBWCharDefault are indicated.

com.ibm.CORBA.ORBWCharDefault

Specifies the default code set that the ORB uses for transmission of wide character data when no code set for wide character data is found in the tagged component in the Interoperable Object Reference (IOR) or in the GIOP service context. If no code set for wide character data is found and this property is not set, the ORB raises an exception, as specified in the CORBA specification. No default value is set for this property. The only valid code set values for this property are `UCS2` or `UTF16`.

The CORBA code set negotiation and conversion framework specifies the use of code set registry IDs as defined in the Open Software Foundation (OSF) code set registry. The ORB translates the Java file.encoding names shown in the following table to the corresponding OSF registry IDs. These IDs are then used by the ORB in the IOR Code set tagged component and GIOP code set service context as specified in the CORBA and IIOP specification.

Table 68. OSF code set registry IDs for Java file.encoding names. The following table lists the OSF code set registry IDs for the Java file.encoding names.

Java name	OSF registry ID	Comments
ASCII	0x00010020	
ISO8859_1	0x00010001	
ISO8859_2	0x00010002	
ISO8859_3	0x00010003	
ISO8859_4	0x00010004	
ISO8859_5	0x00010005	
ISO8859_6	0x00010006	
ISO8859_7	0x00010007	
ISO8859_8	0x00010008	
ISO8859_9	0x00010009	
ISO8859_15_FDIS	0x0001000F	
Cp1250	0x100204E2	
Cp1251	0x100204E3	
Cp1252	0x100204E4	
Cp1253	0x100204E5	
Cp1254	0x100204E6	
Cp1255	0x100204E7	
Cp1256	0x100204E8	
Cp1257	0x100204E9	

Table 68. OSF code set registry IDs for Java file.encoding names (continued). The following table lists the OSF code set registry IDs for the Java file.encoding names.

Java name	OSF registry ID	Comments
Cp943C	0x100203AF	
Cp943	0x100203AF	
Cp949C	0x100203B5	
Cp949	0x100203B5

Cp33722C	0x100283BA	
Cp33722	0x100283BA	
Cp930	0x100203A2	
Cp1047	0x10020417	
UCS2	0x00010100	Valid only for the ORBWCharDefault
UTF8	0x05010001	
UTF16	0x00010109	Valid only for the ORBWCharDefault

Chapter 19. Administering OSGi Applications

Configure an enterprise bundle archive (EBA) asset, and maintain the bundle versions used by the EBA asset. Administer bundles, composite bundles, composite bundle extensions, and bundle repositories.

Before you begin

This topic assumes that you have already packaged your OSGi application as an enterprise bundle archive (EBA) file, and imported it into WebSphere Application Server, as described in Developing and deploying an OSGi application. You might also have added one or more composite bundle extensions to the deployed application.

Procedure

- Check the bundle download status of an EBA asset.

  Updating an asset to use a new bundle version might require bundle downloads. You cannot update an asset until bundle downloads are complete from any previous update. Before you try and update bundle versions, you can check the bundle download status of the asset. This status is either “Bundles downloading...”, “Bundle downloads are complete”, or “No bundles downloads are required”.
- Check the update status of an OSGi composition unit.

  When you change the versions of bundles or composite bundles that an enterprise OSGi application uses, or add or remove a composite bundle extension, the bundles used by the deployed application can get out of synchronization with those that are available. To check that your business-level application is running the most recent version of the EBA asset and any composite bundle extensions, you check the update status of the associated OSGi composition unit.
- Update bundle versions for an EBA asset.

  After you import your OSGi application as an asset, newer versions of the bundles or composite bundles that the asset uses might become available. You can configure the deployed asset to use an updated version of any bundle or composite bundle that is used by the asset. You can choose to use a specific bundle version, or to pull in the latest compatible version. Use either of the following methods:
  - Update bundle versions using the administrative console.
  - Update bundle versions using the editAsset command.
- Maintain an OSGi composition unit.

  Whenever an enterprise bundle archive (EBA) asset is updated, you can (optionally) update the associated composition unit. You might also update a composition unit to add or remove a composite bundle extension. If any updates need configuration changes, you can also modify the configuration information for the composition unit.
- Administer bundle repositories.

  OSGi applications can share a large number of common utility bundles. To simplify maintenance, and reduce the application footprint, the application does not need to include its own copy of each utility bundle. Instead, bundles can be hosted in a bundle repository, from where they are retrieved during deployment. You can administer bundles and composite bundles held in the internal bundle repository of the product, and also add links to external bundle repositories.
- Export and import a deployment manifest file.

  You can export the deployment manifest file from an application, then import the manifest file into another instance of the same application located somewhere else. This process is useful when an application moves from one environment to another, for example from a test environment to a production environment.

Updating bundle versions for an EBA asset

After you import your OSGi application as an asset, newer versions of the bundles or composite bundles that the asset uses might become available. You can configure the deployed asset to use an updated version of any bundle or composite bundle that is used by the asset. You can choose to use a specific bundle version, or to pull in the latest compatible version.

Before you begin

You can update bundle and composite bundle versions for an EBA asset by using the administrative console as described in this topic, or by using wsadmin commands as described in “Updating bundle versions for an EBA asset using the editAsset command” on page 1049.

About this task

When you first create an OSGi application, each bundle and composite bundle in the application is either directly contained in the EBA file or pulled in by reference. After you import your application as an asset, you can no longer change the direct contents of the asset. To update bundles and composite bundles that are specified in an asset, you add the updated versions to a repository then apply the updates to the asset. The asset is not updated automatically when new bundle versions become available; it is up to you to decide if and when to update the asset.

For each bundle or composite bundle specified by your EBA asset you can select either of the following options:

- Use a specific available bundle version.
- Use any version. In this case, the latest available version that is compatible with your selections for other bundles is used.

After you make your selections for this asset, the system tries to resolve the changes you have requested, and shows you the results. When you have selected a working configuration, you can commit your selections and the bundle version updates for the asset are applied.

You cannot update bundles that are provisioned by the runtime environment.

Note: When an EBA asset is updated, the update does not automatically affect the running business-level application. To update the running application, you update the composition unit of the business-level application that contains the asset.

For transitioning users: In the WebSphere Application Server Version 7 Feature Pack for OSGi Applications and Java Persistence API 2.0, bundle changes to the asset are applied by restarting the business-level application, rather than by updating the composition unit. The current approach means that many bundle changes can be applied in place, without restarting the running business-level application.

Procedure

1. Start the administrative console.
2. Navigate to **Applications** > **Application Types** > **Assets** > ***asset_name***.

   The Asset settings panel is displayed.
3. Check the current bundle download status for all bundles and composite bundles for this asset.

   If the asset has previously been updated, the bundle downloads for the previous update must have completed.

   The current bundle download status for all bundles and composite bundles for this asset is displayed in the EBA Dependencies section. This status is either “Bundles downloading...”, “Bundle downloads are complete”, or “No bundles downloads are required”.

If the bundle downloads for any previous update have completed, the option to update bundle versions is available under the Additional Properties section.

4. Click **[Additional Properties] Update bundle versions in this application**. The Update bundle versions in this application [Settings] panel is displayed. This panel contains a tabular overview of the bundles and composite bundles currently deployed in the asset. *Application bundles* are listed separately from *use bundles*.
5. Choose the update bundle version preference for each bundle in this application.

   In the table, you can select the update preference for each bundle from a list. You can choose either of the following options:

   - Choose a specific available bundle version. For example, “1.0.0”.
   - Choose “No preference”. If you select this option, the latest available version that is compatible with your other bundle selections is used.
6. Click **Preview**. A similar table is displayed in the Preview bundle versions update [Settings] panel, showing the result of the proposed changes to the bundle versions in this application. If the changes resolve successfully, the following message is displayed: “The selected bundle versions can be resolved, so you can now create a new deployment with the proposed bundle versions. The new deployment will not affect any composition units for this asset until the composition units are updated to use the new deployment.” Otherwise, the message displayed is “The selected versions cannot be resolved, so you cannot create a new deployment with the proposed bundle versions.”
7. Optional: If the changes have not been successfully resolved, click **Cancel** to return to the Update bundle versions in this application [Settings] panel, then select a different update preference for each bundle that could not be resolved.
8. When you have selected a working configuration, click **Create**. The bundle and composite bundle version updates for the asset are applied.
9. Save your changes to the master configuration. The bundle updates are downloaded.

What to do next

If you plan to update the composition unit at this time, check that all bundle downloads are complete. See “Checking the update status of an OSGi composition unit” on page 1077.

Updating bundle versions for an EBA asset using the editAsset command

After you import your OSGi application as an asset, newer versions of the bundles or composite bundles that the asset uses might become available. You can use the editAsset command to configure the deployed asset to use an updated version of any bundle or composite bundle that is used by the asset. You can choose to use a specific bundle version, or to pull in the latest compatible version.

Before you begin

You can update bundle and composite bundle versions for an EBA asset by using wsadmin commands as described in this topic, or by using the administrative console as described in “Updating bundle versions for an EBA asset” on page 1048.

About this task

When you first create an OSGi application, each bundle and composite bundle in the application is either directly contained in the EBA file or pulled in by reference. After you import your application as an asset, you can no longer change the direct contents of the asset. To update bundles and composite bundles that are specified in an asset, you add the updated versions to a repository then apply the updates to the asset. The asset is not updated automatically when new bundle versions become available; it is up to you to decide if and when to update the asset.

For each bundle or composite bundle specified by your EBA asset you can select either of the following options:

- Use a specific available bundle version.
- Use any version. In this case, the latest available version that is compatible with your selections for other bundles is used.

After you make your selections for this asset, the system tries to resolve the changes you have requested, and shows you the results. When you have selected a working configuration, the bundle and composite bundle version updates for the asset are applied.

You cannot update bundles that are provisioned by the runtime environment.

Note: When an EBA asset is updated, the update does not automatically affect the running business-level application. To update the running application, you update the composition unit of the business-level application that contains the asset.

For transitioning users: In the WebSphere Application Server Version 7 Feature Pack for OSGi Applications and Java Persistence API 2.0, bundle changes to the asset are applied by restarting the business-level application, rather than by updating the composition unit. The current approach means that many bundle changes can be applied in place, without restarting the running business-level application.

Procedure

1. Check the current bundle download status for all bundles in this asset.

   If the asset has previously been updated, the bundle downloads for the previous update must have completed.

   You can use the editCompUnit wsadmin command to check the bundle download status for an asset. This command checks the status of the associated OSGi composition unit, as described in “Checking the update status of an OSGi composition unit” on page 1077. This status is one of the following values:

   - Using latest OSGi application deployment.
   - New OSGi application deployment not yet available because it requires bundles that are still downloading.
   - New OSGi application deployment available.
   - New OSGi application deployment cannot be applied because bundle downloads have failed.

   Wait until the bundle downloads for any previous update have completed.
2. Choose the update bundle version preference for each bundle in this application.

   To select bundle versions for an EBA asset using the editAsset command, open a wsadmin command prompt then run the following jython command. Under the **-UpdateAppContentVersions** parameter, include an entry (that is, the *bundle_name current_version* and *update_preference*) for each bundle that is listed in the application manifest between the application content header and the use bundle header. Include every bundle, whether or not you are updating the bundle version.

   For transitioning users: In the WebSphere Application Server Version 7 Feature Pack for OSGi Applications and Java Persistence API 2.0, bundle changes to the asset are applied by restarting the business-level application. In Version 8, these changes are applied by updating the composition unit. To enable the current approach, the **UpdateAppContentVersionsStep** parameter has been replaced with the **UpdateAppContentVersions** parameter, and instead of restarting the business-level application you run the editCompUnit command with the **CompUnitStatusStep** parameter. See the following troubleshooting tip: The behavior has changed for using wsadmin commands to update bundle versions.

```
AdminTask.editAsset('[
  -assetID asset_name
  -UpdateAppContentVersions [
    [bundle_1_name current_version update_preference]
    [bundle_2_name current_version update_preference]
    [bundle_3_name current_version update_preference]
    [bundle_4_name current_version update_preference]
    [bundle_5_name current_version update_preference]
  ]]')
```

Notes:

- *current_version* specifies either a bundle version number, for example `1.0.0`, or `NOT_DEPLOYED` for shared bundles (that is, *use bundles*) that are declared in the application manifest but not deployed by the runtime environment. This argument describes the current configuration of the bundle, and is not used to change the configuration.
- *update_preference* specifies the new bundle version preference. This is either a bundle version number, for example `1.0.0`, or `NOT_DEPLOYED` for shared bundles, or `NO_PREF` if you want the system to choose a bundle version for you. If you do not want to update the version for a given bundle, set this attribute to the same value that you are using for the *current_version* attribute.

For more information about using the editAsset command, see BLAManagement command group for the AdminTask object using wsadmin scripting.

After you make your selections for this asset, the system tries to resolve the changes you have requested, and shows you the results. When you have selected a working configuration, the bundle and composite bundle version updates for the asset are applied.

3. Save your changes to the master configuration.

   To save your configuration changes, use the following command:

   ```
   AdminConfig.save()
   ```

   The bundle updates are downloaded.

What to do next

If you plan to update the composition unit at this time, check that all bundle downloads are complete. See “Checking the update status of an OSGi composition unit” on page 1077.

Maintaining an OSGi composition unit

Whenever an enterprise bundle archive (EBA) asset is updated, you can (optionally) update the associated composition unit. You might also update a composition unit to add or remove a composite bundle extension. If any updates need configuration changes, you can also modify the configuration information for the composition unit.

About this task

An OSGi composition unit consists of an EBA asset, (optionally) one or more composite bundle extensions, and configuration information for running the asset and composite bundle extensions in a business-level application. If a new OSGi application deployment is available, you can update the OSGi composition unit so that the business-level application uses the newer configuration.

If any updates need configuration changes, you can also modify the configuration information for the composition unit. The configuration information can include HTTP session management, context roots, virtual hosts, security roles, run-as roles, and web application or Blueprint resource reference bindings for your OSGi application.

Procedure

- Add or remove composite bundle extensions for an OSGi composition unit

  Use either of the following methods:

  – Add or remove composite bundle extensions using the administrative console.
  – Add or remove composite bundle extensions using wsadmin commands.
- Update an OSGi composition unit.

  Use either of the following methods:

  – Update an OSGi composition unit using the administrative console.
  – Update an OSGi composition unit using the editCompUnit command.

  When all bundle downloads are complete, you can update the OSGi composition unit so that the business-level application uses the newer configuration. If any of the updates contain configuration options, you update the configuration information. You can also take the opportunity to make additional, non-essential configuration changes.
- Modify the configuration of an OSGi composition unit.

  You can modify the configuration information for an OSGi composition unit at any time by using either of the following methods:

  – Modify the configuration of an OSGi composition unit using the administrative console.
  – Modify the configuration of an OSGi composition unit using wsadmin commands.

Results

When you save the changes to the composition unit, the associated business-level application is updated to use the new configuration. If the business-level application is running, the bundle and configuration updates are applied immediately. If possible (that is, depending on the nature of the updates) the system applies the updates without restarting the application. If new packages are imported, or new services injected, then the application is restarted. These packages and services can come from newly-provisioned bundles, or from bundles that have already been provisioned.

Updating an OSGi composition unit

If a new OSGi application deployment is available, you can update the OSGi composition unit so that the business-level application uses the newer configuration. If any of the updates contain configuration options, a wizard prompts you to update the configuration information.

Before you begin

This topic assumes that you have either updated the asset that the composition unit contains, or added a composite bundle as an extension to the composition unit. You do not have to update the composition unit every time you update the asset or add a composite bundle extension. You cannot update the composition unit until all bundle downloads are complete.

You can update an OSGi composition unit by using the administrative console as described in this topic, or by using wsadmin commands as described in “Updating an OSGi composition unit using the editCompUnit command” on page 1054.

About this task

An OSGi composition unit consists of an EBA asset, (optionally) one or more composite bundle extensions, and configuration information for running the asset and composite bundle extensions in a business-level application. The configuration information can include HTTP session management, context roots, virtual hosts, security roles, run-as roles, and web application or Blueprint resource reference bindings for your OSGi application.

When all bundle downloads are complete, you can update the OSGi composition unit so that the business-level application uses the newer configuration. If any of the updates contain configuration options, a wizard prompts you to update the configuration information. You can also take the opportunity to make additional, non-essential configuration changes.

For transitioning users: In the WebSphere Application Server Version 7 Feature Pack for OSGi Applications and Java Persistence API 2.0, bundle changes to the asset are applied by restarting the business-level application, rather than by updating the composition unit. The current approach means that many bundle changes can be applied in place, without restarting the running business-level application.

This topic describes the specific task of updating an OSGi composition unit. The more generalized task of updating the configuration of any composition unit is described in Updating business-level applications.

Procedure

1. Start the administrative console.
2. Navigate to **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***composition_unit_name***.

   The Composition unit settings panel is displayed. The deployment status is displayed under **[General Properties] OSGi application deployment status**, and shows one of the following values:

   - Using latest OSGi application deployment.
   - New OSGi application deployment not yet available because it requires bundles that are still downloading.
   - New OSGi application deployment available.
   - New OSGi application deployment cannot be applied because bundle downloads have failed.

   If the status is “New OSGi application deployment available”, the **Update to latest deployment ...** button is available.
3. Update the composition unit to use the latest version of the EBA asset or composite bundle extension.

   If the status is “New OSGi application deployment available”, click **Update to latest deployment ...**. The Preview composition unit upgrade [Settings] panel is displayed.

   Because multiple updates might be available, and because updates do not have to be applied immediately, you might not be fully aware of the changes that you are about to make to the deployed application. So that you can see the cumulative effect of all the changes, this panel displays the complete list, bundle by bundle, of the updates that are about to be applied. If the result is not what you want, you can cancel the update. Otherwise, click **OK**.
4. Update the configuration information for running the asset or composite bundle extension in the business-level application.

   Bundle changes might also require configuration changes to the composition unit. For example, if you update a bundle in an EBA asset, or replace a composite bundle extension, you might introduce a resource that needs additional configuration, such as a new or changed Blueprint resource reference, or security role mapping.

   If any of the updates contain configuration options, a wizard prompts you to update the configuration information. This wizard is based on the Set options settings wizard that you use when creating a new OSGi composition unit. See Adding an EBA asset to a composition unit using the administrative console.
5. Save your changes to the master configuration.

Results

When you save the changes to the composition unit, the associated business-level application is updated to use the new configuration. If the business-level application is running, the bundle and configuration updates are applied immediately. If possible (that is, depending on the nature of the updates) the system

applies the updates without restarting the application. If new packages are imported, or new services injected, then the application is restarted. These packages and services can come from newly-provisioned bundles, or from bundles that have already been provisioned.

Updating an OSGi composition unit using the editCompUnit command

Use the editCompUnit command to select a composition unit that contains an enterprise OSGi application, and update the composition unit so that the business-level application uses the newer configuration. If any of the updates contain configuration options, run the editCompUnit command a second time to update the configuration information. You can also take the opportunity to make additional, non-essential configuration changes.

Before you begin

This topic assumes that you have either updated the asset that the composition unit contains, or added a composite bundle as an extension to the composition unit. You do not have to update the composition unit every time you update the asset or add a composite bundle extension. You cannot update the composition unit until all bundle downloads are complete.

You can update an OSGi composition unit by using the editCompUnit command as described in this topic, or by using the administrative console as described in “Updating an OSGi composition unit” on page 1052.

About this task

An OSGi composition unit consists of an EBA asset, (optionally) one or more composite bundle extensions, and configuration information for running the asset and composite bundle extensions in a business-level application. The configuration information can include HTTP session management, context roots, virtual hosts, security roles, run-as roles, and web application or Blueprint resource reference bindings for your OSGi application.

When all bundle downloads are complete, you can update the OSGi composition unit so that the business-level application uses the newer configuration. If any of the updates contain configuration options, run the editCompUnit command a second time to update the configuration information. You can also take the opportunity to make additional, non-essential configuration changes.

For transitioning users: In the WebSphere Application Server Version 7 Feature Pack for OSGi Applications and Java Persistence API 2.0, bundle changes to the asset are applied by restarting the business-level application, rather than by updating the composition unit. The current approach means that many bundle changes can be applied in place, without restarting the running business-level application. See the following troubleshooting tip: The behavior has changed for using wsadmin commands to update bundle versions.

Procedure

1. Check the update status of the composition unit.

   There are four distinct deployment statuses for an OSGi composition unit:

   - Using latest OSGi application deployment.
   - New OSGi application deployment not yet available because it requires bundles that are still downloading.
   - New OSGi application deployment available.
   - New OSGi application deployment cannot be applied because bundle downloads have failed.

2. Update the composition unit to use the latest version of the EBA asset or composite bundle extension.

   If the status is “New OSGi application deployment available”, open a wsadmin command prompt then run the following jython command:

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=bla_name
  -cuID WebSphere:cuname=cu_name
  -CompUnitStatusStep [[asset_name.eba true]]
]')
```

For example:

```
AdminTask.editCompUnit('[
  -blaId WebSphere:blaname=test.app
  -cuId WebSphere:cuname=com.ibm.ws.eba.extension.componenttest_0001.eba
  -CompUnitStatusStep [[com.ibm.ws.eba.extension.componenttest.eba true]]
]')
```

3. If required, update the configuration information for running the asset in the business-level application.

   Bundle changes might also require configuration changes to the composition unit. For example, if you update a bundle in an EBA asset, or replace a composite bundle extension, you might introduce a resource that needs additional configuration, such as a new or changed Blueprint resource reference, or security role mapping.

   If any of the updates contain configuration options, run the editCompUnit command a second time to update the configuration information. You can also take the opportunity to make additional, non-essential configuration changes. See “Modifying the configuration of an OSGi composition unit using wsadmin commands” on page 1065.

4. Save your changes to the master configuration.

   To save your configuration changes, use the following command:

   ```
   AdminConfig.save()
   ```

Results

When you save the changes to the composition unit, the associated business-level application is updated to use the new configuration. If the business-level application is running, the bundle and configuration updates are applied immediately. If possible (that is, depending on the nature of the updates) the system applies the updates without restarting the application. If new packages are imported, or new services injected, then the application is restarted. These packages and services can come from newly-provisioned bundles, or from bundles that have already been provisioned.

Adding or removing extensions for an OSGi composition unit

Add composite bundle extensions to, or remove them from, a composition unit that contains an enterprise OSGi application.

Before you begin

This topic assumes that you have developed a composite bundle, and added it to the internal bundle repository or to an external repository that can process composite bundles. See Developing a composite bundle.

You can manage extensions for a composition unit by using the administrative console as described in this topic, or by using wsadmin commands as described in “Adding or removing extensions for an OSGi composition unit using wsadmin commands” on page 1056.

About this task

After you import the enterprise bundle archive (EBA) file for your OSGi application as an asset, you can update versions of existing bundles but you cannot add extra bundles to the asset. However, after you have added the asset as a composition unit to a business-level application, you can extend the business-level application by adding one or more composite bundles to the composition unit.

You can add a composite bundle to, or remove it from, a composition unit. To update an extension to one with newer constituent bundles, you remove the composite bundle from the composition unit then add a new version of the composite bundle.

You can also view read-only information about each listed composite bundle.

Procedure

1. Start the administrative console.
2. Navigate to **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***composition_unit_name*** > **[Additional Properties] Manage extensions for this composition unit**.

   The Manage extensions for this composition unit [Collection] panel is displayed. This panel lists all the composite bundle extensions that are currently added to this composition unit. To view read-only information about a composite bundle, click the composite bundle name in the list.
3. Add or remove composite bundle extensions.
   - Add one or more composite bundles as extensions to a composition unit.
     a. In the Manage extensions for this composition unit [Collection] panel, click **Add**. The Add extensions [Collection] panel is displayed.

        This panel lists all the composite bundles that are currently available to be added to the composition unit. That is, all composite bundles that are installed in an available bundle repository, and that have not already been added as a composite bundle extension or used by a deployed EBA asset. To view read-only information about a composite bundle, click the composite bundle name in the list.
     b. Select one or more composite bundles to add.
     c. Click **Add**. The composite bundle is added, and displayed in the list of composite bundle extensions in the Manage extensions for this composition unit [Collection] form.
   - Remove one or more composite bundle extensions from a composition unit.
     a. In the Manage extensions for this composition unit [Collection] panel, select one or more composite bundle extensions to remove.
     b. Click **Remove**. The selected composite bundles are removed, and the updated list of composite bundle extensions is displayed.
4. Save your changes to the master configuration. If you extended a deployed OSGi application, the composite bundle, including its constituent bundles, is downloaded.

What to do next

If you plan to update the composition unit at this time, check that all bundle downloads are complete. See “Checking the update status of an OSGi composition unit” on page 1077.

Adding or removing extensions for an OSGi composition unit using wsadmin commands

Use the addOSGiExtension or addOSGiExtensions command to add composite bundle extensions to a composition unit that contains an enterprise OSGi application. Similarly, use the removeOSGiExtension or removeOSGiExtensions command to remove composite bundle extensions. Use the listOSGiExtensions command to list all the extensions that are currently added to the composition unit.

Before you begin

This topic assumes that you have developed a composite bundle, and added it to the internal bundle repository or to an external repository that can process composite bundles. See Developing a composite bundle.

You can manage extensions for a composition unit by using wsadmin commands as described in this topic, or by using the administrative console as described in “Adding or removing extensions for an OSGi composition unit” on page 1055.

About this task

After you import the enterprise bundle archive (EBA) file for your OSGi application as an asset, you can update versions of existing bundles but you cannot add extra bundles to the asset. However, after you have added the asset as a composition unit to a business-level application, you can extend the business-level application by adding one or more composite bundles to the composition unit.

You can add a composite bundle to, or remove it from, a composition unit. To update an extension to one with newer constituent bundles, you remove the composite bundle from the composition unit then add a new version of the composite bundle.

Procedure

1. Optional: List composite bundle extensions.

   Use the listOSGiExtensions command to list the symbolic names and versions of all the extensions that are currently added to a composition unit.

   ```
   AdminTask.listOSGiExtensions('-cuName cu_name')
   ```

   Note: The output from the listOSGiExtensions command is formatted so that you can copy the list of extensions, then paste them into the removeOSGiExtensions command.

   For more information, see “listOSGiExtensions command” on page 1061.

2. Add or remove composite bundle extensions.

   - Add one or more composite bundles as extensions to a composition unit.

     Use the addOSGiExtension or addOSGiExtensions command:

     ```
     AdminTask.addOSGiExtension('
       -cuName cu_name
       -symbolicName cba_symbolic_name
       -version cba_version
     ')
     ```

     ```
     AdminTask.addOSGiExtensions([
       '-cuName', 'cu_name',
       '-extensions',
         'cba1_symbolic_name;cba1_version
          cba2_symbolic_name;cba2_version
          cba3_symbolic_name;cba3_version
         '
     ])
     ```

     The composite bundle must be available in the internal bundle repository, or in an external repository that can process composite bundles.

     For more information, see “addOSGiExtension command” on page 1058 or “addOSGiExtensions command” on page 1060.

   - Remove one or more composite bundle extensions from a composition unit.

     Use the removeOSGiExtension or removeOSGiExtensions command:

     ```
     AdminTask.removeOSGiExtension('
       -cuName cu_name
       -symbolicName cba_symbolic_name
       -version cba_version
     ')
     ```

     ```
     AdminTask.removeOSGiExtensions([
       '-cuName', 'cu_name',
       '-extensions',
         'cba1_symbolic_name;cba1_version
     ```

```
        cba2_symbolic_name;cba2_version
        cba3_symbolic_name;cba3_version
      '
])
```

Note: The output from the listOSGiExtensions command is formatted so that you can copy the list of extensions, then paste them into the removeOSGiExtensions command.

For more information, see “removeOSGiExtension command” on page 1059 or “removeOSGiExtensions command” on page 1062.

3. Save your changes to the master configuration.

   To save your configuration changes, use the following command:

   ```
   AdminConfig.save()
   ```

   If you extended a deployed OSGi application, the composite bundle, including its constituent bundles, is downloaded.

What to do next

If you plan to update the composition unit at this time, check that all bundle downloads are complete. See “Checking the update status of an OSGi composition unit” on page 1077.

addOSGiExtension command:

Use the addOSGiExtension command to add a composite bundle as an extension to a composition unit.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('OSGiApplicationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration by using the following command:

```
AdminConfig.save()
```

Purpose

This command adds a composite bundle as an extension to a composition unit. The composite bundle must be available in the internal bundle repository, or in an external repository that can process composite bundles.

Target object

The specified composition unit.

Required parameters

-cuName *cu_name*
The name of the composition unit.

-symbolicName *cba_symbolic_name*
The non-localizable name for this composite bundle.

-version *cba_version*
The version of this composite bundle.

The composite bundle version is in the form *n.n.n*, for example `1.1.0`. The symbolic name, together with the version, identifies a unique composite bundle.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.addOSGiExtension('
  -cuName cu_name
  -symbolicName cba_symbolic_name
  -version cba_version
')
```

removeOSGiExtension command:

Use the removeOSGiExtension command to remove a composite bundle extension from a composition unit.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('OSGiApplicationCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

After using the command, save your changes to the master configuration by using the following command:

```
AdminConfig.save()
```

Purpose

This command removes a composite bundle extension from a composition unit.

Target object

The specified composition unit.

Required parameters

-cuName *cu_name*
The name of the composition unit.

-symbolicName *cba_symbolic_name*
The non-localizable name for this composite bundle.

-version *cba_version*
The version of this composite bundle.

The composite bundle version is in the form *n.n.n*, for example `1.1.0`. The symbolic name, together with the version, identifies a unique composite bundle.

Note: You can use the listOSGiExtensions command to list the symbolic names and versions of all the extensions that are currently added to a composition unit.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.removeOSGiExtension('
  -cuName cu_name
  -symbolicName cba_symbolic_name
  -version cba_version
')
```

addOSGiExtensions command:

Use the addOSGiExtensions command to add several composite bundles as extensions to a composition unit.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('OSGiApplicationCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

After using the command, save your changes to the master configuration by using the following command:

```
AdminConfig.save()
```

Purpose

This command adds several composite bundles as extensions to a composition unit. The composite bundles must be available in the internal bundle repository, or in an external repository that can process composite bundles.

Target object

The specified composition unit.

Required parameters

-cuName *cu_name*
The name of the composition unit.

-extensions

A list of the composite bundle extensions to be added. Each list entry contains the symbolic name and the version for a composite bundle. The symbolic name, together with the version, identifies a unique composite bundle.

cba_symbolic_name
The non-localizable name for this composite bundle.

cba_version
The version of this composite bundle.

The composite bundle version is in the form *n.n.n*, for example `1.1.0`.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.addOSGiExtensions([
  '-cuName', 'cu_name',
  '-extensions',
    'cba1_symbolic_name;cba1_version
     cba2_symbolic_name;cba2_version
     cba3_symbolic_name;cba3_version
    '
])
```

listOSGiExtensions command:

Use the listOSGiExtensions command to list the symbolic names and versions of all the extensions that are currently added to a composition unit.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('OSGiApplicationCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

Purpose

This command lists the symbolic names and versions of all the extensions that are currently added to a composition unit. The output from the listOSGiExtensions command is formatted so that you can copy the list of extensions, then paste them into the removeOSGiExtensions command.

Target object

The specified composition unit.

Required parameters

-cuName *cu_name*
The name of the composition unit.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.listOSGiExtensions('-cuName cu_name')
```

removeOSGiExtensions command:

Use the removeOSGiExtensions command to remove several composite bundle extensions from a composition unit.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('OSGiApplicationCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

After using the command, save your changes to the master configuration by using the following command:

```
AdminConfig.save()
```

Purpose

This command removes several composite bundle extensions from a composition unit.

You can use the listOSGiExtensions command to list the symbolic names and versions of all the extensions that are currently added to a composition unit. The output from the listOSGiExtensions command is formatted so that you can copy the list of extensions, then paste them into the removeOSGiExtensions command.

Target object

The specified composition unit.

Required parameters

-cuName *cu_name*
The name of the composition unit.

-extensions

A list of the composite bundle extensions to be removed. Each list entry contains the symbolic name and the version for a composite bundle. The symbolic name, together with the version, identifies a unique composite bundle.

cba_symbolic_name
The non-localizable name for this composite bundle.

cba_version
The version of this composite bundle.

The composite bundle version is in the form *n.n.n*, for example `1.1.0`.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.removeOSGiExtensions([
  '-cuName', 'cu_name',
  '-extensions',
    'cba1_symbolic_name;cba1_version
     cba2_symbolic_name;cba2_version
     cba3_symbolic_name;cba3_version
    '
])
```

Modifying the configuration of an OSGi composition unit

You can modify the configuration information for a composition unit that contains an enterprise OSGi application. An OSGi composition unit consists of an EBA asset, (optionally) one or more composite bundle extensions, and configuration information for running the asset and composite bundle extensions in a business-level application. The configuration information can include HTTP session management, context roots, virtual hosts, security roles, run-as roles, and web application or Blueprint resource reference bindings for your OSGi application.

Before you begin

You can modify the configuration of an OSGi composition unit by using the administrative console as described in this topic, or by using wsadmin commands as described in “Modifying the configuration of an OSGi composition unit using wsadmin commands” on page 1065.

About this task

An OSGi composition unit consists of an EBA asset, (optionally) one or more composite bundle extensions, and some or all of the following configuration information:

- Mappings from the composition unit to a target application server, web server or cluster.
- Configuration of the application's session manager, context roots or virtual hosts.
- Bindings to any associated web applications or blueprint resource references.
- Mappings from security roles to particular users or groups.

You first specify the configuration of an EBA asset or composite bundle extension when you add it to a composition unit. If bundles in the asset or composite bundle extension are subsequently changed, or if you need to remap resources, you can update the configuration. For example, if you update a bundle in an EBA asset, or replace a composite bundle extension, you might introduce a resource that needs additional configuration, such as a new or changed Blueprint resource reference, or security role mapping.

This topic describes the specific task of modifying the configuration of an OSGi composition unit. The more generalized task of modifying the configuration of any composition unit is described in Updating business-level applications.

Procedure

1. Start the administrative console.
2. Navigate to **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***composition_unit_name***.

   The Composition unit settings panel is displayed.
3. Under the **Additional Properties** section, click any of the following options then modify the settings as required.
   - **Session management**

     Configure HTTP session management for the web application bundles. For more information, see Configuring session management by level.

     The Session management option is only visible if the OSGi application uses web application bundles.
   - **Map context roots**

     Select a web application bundle (WAB) from the list, then enter the context root for the WAB. For example, `/sample`. For more information, see Context root for web application bundles [Settings].

     The Map context roots option is only visible if the application uses web application bundles.
   - **Virtual hosts**

     The list of available WABs in this asset is displayed. For each WAB, you can change the associated virtual host by selecting a different one from the list. If you specify an existing virtual host in the `ibm-web-bnd.xml` or `.xmi` file for a given WAB, the specified virtual host is set by default. Otherwise, the default virtual host setting is `default_host`. For more information, see Virtual hosts for web application bundles [Settings].

     The Virtual hosts option is only visible if the application uses web application bundles.
   - **Security role to user/group mapping**

     Change the security mapping as needed. For more information, see Security role to user or group mapping [Settings].

The Security role to user/group mapping option is only visible if the application uses security roles.

- **Map RunAs roles to users**

  You can map a specified user identity and password to a RunAs role. This enables you to specify application-specific privileges for individual users, so that they can run specific tasks using another user identity. For more information, see Map RunAs roles to users [Collection].

  The Map RunAs roles to users option is only visible if the application uses RunAs roles.

- **Bind Blueprint resource references**

  The list of available Blueprint resource references in this asset is displayed. For each reference, you can optionally select an authentication alias from the list. Default authentication aliases (from `ibm-eba-bnd.xml` files) are offered only if they exist on every target server or cluster. For more information, see Blueprint resource reference bindings [Settings].

  The Bind Blueprint resource references option is only visible if the bundle includes Blueprint resource reference declarations.

- **Web module message destination and resource environment reference bindings**

  The list of available web application message destination and resource environment references in this asset is displayed. That is, resources of type message-destination-ref (message destination reference) or resource-env-ref (resource environment reference), as defined in the Java specification JSR-250: Common Annotations for the Java Platform. For each reference, specify the JNDI name under which the resource is known in the runtime environment. For more information, see Web module message destination and resource environment reference bindings [Settings].

  The Web module message destination and resource environment reference bindings option is only visible if the bundle includes a web application.

- **Web module resource reference bindings**

  The list of available web application resource references in this asset is displayed. That is, resources of type resource-ref (resource reference), as defined in the Java specification JSR-250: Common Annotations for the Java Platform. For each reference, specify the JNDI name under which the resource is known in the runtime environment. Optionally, set authentication properties and extended data source custom properties, which affect how the resource is accessed at run time. To specify the JNDI name mapping, either type the JNDI name into the box, or click **Browse...** then select the resource reference from the list of available resources. To modify the authentication method or set extended data source custom properties, select a single reference then click **Modify Resource Authentication Method...** or **Extended Properties...**. For more information, see Web module resource reference bindings [Settings].

  The Web module resource reference bindings option is only visible if the bundle includes a web application.

4. Save your changes to the master configuration.

Results

When you save the changes to the composition unit, the associated business-level application is updated to use the new configuration. If the business-level application is running, the bundle and configuration updates are applied immediately. If possible (that is, depending on the nature of the updates) the system applies the updates without restarting the application. If new packages are imported, or new services injected, then the application is restarted. These packages and services can come from newly-provisioned bundles, or from bundles that have already been provisioned.

Modifying the configuration of an OSGi composition unit using wsadmin commands

You can use the editCompUnit command and the AdminConfig commands to modify the configuration information for a composition unit that contains an enterprise OSGi application. An OSGi composition unit consists of an EBA asset, (optionally) one or more composite bundle extensions, and configuration information for running the asset and composite bundle extensions in a business-level application. The

configuration information can include HTTP session management, context roots, virtual hosts, security roles, run-as roles, and web application or Blueprint resource reference bindings for your OSGi application.

Before you begin

You can modify the configuration of an OSGi composition unit by using wsadmin commands as described in this topic, or by using the administrative console as described in “Modifying the configuration of an OSGi composition unit” on page 1063.

About this task

An OSGi composition unit consists of an EBA asset, (optionally) one or more composite bundle extensions, and some or all of the following configuration information:

- Mappings from the composition unit to a target application server, web server or cluster.
- Configuration of the application's session manager, context roots or virtual hosts.
- Bindings to any associated web applications or blueprint resource references.
- Mappings from security roles to particular users or groups.

You first specify the configuration of an EBA asset or composite bundle extension when you add it to a composition unit. If bundles in the asset or composite bundle extension are subsequently changed, or if you need to remap resources, you can update the configuration. For example, if you update a bundle in an EBA asset, or replace a composite bundle extension, you might introduce a resource that needs additional configuration, such as a new or changed Blueprint resource reference, or security role mapping.

To configure all elements of the composition unit except the HTTP session manager, you use the editCompUnit command. To configure the HTTP session manager, you use the AdminConfig commands to configure the deployed object represented by the *appDeploy* variable.

In the following procedure, all the steps and substeps are optional. You only need to re-configure the elements that have changed.

Procedure

- Configure all elements of the composition unit except the HTTP session manager.

  Each of the following substeps describes the syntax for modifying a single element of the composition unit using the editCompUnit command. You can run the command once for each element, or you can modify several elements in a batch.

  For several of the elements, the values you specify include bundle identifiers. If your EBA asset includes or references composite bundles, the command syntax is slightly different. For clarity, the differences for composite bundles are described, step by step, in a linked topic.

  1. Identify the composition unit that you want to edit.

     You identify a particular composition unit by specifying its business-level application ID and composition unit ID. Whenever you run the editCompUnit command, you must always include these two parameters in the command.

     -blaID
     Specifies the configuration ID of the business-level application.

     -cuID
     Specifies the ID of the composition unit.

     The jython syntax for this aspect of the command is as follows:

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=bla_name
  -cuID WebSphere:cuname=cu_name
  ...
]')
```

For example:

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=helloWorldService
  -cuID WebSphere:cuname=com.ibm.ws.eba.helloWorldService_0001.eba
  ...
]')
```

2. Map the target node and server, or the target cluster.

   You cannot edit the deployable unit URI (which, for a composition unit that contains an OSGi application, is `ebaDeploymentUnit`). You can edit the target node and server, or the target cluster. To add an additional target, you use the plus sign character (+) as a prefix.

   If the target is one cluster, the jython syntax for this aspect of the command is as follows:

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=bla_name
  -cuID WebSphere:cuname=cu_name
  -MapTargets [[ebaDeploymentUnit WebSphere:cluster=cluster_name]]
]')
```

   For example:

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=helloWorldService
  -cuID WebSphere:cuname=com.ibm.ws.eba.helloWorldService_0001.eba
  -MapTargets [[ebaDeploymentUnit WebSphere:cluster=cluster1]]
]')
```

   If the target is two servers, the jython syntax for this aspect of the command is as follows::

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=bla_name
  -cuID WebSphere:cuname=cu_name
  -MapTargets [
    [ebaDeploymentUnit WebSphere:node=node_name,server=server_name+
                       WebSphere:node=node2_name,server=server2_name]]
]')
```

   For example:

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=helloWorldService
  -cuID WebSphere:cuname=com.ibm.ws.eba.helloWorldService_0001.eba
  -MapTargets [
    [ebaDeploymentUnit WebSphere:node=node01,server=server1+
                       WebSphere:node=node01,server=web1]]
]')
```

3. Define WAB context roots.

   Context roots determine where the web pages of a particular web application bundle (WAB) are found at run time. The context root that you specify here is combined with the defined server mapping to compose the full URL that you enter to access the pages of the WAB. For example, if the application server default host is www.example.com:8080 and the context root of the WAB is /sample, the web pages are available at www.example.com:8080/sample.

   The jython syntax for this aspect of the command is as follows. The bundles listed under the **ContextRootStep** need to be all the WABs contained in the OSGi application.

   Note: For composite bundles, the syntax is slightly different. See Step: Define context roots for web application bundles (WABs) in composite bundles.

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=bla_name
  -cuID WebSphere:cuname=cu_name
  -ContextRootStep [
    [bundle_symbolic_name_1 bundle_version_1 context_root_1]
    [bundle_symbolic_name_2 bundle_version_2 context_root_2]]
]')
```

For example, for an EBA file that contains two WABs (com.ibm.ws.eba.helloWorldService.web at version 1.0.0, which is to be mapped to /hello/web, and com.ibm.ws.eba.helloWorldService.withContextRoot at version 0.9.0, which is to be mapped to /hello/service), this aspect of the command is as follows:

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=helloWorldService
  -cuID WebSphere:cuname=com.ibm.ws.eba.helloWorldService_0001.eba
  -ContextRootStep [
    [com.ibm.ws.eba.helloWorldService.web 1.0.0 "/hello/web"]
    [com.ibm.ws.eba.helloWorldService.withContextRoot 0.9.0 "/hello/service"]]
]')
```

4. Map WABs to virtual hosts.

   You use a virtual host to associate a unique port with a web application. The aliases of a virtual host identify the port numbers defined for that virtual host. A port number specified in a virtual host alias is used in the URL that is used to access artifacts such as servlets and JavaServer Page (JSP) files in a web application. For example, the alias myhost:8080 is the *host_name:port_number* portion of the URL http://myhost:8080/sample.

   Each WAB that is contained in a deployed asset must be mapped to a virtual host. WABs can be installed on the same virtual host, or dispersed among several virtual hosts.

   If you specify an existing virtual host in the ibm-web-bnd.xml or .xmi file for a given WAB, the specified virtual host is set by default. Otherwise, the default virtual host setting is default_host, which provides several port numbers through its aliases:

   80 An internal, insecure port used when no port number is specified
   9080 An internal port
   9443 An external, secure port

   Unless you want to isolate your WAB from other WABs or resources on the same node, default_host is a suitable virtual host. In addition to default_host, WebSphere Application Server provides admin_host, which is the virtual host for the administrative console system application. admin_host is on port 9060. Its secure port is 9043. Do not select admin_host unless the WAB relates to system administration.

   The jython syntax for this aspect of the command is as follows.

   Note: For composite bundles, the syntax is slightly different. See Step: Map WABs in composite bundles to virtual hosts.

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=bla_name
  -cuID WebSphere:cuname=cu_name
  -VirtualHostMappingStep [
    [bundle_symbolic_name_1 bundle_version_1
    web_module_name_1 virtual_host_1]
    [bundle_symbolic_name_2 bundle_version_2
     web_module_name_2 virtual_host_2]]
]')
```

   For example, for an EBA file containing two WABs (com.ibm.ws.eba.helloWorldService.web at version 1.0.0, which is to be mapped to default_host, and com.ibm.ws.eba.helloWorldService.withContextRoot at version 0.9.0, which is to be mapped to test_host), this aspect of the command is as follows:

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=helloWorldService
  -cuID WebSphere:cuname=com.ibm.ws.eba.helloWorldService_0001.eba
  -VirtualHostMappingStep [
    [com.ibm.ws.eba.helloWorldService.web 1.0.0
    "HelloWorld service" default_host]
    [com.ibm.ws.eba.helloWorldService.withContextRoot 0.9.0
    "HelloWorld second service" test_host]]
]')
```

5. Map security roles to users or groups.

   The jython syntax for this aspect of the command is as follows:

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=bla_name
  -cuID WebSphere:cuname=cu_name
  -MapRolesToUsersStep [
    [role_name everyone?
    all_authenticated_in_realm?
    usernames groups]]
]')
```

   Key:

   - *role_name* is a role name defined in the application.
   - *everyone?* is set to Yes or No, to specify whether or not everyone is in the role.
   - *all_authenticated_in_realm?* is set to Yes or No, to specify whether or not all authenticated users can access the application realm.
   - *usernames* is a list of WebSphere Application Server user names, separated by the "|" character.
   - *groups* is a list of WebSphere Application Server groups, separated by the "|" character.

   Note: For *usernames*, and *groups*, the empty string "" means "use the default or existing value". The default value is usually that no users or groups are bound to the role. However, when an application contains an `ibm-application-bnd.xmi` file, the default value for *usernames* is obtained from this file. If you are deploying an application that contains an `ibm-application-bnd.xmi` file, and you want to remove the bound users, specify just the "|" character (which is the separator for multiple user names). This explicitly specifies "no users", and therefore guarantees that no users are bound to the role.

   For example:

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=helloWorldService
  -cuID WebSphere:cuname=com.ibm.ws.eba.helloWorldService_0001.eba
  -MapRolesToUsersStep [
    [ROLE1 No Yes "" ""]
    [ROLE2 No No WABTestUser1 ""]
    [ROLE3 No No "" WABTestGroup1]
    [ROLE4 Yes No "" ""]]
]')
```

   For more information about the -MapRolesToUsersStep option, see the information for the $AdminApp install command “MapRolesToUsers” option. This is the equivalent option for Java EE applications. For more general information, see Security role to user or group mapping.

6. Map RunAs roles to users

   You can map a specified user identity and password to a RunAs role. This enables you to specify application-specific privileges for individual users, so that they can run specific tasks using another user identity. The jython syntax for this aspect of the command is as follows:

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=bla_name
  -cuID WebSphere:cuname=cu_name
  -MapRunAsRolesToUsersStep [
    [role_name user_name password]]
]')
```

   For example:

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=helloWorldService
  -cuID WebSphere:cuname=com.ibm.ws.eba.helloWorldService_0001.eba
```

```
  -MapRunAsRolesToUsersStep [
    [Role1 User1 password1]
    [AdminRole User3 password3]]
]')
```

For more information about the -MapRunAsRolesToUsers option, see the information for the $AdminApp install command “MapRunAsRolesToUsers” option. This is the equivalent option for Java EE applications. For more general information, see Map RunAs roles to users.

7. Add authentication aliases to Blueprint resource references.

   Blueprint components can access WebSphere Application Server resource references. Each reference is declared in a Blueprint XML file, and can be secured using a Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) authentication alias. Each bundle in an OSGi application can contain any number of resource reference declarations in its various Blueprint XML files.

   When you secure resource references, those resource references can be bound only to JCA authentication aliases that exist on every server or cluster on which the application is deployed. An OSGi application can be deployed to multiple servers and clusters that are in the same security domain. Therefore, each JCA authentication alias must exist in either the security domain of the target servers and clusters, or the global security domain.

   You must declare the resource references in the Blueprint XML file. For example:

```
<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0"
  xmlns:rr="http://www.ibm.com/appserver/schemas/8.0/blueprint/resourcereference">
  <!-- Other Blueprint declarations ... -->

  <rr:resource-reference id="resourceRef"
          interface="javax.sql.DataSource"
          filter="(osgi.jndi.service.name=jdbc/Account)">
    <rr:res-auth>Container</rr:res-auth>
    <rr:res-sharing-scope>Shareable</rr:res-sharing-scope>
  </rr:resource-reference>
</blueprint>
```

   This declaration includes the resource reference ID (for example `resourceRef`), the service filter (for example `jdbc/Account`), the authentication type (for example `Container`), and the sharing setting (for example `Shareable`).

   The Blueprint resource references to authentication alias bindings for each bundle are stored in a file `ibm-eba-bnd.xml` in the `META-INF` directory of that bundle. If an OSGi application contains any of these files when it is deployed as an asset, these files provide the default authentication alias values that are used when binding the resource references. For example:

```
<eba-bnd xmlns="http://www.ibm.com/blueprintbinding.xsd">
  <resource-ref>
    <jndi-name>jdbc/Acount</jndi-name>
    <authentication-alias>Alias1</authentication-alias>
    <interface>javax.sql.DataSource</interface>
    <authentication>Container</authentication>
    <sharing-scope>Shareable</sharing-scope>
    <id>resourceRef</id>
  </resource-ref>
</eba-bnd>
```

   The jython syntax for this aspect of the command is as follows.

   Note: For composite bundles, the syntax is slightly different. See Step: Add authentication aliases to Blueprint resource references in composite bundles.

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=bla_name
  -cuID WebSphere:cuname=cu_name
  -BlueprintResourceRefPostDeployStep [
    [
```

```
    bundle_symbolic_name
    bundle_version
    blueprint_resource_reference_id
    interface_name
    jndi_name
    authentication_type
    sharing_setting
    authentication_alias_name
    ]]
]')
```

Note: The value for *jndi_name* must match the jndi name that you declare in the **filter** attribute of the resource reference element in the Blueprint XML file.

For example, for an EBA file that contains a bundle `com.ibm.ws.eba.helloWorldService.properties.bundle.jar` at Version 1.0.0, which is to be bound to authentication alias `alias1`, the command is as follows:

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=helloWorldService
  -cuID WebSphere:cuname=com.ibm.ws.eba.helloWorldService_0001.eba
  -BlueprintResourceRefPostDeployStep[
    [com.ibm.ws.eba.helloWorldService.properties.bundle 1.0.0 resourceRef
    javax.sql.DataSource jdbc/Account Container Shareable alias1]]
]')
```

8. Bind web module message destination and resource environment references.

   Binding a resource reference maps a resource dependency of the web application to an actual resource available in the server runtime environment. At a minimum, this can be achieved by using a mapping that specifies the JNDI name under which the resource is known in the runtime environment. By default, the JNDI name is the resource ID that you specified in the `web.xml` file during development of the web application bundle (WAB). Use this option to bind resources of type message-destination-ref (message destination reference) or resource-env-ref (resource environment reference), as defined in the Java specification JSR-250: Common Annotations for the Java Platform.

   The jython syntax for this aspect of the command is as follows.

   Note: For composite bundles, the syntax is slightly different. See Step: Bind web module message destination and resource environment references in composite bundles.

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=bla_name
  -cuID WebSphere:cuname=cu_name
  -WebModuleMsgDestRefs [
    [
    bundle_symbolic_name
    bundle_version
    resource_reference_id
    resource_type
    target_jndi_name
    ]]
]')
```

   For example:

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=helloWorldService
  -cuID WebSphere:cuname=com.ibm.ws.eba.helloWorldService_0001.eba
  -WebModuleMsgDestRefs [
    [com.ibm.ws.eba.helloWorldService.web 1.0.0
    jms/myQ javax.jms.Queue jms/workQ]
    [com.ibm.ws.eba.helloWorldService.web 1.0.0
    jms/myT javax.jms.Topic jms/notificationTopic]]
]')
```

9. Bind web module resource references.

Binding a resource reference maps a resource dependency of the web application to an actual resource available in the server runtime environment. At a minimum, this can be achieved by using a mapping that specifies the JNDI name under which the resource is known in the runtime environment. By default, the JNDI name is the resource ID that you specified in the `web.xml` file during development of the web application bundle (WAB). Use this option to bind resources of type resource-ref (resource reference), as defined in the Java specification JSR-250: Common Annotations for the Java Platform.

The jython syntax for this aspect of the command is as follows.

Note: For composite bundles, the syntax is slightly different. See Step: Bind web module resource references in composite bundles.

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=bla_name
  -cuID WebSphere:cuname=cu_name
  -WebModuleResourceRefs [
    [
    bundle_symbolic_name
    bundle_version
    resource_reference_id
    resource_type
    target_jndi_name
    login_configuration
    login_properties
    extended_properties
    ]]
]')
```

For example:

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=helloWorldService
  -cuID WebSphere:cuname=com.ibm.ws.eba.helloWorldService_0001.eba
  -WebModuleResourceRefs [
    [com.ibm.ws.eba.helloWorldService.web 1.0.0
    jdbc/jtaDs javax.sql.DataSource
    jdbc/helloDs "" "" ""]
    [com.ibm.ws.eba.helloWorldService.web 1.0.0
    jdbc/nonJtaDs javax.sql.DataSource
    jdbc/helloDsNonJta "" "" "extprop1=extval1"]]
]')
```

Note: If you use multiple extended properties, the jython syntax is `"extprop1=extval1,extprop2=extval2"`.

- Configure the HTTP session manager.

  To configure the HTTP session manager, you use the AdminConfig commands to configure the deployed object represented by the *appDeploy* variable. Session management for OSGi applications is configured in the same way as for enterprise applications, except for a minor difference in syntax when getting the deployed object.

  1. Get the deployed object.

     Use the instructions given in Configuring applications for session management using scripting. Note that, for enterprise applications, you use the following two line script:

     ```
     deployments = AdminConfig.getid('/Deployment:myApp/')
     appDeploy = AdminConfig.showAttribute(deployments, 'deployedObject')
     ```

     For OSGi applications, the equivalent script is the following single line:

     ```
     appDeploy = AdminTask.getOSGiApplicationDeployedObject('-cuName cu_name')
     ```

     where *cu_name* is the name of the composition unit. For example:

```
appDeploy = AdminTask.getOSGiApplicationDeployedObject('
  -cuName com.ibm.ws.eba.helloWorldService_0001.eba')
```

2. Create or modify the session management options.

   Use the instructions given in Configuring applications for session management using scripting. The command usage for creating and modifying session management options is exactly the same for enterprise applications and OSGi applications.

What to do next

After using these commands, save your changes to the master configuration by using the following command:

```
AdminConfig.save()
```

When you save the changes to the composition unit, the associated business-level application is updated to use the new configuration. If the business-level application is running, the bundle and configuration updates are applied immediately. If possible (that is, depending on the nature of the updates) the system applies the updates without restarting the application. If new packages are imported, or new services injected, then the application is restarted. These packages and services can come from newly-provisioned bundles, or from bundles that have already been provisioned.

Modifying the configuration of an OSGi composition unit that includes composite bundles using the editCompUnit command:

You can use the editCompUnit command to modify the configuration information for a composition unit that contains an enterprise bundle archive (EBA) asset. If the EBA asset includes composite bundles, the command syntax is slightly different.

Before you begin

For a full description of how you modify this configuration information, see “Modifying the configuration of an OSGi composition unit using wsadmin commands” on page 1065. When you work through that task, each step where the syntax is different for composite bundles is linked to an equivalent step in this task.

About this task

An OSGi composition unit includes an EBA asset and some or all of the following configuration information:

- Mappings from the composition unit to a target application server, web server or cluster.
- Configuration of the application's session manager, context roots or virtual hosts.
- Bindings to any associated web applications or blueprint resource references.
- Mappings from security roles to particular users or groups.

For several of the elements, the values you specify include bundle identifiers. If your EBA asset includes or references composite bundles, the command syntax is slightly different. The differences for composite bundles are described in the following steps.

Procedure

- Define context roots for web application bundles (WABs) in composite bundles.

  The jython syntax for this aspect of the command is as follows:

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=bla_name
  -cuID WebSphere:cuname=cu_name
```

```
  -ContextRootStep [
    [bundle_symbolic_name_1 bundle_version_1 context_root_1]
    [bundle_symbolic_name_2 bundle_version_2 context_root_2]]
]')
```

For composite bundles, the bundle symbolic name has the following syntax:

```
CBA.symbolic.Name_CBA.bundle.version/WAB.symbolic.name
```

For example, for a composite bundle `com.ibm.ws.eba.helloWorldCBA` at version 1.0.0 that contains two WABs (`com.ibm.ws.eba.helloWorldService.web` at version 1.0.0, which is to be mapped to `/hello/web`, and `com.ibm.ws.eba.helloWorldService.withContextRoot` at version 0.9.0, which is to be mapped to `/hello/service`), this aspect of the command is as follows:

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=helloWorldService
  -cuID WebSphere:cuname=com.ibm.ws.eba.helloWorldService_0001.eba
  -ContextRootStep [
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web 1.0.0
    "/hello/web"]
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.withContextRoot 0.9.0
    "/hello/service"]]
]')
```

Note: For bundles other than composite bundles, the syntax is slightly different. See Step: Define WAB context roots.

- Map WABs in composite bundles to virtual hosts.

  The jython syntax for this aspect of the command is as follows:

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=bla_name
  -cuID WebSphere:cuname=cu_name
  -VirtualHostMappingStep [
    [bundle_symbolic_name_1 bundle_version_1
    web_module_name_1 virtual_host_1]
    [bundle_symbolic_name_2 bundle_version_2
     web_module_name_2 virtual_host_2]]
]')
```

  For composite bundles, the bundle symbolic name has the following syntax:

```
CBA.symbolic.Name_CBA.bundle.version/WAB.symbolic.name
```

  For example, for a composite bundle `com.ibm.ws.eba.helloWorldCBA` at version 1.0.0 that contains two WABs (`com.ibm.ws.eba.helloWorldService.web` at version 1.0.0, which is to be mapped to `default_host`, and `com.ibm.ws.eba.helloWorldService.withContextRoot` at version 0.9.0, which is to be mapped to `test_host`), this aspect of the command is as follows:

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=helloWorldService
  -cuID WebSphere:cuname=com.ibm.ws.eba.helloWorldService_0001.eba
  -VirtualHostMappingStep [
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web
    1.0.0 "HelloWorld service" default_host]
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.withContextRoot
    0.9.0
    "HelloWorld second service" test_host]]
]')
```

  Note: For bundles other than composite bundles, the syntax is slightly different. See Step: Map WABs to virtual hosts.

- Add authentication aliases to Blueprint resource references in composite bundles.

  The jython syntax for this aspect of the command is as follows.

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=bla_name
  -cuID WebSphere:cuname=cu_name
```

```
  -BlueprintResourceRefPostDeployStep [
    [
    bundle_symbolic_name
    bundle_version
    blueprint_resource_reference_id
    interface_name
    jndi_name
    authentication_type
    sharing_setting
    authentication_alias_name
    ]]
]')
```

Notes:

- For composite bundles, the bundle symbolic name has the following syntax:

  ```
  CBA.symbolic.Name_CBA.bundle.version/inner_bundle.symbolic.name
  ```

- The value for *jndi_name* must match the jndi name that you declare in the **filter** attribute of the resource reference element in the Blueprint XML file.

For example, for a composite bundle `com.ibm.ws.eba.helloWorldCBA` at version 1.0.0 that contains a bundle `com.ibm.ws.eba.helloWorldService.properties.bundle.jar` at Version 1.0.0, which is to be bound to authentication alias `alias1`, the command is as follows:

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=helloWorldService
  -cuID WebSphere:cuname=com.ibm.ws.eba.helloWorldService_0001.eba
  -BlueprintResourceRefPostDeployStep[
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.properties.bundle
    1.0.0 resourceRef javax.sql.DataSource jdbc/Account Container Shareable alias1]]
]')
```

Note: For bundles other than composite bundles, the syntax is slightly different. See Step: Add authentication aliases to Blueprint resource references.

- Bind web module message destination and resource environment references in composite bundles.

  The jython syntax for this aspect of the command is as follows.

  ```
  AdminTask.editCompUnit('[
    -blaID WebSphere:blaname=bla_name
    -cuID WebSphere:cuname=cu_name
    -WebModuleMsgDestRefs [
      [
      bundle_symbolic_name
      bundle_version
      resource_reference_id
      resource_type
      target_jndi_name
      ]]
  ]')
  ```

  For composite bundles, the bundle symbolic name has the following syntax:

  ```
  CBA.symbolic.Name_CBA.bundle.version/WAB.symbolic.name
  ```

  For example:

  ```
  AdminTask.editCompUnit('[
    -blaID WebSphere:blaname=helloWorldService
    -cuID WebSphere:cuname=com.ibm.ws.eba.helloWorldService_0001.eba
    -WebModuleMsgDestRefs [
      [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web
      1.0.0
      jms/myQ javax.jms.Queue
      jms/workQ]
      [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web
  ```

```
    1.0.0
    jms/myT javax.jms.Topic
    jms/notificationTopic]]
]')
```

Note: For bundles other than composite bundles, the syntax is slightly different. See Step: Bind web module message destination and resource environment references.

- Bind web module resource references in composite bundles.

  The jython syntax for this aspect of the command is as follows.

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=bla_name
  -cuID WebSphere:cuname=cu_name
  -WebModuleResourceRefs [
    [
    bundle_symbolic_name
    bundle_version
    resource_reference_id
    resource_type
    target_jndi_name
    login_configuration
    login_properties
    extended_properties
    ]]
]')
```

  For composite bundles, the bundle symbolic name has the following syntax:

```
CBA.symbolic.Name_CBA.bundle.version/WAB.symbolic.name
```

  For example:

```
AdminTask.editCompUnit('[
  -blaID WebSphere:blaname=helloWorldService
  -cuID WebSphere:cuname=com.ibm.ws.eba.helloWorldService_0001.eba
  -WebModuleResourceRefs [
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web
    1.0.0
    jdbc/jtaDs javax.sql.DataSource
    jdbc/helloDs "" "" ""]
    [com.ibm.ws.eba.helloWorldCBA_1.0.0/com.ibm.ws.eba.helloWorldService.web
    1.0.0
    jdbc/nonJtaDs javax.sql.DataSource
    jdbc/helloDsNonJta "" "" "extprop1=extval1"]]
]')
```

  Notes:

  – If you use multiple extended properties, the jython syntax is `"extprop1=extval1,extprop2=extval2"`.

  – For bundles other than composite bundles, the syntax is slightly different. See Step: Bind web module resource references.

Checking the bundle download status of an EBA asset

Updating an asset to use a new bundle version might require bundle downloads. You cannot update an asset until bundle downloads are complete from any previous update. Before you try and update bundle versions, you can check the bundle download status of the asset.

Before you begin

In addition to the approach given in this task, you can also check the bundle download status indirectly, by checking the status of the associated OSGi composition unit as described in “Checking the update status of an OSGi composition unit” on page 1077.

About this task

You use the administrative console to check the bundle download status of an EBA asset. This status is either “Bundles downloading...”, “Bundle downloads are complete”, or “No bundles downloads are required”.

Procedure

1. Start the administrative console.
2. Navigate to **Applications** > **Application Types** > **Assets** > ***asset_name***.
   The Asset settings panel is displayed.

Results

The current bundle download status for all bundles and composite bundles for this asset is displayed in the EBA Dependencies section. If the bundle downloads for any previous update have completed, the option to update bundle versions is available under the Additional Properties section.

What to do next

- If bundle downloads for the asset are complete, or no bundle downloads are required, you can update the asset as described in “Updating bundle versions for an EBA asset” on page 1048.
- If a new version of the EBA asset is available, and all bundle downloads for the asset are complete, you can update the OSGi composition unit so that the business-level application uses the newer configuration. See “Updating an OSGi composition unit” on page 1052.

Checking the update status of an OSGi composition unit

When you change the versions of bundles or composite bundles that an enterprise OSGi application uses, or add or remove a composite bundle extension, the bundles used by the deployed application can get out of synchronization with those that are available. To check that your business-level application is running the most recent version of the EBA asset and any composite bundle extensions, you check the update status of the associated OSGi composition unit.

About this task

When an EBA asset is updated, or a composite bundle extension is added or replaced, the update does not automatically affect the running business-level application. To update the running application, you update the composition unit of the business-level application that contains the asset.

The deployment status shows whether an updated version is available of the EBA asset or composite bundle extension that is contained in the composition unit. There are four distinct deployment statuses for an OSGi composition unit:

Using latest OSGi application deployment.
The composition unit is running the latest configuration of the backing asset and any composite bundle extensions.

New OSGi application deployment not yet available because it requires bundles that are still downloading.
The bundle downloads that were started after you last updated an asset, or added a composite bundle extension, have not yet finished.

New OSGi application deployment available.
The backing asset is available at a newer configuration than the configuration that is currently running in this composition unit, or a composite bundle extension has been added or replaced.

New OSGi application deployment cannot be applied because bundle downloads have failed.
The bundle downloads that were started after you last updated an asset, or added a composite

bundle extension, have not succeeded. Resolve the problem, then download the bundles again. See “Interacting with the OSGi bundle cache” on page 1095.

You can check whether the OSGi composition unit is up to date by using the administrative console, or by using the viewCompUnit command.

Procedure

- Check the update status of the OSGi composition unit using the administrative console.
  1. Start the administrative console.
  2. Navigate to **Applications** > **Application Types** > **Business-level applications** > ***application_name*** > ***composition_unit_name***.

  The Composition unit settings panel is displayed. The deployment status is displayed under **[General Properties] OSGi application deployment status**, and shows one of the following values:
  - Using latest OSGi application deployment.
  - New OSGi application deployment not yet available because it requires bundles that are still downloading.
  - New OSGi application deployment available.
  - New OSGi application deployment cannot be applied because bundle downloads have failed.
- Check the update status of the OSGi composition unit using the viewCompUnit command.
  1. Open a wsadmin command prompt.
  2. Run the following jython command:

     ```
     AdminTask.viewCompUnit('[-blaID WebSphere:blaname=bla_name
                             -cuID WebSphere:cuname=cu_name ]')
     ```

     For more information about using the viewCompUnit command, see the step “Display composition units and configuration settings” in topic Managing composition units using wsadmin scripting.

  The set of information about the OSGi composition unit is displayed, including the composition unit status. This status is one of the following values:
  - Using latest OSGi application deployment.
  - New OSGi application deployment not yet available because it requires bundles that are still downloading.
  - New OSGi application deployment available.
  - New OSGi application deployment cannot be applied because bundle downloads have failed.

What to do next

- If there is no update in progress, or bundle downloads for the asset have not succeeded, you can update the asset as described in “Updating bundle versions for an EBA asset” on page 1048.
- If a new OSGi application deployment is available, you can update the OSGi composition unit so that the business-level application uses the newer configuration. See “Updating an OSGi composition unit” on page 1052.

Administering bundle repositories

OSGi applications can share a large number of common utility bundles. To simplify maintenance, and reduce the application footprint, the application does not need to include its own copy of each utility bundle. Instead, bundles can be hosted in a bundle repository, from where they are retrieved during deployment. You can administer bundles and composite bundles held in the internal bundle repository of the product, and also add links to external bundle repositories.

About this task

WebSphere Application Server includes an internal bundle repository, in which you can store the bundles and composite bundles for your OSGi applications. The external bundle repositories are bundle repositories that are available outside of WebSphere Application Server. If your OSGi applications reference bundles that are stored in an external bundle repository, you must configure a link (name and URL) to the repository so that the provisioner can retrieve the bundles when required. When an OSGi application is imported as an asset, the provisioner attempts to satisfy all its dependencies by using the contents of the asset, the contents of the internal bundle repository, and the contents of any available external bundle repositories.

You can link to any external bundle repository that complies with the OSGi Alliance RFC-0112 Bundle Repository Draft Specification. Such a repository consists of a website with a bundle repository XML file that describes an OSGi-compliant repository. Depending on how the external bundle repository is implemented, you might not be able to use it to provision services, or to store composite bundles or bundles referenced by composite bundles.

If your bundle includes Blueprint XML files that specify service or reference elements, and the bundle is included in a EBA asset or installed in the internal bundle repository, then these elements are respected during provisioning and appropriate services are provisioned when needed. For more information, see Provisioning for OSGi applications.

Procedure

- Move bundles from an OSGi application to a bundle repository.

  You can change the configuration of an enterprise OSGi application so that bundles and composite bundles that were directly contained in the enterprise bundle archive (EBA) file are instead pulled in by reference and provisioned from a repository. Before you deploy the application, you can move bundles or composite bundles from the EBA file to a bundle repository. You might want to do this to decrease the size of the EBA file, or so that bundles can be shared between multiple applications rather than each application deploying its own copy of a common library.
- List, delete, add, or show details for bundles and composite bundles in the internal bundle repository.

  Do this using the administrative console or wsadmin commands:
  - “Administering bundles in the internal bundle repository” on page 1080
  - “Administering bundles in the internal bundle repository using wsadmin commands” on page 1081
- List, delete, add, modify, or show details for links to external bundle repositories.

  Do this using the administrative console or wsadmin commands:
  - “Administering links to external bundle repositories” on page 1088
  - “Administering links to external bundle repositories using wsadmin commands” on page 1089
- Interact with the OSGi bundle cache.

Moving bundles from an OSGi application to a bundle repository

You can change the configuration of an enterprise OSGi application so that bundles and composite bundles that were directly contained in the enterprise bundle archive (EBA) file are instead pulled in by reference and provisioned from a repository.

Before you begin

After you import your application as an asset, you can no longer change the direct contents of the asset.To update bundles and composite bundles that are specified in an asset, you add the updated versions to a repository then apply the updates to the asset. See Updating bundle versions in a deployed OSGi application.

About this task

When you first create an OSGi application, each bundle and composite bundle in the application is either directly contained in the EBA file or pulled in by reference. Before you deploy the application, you can move bundles or composite bundles from the EBA file to a bundle repository. You might want to do this to decrease the size of the EBA file, or so that bundles can be shared between multiple applications rather than each application deploying its own copy of a common library.

Composite bundles, and any bundles that are used by composite bundles, can be moved to the internal bundle repository or to an external repository that can process composite bundles. You can move the whole composite bundle to the repository, or move one or more of the bundles that the composite bundle uses to the repository. For more information, see Composite bundles.

Procedure

1. Use your preferred development tool to remove the bundle or composite bundle from the EBA file.
   See Developing and deploying an OSGi application.
2. Ensure that the EBA file has an application manifest and that the bundle or composite bundle is listed in the Application-Content header of the application manifest.
   See Enterprise bundle archives.
3. Install the bundle that you removed into a bundle repository.
   Composite bundles, and bundles referenced by composite bundles, are installed in the internal bundle repository or in an external repository that can process composite bundles. See “Administering bundle repositories” on page 1078.

What to do next

You can deploy your OSGi application. See Deploying an OSGi application as a business-level application.

Administering bundles in the internal bundle repository

Use the administrative console to list, delete, add, or show further details for bundles and composite bundles that are held in the bundle repository that is included in the product.

Before you begin

You can administer bundles and composite bundles in the internal bundle repository by using the administrative console as described in this topic, or by using wsadmin commands as described in “Administering bundles in the internal bundle repository using wsadmin commands” on page 1081.

About this task

WebSphere Application Server includes an internal bundle repository, in which you can store the bundles and composite bundles for your OSGi applications.

If your OSGi applications are configured to expect to find certain bundles in the internal bundle repository, you must add those bundles to the repository. Composite bundles can either be included directly in your applications, or provisioned from the internal bundle repository or from an external repository that can process composite bundles. If your bundle includes Blueprint XML files that specify service or reference elements, and the bundle is included in a EBA asset or installed in the internal bundle repository, then these elements are respected during provisioning and appropriate services are provisioned when needed. For more information, see Provisioning for OSGi applications.

You can install bundles singly, or you can install a set of bundles packaged as a compressed archive file with a `.zip` file extension. In both cases, the bundles are available individually in the repository. If you install a composite bundle in a bundle repository, and the composite bundle includes bundles by reference,

you must ensure that the referenced bundles are also available in the same repository. If you use the internal bundle repository, and the composite bundle directly contains bundles, the contained bundles are not listed separately and are only available as part of the composite bundle. For more information, see Composite bundles.

You can list, delete, add, or show further details for bundles and composite bundles that are held in the internal bundle repository.

Procedure

1. Start the administrative console.
2. Navigate to **Environment** > **OSGi bundle repositories** > **Internal bundle repository**.

   The list of bundles and composite bundles stored in the internal bundle repository is displayed in the Internal bundle repository [Collection] form.
3. Delete, add, or show details of bundles that are held in the internal bundle repository.
   - To delete one or more bundles from the repository, select the required bundles then click **Delete**.

     You cannot delete a bundle if it is referenced by a composite bundle. You must delete the composite bundle first, then delete the bundle.
   - To add a new bundle or composite bundle to the repository:
     a. Click **New**. The Upload bundle [Settings] form is displayed.
     b. Enter the path to the bundle, composite bundle or grouped-up set of bundles that you want to add. Each individual bundle must be packaged as a `.jar` file, and must contain a suitably-configured bundle manifest file. Each composite bundle must be packaged as a compressed archive file with a `.cba` file extension, and must contain a suitably-configured composite bundle manifest file. Each grouped-up set of bundles must be packaged as a compressed archive file with a `.zip` file extension.
     c. Click **OK**. The file is uploaded, and displayed in the list of bundles and composite bundles in the Internal bundle repository [Collection] form.
   - To show the details for an existing bundle or composite bundle in the repository, click the name of the bundle or composite bundle. The details are displayed in the Internal bundle repository [Settings] form. You cannot modify these details.
4. If you added or removed a bundle or composite bundle, save your changes to the master configuration.

What to do next

- If you updated a bundle or composite bundle, and you want to update an asset that uses it, see “Updating bundle versions for an EBA asset” on page 1048.
- If you added or updated a bundle or composite bundle, and you want to install an enterprise OSGi application that uses it, see Deploying an OSGi application as a business-level application.
- If you added or updated a composite bundle, and you want to use it to extend a composition unit, see “Adding or removing extensions for an OSGi composition unit” on page 1055.

Administering bundles in the internal bundle repository using wsadmin commands

Use wsadmin commands to list, add, remove, or show further details for bundles and composite bundles that are held in the bundle repository that is included in the product.

Before you begin

You can administer bundles and composite bundles in the internal bundle repository by using wsadmin commands as described in this topic, or by using the administrative console as described in “Administering bundles in the internal bundle repository” on page 1080.

About this task

WebSphere Application Server includes an internal bundle repository, in which you can store the bundles and composite bundles for your OSGi applications.

If your OSGi applications are configured to expect to find certain bundles in the internal bundle repository, you must add those bundles to the repository. Composite bundles can either be included directly in your applications, or provisioned from the internal bundle repository or from an external repository that can process composite bundles. If your bundle includes Blueprint XML files that specify service or reference elements, and the bundle is included in a EBA asset or installed in the internal bundle repository, then these elements are respected during provisioning and appropriate services are provisioned when needed. For more information, see Provisioning for OSGi applications.

You can install bundles singly, or you can install a set of bundles packaged as a compressed archive file with a `.zip` file extension. In both cases, the bundles are available individually in the repository. If you install a composite bundle in a bundle repository, and the composite bundle includes bundles by reference, you must ensure that the referenced bundles are also available in the same repository. If you use the internal bundle repository, and the composite bundle directly contains bundles, the contained bundles are not listed separately and are only available as part of the composite bundle. For more information, see Composite bundles.

You can list, add, remove, or show further details for bundles and composite bundles that are held in the internal bundle repository.

Procedure

- List all bundles and composite bundles that are held in the internal bundle repository.

  Use the listLocalRepositoryBundles command. For example:

  ```
  AdminTask.listLocalRepositoryBundles()
  ```

  For more information, see “listLocalRepositoryBundles command” on page 1083.

  Notes:

  - The list includes any bundles that you have added since you last saved your changes, and excludes any bundles that you have removed since you last saved your changes.
  - The output from this command is formatted so that you can copy the list of bundles, then paste them into the removeLocalRepositoryBundles command.

- Add a bundle, composite bundle or grouped-up set of bundles to the internal bundle repository.

  Use the addLocalRepositoryBundle command. For example:

  ```
  AdminTask.addLocalRepositoryBundle('-file path')
  ```

  Each individual bundle must be packaged as a `.jar` file, and must contain a suitably-configured bundle manifest file. Each composite bundle must be packaged as a compressed archive file with a `.cba` file extension, and must contain a suitably-configured composite bundle manifest file. Each grouped-up set of bundles must be packaged as a compressed archive file with a `.zip` file extension.

  For more information, see “addLocalRepositoryBundle command” on page 1084.

- Remove one or more bundles or composite bundles from the internal bundle repository.

  Use the removeLocalRepositoryBundle or removeLocalRepositoryBundles command. For example:

  ```
  AdminTask.removeLocalRepositoryBundle('-symbolicName bundle_symbolic_name
                                        -version bundle_version')
  ```

```
AdminTask.removeLocalRepositoryBundles([
    'bundle1_symbolic_name;bundle1_version
     bundle2_symbolic_name;bundle2_version
     bundle3_symbolic_name;bundle3_version
    '
])
```

Notes:

- The output from the listLocalRepositoryBundles command is formatted so that you can copy the list of bundles, then paste them into the removeLocalRepositoryBundles command.
- You cannot remove composite bundles at the same time as you remove any bundles that they reference. You must first remove the composite bundles, then run the removeLocalRepositoryBundles command a second time to remove the referenced bundles.

For more information, see “removeLocalRepositoryBundle command” on page 1085 and “removeLocalRepositoryBundles command” on page 1086.

- Show further details (for example, imported packages, exported packages, and required bundles) for a bundle or composite bundle in the internal bundle repository.

  Use the showLocalRepositoryBundle command. For example:

  ```
  AdminTask.showLocalRepositoryBundle('-symbolicName bundle_symbolic_name
                                      -version bundle_version')
  ```

  For more information, see “showLocalRepositoryBundle command” on page 1087.

What to do next

- If you added or removed a bundle or composite bundle, save your changes to the master configuration.
- If you updated a bundle or composite bundle, and you want to update an asset that uses it, see “Updating bundle versions for an EBA asset using the editAsset command” on page 1049.
- If you added or updated a bundle or composite bundle, and you want to install an enterprise OSGi application that uses it, see Deploying an OSGi application as a business-level application.
- If you added or updated a composite bundle, and you want to use it to extend a composition unit, see “Adding or removing extensions for an OSGi composition unit using wsadmin commands” on page 1056..

listLocalRepositoryBundles command:

Use the listLocalRepositoryBundles command to list all bundles held in the bundle repository that is included in the product.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('OSGiApplicationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command lists all bundles that are held in the internal bundle repository. The list includes any bundles that you have added since you last saved your changes, and excludes any bundles that you have removed since you last saved your changes.

Target object

None.

Required parameters

None.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.listLocalRepositoryBundles()
```

addLocalRepositoryBundle command:

Use the addLocalRepositoryBundle command to add a bundle, composite bundle or grouped-up set of bundles to the internal bundle repository that is included in the product.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('OSGiApplicationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration by using the following command:

```
AdminConfig.save()
```

Purpose

This command adds a bundle, a composite bundle or a grouped-up set of bundles to the internal bundle repository.

You can install bundles singly, or you can install a set of bundles packaged as a compressed archive file with a `.zip` file extension. In both cases, the bundles are available individually in the repository. If you install a composite bundle in a bundle repository, and the composite bundle includes bundles by reference, you must ensure that the referenced bundles are also available in the same repository. If you use the

internal bundle repository, and the composite bundle directly contains bundles, the contained bundles are not listed separately and are only available as part of the composite bundle. For more information, see Composite bundles.

Target object

None

Required parameters

-file *path*
The path and file name of a compressed archive file that has a `.jar`, `.cba` or `.zip` file extension and is available on the server file system.

Each individual bundle must be packaged as a `.jar` file, and must contain a suitably-configured bundle manifest file. Each composite bundle must be packaged as a compressed archive file with a `.cba` file extension, and must contain a suitably-configured composite bundle manifest file. Each grouped-up set of bundles must be packaged as a compressed archive file with a `.zip` file extension.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.addLocalRepositoryBundle('-file path')
```

removeLocalRepositoryBundle command:

Use the removeLocalRepositoryBundle command to remove a bundle or composite bundle from the bundle repository that is included in the product.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('OSGiApplicationCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration by using the following command:

```
AdminConfig.save()
```

Purpose

This command removes a bundle or composite bundle from the internal bundle repository.

You cannot delete a bundle if it is contained in, or referenced by, a composite bundle. You must delete the composite bundle first, then delete the bundle.

Target object

The specified bundle.

Required parameters

-symbolicName *bundle_symbolic_name*
One of the following:
- The non-localizable name for this bundle.
- The bundle symbolic name of this composite bundle.

The bundle symbolic name, together with the bundle version, identifies a unique bundle.

-version *bundle_version*
One of the following:
- The version of this bundle.
- The version of this composite bundle.

The bundle version is in the form *n.n.n*, for example `1.1.0`. The bundle symbolic name, together with the bundle version, identifies a unique bundle.

Note: You can use the listLocalRepositoryBundles command to list the symbolic names and versions of the bundles currently held in the repository.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.removeLocalRepositoryBundle('-symbolicName bundle_symbolic_name
                                       -version bundle_version')
```

removeLocalRepositoryBundles command:

Use the removeLocalRepositoryBundles command to remove bundles and composite bundles from the bundle repository that is included in the product.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:
- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('OSGiApplicationCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration by using the following command:

```
AdminConfig.save()
```

Purpose

This command removes bundles and composite bundles from the internal bundle repository.

You cannot remove composite bundles at the same time as you remove any bundles that they reference. You must first remove the composite bundles, then run the removeLocalRepositoryBundles command a second time to remove the referenced bundles.

You can use the listLocalRepositoryBundles command to list the symbolic names and versions of the bundles currently held in the repository. The output from the listLocalRepositoryBundles command is formatted so that you can copy the list of bundles, then paste them into the removeLocalRepositoryBundles command.

Target object

The specified bundles.

Required parameters

A list of the bundles to be removed.

The list entry for each bundle or composite bundle contains the bundle symbolic name and the bundle version. The bundle version is in the form *n.n.n*, for example `1.1.0`. The bundle symbolic name, together with the bundle version, identifies a unique bundle.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.removeLocalRepositoryBundles([
    'bundle1_symbolic_name;bundle1_version
     bundle2_symbolic_name;bundle2_version
     bundle3_symbolic_name;bundle3_version
    '
])
```

showLocalRepositoryBundle command:

Use the showLocalRepositoryBundle command to show further details (in particular all manifest header entries) for a bundle in the bundle repository that is included in the product.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('OSGiApplicationCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

Purpose

This command shows the values of the following properties for the specified bundle stored in the internal bundle repository:

- Bundle symbolic name
- Bundle version
- Bundle name
- Bundle description
- Imported packages
- Exported packages
- Required bundles

For more information about these properties, see Internal bundle repository [Settings].

Target object

The specified bundle.

Required parameters

-symbolicName *bundle_symbolic_name*
The non-localizable name for this bundle. The bundle symbolic name, together with the bundle version, identifies a unique bundle.

-version *bundle_version*
The version of this bundle. The bundle version is in the form *n.n.n*, for example `1.1.0`. The bundle symbolic name, together with the bundle version, identifies a unique bundle.

Note: You can use the listLocalRepositoryBundles command to list the symbolic names and versions of the bundles currently held in the repository.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.showLocalRepositoryBundle('-symbolicName bundle_symbolic_name
                                    -version bundle_version')
```

Administering links to external bundle repositories

Use the administrative console to list, delete, add, modify, or show details for links to external bundle repositories.

Before you begin

You can administer links to external bundle repositories by using the administrative console as described in this topic, or by using wsadmin commands as described in “Administering links to external bundle repositories using wsadmin commands.”

About this task

The external bundle repositories are bundle repositories that are available outside of WebSphere Application Server. If your OSGi applications reference bundles that are stored in an external bundle repository, you must configure a link (name and URL) to the repository so that the provisioner can retrieve the bundles when required. When an OSGi application is imported as an asset, the provisioner attempts to satisfy all its dependencies by using the contents of the asset, the contents of the internal bundle repository, and the contents of any available external bundle repositories.

Depending on how the external bundle repository is implemented, you might not be able to use it to provision services, or to store composite bundles or bundles referenced by composite bundles. If your bundle includes Blueprint XML files that specify service or reference elements, and the bundle is included in a EBA asset or installed in the internal bundle repository, then these elements are respected during provisioning and appropriate services are provisioned when needed. For more information, see Provisioning for OSGi applications.

Procedure

1. Start the administrative console.
2. Navigate to **Environment** > **OSGi bundle repositories** > **External bundle repositories**.

   The list of external bundle repository links is displayed in the External bundle repositories [Collection] form.
3. Delete, add, show, or modify links to external bundle repositories.
   - To delete one or more repository links from the list, select the required links then click **Delete**.
   - To add a new link to an external bundle repository, click **New** then type the link properties (name, optional description, and URL of the bundle repository XML file) into the External bundle repositories [Settings] form.
   - To show or modify an existing link to an external bundle repository, click the name of the link. The link properties are displayed. If required, modify the link properties (optional description, and URL of the bundle repository XML file) in the External bundle repositories [Settings] form. You cannot modify the **bundle repository name** property.
4. If you add, modify, or remove a link to an external bundle repository, save your changes to the master configuration.

   If you add or modify a link to an external bundle repository, you must save the changes before you can install an enterprise bundle archive (EBA) that depends on a bundle in that repository.

Administering links to external bundle repositories using wsadmin commands

Use wsadmin commands to list, remove, add, modify, or show details for links to external bundle repositories.

Before you begin

You can administer links to external bundle repositories by using wsadmin commands as described in this topic, or by using the administrative console as described in “Administering links to external bundle repositories” on page 1088.

About this task

The external bundle repositories are bundle repositories that are available outside of WebSphere Application Server. If your OSGi applications reference bundles that are stored in an external bundle repository, you must configure a link (name and URL) to the repository so that the provisioner can retrieve the bundles when required. When an OSGi application is imported as an asset, the provisioner attempts to satisfy all its dependencies by using the contents of the asset, the contents of the internal bundle repository, and the contents of any available external bundle repositories.

Depending on how the external bundle repository is implemented, you might not be able to use it to provision services, or to store composite bundles or bundles referenced by composite bundles. If your bundle includes Blueprint XML files that specify service or reference elements, and the bundle is included in a EBA asset or installed in the internal bundle repository, then these elements are respected during provisioning and appropriate services are provisioned when needed. For more information, see Provisioning for OSGi applications.

Procedure

- List all links to external bundle repositories.

  Use the listExternalBundleRepositories command. For example:

  ```
  AdminTask.listExternalBundleRepositories()
  ```

  For more information, see “listExternalBundleRepositories command” on page 1091.

  Note: The list includes any repository links that you have added since you last saved your changes, and excludes any repository links that you have removed since you last saved your changes.
- Show the configured parameters of an external bundle repository.

  Use the showExternalBundleRepository command. For example:

  ```
  AdminTask.showExternalBundleRepository('-name bundle_repository_name')
  ```

  For more information, see “showExternalBundleRepository command” on page 1094.
- Remove a link to an external bundle repository.

  Use the removeExternalBundleRepository command. For example:

  ```
  AdminTask.removeExternalBundleRepository('-name bundle_repository_name')
  ```

  For more information, see “removeExternalBundleRepository command” on page 1091.
- Add a link to an external bundle repository.

  Use the addExternalBundleRepository command. For example:

  ```
  AdminTask.addExternalBundleRepository('-name bundle_repository_name
                                 -url bundle_repository_URL
                                [-description bundle_repository_description]')
  ```

  Square brackets (“[ ]”) indicate that a parameter is optional.

  For more information, see “addExternalBundleRepository command” on page 1092.
- Modify a link to an external bundle repository.

  Use the modifyExternalBundleRepository command. For example:

  ```
  AdminTask.modifyExternalBundleRepository('-name bundle_repository_name
                                [-url bundle_repository_URL]
                                [-description bundle_repository_description]')
  ```

  Square brackets (“[ ]”) indicate that a parameter is optional.

  For more information, see “modifyExternalBundleRepository command” on page 1093.

What to do next

If you add, modify, or remove a link to an external bundle repository, save your changes to the master configuration.

If you add or modify a link to an external bundle repository, you must save the changes before you can install an enterprise bundle archive (EBA) that depends on a bundle in that repository.

listExternalBundleRepositories command:

Use the listExternalBundleRepositories command to list all links to external bundle repositories.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('OSGiApplicationCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command lists all links to external bundle repositories. The list includes any repository links that you have added since you last saved your changes, and excludes any repository links that you have removed since you last saved your changes.

Target object

None.

Required parameters

None.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.listExternalBundleRepositories()
```

removeExternalBundleRepository command:

Use the removeExternalBundleRepository command to remove a link to an external bundle repository.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('OSGiApplicationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration by using the following command:

```
AdminConfig.save()
```

Purpose

This command removes a link to an external bundle repository.

Target object

The specified bundle repository link.

Required parameters

-name *bundle_repository_name*
The name by which the bundle repository link is known. You can use the listExternalBundleRepositories command to list the names of existing bundle repository links.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.removeExternalBundleRepository('-name bundle_repository_name')
```

addExternalBundleRepository command:

Use the addExternalBundleRepository command to add a link to an external bundle repository.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('OSGiApplicationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration by using the following command:

```
AdminConfig.save()
```

Purpose

This command adds a link to an external bundle repository.

Target object

None

Required parameters

-name *bundle_repository_name*
The name by which you want the external bundle repository link to be known.

-url *bundle_repository_URL*
The URL of the bundle repository XML file. For example, `http://external_location/repository.xml`.

Conditional parameters

None.

Optional parameters

-description *bundle_repository_description*
An optional description of the bundle repository.

Example

```
AdminTask.addExternalBundleRepository('-name bundle_repository_name
                                -url http://external_location/repository.xml
                               [-description bundle_repository_description]')
```

Square brackets (“[ ]”) indicate that a parameter is optional.

modifyExternalBundleRepository command:

Use the modifyExternalBundleRepository command to modify a link to an external bundle repository.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('OSGiApplicationCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration by using the following command:

```
AdminConfig.save()
```

Purpose

This command modifies a link to an external bundle repository.

Target object

The specified external bundle repository link.

Required parameters

-name *bundle_repository_name*
The name of the external bundle repository link. You cannot change this value. You can use the listExternalBundleRepositories command to list the names of existing bundle repository links.

Conditional parameters

None.

Optional parameters

-url *bundle_repository_URL*
The modified URL for the external bundle repository XML file.

-description *bundle_repository_description*
The modified description of the external bundle repository link.

Example

```
AdminTask.modifyExternalBundleRepository('-name bundle_repository_name
                              [-url http://external_location/repository.xml]
                              [-description bundle_repository_description]')
```

Square brackets ("[ ]") indicate that a parameter is optional.

showExternalBundleRepository command:

Use the showExternalBundleRepository command to show the configured parameters of an external bundle repository.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('OSGiApplicationCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command shows the name, description when available, and URL of the bundle repository XML file, of an external bundle repository.

Target object

None.

Required parameters

-name *repository_name*
The name of a link to an external bundle repository.

Note: You can use the listExternalBundleRepositories command to list all links to external bundle repositories.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.showExternalBundleRepository(-name ExternalRepository1)
```

Interacting with the OSGi bundle cache

The bundle cache is a cell-wide store (or server-wide for single-server systems) of bundles that are referenced by OSGi applications, and that have been downloaded from both internal and external repositories. You can interact with the bundle cache using either the administrative console, or the methods of the OSGi BundleCacheManager MBean.

About this task

You can get an up-to-date list of the bundles in the bundle cache, check if all bundles have been successfully downloaded, and request that one or more bundles be downloaded again. For a given bundle you can view the bundle size, the download status, and a list of the assets and composition units that use the bundle. You can also view and refresh the repository URL for the repository that hosts the bundle.

The main differences between interacting with the OSGi bundle cache using the administrative console and using the MBean interface are as follows:

- You can use the Bundle cache [Collection] panel to change the sort order in the table, and to filter by (for example) bundle name, or by bundle state.
- You can use the MBean interface to remove a bundle from the cache.

The methods for the OSGi BundleCacheManager MBean interface are documented in the Additional Application Programming Interfaces (APIs) section of the generated API documentation.

You use the MBean methods with the AdminControl object of the wsadmin scripting client. For example:

```
objNameString = AdminControl.completeObjectName('WebSphere:type=BundleCacheManager,*')
print AdminControl.invoke(objNameString, 'areAllDownloadsComplete')
```

For more information about using MBean methods with the AdminControl object, see the “invoke” and “invoke_jmx” sections of Commands for the AdminControl object using wsadmin scripting.

Some common tasks for which you might interact with the bundle cache are as follows:

Procedure

- Interrogate the state of bundles.

  You can use the MBean interface to complete the following tasks:

  – Check the state of a specific bundle.
  – List the completed downloads.
  – List the unsuccessful downloads.

  Similarly, the state of all bundles is displayed on the Bundle cache [Collection] panel. This is one of the following states:

  Unknown
  The bundle is not in the bundle cache and there has been no request to download the bundle.

  Download requested
  A request has been issued to download the bundle, but the download has not yet begun.

  Downloading
  The bundle is downloading.

  Downloaded
  The bundle download is complete.

  Failed The bundle download has failed.

  Unsaved
  The bundle is unsaved if you have imported an asset and not yet saved your changes to the master configuration.

  The bundle is not downloaded until you save your changes.

- Check that all bundle downloads are complete before adding an enterprise bundle archive (EBA) asset to a business-level application.

  If all bundle downloads are complete, the state of every bundle is displayed as “Downloaded” on the Bundle cache [Collection] panel.

  You can use scripting to import an EBA file as an asset, then add the EBA asset to a business-level application. However, you cannot add the asset to the application until all the bundles are downloaded. You might therefore choose to code your script to call the areAllDownloadsComplete () method, then wait until the method confirms that all bundles are downloaded before adding the EBA asset to the business-level application.

- Resolve an unsuccessful bundle download.

  If a bundle does not download, complete the following steps:

  1. Fix the cause (for example an incorrect repository address, or a network failure).

     The Bundle cache [Settings] form for the bundle shows the repository address, and includes a button to refresh this address. This is useful if a bundle has been moved, for example from the internal bundle repository to an external repository. If the bundle state is “Failed”, the “Bundle download exceptions” pane is displayed. This pane contains trace information to help you understand why the bundle download has failed.

  2. Download the bundle again.

     Use either of the following approaches:

     – Use the resetBundleDownload () method to make the bundle available for download again, then use the downloadBundles () method to retry the download.
     – On the Bundle cache [Collection] panel, select one or more bundles then click **Download Bundle Again**.

- Remove a bundle from the cache.

  You can only do this using the MBean interface. Before you do this, make sure that no application is running that uses this bundle.

Use the removeBundleFromCache () method to remove a bundle from the bundle cache.

Exporting and importing a deployment manifest file

You can export the deployment manifest file from an application, then import the manifest file into another instance of the same application located somewhere else. This process is useful when an application moves from one environment to another, for example from a test environment to a production environment.

About this task

A deployment manifest file, `META-INF/DEPLOYMENT.MF`, is created automatically when you import an EBA asset. The deployment manifest file lists, at specific versions, all the bundles and composite bundles that make up the application, including bundles that are determined following dependency analysis. The manifest file is used to ensure that each time an application server starts, the bundles that make up the application are the same.

You can export the current deployment manifest from an EBA asset, then import the deployment manifest into another asset that contains the same application. The target asset then uses the imported manifest instead of the generated manifest. This is useful during application development, when an application is fully tested and moves to a production environment. By importing the deployment manifest from the test environment, you ensure that the bundles and their versions that make up the application in the production environment are exactly the same as the bundles that make up the application in the test environment.

Note: Do not edit an exported manifest file. Only use the export and import options in situations where you can treat the exported file as a “black box”.

Procedure

- Export the deployment manifest file from an EBA asset.

  You might want to do this to save the information, or to import it into another identical application.
- Import the deployment manifest file to an EBA asset.

  When you import the file, the bundles are resolved. If the bundles cannot be resolved, the import does not complete and an exception message is generated.

Exporting a deployment manifest

You can export the current deployment manifest file from an enterprise bundle archive (EBA) asset. You might want to do this to save the information, or to import it into another identical application.

Before you begin

You can export a deployment manifest by using the administrative console as described in this topic, or by using wsadmin commands, as described in “Exporting a deployment manifest using the exportDeploymentManifest command” on page 1098.

About this task

A deployment manifest file, `META-INF/DEPLOYMENT.MF`, is created automatically when you import an EBA asset. The deployment manifest file lists, at specific versions, all the bundles and composite bundles that make up the application, including bundles that are determined following dependency analysis. The manifest file is used to ensure that each time an application server starts, the bundles that make up the application are the same.

You can export the current deployment manifest from an EBA asset, then import the deployment manifest into another asset that contains the same application. The target asset then uses the imported manifest instead of the generated manifest. This is useful during application development, when an application is

fully tested and moves to a production environment. By importing the deployment manifest from the test environment, you ensure that the bundles and their versions that make up the application in the production environment are exactly the same as the bundles that make up the application in the test environment. Do not edit an exported manifest file. Only use the export and import options in situations where you can treat the exported file as a “black box”.

Procedure

1. Start the administrative console.
2. Navigate to **Applications** > **Application Types** > **Assets**.
3. Click the name of the asset from which you want to export the deployment manifest. The Asset settings panel is displayed.
4. Click **[Additional Properties] Export the deployment manifest from this application**.
5. Use the web browser dialog that is displayed to save the file to your required location. If the dialog does not offer the options that you need, check you web browser options, for example the options to download or save files.

Results

The current deployment manifest for the application is exported.

What to do next

The deployment manifest is available to import into an EBA asset. See “Importing a deployment manifest” on page 1100.

Exporting a deployment manifest using the exportDeploymentManifest command

You can use this command to export the current deployment manifest file from an enterprise bundle archive (EBA) asset. You might want to do this to save the information, or to import it into another identical application.

Before you begin

You can export a deployment manifest by using wsadmin commands, as described in this topic, or by using the administrative console, as described in “Exporting a deployment manifest” on page 1097.

About this task

A deployment manifest file, `META-INF/DEPLOYMENT.MF`, is created automatically when you import an EBA asset. The deployment manifest file lists, at specific versions, all the bundles and composite bundles that make up the application, including bundles that are determined following dependency analysis. The manifest file is used to ensure that each time an application server starts, the bundles that make up the application are the same.

You can export the current deployment manifest from an EBA asset, then import the deployment manifest into another asset that contains the same application. The target asset then uses the imported manifest instead of the generated manifest. This is useful during application development, when an application is fully tested and moves to a production environment. By importing the deployment manifest from the test environment, you ensure that the bundles and their versions that make up the application in the production environment are exactly the same as the bundles that make up the application in the test environment. Do not edit an exported manifest file. Only use the export and import options in situations where you can treat the exported file as a “black box”.

Procedure

1. Start the wsadmin scripting client if it is not already running.
2. Use the exportDeploymentManifest command. For example:

```
AdminTask.exportDeploymentManifest('[-asset
com.ibm.ws.eba.example.blabber.app.eba -path /test/temp/]')
```

Results

The current deployment manifest for the application is exported.

What to do next

The deployment manifest is available to import into an EBA asset. See “Importing a deployment manifest using the importDeploymentManifest command” on page 1101.

exportDeploymentManifest command:

Use the exportDeploymentManifest command to export the current deployment manifest, the `DEPLOYMENT.MF` file, from an enterprise bundle archive (EBA) asset. You might want to do this to save the information, or to import it into another identical application.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('OSGiApplicationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command exports the current deployment manifest from an EBA asset.

Target object

None.

Required parameters

-asset
The name of the EBA asset to export the deployment manifest from. This must be an installed EBA asset.

-path
The file path for the location of the exported deployment manifest. If the location does not exist, the export process creates it.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.exportDeploymentManifest('[-asset
com.ibm.ws.eba.example.blabber.app.eba -path /test/temp/]')
```

Importing a deployment manifest

You can import a suitable deployment manifest to an enterprise bundle archive (EBA) asset. When you import the file, the bundles are resolved. If the bundles cannot be resolved, the import does not complete and an exception message is generated.

Before you begin

The file to import must be a valid deployment manifest file, using the naming format *file_name*.MF, for example DEPLOYMENT_TEST.MF. When you import the deployment manifest into the EBA asset, the file is renamed to DEPLOYMENT.MF.

For the import to succeed, the following conditions must be met:

- The deployment manifest to import must correspond with the application manifest of the OSGi application that is contained in the EBA asset.
- The bundles and their versions that are listed in the deployment manifest must be available, either within the EBA file or from a bundle repository.
- If the asset has previously been updated, the bundle downloads for the previous update must have completed. See “Checking the bundle download status of an EBA asset” on page 1076.

You can import a deployment manifest by using the administrative console, as described in this topic, or by using wsadmin commands, as described in “Importing a deployment manifest using the importDeploymentManifest command” on page 1101.

About this task

A deployment manifest file, META-INF/DEPLOYMENT.MF, is created automatically when you import an EBA asset. The deployment manifest file lists, at specific versions, all the bundles and composite bundles that make up the application, including bundles that are determined following dependency analysis. The manifest file is used to ensure that each time an application server starts, the bundles that make up the application are the same.

You can export the deployment manifest file from an application, then import the manifest file into another instance of the same application located somewhere else. This is useful during application development, when an application is fully tested and moves to a production environment. By importing the deployment manifest from the test environment, you ensure that the bundles and their versions that make up the application in the production environment are exactly the same as the bundles that make up the application in the test environment.

When you import a deployment manifest into an EBA asset, the content of the deployment manifest must correspond with the existing application manifest in the EBA asset.

The application resolving process checks whether the deployment manifest contains all the required bundles. It should not need to pull in extra bundles to resolve the EBA asset.

Procedure

1. Start the administrative console.
2. Navigate to **Applications** > **Application Types** > **Assets**.
3. Click the name of the asset into which you want to import the deployment manifest. The Asset settings panel is displayed. If the bundle downloads for any previous update have completed, then the option to import a deployment manifest is displayed under the Additional Properties section.
4. Click **[Additional Properties] Import a deployment manifest into this application**.

   The Import a deployment manifest into this application panel is displayed.
5. Click **Local file system** or **Remote file system**, as required, then enter the fully-qualified path to the deployment manifest file that you want to import. The file must be a valid deployment manifest, with a `.MF` file extension.
6. Click **OK**. The deployment manifest is checked to ensure that the bundles that it lists can be resolved, then it is imported into the EBA asset. The file name changes to `DEPLOYMENT.MF`. Any new bundles that are required to provision the application are downloaded.
7. Save your changes to the master configuration.
8. Optional: Check the update status of the composition unit.

   If you plan to update the composition unit at this time, check the update status of the associated OSGi composition unit. This status is one of the following values:
   - Using latest OSGi application deployment.
   - New OSGi application deployment not yet available because it requires bundles that are still downloading.
   - New OSGi application deployment available.
   - New OSGi application deployment cannot be applied because bundle downloads have failed.
9. Optional: Update the composition unit to the latest deployment.

   When all bundle downloads are complete, you can update the OSGi composition unit so that the business-level application uses the newer configuration. You do not have to update the composition unit every time you update the asset. If any of the updates contain configuration options, you update the configuration information. You can also take the opportunity to make additional, non-essential configuration changes. When you save the changes to the composition unit, the associated business-level application is updated to use the new configuration. If the business-level application is running, the bundle and configuration updates are applied immediately. If possible (that is, depending on the nature of the updates) the system applies the updates without restarting the application. If new packages are imported, or new services injected, then the application is restarted. These packages and services can come from newly-provisioned bundles, or from bundles that have already been provisioned.

Importing a deployment manifest using the importDeploymentManifest command

You can use this command to import a suitable deployment manifest to an enterprise bundle archive (EBA) asset. When you import the file, the bundles are resolved. If the bundles cannot be resolved, the import does not complete and an exception message is generated.

Before you begin

The file to import must be a valid deployment manifest file, using the naming format *file_name*`.MF`, for example `DEPLOYMENT_TEST.MF`. When you import the deployment manifest into the EBA asset, the file is renamed to `DEPLOYMENT.MF`.

For the import to succeed, the following conditions must be met:

- The deployment manifest to import must correspond with the application manifest of the OSGi application that is contained in the EBA asset.
- The bundles and their versions that are listed in the deployment manifest must be available, either within the EBA file or from a bundle repository.

- If the asset has previously been updated, the bundle downloads for the previous update must have completed. See “Checking the bundle download status of an EBA asset” on page 1076.

You can import a deployment manifest by using the wsadmin commands, as described in this topic, or by using administrative console, as described in “Importing a deployment manifest” on page 1100.

About this task

A deployment manifest file, `META-INF/DEPLOYMENT.MF`, is created automatically when you import an EBA asset. The deployment manifest file lists, at specific versions, all the bundles and composite bundles that make up the application, including bundles that are determined following dependency analysis. The manifest file is used to ensure that each time an application server starts, the bundles that make up the application are the same.

You can export the deployment manifest file from an application, then import the manifest file into another instance of the same application located somewhere else. This is useful during application development, when an application is fully tested and moves to a production environment. By importing the deployment manifest from the test environment, you ensure that the bundles and their versions that make up the application in the production environment are exactly the same as the bundles that make up the application in the test environment.

When you import a deployment manifest into an EBA asset, the content of the deployment manifest must correspond with the existing application manifest in the EBA asset.

The application resolving process checks whether the deployment manifest contains all the required bundles. It should not need to pull in extra bundles to resolve the EBA asset.

Procedure

1. Start the wsadmin scripting client if it is not already running.
2. Use the importDeploymentManifest command. For example:

   ```
   AdminTask.importDeploymentManifest('[-asset
   com.ibm.ws.eba.example.blabber.app.eba -file /test/temp/DEPLOYMENT.MF]')
   ```

   The deployment manifest is checked to ensure that the bundles that it lists can be resolved.
3. Save your changes to the master configuration.

   To save your configuration changes, use the following command:

   ```
   AdminConfig.save()
   ```

   The deployment manifest is imported into the EBA asset and any new bundles that are required to provision the application are downloaded. The file name changes to `DEPLOYMENT.MF`.
4. Optional: Check the update status of the composition unit.

   If you plan to update the composition unit at this time, check the update status of the associated OSGi composition unit. This status is one of the following values:
   - Using latest OSGi application deployment.
   - New OSGi application deployment not yet available because it requires bundles that are still downloading.
   - New OSGi application deployment available.
   - New OSGi application deployment cannot be applied because bundle downloads have failed.
5. Optional: Update the composition unit to the latest deployment.

   When all bundle downloads are complete, you can update the OSGi composition unit so that the business-level application uses the newer configuration. You do not have to update the composition unit every time you update the asset. If any of the updates contain configuration options, you update

the configuration information. You can also take the opportunity to make additional, non-essential configuration changes. When you save the changes to the composition unit, the associated business-level application is updated to use the new configuration. If the business-level application is running, the bundle and configuration updates are applied immediately. If possible (that is, depending on the nature of the updates) the system applies the updates without restarting the application. If new packages are imported, or new services injected, then the application is restarted. These packages and services can come from newly-provisioned bundles, or from bundles that have already been provisioned.

importDeploymentManifest command:

Use the importDeploymentManifest command to import a deployment manifest to an enterprise bundle archive (EBA) asset. When you import the file, the bundles are resolved. If the bundles cannot be resolved, the import does not complete and an exception message is generated.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('OSGiApplicationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration by using the following command:

```
AdminConfig.save()
```

Purpose

This command imports a deployment manifest to an EBA asset.

For the import to succeed, the following conditions must be met:

- The deployment manifest to import must correspond with the application manifest of the OSGi application that is contained in the EBA asset.
- The bundles and their versions that are listed in the deployment manifest must be available, either within the EBA file or from a bundle repository.
- If the asset has previously been updated, the bundle downloads for the previous update must have completed. See “Checking the bundle download status of an EBA asset” on page 1076.

When the deployment manifest is successfully imported to the EBA asset, its file name changes to `DEPLOYMENT.MF`, and any new bundles that are required to provision the application are downloaded.

Target object

None.

Required parameters

`-asset`
The name of the EBA asset to import the deployment manifest into. This must be an installed EBA asset.

-file
The fully qualified file path for the location of the deployment manifest to import.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.importDeploymentManifest('[-asset
com.ibm.ws.eba.example.blabber.app.eba -file /test/temp/DEPLOYMENT.MF]')
```

Default messaging provider, JMS resources

WebSphere Application Server supports asynchronous messaging through the use of the Java Message Service (JMS).

The default messaging provider enables enterprise applications deployed on WebSphere Application Server to perform asynchronous messaging without the need for you to install a JMS provider. The default messaging provider is installed and runs as part of WebSphere Application Server.

The default messaging provider is based on service integration technologies. You can use the WebSphere Application Server administrative console to configure JMS resources:

- *JMS connection factories* that applications use to connect to a service integration bus.
- *JMS queues* that applications use to send messages to and receive messages from. An application sends messages to a specific queue and those messages are retrieved and processed by another application listening to that queue. JMS queues are assigned to queue destinations on a service integration bus. Such JMS queues are available, over a long period of time, to all applications with access to the bus.
- *JMS topics* that applications can use as named collection points for messages. To send messages, applications publish messages to topics. To receive messages, applications subscribe to topics. JMS topics are assigned to topic spaces on the bus. Such JMS topics are available, over a long period of time, to all applications with access to the bus.

Chapter 20. OSGiApplicationCommands: OSGi Applications administrative commands for the AdminTask object

You can use these administrative commands to manage your OSGi applications.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided so that you can make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('OSGiApplicationCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

addExternalBundleRepository command

Use the addExternalBundleRepository command to add a link to an external bundle repository.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('OSGiApplicationCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

After using the command, save your changes to the master configuration by using the following command:

```
AdminConfig.save()
```

Purpose

This command adds a link to an external bundle repository.

Target object

None

Required parameters

-name *bundle_repository_name*
The name by which you want the external bundle repository link to be known.

-url *bundle_repository_URL*
The URL of the bundle repository XML file. For example, `http://external_location/repository.xml`.

Conditional parameters

None.

Optional parameters

-description *bundle_repository_description*
An optional description of the bundle repository.

Example

```
AdminTask.addExternalBundleRepository('-name bundle_repository_name
                                -url http://external_location/repository.xml
                               [-description bundle_repository_description]')
```

Square brackets ("[ ]") indicate that a parameter is optional.

addLocalRepositoryBundle command

Use the addLocalRepositoryBundle command to add a bundle, composite bundle or grouped-up set of bundles to the internal bundle repository that is included in the product.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('OSGiApplicationCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

After using the command, save your changes to the master configuration by using the following command:

```
AdminConfig.save()
```

Purpose

This command adds a bundle, a composite bundle or a grouped-up set of bundles to the internal bundle repository.

You can install bundles singly, or you can install a set of bundles packaged as a compressed archive file with a `.zip` file extension. In both cases, the bundles are available individually in the repository. If you install a composite bundle in a bundle repository, and the composite bundle includes bundles by reference, you must ensure that the referenced bundles are also available in the same repository. If you use the internal bundle repository, and the composite bundle directly contains bundles, the contained bundles are not listed separately and are only available as part of the composite bundle. For more information, see Composite bundles.

Target object

None

Required parameters

-file *path*
The path and file name of a compressed archive file that has a `.jar`, `.cba` or `.zip` file extension and is available on the server file system.

Each individual bundle must be packaged as a `.jar` file, and must contain a suitably-configured bundle manifest file. Each composite bundle must be packaged as a compressed archive file with a `.cba` file extension, and must contain a suitably-configured composite bundle manifest file. Each grouped-up set of bundles must be packaged as a compressed archive file with a `.zip` file extension.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.addLocalRepositoryBundle('-file path')
```

addOSGiExtension command

Use the addOSGiExtension command to add a composite bundle as an extension to a composition unit.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('OSGiApplicationCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration by using the following command:

```
AdminConfig.save()
```

Purpose

This command adds a composite bundle as an extension to a composition unit. The composite bundle must be available in the internal bundle repository, or in an external repository that can process composite bundles.

Target object

The specified composition unit.

Required parameters

-cuName *cu_name*
The name of the composition unit.

-symbolicName *cba_symbolic_name*
The non-localizable name for this composite bundle.

-version *cba_version*
The version of this composite bundle.

The composite bundle version is in the form *n.n.n*, for example `1.1.0`. The symbolic name, together with the version, identifies a unique composite bundle.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.addOSGiExtension('
  -cuName cu_name
  -symbolicName cba_symbolic_name
  -version cba_version
')
```

addOSGiExtensions command

Use the addOSGiExtensions command to add several composite bundles as extensions to a composition unit.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('OSGiApplicationCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

After using the command, save your changes to the master configuration by using the following command:

```
AdminConfig.save()
```

Purpose

This command adds several composite bundles as extensions to a composition unit. The composite bundles must be available in the internal bundle repository, or in an external repository that can process composite bundles.

Target object

The specified composition unit.

Required parameters

-cuName *cu_name*
The name of the composition unit.

-extensions

A list of the composite bundle extensions to be added. Each list entry contains the symbolic name and the version for a composite bundle. The symbolic name, together with the version, identifies a unique composite bundle.

cba_symbolic_name
The non-localizable name for this composite bundle.

cba_version
The version of this composite bundle.

The composite bundle version is in the form *n.n.n*, for example `1.1.0`.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.addOSGiExtensions([
  '-cuName', 'cu_name',
  '-extensions',
    'cba1_symbolic_name;cba1_version
     cba2_symbolic_name;cba2_version
     cba3_symbolic_name;cba3_version
    '
])
```

exportDeploymentManifest command

Use the exportDeploymentManifest command to export the current deployment manifest, the `DEPLOYMENT.MF` file, from an enterprise bundle archive (EBA) asset. You might want to do this to save the information, or to import it into another identical application.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('OSGiApplicationCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

Purpose

This command exports the current deployment manifest from an EBA asset.

Target object

None.

Required parameters

-asset
The name of the EBA asset to export the deployment manifest from. This must be an installed EBA asset.

-path
The file path for the location of the exported deployment manifest. If the location does not exist, the export process creates it.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.exportDeploymentManifest('[-asset
com.ibm.ws.eba.example.blabber.app.eba -path /test/temp/]')
```

importDeploymentManifest command

Use the importDeploymentManifest command to import a deployment manifest to an enterprise bundle archive (EBA) asset. When you import the file, the bundles are resolved. If the bundles cannot be resolved, the import does not complete and an exception message is generated.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('OSGiApplicationCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

After using the command, save your changes to the master configuration by using the following command:

```
AdminConfig.save()
```

Purpose

This command imports a deployment manifest to an EBA asset.

For the import to succeed, the following conditions must be met:

- The deployment manifest to import must correspond with the application manifest of the OSGi application that is contained in the EBA asset.
- The bundles and their versions that are listed in the deployment manifest must be available, either within the EBA file or from a bundle repository.
- If the asset has previously been updated, the bundle downloads for the previous update must have completed. See “Checking the bundle download status of an EBA asset” on page 1076.

When the deployment manifest is successfully imported to the EBA asset, its file name changes to `DEPLOYMENT.MF`, and any new bundles that are required to provision the application are downloaded.

Target object

None.

Required parameters

-asset
The name of the EBA asset to import the deployment manifest into. This must be an installed EBA asset.

-file
The fully qualified file path for the location of the deployment manifest to import.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.importDeploymentManifest('[-asset
com.ibm.ws.eba.example.blabber.app.eba -file /test/temp/DEPLOYMENT.MF]')
```

listExternalBundleRepositories command

Use the listExternalBundleRepositories command to list all links to external bundle repositories.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('OSGiApplicationCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

Purpose

This command lists all links to external bundle repositories. The list includes any repository links that you have added since you last saved your changes, and excludes any repository links that you have removed since you last saved your changes.

Target object

None.

Required parameters

None.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.listExternalBundleRepositories()
```

listLocalRepositoryBundles command

Use the listLocalRepositoryBundles command to list all bundles held in the bundle repository that is included in the product.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('OSGiApplicationCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command lists all bundles that are held in the internal bundle repository. The list includes any bundles that you have added since you last saved your changes, and excludes any bundles that you have removed since you last saved your changes.

Target object

None.

Required parameters

None.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.listLocalRepositoryBundles()
```

listOSGiExtensions command

Use the listOSGiExtensions command to list the symbolic names and versions of all the extensions that are currently added to a composition unit.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('OSGiApplicationCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command lists the symbolic names and versions of all the extensions that are currently added to a composition unit. The output from the listOSGiExtensions command is formatted so that you can copy the list of extensions, then paste them into the removeOSGiExtensions command.

Target object

The specified composition unit.

Required parameters

-cuName *cu_name*
The name of the composition unit.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.listOSGiExtensions('-cuName cu_name')
```

modifyExternalBundleRepository command

Use the modifyExternalBundleRepository command to modify a link to an external bundle repository.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('OSGiApplicationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration by using the following command:

```
AdminConfig.save()
```

Purpose

This command modifies a link to an external bundle repository.

Target object

The specified external bundle repository link.

Required parameters

-name *bundle_repository_name*
The name of the external bundle repository link. You cannot change this value. You can use the listExternalBundleRepositories command to list the names of existing bundle repository links.

Conditional parameters

None.

Optional parameters

-url *bundle_repository_URL*
The modified URL for the external bundle repository XML file.

-description *bundle_repository_description*
The modified description of the external bundle repository link.

Example

```
AdminTask.modifyExternalBundleRepository('-name bundle_repository_name
                              [-url http://external_location/repository.xml]
                              [-description bundle_repository_description]')
```

Square brackets (“[ ]”) indicate that a parameter is optional.

removeExternalBundleRepository command

Use the removeExternalBundleRepository command to remove a link to an external bundle repository.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('OSGiApplicationCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

After using the command, save your changes to the master configuration by using the following command:

```
AdminConfig.save()
```

Purpose

This command removes a link to an external bundle repository.

Target object

The specified bundle repository link.

Required parameters

-name *bundle_repository_name*
The name by which the bundle repository link is known. You can use the listExternalBundleRepositories command to list the names of existing bundle repository links.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.removeExternalBundleRepository('-name bundle_repository_name')
```

removeLocalRepositoryBundle command

Use the removeLocalRepositoryBundle command to remove a bundle or composite bundle from the bundle repository that is included in the product.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('OSGiApplicationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration by using the following command:

```
AdminConfig.save()
```

Purpose

This command removes a bundle or composite bundle from the internal bundle repository.

You cannot delete a bundle if it is contained in, or referenced by, a composite bundle. You must delete the composite bundle first, then delete the bundle.

Target object

The specified bundle.

Required parameters

-symbolicName *bundle_symbolic_name*
One of the following:

- The non-localizable name for this bundle.
- The bundle symbolic name of this composite bundle.

The bundle symbolic name, together with the bundle version, identifies a unique bundle.

-version *bundle_version*
One of the following:

- The version of this bundle.
- The version of this composite bundle.

The bundle version is in the form *n.n.n*, for example `1.1.0`. The bundle symbolic name, together with the bundle version, identifies a unique bundle.

Note: You can use the listLocalRepositoryBundles command to list the symbolic names and versions of the bundles currently held in the repository.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.removeLocalRepositoryBundle('-symbolicName bundle_symbolic_name
                                       -version bundle_version')
```

removeLocalRepositoryBundles command

Use the removeLocalRepositoryBundles command to remove bundles and composite bundles from the bundle repository that is included in the product.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('OSGiApplicationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration by using the following command:

```
AdminConfig.save()
```

Purpose

This command removes bundles and composite bundles from the internal bundle repository.

You cannot remove composite bundles at the same time as you remove any bundles that they reference. You must first remove the composite bundles, then run the removeLocalRepositoryBundles command a second time to remove the referenced bundles.

You can use the listLocalRepositoryBundles command to list the symbolic names and versions of the bundles currently held in the repository. The output from the listLocalRepositoryBundles command is formatted so that you can copy the list of bundles, then paste them into the removeLocalRepositoryBundles command.

Target object

The specified bundles.

Required parameters

A list of the bundles to be removed.

The list entry for each bundle or composite bundle contains the bundle symbolic name and the bundle version. The bundle version is in the form *n.n.n*, for example `1.1.0`. The bundle symbolic name, together with the bundle version, identifies a unique bundle.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.removeLocalRepositoryBundles([
    'bundle1_symbolic_name;bundle1_version
     bundle2_symbolic_name;bundle2_version
     bundle3_symbolic_name;bundle3_version
    '
])
```

removeOSGiExtension command

Use the removeOSGiExtension command to remove a composite bundle extension from a composition unit.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('OSGiApplicationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration by using the following command:

```
AdminConfig.save()
```

Purpose

This command removes a composite bundle extension from a composition unit.

Target object

The specified composition unit.

Required parameters

-cuName *cu_name*
The name of the composition unit.

-symbolicName *cba_symbolic_name*
The non-localizable name for this composite bundle.

-version *cba_version*
The version of this composite bundle.

The composite bundle version is in the form *n.n.n*, for example `1.1.0`. The symbolic name, together with the version, identifies a unique composite bundle.

Note: You can use the listOSGiExtensions command to list the symbolic names and versions of all the extensions that are currently added to a composition unit.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.removeOSGiExtension('
  -cuName cu_name
  -symbolicName cba_symbolic_name
  -version cba_version
')
```

removeOSGiExtensions command

Use the removeOSGiExtensions command to remove several composite bundle extensions from a composition unit.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('OSGiApplicationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration by using the following command:

```
AdminConfig.save()
```

Purpose

This command removes several composite bundle extensions from a composition unit.

You can use the listOSGiExtensions command to list the symbolic names and versions of all the extensions that are currently added to a composition unit. The output from the listOSGiExtensions command is formatted so that you can copy the list of extensions, then paste them into the removeOSGiExtensions command.

Target object

The specified composition unit.

Required parameters

-cuName *cu_name*
The name of the composition unit.

-extensions

A list of the composite bundle extensions to be removed. Each list entry contains the symbolic name and the version for a composite bundle. The symbolic name, together with the version, identifies a unique composite bundle.

cba_symbolic_name
The non-localizable name for this composite bundle.

cba_version
The version of this composite bundle.

The composite bundle version is in the form *n.n.n*, for example `1.1.0`.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.removeOSGiExtensions([
  '-cuName', 'cu_name',
  '-extensions',
    'cba1_symbolic_name;cba1_version
     cba2_symbolic_name;cba2_version
     cba3_symbolic_name;cba3_version
    '
])
```

showExternalBundleRepository command

Use the showExternalBundleRepository command to show the configured parameters of an external bundle repository.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('OSGiApplicationCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command shows the name, description when available, and URL of the bundle repository XML file, of an external bundle repository.

Target object

None.

Required parameters

-name *repository_name*
The name of a link to an external bundle repository.

Note: You can use the listExternalBundleRepositories command to list all links to external bundle repositories.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.showExternalBundleRepository(-name ExternalRepository1)
```

showLocalRepositoryBundle command

Use the showLocalRepositoryBundle command to show further details (in particular all manifest header entries) for a bundle in the bundle repository that is included in the product.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts.

Command-line help is provided for OSGi Applications commands:

- For a list of the available OSGi Applications commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('OSGiApplicationCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command shows the values of the following properties for the specified bundle stored in the internal bundle repository:

- Bundle symbolic name
- Bundle version
- Bundle name
- Bundle description
- Imported packages
- Exported packages
- Required bundles

For more information about these properties, see Internal bundle repository [Settings].

Target object

The specified bundle.

Required parameters

-symbolicName *bundle_symbolic_name*
The non-localizable name for this bundle. The bundle symbolic name, together with the bundle version, identifies a unique bundle.

-version *bundle_version*
The version of this bundle. The bundle version is in the form *n.n.n*, for example `1.1.0`. The bundle symbolic name, together with the bundle version, identifies a unique bundle.

Note: You can use the listLocalRepositoryBundles command to list the symbolic names and versions of the bundles currently held in the repository.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.showLocalRepositoryBundle('-symbolicName bundle_symbolic_name
                                    -version bundle_version')
```

Chapter 21. Administering Portlet applications

This page provides a starting point for finding information about portlet applications, which are special reusable Java servlets that appear as defined regions on portal pages. Portlets provide access to many different applications, services, and web content.

Portlet container settings and custom properties

Portlet container settings

Use this page to configure and manage the portlet container of this application server.

To view this administrative console page, click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **Portlet Container Settings** > **Portlet container**.

Enable portlet fragment cache

Specifies whether to create a cached entry when a portlet is invoked, similar to servlet caching of the web container settings.

Portlet fragment caching requires that servlet caching is enabled. Therefore, enabling portlet fragment caching automatically enables servlet caching. Disabling servlet caching automatically disables portlet fragment caching.

Portlet container custom properties

You can configure name-value pairs of data, where the name is a property key and the value is a string value that you can use to set internal system configuration properties. Defining a new property enables you to configure a setting beyond that which is available in the administrative console. The following is a list of the available Portlet container custom properties.

To specify Portlet container custom properties:

1. In the administrative console click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name*** > **Portlet Container Settings** > **Portlet container**.
2. Under **Additional Properties** select **Custom Properties**.
3. On the Custom Properties page, click **New**.
4. On the settings page, enter the name of the custom property that you want to configure in the **Name** field and the value that you want to set it to in the **Value** field.
5. Click **Apply** or **OK**.
6. Click **Save** on the console task bar to save your configuration changes.
7. Restart the server.

You can use the custom properties page to define the following portlet container custom properties:

- "useShortMBeanNames"

useShortMBeanNames

Portlet MBeans are registered by both their short name and full name. To enable the use of short MBean names for Portlet and PortletApplication MBeans, create the following name-value pair:

Name	Value
useShortMBeanNames	true

The default is false.

MBeans registered by the full identifiable name, have the following format:

```
<ApplicationName>#<WARfilename.war>_portlet.<portlet_name> for the Portlet MBean
<ApplicationName>#<WARfilename.war>_portlet for the PortletApplication MBean
```

where <..> is replaced by the corresponding application data. For example, `SampleApplication#SamplePortlet.war_portlet.SamplePortlet`.

Portlet and PortletApplication MBeans

The MBeans of type portlet and portletapplication provide information about a given portlet application and its portlets. Through the MBean of type portletapplication, you can retrieve a list of names of all portlets that belong to a portlet application. By querying the MBean of type portlet with a given portlet name, you can retrieve portlet specific information from the MBean of type portlet.

Each MBean that corresponds to a portlet or portlet application is uniquely identifiable by its name. Portlet applications are not required to have a name set within the `portlet.xml`. The MBean name for MBeans of the portletapplication type is the enterprise archive (EAR) file name followed by "#" and the web module name concatenated with the string "_portlet". For example, portletapplication type MBeans have the following format:

```
<EarFileName>#<WarFileName>_portlet
```

The name chosen for the MBean of type portlet is the name of the MBean of type portletapplication that the portlet belongs to, concatenated with the portlet name:

```
<EarFileName>#<WarFileName>_portlet.<portletname>
```

The following is an example of the resulting PortletApplication MBean name and portlet names:

```
EarName             SampleEar
WebModule             SampleWar.war

PortletApplication MBean name:   SampleEar#SampleWar_portlet
Portlet:             SampleEar#SampleWar_portlet.BookmarkPortlet
```

The MBean names have been changed compared to version 6.1, because the old naming patterns are not unique and can lead to problems under certain circumstances. If you rely on the old naming pattern, you can set the portlet container custom property, `useShortMBeanNames`, to true to activate the previous known MBean names. Because this is a performance impact, you might not want to activate the old naming pattern if it is not necessary.

A full stop separates the preceding web module name from the portlet name. Review the Portlet and PortletApplication MBean type API documentation for additional information. The generated API documentation is available in the information center table of contents from the path, **Reference** > **Administrator** > **API documentation** > **MBean interfaces**.

The following code is an example of how to invoke the MBean of type portletapplication for an application with the name, SampleWar.

```
String myPortletApplicationName = "SampleEar#SampleWar_portlet";
This name is composed by the Ear file name followed by "#" and
the web module name concatenated with the substring "_portlet"

com.ibm.websphere.management.AdminService adminService =
  com.ibm.websphere.management.AdminServiceFactory.getAdminService();
javax.management.ObjectName on =
  new ObjectName("WebSphere:type=PortletApplication,name=" + myPortletApplicationName + ",*");

Iterator onIter = adminService.queryNames(on, null).iterator();
```

```
while(onIter.hasNext())
{
 on = (ObjectName)onIter.next();
}

String ctxRoot = (java.lang.String)adminService.getAttribute(on, "webApplicationContextRoot");
```

In the previous example, the MBeanServer is first queried for an MBean of type portletapplication. If this query is successful, the webApplicationContextRoot attribute is retrieved on that MBean or the first MBean that is found. The result is stored in the ctxRoot variable. This variable now contains the context root of the web application that contains the portlet application that was searched. The variable is similar to "/bookmark".

The next code example demonstrates how to invoke the MBean of type portlet for a portlet with the name, BookmarkPortlet.

```
String myPortletName = "SampleEar#SampleWar_portlet.BookmarkPortlet";
This name is composed by the name of the MBean of type portletapplication and
the portlet name, separated by a full stop because the same portlet name may
be used within different web modules, but must be unique within the system.

com.ibm.websphere.management.AdminService adminService =
  com.ibm.websphere.management.AdminServiceFactory.getAdminService();
javax.management.ObjectName on =
  new ObjectName("WebSphere:type=Portlet,name=" + myPortletName + ",*");
Iterator iter = adminService.queryNames(on, null).iterator();

while(iter.hasNext())
{
 on = (ObjectName)iter.next;
}

java.util.Locale locale = (java.util.Locale) adminService.getAttribute(on, "defaultLocale");
```

The locale returned by the method getAttribute method for the MBean is the default locale defined for this portlet.

Full names for Portlet and PortletApplication MBeans

MBeans are also registered by the full identifiable name:

```
<ApplicationName>#<WARfilename.war>_portlet.<portlet_name> for the Portlet MBean
<ApplicationName>#<WARfilename.war>_portlet for the PortletApplication MBean
```

where <..> is replaced by the corresponding application data. For example, `SampleApplication#SamplePortlet.war_portlet.SamplePortlet`. You can enable the short MBean names by setting the `useShortMBeanNames` portlet container custom property to true.

Chapter 22. Administering Scheduler service

This page provides a starting point for finding information about the scheduler service, a WebSphere programming extension responsible for starting actions at specific times or intervals.

Schedulers are persistent and transactional timer services that run Enterprise JavaBeans methods or send Java Message Service messages using any Java Message Service messages using any Java Platform, Enterprise Edition (Java EE) server application.

The scheduler service helps minimize IT costs and increase application speed and responsiveness by maximizing utilization of existing computing resources.

The scheduler service provides the ability to reliably process workloads using parallel processing and schedule resource-intensive tasks to process during low traffic off-hours.

Installing default scheduler calendars

Scheduler calendars

The scheduler provides stateless session bean interfaces which allow creating common calendars which can be used by the scheduler and any Java Platform, Enterprise Edition (Java EE) application.

The `SchedulerCalendars.ear` application is available and provides a default UserCalendar Enterprise Java Beans (EJB) implementation which allows using the SIMPLE and CRON calendars. Although this application is not required when using the scheduler, it is available to use from any Java EE application.

For details on how the SIMPLE and CRON calendars behave, see the API documentation for the com.ibm.websphere.scheduler.UserCalendar interface.

Specifying a UserCalendar with the scheduler

A UserCalendar is specified using the setUserCalendar() method of the TaskInfo interface of the scheduler. This interface allows you to select the Java Naming and Directory Interface (JNDI) name of the home interface of a UserCalendar bean. Because some UserCalendar bean implementations might handle multiple types of calendars, the interface also allows you to optionally select which type of calendar to use. A list of valid calendar types can be retrieved by invoking the getCalendarNames() method of the UserCalendar interface.

If the setUserCalendar() method is not invoked, or if a value of null or empty-string is specified for the home JNDI name parameter, then the default UserCalendar is used internally by the scheduler. When the default UserCalendar is accessed internally, it is not necessary that the `SchedulerCalendars.ear` system application be installed.If you want to use the default UserCalendar with a CRON entry, you must switch to the CRON entry manually. The following code sample shows this switch:

```
BeanTaskInfo taskInfo = (BeanTaskInfo)scheduler.createTaskInfo(BeanTaskInfo.class);
String calendarVariant = "CRON";
taskInfo.setUserCalendar(null, calendarVariant);
// cron table entry
String cronTableEntry = "0 17,20,23 * ? * *";
taskInfo.setStartTimeInterval(cronTableEntry);
```

You might want to use the default UserCalendar directly in your other Java EE applications, apart from the scheduler. In this case, you may use the UserCalendarHome.DEFAULT_CALENDAR_JNDI_NAME value to look up the default UserCalendar from your applications. You may also supply this value to the setUserCalendar() method of the TaskInfo interface. You will need to ensure the `SchedulerCalendars.ear` system application was either automatically installed or that you have installed it manually.

Installing default scheduler calendars

The default scheduler SIMPLE and CRON calendars are available in the `SchedulerCalendars.ear` system application and are automatically installed on standalone server profiles. System applications cannot be installed and uninstalled like traditional Java Platform, Enterprise Edition (Java EE) applications.

About this task

The following steps are required to map the `SchedulerCalendars.ear` system application on a server or cluster in a network deployment environment.

Procedure

1. Start the wsadmin tool and connect to the deployment manager.
2. Install the system application.
   - To install on a non-clustered server:
     - Using Jacl:

       ```
       $AdminApp install
       "/${WAS_INSTALL_ROOT}/systemApps/SchedulerCalendars.
       ear" {-systemApp -appname SchedulerCalendars -cell
        mycell -node mynode -server myserver}
       ```

     - Using Jython list:

       ```
       AdminApp.install('${WAS_INSTALL_ROOT}/systemApps/
       SchedulerCalendars.ear', ['-systemApp', '–appname',
        'SchedulerCalendars','-cell', 'mycell', '-node',
        'mynode', '-server', 'myserver'])
       ```

     - Using Jython string:

       ```
       AdminApp.install('${WAS_INSTALL_ROOT}/systemApps/
       SchedulerCalendars.ear', '[-systemApp –appname
        SchedulerCalendars –cell mycell –node mynode
        -server myserver]')
       ```

       Where:

Table 69. Variable options.. Variable values and options

Value	Option
mycell	the value of the cell option
mynode	the value of the node option
myserver	the value of the server option

   - To install on a cluster:
     - Using Jacl:

       ```
       $AdminApp install
       "\${WAS_INSTALL_ROOT}/systemApps/SchedulerCalendars.
       ear" {-systemApp -appname SchedulerCalendars -cell
        mycell -cluster mycluster}
       ```

     - Using Jython list:

       ```
       AdminApp.install('${WAS_INSTALL_ROOT}/systemApps/
       SchedulerCalendars.ear', ['-systemApp', '–appname',
        'SchedulerCalendars','-cell', 'mycell', '-cluster',
        'mycluster'])
       ```

     - Using Jython string:

       ```
       AdminApp.install('${WAS_INSTALL_ROOT}/systemApps/
       SchedulerCalendars.ear', '[-systemApp –appname
        SchedulerCalendars –cell mycell -cluster mycluster]')
       ```

       Where:

Table 70. Variable options.. Variable values and options

Value	Option
mycell	the value of the cell option
mycluster	the value of the cluster option

3. Save the configuration changes. Refer to the Saving configuration changes with the wsadmin tool topic for more information.

Uninstalling default scheduler calendars

The default scheduler SIMPLE and CRON calendars are available in the `SchedulerCalendars.ear` system application and are automatically installed on standalone server profiles. System applications cannot be installed and uninstalled like traditional Java Platform, Enterprise Edition (Java EE) applications.

About this task

Remove the SchedulerCalendars system application on federated node, as follows:

Procedure

1. Open a command window on the federated node.
2. Run the following command:

   On Unix platforms:

   ```
   $Install_Root/bin/wsadmin.sh -conntype none -profile $Profile_Name
   ```

   On Windows platforms:

   ```
   $Install_Root/bin/wsadmin -conntype none -profile $Profile_Name
   ```

   where:

   - *Install_Root* is the directory where WebSphere Application Server is installed.
   - *Profile_Name* is the name of the profile where the target server is located.
3. At the **wsadmin>** prompt, enter the following command for each server that exists on the node where you want to have the SchedulerCalendars application available:

   ```
   wsadmin> $AdminApp uninstall SchedulerCalendars "-cell $MyCell -node $MyNode -server $MyServer"
   ```

   where:

   - *$Install_Root* is the directory where WebSphere Application Server is installed.
   - *$MyCell*, *$MyNode*, and *$MyServer* are the values with the name of the cell, node, and server.

   Important: Each of these values are case-sensitive.
4. Repeat step three for each server in the current profile for which you will uninstall the SchedulerCalendars application.
5. When uninstallation is complete for the system application on all appropriate servers, enter the following commands:

   ```
   wsadmin> $AdminConfig save
   wsadmin> exit
   ```
6. Using the Administrative Console or scripting, start or restart the servers to unload the SchedulerCalendars application.

Results

The SchedulerCalendars application should now be removed.

Example: Using default scheduler calendars

The SIMPLE and CRON calendars can be used from any J2EE application. This topic describes that process.

Using default scheduler calendars involves looking-up the default UserCalendarHome Enterprise JavaBeans (EJB) home object, creating the UserCalendar bean and calling the applyDelta() method. For details on the applyDelta method as well as the syntax for the SIMPLE and CRON calendars, see the UserCalendar interface topic.

Example:

```
import java.util.Date;
import javax.naming.InitialContext;
import javax.rmi.PortableRemoteObject;
import com.ibm.websphere.scheduler.UserCalendar;
import com.ibm.websphere.scheduler.UserCalendarHome;

// Create an initial context
InitialContext ctx = new InitialContext();

// Lookup and narrow the default UserCalendar home.
UserCalendarHome defaultCalHome=(UserCalendarHome)
 PortableRemoteObject.narrow(ctx.lookup(
      UserCalendarHome.DEFAULT_CALENDAR_JNDI_NAME),
    UserCalendarHome.class);

// Create the default UserCalendar instance.
UserCalendar defaultCal = defaultCalHome.create();

// Calculate a date using CRON based on the current
// date and time.  Return the next date that is
// Saturday at 2AM
Date newDate =
    defaultCal.applyDelta(new Date(),
        "CRON", "0 0 2 ? * SAT");
```

Managing schedulers

Managing schedulers

Schedulers are configured using the administrative console, configuration service or scripting and are available to all servers on which a scheduler is visible.

About this task

You can create multiple schedulers within a single server, cluster, node or cell. Each configured scheduler is an independent task scheduling engine that has a unique Java Naming and Directory Interface (JNDI) name, persistent storage device and daemon.

Procedure

1. Configure schedulers.
2. Create the database for schedulers.

Scheduler daemon

A scheduler daemon is a background thread that searches for tasks to run in the database.

A scheduler daemon is started for each scheduler defined on each server. If `Scheduler 1` is configured on `server1`, then only one scheduler daemon runs on `server1` unless it is cloned. If `Scheduler 1` is defined at the node scope level, then the scheduler will run on each server within that node.

The poll interval determines the frequency at which the persistent store is queried. By default, this value is set to 30 seconds. When a task is found that is scheduled to run within the current poll interval, an asynchronous beans alarm is set. The task then runs as close to this time as possible using an alarm thread from the scheduler's associated work manager. Thus, the number of alarm threads configured on the work manager determines how many concurrent tasks are executed. No tasks are lost. If we reach this limit, then new tasks are simply queued to be executed when an alarm thread becomes available. The actual firing time is dictated by server load and availability of free threads in the alarm thread pool of the associated work manager.

Scheduler daemons in a cluster

When multiple schedulers are configured to use the same tables (as is the case in a clustered environment), any of the daemons can find a task and set the alarm in its Java virtual machine (JVM). The task is executed in the virtual machine where the scheduler daemon first runs, until the daemon is stopped and another daemon starts. If an application on `server1` schedules a task to run and `server2` was started before `server1`, then the task runs on `server2`.

Example: Stopping and starting scheduler daemons using Java Management Extensions API

Use the wsadmin scripting tool to invoke a `Jacl` script and stop and start a scheduler daemon.

This example JACL script can be invoked using the wsadmin scripting tool. It will attempt to stop and start a scheduler daemon.

```
# Example JACL Script to restart a Scheduler Daemon

set schedJNDIName sched/MyScheduler

# Find the WASScheduler MBean
regsub -all {/} $schedJNDIName "." schedJNDIName
set mbeanName Scheduler_$schedJNDIName
puts "Looking up Scheduler MBean $mbeanName"
set sched [$AdminControl queryNames WebSphere:*,type=WASScheduler,name=$mbeanName]

# Invoke the stopDaemon operation.
puts "Stopping the daemon..."
$AdminControl invoke $sched stopDaemon
puts "The daemon has stopped."

# Invoke the startDaemon operation.
puts "Starting the daemon..."
$AdminControl invoke $sched startDaemon 0
puts "The daemon has started."
```

Example: Dynamically changing scheduler daemon poll intervals using Java Management Extensions API

Use the wsadmin scripting tool to invoke a `Jacl` script and dynamically change scheduler daemon poll intervals.

To dynamically change scheduler daemon poll intervals, use the wsadmin scripting tool to invoke this example `JACL` script. Invoking this example sets the poll interval of the scheduler daemon to 60 seconds.

```
# Example JACL Script to set the Scheduler daemon's poll interval

set schedJNDIName sched/MyScheduler

# Find the WASScheduler MBean
regsub -all {/} $schedJNDIName "." schedJNDIName
set mbeanName Scheduler_$schedJNDIName
puts "Looking-up Scheduler MBean $mbeanName"
```

```
set sched [$AdminControl queryNames WebSphere:*,type=WASScheduler,name=$mbeanName]

# Set the poll interval to 60 seconds (60000 ms)
$AdminControl setAttribute $sched pollInterval 60000
puts "Poll interval set."
```

Configuring schedulers

Before your application can make use of the scheduler service, you must configure a scheduler using the administrative console, configuration service or scripting. Conceptually, a scheduler is similar to a data source in that you must specify various configuration attributes, including a JNDI name where the instance is bound. Once defined, an application using the Scheduler API or WASScheduler MBean can look up the scheduler object and call various methods to manage tasks.

About this task

The scheduler service is always enabled. In previous versions of the product, the scheduler service could be disabled using the administrative console or configuration service. Scheduler service configuration objects are present in the configuration service, but the enabled attribute is ignored.

To achieve high availability, you can configure a duplicate scheduler on each server in a cluster, or create a scheduler at the cluster scope. For example, each server that contains a scheduler with the JNDI name `sched/MyScheduler`, with the same database configuration parameters (data source and table prefix) behaves as a single clustered scheduler. Each server in the scheduler cluster has a running scheduler instance, which increases the number of poll daemons and allows automatic failover. For more information on creating clusters for high availability, see the article, "WebSphere Enterprise Scheduler planning and administration guide."

Typically, create schedulers at the server or cluster scope. Scheduler poll daemons run in each server within the configured scope, which means that if you create a scheduler at the node or cell scope, the scheduler poll daemon can attempt to run tasks on any of the servers in the node or cell. If applications are not mapped uniformly over each server in that scope, the scheduler might not run tasks correctly. Because applications are mapped to servers and clusters, there is less chance for error and less competition between daemons to run tasks.

Depending on your preferred method of configuration, select one of the following steps to configure schedulers.

Procedure

1. Configuring schedulers using the administrative console.
2. Configuring schedulers using Java Management Extensions API (JMX).

Results

A scheduler is configured and ready to use.

Configuring scheduler default transaction isolation

The scheduler uses read-committed transaction isolation, by default, when reading tasks using the get or find APIs on the com.ibm.websphere.scheduler.Scheduler interface and WASScheduler MBean. The default behavior for a scheduler can be changed to read-uncommitted, which allows the get and find methods to return the current or next state of the task in the database. This topic describes how to change the default behavior for the get and find methods.

About this task

See the scheduler API documentation to view the com.ibm.websphere.scheduler.TaskInfo.setTaskExecutionOptions() method, which details how to return the next state of the task or the current state of the task.

Attention: If the scheduler database does not support uncommitted reads, such as Oracle, this parameter has no effect.

To change the default behavior for the get and find methods, complete the following steps:

Procedure

1. From the administrative console, click **Resources** > **Schedulers** > *scheduler_name*.
2. Click **Custom Properties**.
3. Click **New**.
4. Add the following properties:

Name	defaultReadTransactionIso
Type	java.lang.Integer
Value	`1 (for read-uncommitted transaction isolation)` `2 (for read-committed transaction isolation)`

5. Click **Apply** or
6. Click **OK**.
7. Save the changes and verify that you initiate a file synchronization before restarting the servers.
8. Restart the application server for the changes to take effect.

Configuring schedulers using the administrative console

Schedulers can be created or configured using the administrative console.

Procedure

1. Start the administrative console.
2. Select **Resources** > **Schedulers**.
3. Click **New**.
4. Specify configuration settings.

   Fields marked with an asterisk (*) are required. The settings are described in detail in the topic "Scheduler settings".

   bprac: If you do not require interoperability with PME Version 5.0 tasks, under Additional Properties, click **Custom Properties > New**. Then specify `disableV50TaskInteroperability` in the **Name** field, `true` in the **Value** field, and select `java.lang.boolean` from the list of available Type options. When this property is set to `true`, tablespace scans that are only required for PME Version 5.0 tasks no longer occur.
5. Click **OK** or **Apply** to save the changes.
6. Save the changes to the configuration repository.

Results

A scheduler is now configured and ready to use for newly installed applications. If the scheduler JNDI name is not yet visible to your application, restarting the application or restarting application server will allow the scheduler to be seen.

When schedulers are created for the first time, the poll daemon will not automatically start and must be started manually and will only start automatically the next time the server is started. To start the poll daemon manually, refer to the scheduler daemons topic.

Attention: Changes to existing scheduler configurations will not take affect until after the application server is restarted.

Schedulers collection:

Use this page to manage scheduler configurations. Schedulers are persistent and transactional timer services that can run business logic. Each scheduler runs tasks independently and has a programming interface accessible from Java Platform, Enterprise Edition (Java EE) applications using the Java Naming and Directory Interface (JNDI). You can also manage schedulers using a Java Management Extensions (JMX) MBean. See the scheduler documentation in the Information Center for details on how to configure and use schedulers.

To view this administrative console page, click **Resources > Schedulers**.

Name:

Specifies the name of the data source where persistent tasks are stored.

Data type String

JNDI name:

Specifies the JNDI name of the work manager, which is used to manage the number of tasks that can run concurrently with the scheduler. The work manager also can limit the amount of Java EE context applied to the task.

The JNDI name specifies where this scheduler instance is bound in the name space. Clients can look this name up directly, although the use of resource references is recommended.

Data type String

Scope:

Specifies the scope of the configured resource. This value indicates the location for the configuration file.

Data source JNDI name:

Specifies the alias for the user name and password that are used to access the data source.

Any data source available in the name space can be used with a scheduler. Multiple schedulers can share a single data source while using different tables by specifying a table prefix.

Data type String

Table prefix:

Specifies the string prefix to affix to the scheduler tables.

Multiple independent schedulers can share the same database if each instance specifies a different prefix string.

Data type	String

Poll interval:

Specifies the interval, in seconds, that a scheduler polls the database. The default value is appropriate for most applications.

Each poll operation can be consuming. If the interval is extremely small and there are many scheduled tasks, polling can consume a large portion of system resources.

Data type	Integer
Units	Seconds
Default	30
Range	Any positive long integer

Work manager JNDI name:

Specifies the JNDI name of the work manager, which is used to manage the number of tasks that can run concurrently with the scheduler. The work manager also can limit the amount of Java EE context applied to the task.

The work manager is a server object that serves as a logical thread pool for the scheduler. Each repeating task that is created using this scheduler uses the **Number of alarm threads** specified in the work manager, which affects the number of tasks that can run concurrently. Use the work manager **Service Names** property to limit the amount of context information that is propagated to the task when it runs.

When a task runs, the task is run in the work manager associated with the scheduler instance. You can control the number of actively running tasks at a given time by configuring schedulers with a specific work manager. The number of tasks that can run concurrently is governed by the **Number of alarm threads** parameter on the work manager.

Verify tables:

Specifies to validate that scheduler data sources, table prefixes, security authentication information and tables are configured correctly.

You can use this verification method in production and development environments without altering database properties.

Create tables:

Specifies to create the necessary tables and indices required for a scheduler to operate.

This method of creating scheduler tables is designed for simple topologies and development environments. Use the supplied scheduler data definition language files for advanced or production environments and for databases that do not support this feature.

Drop tables:

Specifies the removal of tables and indices required for schedulers to operate.

This method of removing scheduler tables and indices is recommended for development environments and does not delete previously scheduled tasks.

Schedulers settings:

Use this page to modify scheduler settings.

To view this administrative console page, click **Resources > Schedulers >** *scheduler_name*.

Scope:

Specifies the scope of the configured resource. This value indicates the location for the configuration file.

Name:

Specifies the name by which this scheduler is known for administrative purposes.

Data type String

JNDI name:

Specifies the name of the data source where persistent tasks are stored.

The Java™ Naming and Directory Interface (JNDI) name specifies where this scheduler instance is bound in the namespace. Clients can look this name up directly, although the use of resource references is recommended.

Data type String

Description:

Specifies the description of this scheduler for administrative purposes.

Data type String

Category:

Specifies a string that can be used to classify or group this scheduler.

Data type String

Data source JNDI name:

Specifies the name of the data source where persistent tasks are stored.

Any data source available in the name space can be used with a scheduler. Multiple schedulers can share a single data source while using different tables by specifying a table prefix.

Data type String

Data source alias:

Specifies the alias for the user name and password that are used to access the data source.

Data type String

Table prefix:

Specifies the string prefix to affix to the scheduler tables. Multiple independent schedulers can share the same database if each scheduler specifies a different prefix string.

Multiple independent schedulers can share the same database if each instance specifies a different prefix string.

Important: Use a table prefix with all capital characters. If lowercase characters are used for the table prefix, they are automatically capitalized at run time.

Data type	String

Poll interval:

Specifies the interval, in seconds, that a scheduler polls the database. The default value is appropriate for most applications.

Each poll operation can be consuming. If the interval is extremely small and there are many scheduled tasks, polling can consume a large portion of system resources.

Data type	Integer
Units	Seconds
Default	30
Range	2000000

Work manager JNDI name:

Specifies the JNDI name of the work manager, which is used to manage the number of tasks that can run concurrently with the scheduler. The work manager also can limit the amount of Java Platform, Enterprise Edition (Java EE) context applied to the task.

The work manager is a server object that serves as a logical thread pool for the scheduler. Each repeating task that is created using this scheduler uses the **Number of alarm threads** specified in the work manager, which affects the number of tasks that can run concurrently. Use the work manager **Service Names** property to limit the amount of context information that is propagated to the task when it runs.

When a task runs, the task is run in the work manager associated with the scheduler instance. You can control the number of actively running tasks at a given time by configuring schedulers with a specific work manager. The number of tasks that can run concurrently is governed by the **Number of alarm threads** parameter on the work manager.

Use administration roles:

Specifies that when this option and administrative security are both enabled, the user administration roles are enforced when the scheduler JMX commands or APIs are used to create and modify tasks. If this option is not enabled, all the users can create and modify tasks.

Schedulers require several user roles to plan for, develop, administer and operate the scheduler service: administrator, developer and operator.

Data type	check box
Default	unchecked

Range	• Operator, Administrator - Calls any of the scheduler MBean or API methods and runs any of the scheduler administrative console functions. • Monitor, Configurator - Calls the scheduler MBean or API methods, but cannot create tasks or modify the state of any tasks. Only read-only methods and properties are accepted.

Configuring schedulers using Java Management Extensions

Schedulers can be created or configured using the Java Management Extensions (JMX) API using one of several scripting languages or Java.

About this task

To run with Java, the following JAR file needs to be present in the program class path: `com.ibm.ws.admin.client_6.1.0.jar`..

Complete these steps when using Java programs that utilize JMX.

Procedure

1. Look up the host and get an administration client handle.
2. Get a configuration service handle.
3. Update the `resource-pme.xml` file using the configuration service, as needed.
   a. Find the SchedulerProvider for a given scope.
   b. Create a SchedulerConfiguration and specify all required parameters identifying the SchedulerProvider as the parent object.
4. Reload the `resource-pme.xml` file to bind the newly created scheduler into the JNDI namespace. Perform this step if you want to use the newly created scheduler immediately, without restarting the application server.
   a. Locate the DataSourceConfigHelper MBean using the name.
   b. Invoke the reload() operation.

Results

A scheduler is now configured and ready to use for newly installed applications. If the scheduler JNDI name is not yet visible to your application, reinstalling the application or restarting the application server will allow the scheduler to be seen.

When schedulers are created for the first time, the poll daemon does not automatically start, and you must start it manually. When you restart the server, the poll daemon starts automatically. To start the poll daemon manually, refer to the scheduler daemons topic.

Note: Changes to existing scheduler configurations will not take affect until after the application server is restarted.

Example: Using scripting to create and configure schedulers:

Use the wsadmin scripting tool to invoke a `Jacl` script and create a SchedulerConfiguration resource.

The following `Jacl` example script can be invoked using the wsadmin scripting tool, which creates a SchedulerConfiguration resource using the DefaultWorkManager at the server scope.

```
# Example JACL Script to create a SchedulerConfiguration
# at the server scope

# Change the cell, node and server to match your environment
set cellName   MyCell
set nodeName   MyNode
set serverName server1

# We can just grab the first provider, since there is only one at the
# server scope level.

set schedProv [$AdminConfig getid /Cell:$cellName/Node:$nodeName/Server:$serverName/
  SchedulerProvider:SchedulerProvider]
if {$schedProv == ""} {
    puts "Unable to find SchedulerProvider for server: $serverName.  Aborting."
    exit
}
puts "Found a SchedulerProvider"

# Create a WorkManager for our scheduler at the server scope.
# We could use any of the other scopes as long as it is at the same
# or higher than the Scheduler's scope.

set wrkMgrProv [$AdminConfig getid /Cell:$cellName/Node:$nodeName/Server:$serverName/
  WorkManagerProvider:WorkManagerProvider/]
if {$wrkMgrProv == ""} {
    puts "Unable to find the WorkManagerProvider for server: $serverName.  Aborting."
    exit
}
puts "Found a WorkManagerProvider"

set wmName             "MyScheduler WorkManager"
set wmJNDIName         "wm/MySchedWorkManager"
set wmIsGrowable       false
set wmMaxThreads       1
set wmMinThreads       0
set wmNumAlarmThreads  10
set wmServiceNames     "com.ibm.ws.i18n;security;UserWorkArea;zos.wlm"
set wmThreadPriority   5

# Setup our DefaultWorkManager attributes
set createAttrs [subst { \
    {isGrowable $wmIsGrowable} \
    {jndiName $wmJNDIName} \
    {maxThreads $wmMaxThreads} \
    {minThreads $wmMinThreads} \
    {name "$wmName"} \
    {numAlarmThreads $wmNumAlarmThreads} \
    {serviceNames "$wmServiceNames"} \
    {threadPriority $wmThreadPriority} }]

puts "Creating a WorkManager"
$AdminConfig create WorkManagerInfo $wrkMgrProv $createAttrs
puts "WorkManager Created"

# Setup our SchedulerConfiguration attributes
set schedulerName          MyScheduler
set schedulerJNDIName      sched/MyScheduler
set datasourceJNDIName     jdbc/MySchedulerDatasource
set datasourceAlias        MySchedulerAlias
set pollInterval           30
set tablePrefix            MSCD
set useAdminRoles          true

set createAttrs [subst { \
  {name $schedulerName} \
  {datasourceJNDIName $datasourceJNDIName} \
```

```
  {datasourceAlias $datasourceAlias} \
  {jndiName $schedulerJNDIName} \
  {pollInterval $pollInterval} \
  {tablePrefix $tablePrefix} \
  {useAdminRoles true} \
  {workManagerInfoJNDIName $wmJNDIName}}]

puts "Creating a Scheduler"
$AdminConfig create SchedulerConfiguration $schedProv $createAttrs
puts "Scheduler created"

# Save the configuration
$AdminConfig save
```

Creating a scheduler resource reference

When you define schedulers in the server configuration, the object instance is bound into the global name space under the configured Java Naming Directory Interface (JNDI) name. You can use a resource reference to avoid manually coding this JNDI name into your application. Using a resource reference allows administrators to map applications to the appropriate schedulers.

About this task

You can alternatively create a scheduler resource reference by editing the XML directly. A Scheduler resource reference is a Java Platform, Enterprise Edition (Java EE) compliant resource that uses the class com.ibm.websphere.scheduler.Scheduler as the object type. For information regarding the XML file format, see the Java EE Specification.

Procedure

1. Start an assembly tool, such as Rational Application Developer.
2. Open the Java EE perspective.
3. Open your Enterprise JavaBeans (EJB) or Web module with the Deployment Descriptor Editor.
4. Click the **Reference** tab at the bottom of the window.
5. Click **Add**.
6. Select the **Resource reference** option.
7. Click **Next**.
8. Complete the Reference fields as shown in the following properties:
   Name The reference name, for example, *sched/MyScheduler*. According to this example, the name you choose has a local reference name of **java:comp/env/*sched/MyScheduler***.
   Type Select **com.ibm.websphere.scheduler.Scheduler**, and click **OK**.
   Authentication
   Select container.
   Description
   Any relevant description.
9. Click finish.
10. (**Optional**) Enter a global JNDI name of a configured scheduler in the JNDI name field in the **Bindings** section of the **Reference** window. You can specify or override this value when you install the application.
11. Save your changes to the deployment descriptor.

Results

A scheduler resource reference is now available to use within your application

Creating the database for schedulers

Each scheduler requires a database in which to store its persistent information. Schedulers use this database for storing tasks and then running them. The choice of database and location should be determined by the application developer and server administrator.

Before you begin

Scheduler performance is ultimately limited by database performance. If you need more tasks per second, you can run the scheduler daemons on larger systems, use clusters for the session beans used by the tasks or partition the tasks by using multiple schedulers. Eventually, however, the scheduler database becomes saturated, and a larger or better-tuned database system is needed. For detailed information on scheduler topologies refer to the "WebSphere Enterprise Scheduler planning and administration guide" technical paper.

Multiple schedulers can share a database when you specify unique table prefix values in each scheduler configuration. This sharing can lower the cost of administering scheduler databases. However, do not configure schedulers with non-unique table prefixes such that two separate servers share the same database table. A lease occurs between a specific database table and a scheduler running on a server. This lease allows one server at a time to own the lease to a specific database table. This process exists to ensure that one server runs schedule events, such as Enterprise JavaBeans (EJB) timers, in a cluster environment. If the server with this lease is unavailable, another server in the cluster obtains the lease.

About this task

Complete the following steps to create scheduler databases.

Procedure

1. Create a database. To create the database for a scheduler or to determine if an existing database is adequate for a scheduler, review the Create scheduler databases topic.
2. Create the scheduler tables. There are three methods for creating the tables for a scheduler:
   a. Create tables for schedulers using the administrative console. Use the administrative console to add, delete and verify database tables through your Web browser. This method is ideal for developers and simple scheduler topologies.
   b. Create tables for schedulers using JMX or scripting.

      Use JMX to add, delete and verify database tables programmatically with Java or scripting. This method is ideal for automating scheduler configurations for simple scheduler topologies.
   c. Create tables for schedulers using DDL files. Manually edit the DDL files using your favorite text editor, and verify that mapping between the table names and the scheduler resources and data sources is correct.

Creating scheduler databases

The scheduler uses the scheduler database for storing and running tasks. To create a scheduler database, your database system must be installed and available.

Before you begin

The performance of schedulers is ultimately limited by the performance of the database. If you need more tasks per second, you can run the scheduler daemons on larger systems or you can use clusters for the session beans used by the tasks. Eventually, however, the task database becomes saturated and you then need a larger or better-tuned database system.

Multiple applications can share a scheduler database. This sharing can lower the cost of administering scheduler databases.

About this task

The scheduler requires a database, a JDBC provider, and a data source.

Procedure

1. Create the database according to the description for your database system:
   - Creating Apache Derby databases for schedulers.
   - Creating a DB2 database for schedulers.
   - Creating a DB2 for iSeries database for schedulers.
   - Creating an Informix database for schedulers.
   - Creating a Microsoft SQL Server database for schedulers.
   - Creating an Oracle database for schedulers.
   - Creating a Sybase database for schedulers.
2. If the database is not on the same machine as your IBM WebSphere Application Server, verify that you can access the database from your application server machine.
3. Configure your JDBC provider and data source. For details, refer to the Creating and configuring a JDBC provider and data source topic. The JDBC driver can be either one-phase or two-phase commit depending on whether other transactions take place using other data sources, for example, while using the scheduler. The data source can represent multiple versions of the product.

Results

The database is created and ready for you to create scheduler tables.

Creating Apache Derby databases for schedulers:

This topic describes how to create Apache Derby databases for schedulers using data definition language (DDL) or structured query language (SQL) files.

About this task

To create Apache Derby databases for schedulers, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. Open a command-line window.
2. Verify that you have administrator rights for the database system.
3. Verify that the database supports Unicode (UTF-8). Otherwise, the database does not store all characters that can be handled in Java code, which results in code page conversion problems when a client uses an incompatible code page.
4. Use the ij utility supplied with the Apache Derby system to create the database. To use ij to create a database called scheddb which is located in `/opt`, for example, you would do the following:

   ```
   ij.sh
   ij>connect '/opt/scheddb;create=true';
   ij>quit;
   ```

   The embedded version of Apache Derby supports only one local connection. If the Application Server product is running and accessing a Apache Derby database, then any attempts to open a second connection to the database from the command line are rejected.

   Note: Add a semi-colon (;) at the end of each command. Otherwise, ij does not execute the command.

5. Exit the ij utility by issuing the quit command: `quit;`

Results

The Apache Derby database for the scheduler service exists.

Creating DB2 databases for schedulers:

This topic describes how to create DB2 databases for scheduler, using data definition language (DDL) or structured query language (SQL) files.

About this task

To create DB2 databases for scheduler, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. Open a DB2 command-line window.
2. Make sure that you have administrator rights for the database system.
3. Verify that the database supports Unicode (UTF-8). Otherwise, it cannot store all the characters that can be handled in Java code, which might result in code page conversion problems, when a client uses an incompatible code page.

   To avoid deadlocks, be sure that the DB2 isolation level is set to "read stability". If necessary, enter the command

   ```
   db2set DB2_RR_TO_RS=YES
   ```

   then restart the DB2 instance to activate the change.
4. In the DB2 command line processor, enter this command to create the database with an example name, `scheddb`:

   ```
   db2 CREATE DATABASE scheddb USING CODESET UTF-8 TERRITORY en-us
   ```

   A DB2 database named `scheddb` has been created.

Results

The DB2 database for the scheduler exists.

Creating DB2 for iSeries databases for schedulers:

This topic describes how to create DB2 for iSeries databases for scheduler, using data definition language (DDL) or structured query language (SQL) files.

About this task

To create DB2 for iSeries databases for scheduler, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. Run the following command to start an interactive SQL session:

   ```
   STRSQL
   ```
2. In interactive SQL, enter this command to create the collection with an example name, `scheddb`:

   ```
   CREATE COLLECTION scheddb
   ```
3. Exit the interactive SQL session.

4. Change the owner for the new collection to QEJBSVR by executing the following command:
   ```
   CHGOBJOWN OBJ(scheddb) OBJTYPE(*LIB) NEWOWN(QEJBSVR)
   ```

   where `scheddb` is the name of the collection you created in the previous step.

Results

The DB2 for iSeries database for the scheduler exists.

Creating Informix databases for schedulers:

This topic describes how to create Informix databases for schedulers, using data definition language (DDL) or structured query language (SQL) files.

About this task

To create Informix databases for schedulers, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. Open a command-line window.
2. Verify that you have administrator rights for the database system.
3. Verify that the database supports Unicode (UTF-8). Otherwise, the database does not store all characters that can be handled in the Java code, which results in code page conversion problems, when a client uses an incompatible code page.
4. If you want to create a new database named `scheddb`, for example, enter the command:
   ```
   dbaccess CREATE DATABASE scheddb with log
   ```

Results

The Informix database for scheduler exists.

Creating Microsoft SQL Server databases for schedulers:

This topic describes how to create Microsoft SQL Server databases for schedulers, using data definition language (DDL) or structured query language (SQL) files.

About this task

To create Microsoft SQL Server databases for schedulers, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. Make sure that you are using a user ID that has administrator rights for the database system.
2. In the **Enterprise Manager**, expand a server group, then expand a server. A Microsoft SQL Server database named `scheddb` is created.
3. Right-click **Databases**, then click **New Database**.
4. Verify that the database supports Unicode (UTF-8). Otherwise, the database does not store all characters that can be handled in the Java code, which results in code page conversion problems, when a client uses an incompatible codepage.
5. Type the name `scheddb`.
6. Modify any default values, and save your changes. The Microsoft SQL Server database, scheddb, is created.

Results

The Microsoft SQL Server database for scheduler exists.

Creating Oracle databases for schedulers:

This topic describes how to create Oracle databases for schedulers, using data definition language (DDL) or structured query language (SQL) files.

About this task

To create Oracle databases for schedulers, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. Open a command-line window.
2. Make sure that you have administrator rights for the database system.
3. Verify that the database supports Unicode (UTF-8). Otherwise, the database does not store all characters that can be handled in the Java code, which results in code page conversion problems, when a client uses an incompatible code page.
4. Use the Database Configuration Assistant to create the database, `scheddb`, for example. Verify that you select the **JServer** option for the database. Use a Unicode code page when creating the database. The text data you pass to the APIs must be compatible with the selected code page.

Results

The Oracle database for scheduler exists.

Creating Sybase databases for schedulers:

This topic describes how to create Sybase databases for schedulers, using data definition language (DDL) or structured query language (SQL) files.

About this task

This topic describes how to create Sybase databases for schedulers, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. Open a command-line window.
2. Make sure that you have administrator rights for the database system.
3. Make sure that you have the DTM option for Sybase ASE installed.
4. Verify that the database supports Unicode (UTF-8). Otherwise, the database does not store all characters that can be handled in the Java code, which results in code page conversion problems, when a client uses an incompatible code page.
5. Use the Sybase isql utility to create the database, `scheddb`, for example. See your Sybase product documentation for details.

Results

The Sybase database for the scheduler exists.

Scheduler table management functions

The administration console and the WASSchedulerConfiguration MBeans provide simplified methods for creating scheduler tables and schema, verifying that the scheduler tables and schema are setup properly and are accessible and removing scheduler tables and schema.

Note: There are limitations when running the table management functions relating to data source access. See the Verifying a connection topic for details on these limitations. If a connection cannot be verified successfully, the scheduler table management functions will fail.

Verify tables

Validates that scheduler data sources, table prefixes, security authentication information and tables are configured correctly. You can use this verification method in production and development environments without altering database properties.

Create tables

Creates the necessary tables and indices required for schedulers to operate. This method of creating scheduler tables is designed for simple topologies and development environments. Use the supplied scheduler data definition language files for advanced or production environments and for databases that do not support this feature. For details, see the topic Creating scheduler tables using the administrative console.

Drop tables

Specifies the removal of tables and indices required for schedulers to operate. This method of removing scheduler tables and indices is recommended for development environments. When you drop tables, the action removes all previously scheduled tasks, and the scheduler no longer operates successfully, until the tables are recreated.

Scheduler table definition

Schedulers require database tables and indices with a table prefix. This page provides reference information about the tables.

Each scheduler requires several database tables and indices to operate. Each table name and index described in this topic requires a table prefix. For example, if the scheduler is configured with a table prefix value, **SCHED_**, the table with the name, **TASK**, would be named **SCHED_TASK**. See Scheduler settings for details on the table prefix.

To create the tables, see Creating the database for schedulers. To see the exact schema definition such as field sizes and types, see Creating scheduler tables using DDL files. This section references the location where the DDL or SQL statements are stored. These statements create the table schema.

Note: The information in this topic is provided for problem determination. Do not alter the scheduler table names, field names or index names. The data content format might change without notice. Be aware of this factor when accessing the tables directly. Modifying data in the tables without using the Scheduler API might cause failures.

TASK

The TASK table contains the tasks that have been scheduled, but not yet purged. The primary key for this table is the TASKID which equates to the getTaskID() method on the com.ibm.websphere.scheduler.TaskStatus interface.

Since there is one row in this table for each task, it is important that the database and table support row-locking. Using page, or table locks, inhibits the scheduler from running tasks concurrently.

Table 71. TASK table.. Displays scheduled tasks

Field name	Purpose and notes
TASKID	Contains all of the tasks that have been scheduled, but not yet purged. The primary key for this table is TASKID which equates to the getTaskID() method on the com.ibm.websphere.scheduler.TaskStatus interface. Since there is one row in this table for each task, it is important that the database and table support row-locking. Using page, or table locks, will inhibit the scheduler from running tasks concurrently.
VERSION	Internal version ID of this row format.
ROW_VERSION	The version of this row. Used for optimistic locking.
TASKTYPE	The type of task: **1**=BeanTaskInfo, **2**=MessageTaskInfo
TASKSUSPENDED	This value indicates if the task is suspended or if it is running. The task is suspended if the value BITWISE AND 1 equals **1**. The task is running if the value BITWISE AND 2 equals **2**.
CANCELLED	The value, **1**, if the task is cancelled.
NEXTFIRETIME	The date in milliseconds using java.util.Date.getTime() when the task is scheduled to run next.
STARTBYINTERVAL	The start-by-interval of the task.
STARTBYTIME	Reserved.
VALIDFROMTIME	The task start time.
VALIDTOTIME	Reserved.
REPEATINTERVAL	The task repeat interval.
MAXREPEATS	The number of times to run the task.
REPEATSLEFT	The number of times the task has yet to run.
TASKINFO	Internal binary data.
NAME	The task name.
AUTOPURGE	The value, **1**, if the task is to automatically purge upon completion.
FAILUREACTION	Reserved.
MAXATTEMPTS	Reserved.
QOS	Reserved.
PARTITIONID	Reserved.
OWNERTOKEN	The task owner.
CREATETIME	The time in milliseconds using java.util.Date.getTime() when the task was created.

The TASK table also has the following indices that are required to allow the scheduler to run and access tasks concurrently:

- TASK_IDX1 – Used to access individual tasks using the Scheduler API.
- TASK_IDX2 – Used by the poll daemon to load expiring tasks.

TREG

The TREG table is used to store scheduler information that is shared between redundant schedulers. This table is not highly used.

Table 72. TREG table.. Displays scheduler information between redundant schedulers

Field name	Purpose and notes
REGKEY	The registry key. This is the primary key of the table.

Table 72. TREG table. (continued). Displays scheduler information between redundant schedulers

REGVALUE	The registry value.

LMGR

The LMGR table is used to track the leases that redundant schedulers use. This table is not highly used.

Table 73. LMGR table.. Displays redundant scheduler leases

Field name	Purpose and notes
LEASENAME	The name of the lease. This is the scheduler JNDI name and is the primary key.
LEASEOWNER	The owner of the lease. The format is `Cell/Node/Server`.
LEASE_EXPIRE_TIME	The time in milliseconds using java.util.Date.getTime() when the lease for the scheduler expires.
DISABLED	Reserved.

LMPR

The LMPR table is used to store arbitrary properties for the lease. This table is not highly utilized.

Table 74. LMPR table.. Displays arbitrary lease properties

Field name	Purpose and notes
LEASENAME	The name of the lease. See the LMGR table.
NAME	The name of the property.
VALUE	The value of the property.

The LMPR table also has the following index:

- LMPR_IDX1 – Used to retrieve properties for a given lease.

Creating scheduler tables using the administrative console

To create scheduler tables using the administrative console, the scheduler requires a database, a Java DataBase Connectivity (JDBC) provider and a data source.

Before you begin

Note: Limitations for Oracle XA databases

> Oracle XA prohibits required schema operations in a global transaction environment. Local transactions are not supported. If you have schedulers that use an Oracle XA data source, either temporarily change the scheduler configuration to use a non-XA Oracle data source, or create the tables manually using the supplied DDL files. If you use the administrative console to create or drop scheduler tables for a scheduler configured to use an Oracle XA data source, then you receive a SchedulerDataStoreException error message, and the operation fails.

Note: Limitations for DB2 z/OS databases

Creating and dropping tables using the administrative console is not supported for DB2 z/OS databases. A database administrator is typically involved with defining and managing databases on DB2 z/OS systems. The administration interface is targeted for the non-database administrator or developer who does not want to know the specifics of setting up the scheduler database. The scheduler has DDL files available for the database administrator to create the required tables.

Procedure

1. Verify that the database to be used for this scheduler is available and accessible by the application server. Review the Creating scheduler databases and tables topic for instructions on creating a database. The remaining steps describe how to create scheduler tables in an existing database.
2. Start the administrative console.
3. Create a JDBC data source that refers to the scheduler database.
4. Test the data source connection.
5. Create a scheduler. This configuration object contains the desired table prefix and the JNDI name of the JDBC data source. Verify that you save the new Scheduler to the configuration repository before you proceed to the next step.
6. Click **Resources** > **Schedulers** to view all defined schedulers.
7. Select one or more schedulers.
8. Click **Create Tables** to create the tables for the selected schedulers in their associated database. The tables and indices you created reflect the table prefixes and data sources specified in each scheduler configuration.
9. Restart the server or start the poll daemon to run scheduler tasks.

Results

Scheduler tables and schema are created.

Creating scheduler tables using scripting and Java Management Extensions

Creating scheduler tables using scripting and Java Management Extensions requires a database, a Java DataBase Connectivity (JDBC) provider, and a data source.

Before you begin

Attention: Limitations for Oracle XA databases

Oracle XA prohibits required schema operations in a global transaction environment. Local transactions are not supported. If you have schedulers that use an Oracle XA data source, either temporarily change the scheduler configuration to use a non-XA Oracle data source, or create the tables manually using the supplied DDL files. If you use the administrative console to create or drop scheduler tables for a scheduler configured to use an Oracle XA data source, then you receive a SchedulerDataStoreException error message, and the operation fails.

Attention: Limitations for DB2 z/OS databases

Creating and dropping tables using the administrative console is not supported for DB2 z/OS databases. A database administrator is typically involved with defining and managing databases on DB2 z/OS systems. The administration interface is targeted for the non-database administrator or developer who does not want to know the specifics of setting up the scheduler database. The scheduler has DDL files available for the database administrator to create the required tables.

Procedure

1. Verify that the database to be used for this Scheduler is available and accessible by the application server. Review the Creating scheduler databases and tables topic for instructions on creating a database. The remainder of these steps describe how to create scheduler tables in an existing database.
2. Launch the wsadmin tool and connect to an application server. This process requires an active server to be available and fails, if you are disconnected from the server.
3. Create a JDBC data source that refers to the scheduler database.
4. Test the data source connection.

5. Create a scheduler. This configuration object contains the desired table prefix and the JNDI name of the JDBC data source. Verify that you save the new Scheduler to the configuration before you proceed to the next step.
6. Run the **createTables** MBean operation.
   a. Look up the SchedulerConfiguration object or use the object you created in a previous step.
   b. Locate the **WASSchedulerConfiguration** MBean.
   c. Run one of the **createTables** MBean operation on the **WASSchedulerConfiguration** object to create the tables for the specified **SchedulerConfiguration** object in its associated database. The tables and indices that you created reflect the table prefix and data source specified in the scheduler configuration.
7. Restart the server or start the poll daemon to run scheduler tasks.

Results

Scheduler tables and schema are created.

Example: Using scripting to verify scheduler tables:

Use the wsadmin scripting tool to invoke a `Jacl` script and verify tables and indices for a scheduler.

The following `Jacl` example script can be invoked using the wsadmin scripting tool, which verifies that the tables and indices are created correctly for a scheduler. See the “Configuring Schedulers” topic for details on how a scheduler is created.

```
# Example JACL Script to verify the scheduler tables

# The name of the scheduler to verify
set schedName "My Scheduler"

puts ""
puts "Looking-up Scheduler Configuration Helper MBean"
puts ""
set schedHelper [$AdminControl queryNames WebSphere:*,type=WASSchedulerCfgHelper]

#Access the configuration object.
set myScheduler [$AdminConfig getid /SchedulerConfiguration:$schedName/]

if {$myScheduler == ""} {
    puts ""
    puts "Error: Scheduler $schedName could not be found."
    puts ""
    exit
}

# Invoke the verifyTables method on the helper MBean.

puts ""
puts "Verifying tables for:"
puts "$myScheduler"
puts ""

if { [catch {$AdminControl invoke $schedHelper verifyTables $myScheduler} errorInfo] } {
    puts ""
    puts "Error verifying tables: $errorInfo"
    puts ""
} else {
    puts ""
    puts "Tables verified successfully."
    puts ""
}
```

Example: Using scripting to create scheduler tables:

Use the wsadmin scripting tool to invoke a Jacl script and create scheduler tables.

The following Jacl example script can be invoked using the wsadmin scripting tool, which creates the scheduler tables for a configured scheduler. See the Configuring Schedulers topic for details on how to create a scheduler.

```
# Example JACL Script to create the scheduler tables

# The name of the scheduler to create tables for
set schedName "My Scheduler"

puts ""
puts "Looking-up Scheduler Configuration Helper MBean"
puts ""
set schedHelper [$AdminControl queryNames WebSphere:*,type=WASSchedulerCfgHelper]

#Access the configuration object.
set myScheduler [$AdminConfig getid /SchedulerConfiguration:$schedName/]

if {$myScheduler == ""} {
    puts ""
    puts "Error: Scheduler with name: $schedName could not be found."
    puts ""
    exit
}

# Invoke the createTables method on the helper MBean.

puts ""
puts "Creating tables for:"
puts "$myScheduler"
puts ""

if {[catch {
    set result [$AdminControl invoke $schedHelper createTables $myScheduler]
    if {$result} {
        puts ""
        puts "Successfully created the tables."
        puts ""
    } else {
        puts ""
        puts "The tables were already created."
        puts ""
    }
  } errorInfo ] } {
    puts ""
    puts $errorInfo
    puts ""
}
```

Example: Using scripting to drop scheduler tables:

Use the wsadmin scripting tool to invoke a Jacl script and remove scheduler tables.

The following Jacl example script can be invoked using the wsadmin scripting tool, which removes the scheduler tables for a configured scheduler. See the “Configuring Schedulers” topic for details on how a scheduler is created

```
# Example JACL Script to drop the scheduler tables

# The name of the scheduler to drop the tables for
set schedName "My Scheduler"

puts ""
puts "Looking-up Scheduler Configuration Helper MBean"
puts ""
```

```
set schedHelper [$AdminControl queryNames WebSphere:*,type=WASSchedulerCfgHelper]

#Access the configuration object.
set myScheduler [$AdminConfig getid /SchedulerConfiguration:$schedName/]

if {$myScheduler == ""} {
    puts ""
    puts "Error: Scheduler with name: $schedName could not be found."
    puts ""
    exit
}

# Invoke the dropTables method on the helper MBean.

puts ""
puts "Dropping tables for:"
puts "$myScheduler"
puts ""

if {[catch {
    set result [$AdminControl invoke $schedHelper dropTables $myScheduler]
    if {$result} {
        puts ""
        puts "Successfully dropped the tables."
        puts ""
    } else {
        puts ""
        puts "The tables were already dropped."
        puts ""
    }
  } errorInfo ] } {
    puts ""
    puts $errorInfo
    puts ""
}
```

Creating scheduler tables using DDL files

This topic provides the steps for creating scheduler tables using DDL files.

Before you begin

Your database system must be installed and available.

The scheduler requires a database, a Java™ Database Connectivity (JDBC) provider, and a data source.

About this task

Complete the following steps to create scheduler tables using DDL files.

Procedure

1. Verify that your database is created. Refer to the Creating scheduler databases topic.
2. Create the database tables according to the instructions for your database system:
   - Creating Apache Derby tables for schedulers
   - Creating DB2 tables for schedulers.
   - Creating DB2 tables for z/OS for schedulers.
   - Creating DB2 for iSeries tables for schedulers.
   - Creating Informix tables for schedulers.
   - Creating Microsoft SQL Server tables for schedulers.
   - Creating Oracle tables for schedulers.

- Creating Sybase tables for schedulers.

The following scripts are deprecated, but will still work:

Table 75. Deprecated scripts.. Deprecated DDL scripts

Deprecated script	New script
createSchemaDB2.ddl	createSchemaMod1DB2.ddl
createSchemaDB2iSeries.ddl	createSchemaMod1DB2iSeries.ddl
createSchemaDerby.ddl	createSchemaMod1Derby.ddl
createSchemaMSSQL.sql	createSchemaMod1MSSQL.sql
createSchemaInformix.sql	createSchemaMod1Informix.sql
createSchemaOracle.ddl	createSchemaMod1Oracle.ddl
createSchemaSybase12.ddl	createSchemaMod1Sybase12.ddl
dropSchemaMSSQL.sql	dropSchemaMod1MSSQL.sql
dropSchemaDB2.ddl	dropSchemaMod1DB2.ddl
dropSchemaDB2iSeries.ddl	dropSchemaMod1DB2iSeries.ddl
dropSchemaDerby.ddl	dropSchemaMod1Derby.ddl
dropSchemaInformix.sql	dropSchemaMod1Informix.sql
dropSchemaOracle.ddl	dropSchemaMod1Oracle.ddl
dropSchemaSybase12.ddl	dropSchemaMod1Sybase12.ddl

Creating Apache Derby tables for schedulers:

This topic describes how to create tables for schedulers on Apache Derby databases, using data definition language (DDL) or structured query language (SQL) files.

Before you begin

This task requires you to configure a database and make it available. Refer to the Creating Cloudscape databases for schedulers topic, for more information.

About this task

To create tables for schedulers on Apache Derby databases, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. Open a command-line window.
2. Create the schema.
   a. Using a text editor, edit the script, *%app_server_root%*\Scheduler\createSchemaMod1Derby.ddl, according to the instructions at the top of the file.

      Attention: When setting the table prefix, capitalize all characters.
   b. Enter one of the following commands.

      Attention: Apache Derby provides both an embedded and network server version. This example is for the embedded version of Apache Derby. See the Apache Derby product documentation for more details on running DDL scripts.
      On Windows systems (using the example name, scheddb):

      ```
      %app_server_root%\derby\bin\embedded\ij.bat %app_server_root%\Scheduler\createSchemaMod1Derby.ddl
      ```

On UNIX systems (using the example name, scheddb):

```
%app_server_root%/derby/bin/embedded/ij.sh %app_server_root%/Scheduler/createSchemaMod1Derby.ddl
```

Results

The Apache Derby tables and schema for the scheduler exist.

Creating DB2 tables for schedulers:

This topic describes how to create tables for scheduler on DB2 databases, using data definition language (DDL) or structured query language (SQL) files.

Before you begin

This task requires you to configure a database and make it available. Refer to the Creating DB2 databases for schedulers topic for more information.

About this task

To create tables for scheduler on DB2 databases, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. Open a DB2 command-line window.
2. Verify that you have administrator rights for the database system.
3. Create the table space and schema.
   a. Analyze the results of your experiences during development and system testing. The size of your database depends on many factors. If possible, distribute table space containers across different logical disks, and implement an appropriate security policy. Consider the performance implications of your choices for buffer pools and log file settings.
   b. Using a text editor, edit the following scripts according to the instruction at the top of each file.

      Note: When setting the table prefix, capitalize all characters.

      `%WAS_HOME%\Scheduler\createTablespaceDB2.ddl, %WAS_HOME%\Scheduler\createSchemaMod1DB2.ddl, %WAS_HOME%\Scheduler\dropSchemaMod1DB2.ddl, and %WAS_HOME%\Scheduler\dropTablespaceDB2.ddl.`
   c. Verify that you are attached to the correct instance. Check the environment variable DB2INSTANCE.
   d. To connect to the database, scheddb, for example, and enter the command:

      ```
      db2 connect to scheddb
      ```
   e. Create the table space. Enter the following command:

      ```
      db2 -tf createTablespaceDB2.ddl
      ```

      Verify that the script output contains no errors. If there were any errors, you can drop the table space using the following script:

      ```
      dropTablespaceDB2.ddl
      ```
   f. To create the schema (tables and indices), in the DB2 command line processor, enter the command `db2 -tf createSchemaMod1DB2.ddl`. Verify that the script output contains no errors. If there were any errors, you can use the following file to drop the schema:

      ```
      dropSchemaMod1DB2.ddl
      ```
   g. Verify that the DB2_RR_TO_RS DB2 flag is set to **YES** to avoid deadlocks. Restart the DB2 instance to activate the change, if needed.

Results

The DB2 tables and schema for the scheduler exist.

Creating DB2 for iSeries tables for schedulers:

This topic describes how to create tables for scheduler on DB2 for iSeries databases, using data definition language (DDL) or structured query language (SQL) files.

Before you begin

This task requires you to configure a database and make it available. See the " Creating DB2 for iSeries databases for schedulers" topic for more information.

About this task

To create tables for scheduler on DB2 for iSeries databases, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. Start a QShell session by running the following command from a CL command line:
   ```
   STRQSH
   ```
2. Create a new IFS directory under your profile directory:
   ```
   mkdir profile_root/scheduler
   ```
   Where *profile_root* is the fully qualified path of the directory that contains your profile.
3. Copy the following scripts to this new directory:
   ```
   %WAS_HOME%/scheduler/createDB2iSeriesSchema.ddl
   %WAS_HOME%/scheduler/dropSchemaDB2iSeries.ddl
   ```
4. Using a text editor, edit these scripts in the new directory. Replace all occurrences of @TABLE_PREFIX@ with <*collection_name*>, <*table_prefix*> where <*collection_name*> is the name of the collection that will be used to store the database files and is the collection that was created in the " Creating DB2 for iSeries databases for schedulers" topic. The <*table_prefix*> precedes each table name.
5. Use the iSeries Navigator to create the database files on your iSeries server.
   a. Start iSeries Navigator.
   b. Expand the iSeries icon to locate the system where you want to create the database files.
   c. Expand **Database**, and right-click the system database.
   d. Select **Run SQL Scripts**.
   e. Select **File** > **Open**.
   f. Navigate to the `createDB2iSeriesSchema.ddl` file in your profile directory.
   g. Select **Run** > **All**.
   h. Select **View** > **Job Log** to verify that the tables were created.
6. Execute the following command to change the owner for the new database files to QEJBSVR:
   ```
   CHGOBJOWN OBJ(*ALL) OBJTYPE(*ALL) NEWOWN(QEJBSVR)
   ```

Results

The DB2 for iSeries tables and schema for the scheduler exist.

Creating Informix tables for schedulers:

This topic describes how to create tables for schedulers on Informix databases, using data definition language (DDL) or structured query language (SQL) files.

Before you begin

This task requires that you configure a database and make it available. Refer to the Creating Informix databases for schedulers topic for more information.

About this task

To create tables for schedulers on Informix databases, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. Open a command-line window.
2. Verify that you have administrator rights for the database system.
3. Create the schema.
   a. Using a text editor, edit the script `%WAS_HOME%\Scheduler\createSchemaMod1Informix.sql` according to the instruction at the top of the file.

      Note: When setting the table prefix, capitalize all characters.
   b. Enter the following command, using the database, `scheddb`, for example:

      ```
      dbaccess scheddb createSchemaMod1Informix.sql
      ```

Results

The Informix tables and schema for the scheduler exist.

Creating Microsoft SQL Server tables for schedulers:

This topic describes how to create tables for schedulers on Microsoft SQL Server databases, using data definition language (DDL) or structured query language (SQL) files.

Before you begin

This task requires you to configure a database and make it available. Refer to the Creating Microsoft SQL Server databases for schedulers topic for more information.

About this task

To create tables for schedulers on Microsoft SQL Server databases, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. Open a command-line window.
2. Change to the directory where the configuration scripts for scheduler are located. This is the Scheduler subdirectory of the IBM WebSphere Application Server installation directory.
3. Use a text editor to edit the schema creation script, `createSchemaMod1MSSQL.sql`, according to the instructions at the beginning of the file.

   Tip: When setting the table prefix, capitalize all characters.
4. Create the schema:

a. Verify that you have administrator rights for the database system. The user ID you use to create the schema must be the one that you configure WebSphere Application Server to use when accessing the database.
b. Run the following script to create the schema (tables and views) :

```
sqlcmd -S <servername> -U<userid> -P<password> -d<databaseName> -i<script name>
```

Results

The Microsoft SQL Server tables and schema for scheduler exist.

Creating Oracle tables for schedulers:

This topic describes how to create tables for schedulers on Oracle databases, using data definition language (DDL) or structured query language (SQL) files.

Before you begin

This task requires you to configure a database and make it available. Refer to the Creating Oracle databases for schedulers topic for more information.

About this task

To create tables for schedulers on Oracle databases, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. Open a command-line window.
2. Make sure that you have administrator rights for the database system.
3. Create the table space and schema.
   a. Using a text editor, edit the following scripts according to the instructions at the top of the files.

      Tip: When setting the table prefix, capitalize all characters.

      %app_server_root%\Scheduler\createTablespaceOracle.ddl and *%app_server_root%*\createSchemaMod1Oracle.ddl
   b. Set the environment variable ORACLE_SID, if you do not want the schema to be created in the default instance.
   c. Run the script, createTablespaceOracle.ddl, to create the table space.

      For test purposes, use the same location for all table spaces and pass the path as a command line argument to the script.
   d. Run the script, createSchemaMod1Oracle.ddl, to create the schema.

Results

The Oracle tables and schema for scheduler exist.

Creating Sybase tables for schedulers:

This topic describes how to create tables for schedulers on Sybase databases, using data definition language (DDL) or structured query language (SQL) files.

Before you begin

This task requires you to configure a database and make it available. Refer to the Creating Sybase databases for schedulers topic for more information.

About this task

To create tables for schedulers on Sybase databases, using data definition language (DDL) or structured query language (SQL) files, use these steps.

Procedure

1. Open a command-line window.
2. Make sure that you have administrator rights for the database system.
3. Make sure that you have the Distributed Transaction Management (DTM) option for Sybase ASE installed.
   a. Set enable DTM to **1** in the Sybase server configuration.
   b. Set enable xact coordination to **1** in the Sybase server configuration.
   c. Add the **dtm_tm_role** role to the Sybase administration user ID. For example, enter the user ID `sa`.
   d. Restart the Sybase server.
4. Use the Sybase isql utility to create a database. For example, enter the database name `scheddb`. See your Sybase product documentation for details.
5. Create the schema:
   a. Using a text editor, edit the following script according to the instructions located at the top of the file.

      Tip: When setting the table prefix, capitalize all characters.

      app_server_root`\Scheduler\createSchemaMod1Sybase12.ddl`
   b. Enter the following command:

      ```
      isql -S <servername> -U <userid> -P <password> -D scheddb -i createSchemaMod1Sybase12.ddl
      ```

Results

The Sybase tables and schema for scheduler exist.

Chapter 23. Administering application security

Setting up, enabling and migrating security

You must address several issues prior to authenticating users, authorizing access to resources, securing applications, and securing communications. These security issues include migration, interoperability, and installation.

About this task

After installing WebSphere Application Server, you can determine the proper level of security that is needed for your environment. By default, administrative security is enabled and provides the authentication of users using the WebSphere administration functions, the use of Secure Sockets Layer (SSL), and the choice of user account repository.

You can also use the following permissions to enhance security:

- Use the getSSLConfig permission to give your application code the ability to call several of the JSSEHelper methods. For more information about these methods, see the description of the com.ibm.websphere.ssl.JSSEHelper API in the Programming interfaces section of the Information Center.
- Use the AdminPermission permission to give your application code the ability to call WebSphere Application Server administrative APIs. See the topic Setting Java 2 security permissions for an example of how to set this permission.
- Use the accessRuntimeClasses permission to give your application code the ability to load classes that are included with the product. If you are operating in an environment that normally restricts access to these classes, this permission enables your application code to bypass this restriction during class loading. See the topic Global security settings for a description of how to set this permission.

The following information is covered in this section:

Procedure

Enable security for all your application servers or for specific application servers in your realm.
For more information, see “Enabling security” on page 1172.

What to do next

After installing WebSphere Application Server and securing your environment, you must authenticate users. For more information, see “Authenticating users” on page 1254.

Migrating, coexisting, and interoperating – Security considerations

Use this topic to migrate the security configuration of previous WebSphere Application Server releases and its applications to the new installation of WebSphere Application Server.

Before you begin

This information addresses the need to migrate your security configurations from a previous release of IBM WebSphere Application Server to WebSphere Application Server 8.0. Complete the following steps to migrate your security configurations:

- If security is enabled in the previous release, obtain the administrative server ID and password of the previous release. This information is needed in order to run certain migration jobs.
- You can optionally disable security in the previous release before migrating the installation. No logon is required during the installation.

Note: In WebSphere Application Server Version 8.0, be aware of the following additional migration requirements for security:

- When migrating from WebSphere Application Server Version 7.x to Version 8.0, if you have a business need to preserve security audit logs from the older release you must first archive the security audit log files in Version 7.x. WebSphere Application Server does not support the migration of security audit log files from the older release to Version 8.0.
- If your WebSphere Application Server Version 7.x environment is enabled for Kerberos, and you are migrating to version 8.0 on a different machine, the keytab and configuration files for Kerberos must be at the same location on the Version 8.0 machine as on the Version 7.x machine or the configuration will not work.

Procedure

Follow the steps in "Migrating product configurations".

Results

The security configuration of previous WebSphere Application Server releases and its applications are migrated to the new installation of WebSphere Application Server Version 8.0.

What to do next

You must migrate any custom class files that are not migrated.

If the previous version instance is configured to enable secure connections using digital certificates that are signed by the Digital Certificate Manager (DCM) local certificate authority, those certificates must be renewed. For example, they must be renewed for the previous version instance, the WebSphere Application Server Version 8.0 profile, and all of the Secure Socket Layer-enabled clients and servers that connect to WebSphere Application Server. For more information, see SSL handshake failure using digital certificates signed by a Digital Certificate Manager (DCM) local certificate authority.

IBM i *SYSTEM certificate stores for applications are deprecated in WebSphere Application Server Version 5. In WebSphere Application Server Version 8.0, you must migrate your applications to use Java keystores.

Interoperating with previous product versions

IBM WebSphere Application Server inter-operates with the previous product versions. Use this topic to configure this behavior.

Before you begin

The current release of the Application Server distinguishes the identities of the user who acts as an administrator, managing the Application Server environment, from the identity of the user that is used for authenticating between servers. In prior releases, the end user had to specify a server user ID and password as the user identity for authenticating between servers. In the current release of the Application Server, the server user ID is generated automatically and internally; however, the end user can specify that the server user ID and password not be automatically generated. This option is especially important in the case of a mixed-release cell, where the server user ID and password are specified in a down-level version of the Application Server. In such a scenario, the end user should opt out of automatically generating the server user ID and instead use the server user ID and password that is specified in the down-level version of the Application Server, in order to ensure backwards compatibility.

Interoperability is achieved only when the Lightweight Third Party Authentication (LTPA) authentication mechanism and a distributed user registry is used such as Lightweight Directory Access Protocol (LDAP) or a distributed Custom user registry. LocalOS on most platforms is not considered a distributed user registry (except on z/OS within the z/OS environment).

Procedure

1. Configure WebSphere Application Server Version 8.0 with the same distributed user registry (that is, LDAP or Custom) that is configured with the previous version. Make sure that the same LDAP user registry is shared by all of the product versions.
   a. In the administrative console, select **Security > Global security**.
   b. Choose an available Realm definition and click **Configure**.
   c. Enter a **Primary administrative user name**. This identity is the user with administrative privileges that is defined in your local operating system. If you are not using the local OS ad the user registry, select the **Server identity that is stored in the user repository**, enter the Server user ID, and the associated password. The user name is used to log on to the administrative console when administrative security is enabled. WebSphere Application Server Version 6.1 requires an administrative user that is distinct from the server user identity so that administrative actions can be audited.

      Attention: In WebSphere Application Server, Version 6.0.x, a single user identity is required for both administrative access and internal process communication. When migrating to Version 8.0, this identity is used as the server user identity. You need to specify another user for the administrative user identity.
   d. When interoperating with Version 6.0.x or previous versions, you must select the Server identity that is stored in the user repository. Enter the **Server user id** and the associated **Password.**
2. Configure the LTPA authentication mechanism. Automatic generation of the LTPA keys should be disabled. If not, keys used by a previous release are lost. Export the current LTPA keys from WebSphere Application Server Version 8.0 and import them into the previous release.
   a. In the administrative console select **Security > Global security**.
   b. From Authentication mechanisms and expiration, click **LTPA**.
   c. Click the **Key set groups** link , then click the key set group that displays in the Key set groups panel.
   d. Clear the **Automatically generate keys** check box.
   e. Click **OK**, then click **Authentication mechanisms and expiration** in the path at the top of the Key set groups panel.
   f. Scroll down to the Cross-cell single sign-on section, and enter a password to use for encrypting the LTPA keys when adding them to the file.
   g. Enter the password again to confirm the password.
   h. Enter the **Fully qualified key file name** that contains the exported keys.
   i. Click **Export keys**.
   j. Follow the instructions provided in the previous release to import the exported LTPA keys into that configuration.
3. If you are using the default SSL configuration, extract all of the signer certificates from the WebSphere Application Server Version 8.0 common trust store. Otherwise, extract signers where necessary to import them into the previous release.
   a. In the administrative console, click **Security > SSL certificate and key management**.
   b. Click **Key stores and certificates**.
   c. Click **NodeDefaultTrustStore**.
   d. Click **Signer certificates**.
   e. Select one signer and click **Extract**.
   f. Enter a unique path and filename for the signer. For example, `/tmp/signer1.arm`.
   g. Click **OK**. Repeat for all of the signers in the trust store.
   h. Check other trust stores for other signers that might need to be shared with the other server. Repeat steps e through h to extract the other signers.

You can also import a signer certificate, which is also called a certificate authority (CA) certificate, from a truststore on a non-z/OS platform server to a z/OS keyring. the z/OS keyring contains the signer certificates that originated on the non-z/OS platform server. For more information, see Importing a signer certificate from a truststore to a z/OS keyring.

4. Add the exported signers to `DummyServerTrustFile.jks` and `DummyClientTrustFile.jks` in the `/etc` directory of the back-level product version. If the previous release is not using the dummy certificate, the signer certificate(s) from the previous release must be extracted and added into the WebSphere Application Server Version 8.0 release to enable SSL connectivity in both directions.
   a. Open the key management utility, iKeyman, for that product version.
   b. Start `ikeyman.bat` or `ikeyman.sh` from the `${USER_INSTALL_ROOT}/bin` directory.
   c. Select **Key Database File > Open**.
   d. Open `${USER_INSTALL_ROOT}/etc/DummyServerTrustFile.jks`.
   e. Enter WebAS for the password.
   f. Select **Add** and enter one of the files extracted in step 2. Continue until you have added all of the signers.
   g. Repeat steps c through f for the `DummyClientTrustFile.jks` file.
5. Verify that the application uses the correct Java Naming and Directory Interface (JNDI) name and naming bootstrap port for performing a naming lookup.
6. Stop and restart all of the servers.

Migrating trust association interceptors

Use this topic to manually migrate trust associations.

Before you begin

Note: Data sources are not supported for use within a Trust Association Interceptor (TAI). Data sources are intended for use within J2EE applications and designed to operate within the EJB and web containers. Trust Association Interceptors do not run within a container, and while data sources may function in the TAI environment, they are untested and not guaranteed to function properly.

The following topics are addressed in this document:
- Changes to the product-provided trust association interceptors
- Migrating product-provided trust association interceptors
- Changes to the custom trust association interceptors
- Migrating custom trust association interceptors

Changes to the product-provided trust association interceptors

For the product-provided implementation for the WebSEAL server, a new optional com.ibm.websphere.security.webseal.ignoreProxy property is added. If this property is set to `true` or `yes`, the implementation does not check for the proxy host names and the proxy ports to match any of the host names and ports that are listed in the com.ibm.websphere.security.webseal.hostnames and the com.ibm.websphere.security.webseal.ports property respectively. For example, if the VIA header contains the following information:

```
HTTP/1.1 Fred (Proxy), 1.1 Sam (Apache/1.1),
HTTP/1.1 webseal1:7002, 1.1 webseal2:7001
```

and the com.ibm.websphere.security.webseal.ignoreProxy property is set to `true` or `yes`, the host name `Fred`, is not used when matching the host names. By default, this property is not set, which implies that any proxy host names and ports that are expected in the VIA header are listed in the host names and the ports properties to satisfy the isTargetInterceptor method.

The previous VIA header information was split onto two lines for illustrative purposes only.

For more information about the com.ibm.websphere.security.webseal.ignoreProxy property, see the article in the information center on configuring single signon using trust association interceptor ++.

Migrating product-provided trust association interceptors

The properties that are located in the `webseal.properties` and `trustedserver.properties` files are not migrated from previous versions of WebSphere Application Server. You must migrate the appropriate properties to WebSphere Application Server Version 6.0.*x* using the trust association panels in the administrative console. For more information, see Configuring trust association interceptors.

Changes to the custom trust association interceptors

If the custom interceptor extends the com.ibm.websphere.security.WebSphereBaseTrustAssociationInterceptor property, implement the following new method to initialize the interceptor:

```
public int init (java.util.Properties props);
```

WebSphere Application Server checks the return status before using the trust association implementation. Zero (0) is the default value for indicating that the interceptor is successfully initialized.

However, if a previous implementation of the trust association interceptor returns a different error status, you can either change your implementation to match the expectations or make one of the following changes:

Method 1:

Add the com.ibm.websphere.security.trustassociation.initStatus property in the trust association interceptor custom properties. Set the property to the value that indicates the interceptor is successfully initialized. All of the other possible values imply failure. In case of failure, the corresponding trust association interceptor is not used.

Method 2:

Add the com.ibm.websphere.security.trustassociation.ignoreInitStatus property in the trust association interceptor custom properties. Set the value of this property to `true`, which tells WebSphere Application Server to ignore the status of this method. If you add this property to the custom properties, WebSphere Application Server does not check the return status, which is similar to previous versions of WebSphere Application Server.

The public int init (java.util.Properties props method replaces the public int init (String propsFile) method.

The init(Properties) method accepts a java.util.Properties object, which contains the set of properties that is required to initialize the interceptor. All of the properties set for an interceptor are sent to this method. The interceptor can then use these properties to initialize itself. For example, in the product-provided implementation for the WebSEAL server, this method reads the hosts and ports so that a request coming in can be verified to come from trusted hosts and ports. A return value of Zero (0) implies that the interceptor initialization is successful. Any other value implies that the initialization is not successful and the interceptor is not used.

The init(String) method still works if you want to use it instead of implementing the init(Properties) method. The only requirement is that you enter the file name containing the custom trust association properties using the **Custom Properties** link of the interceptor in the administrative console or by using scripts. You can enter the property using either of the following methods. The first method is used for backward compatibility with previous versions of WebSphere Application Server.

Method 1:

The same property names used in the previous release are used to obtain the file name. The file name is obtained by concatenating `.config` to the com.ibm.websphere.security.trustassociation.types property value. If the `myTAI.properties` file is located in the *`profile_root`*`/properties` directory, set the following properties:

- com.ibm.websphere.security.trustassociation.types = myTAItype
- com.ibm.websphere.security.trustassociation.myTAItype.config = *profile_root*/properties/myTAI.properties

Method 2:

You can set the com.ibm.websphere.security.trustassociation.initPropsFile property in the trust association custom properties to the location of the file. For example, set the following property:

```
com.ibm.websphere.security.trustassociation.initPropsFile=
profile_root/properties/myTAI.properties
```

The previous line of code is split into two lines for illustrative purposes only. Type as one continuous line.

However, it is highly recommended that your implementation be changed to implement the init(Properties) method instead of relying on the init (String propsfile) method.

Migrating custom trust association interceptors

The trust associations from previous versions of WebSphere Application Server are not automatically migrated to WebSphere Application Server Version 8.0. You can manually migrate these trust associations using the following steps:

Procedure

1. Recompile the implementation file, if necessary.

   For more information, refer to the "Changes to the custom trust association interceptors" section previously discussed in this document.

   a. Enter QSH from a command line to start the QShell environment.

   b. Change to the directory that contains your Java source file.

   c. Enter the command to recompile the implementation file.

```
javac -Djava.version=1.6 -classpath
app_server_root/plugins/com.ibm.ws.runtime.jar:install_root/dev/JavaEE/j2ee.jar your_implementation_file.java
```

2. Copy the custom trust association interceptor class files to a location in your product class path. Copy these class files into the *profile_root*/classes directory.
3. Start WebSphere Application Server.
4. Enable security to use the trust association interceptor. The properties that are located in your custom trust association properties file and in the trustedserver.properties file are not migrated from previous versions of WebSphere Application Server. You must migrate the appropriate properties to WebSphere Application Server Version 8.0 using the trust association panels in the administrative console.

   For more information, see Configuring trust association interceptors.

Migrating Common Object Request Broker Architecture programmatic login to Java Authentication and Authorization Service (CORBA and JAAS)

Use this topic as an example of how to perform programmatic login using the CORBA-based programmatic login APIs.

Before you begin

This document outlines the deprecated Common Object Request Broker Architecture (CORBA) programmatic login APIs and the alternatives that are provided by JAAS. WebSphere Application Server fully supports the Java Authentication and Authorization Service (JAAS) as programmatic login application programming interfaces (API). Refer to the *Securing applications and their environment* PDF for more details on JAAS support.

The following list includes the deprecated CORBA programmatic login APIs.

- `profile_root/installedApps/sampleApp.ear/default_app.war/WEB-INF/classes/ServerSideAuthenticator.java`.
- **org.omg.SecurityLevel2.Credentials**. This API is included with the product, but it is not recommended that you use the API.

The APIs that are provided in WebSphere Application Server are a combination of standard JAAS APIs and a product implementation of standard JAAS interfaces.

The following information is only a summary; refer to the JAAS documentation for your platform located at: http://www.ibm.com/developerworks/java/jdk/security/ .

- Programmatic login APIs:
  - javax.security.auth.login.LoginContext
  - javax.security.auth.callback.CallbackHandler interface: The WebSphere Application Server product provides the following implementation of the javax.security.auth.callback.CallbackHandler interface:
    com.ibm.websphere.security.auth.callback.WSCallbackHandlerImpl
    Provides a non-prompt CallbackHandler handler when the application pushes basic authentication data (user ID, password, and security realm) or token data to product login modules. This API is recommended for server-side login.
    com.ibm.websphere.security.auth.callback.WSGUICallbackHandlerImpl
    Provides a login prompt CallbackHandler handler to gather basic authentication data (user ID, password, and security realm). This API is recommended for client-side login.

    If this API is used on the server side, the server is blocked for input.
  - javax.security.auth.callback.Callback interface:
    javax.security.auth.callback.NameCallback
    Provided by JAAS to pass the user name to the LoginModules interface.
    javax.security.auth.callback.PasswordCallback
    Provided by JAAS to pass the password to the LoginModules interface.
    com.ibm.websphere.security.auth.callback.WSCredTokenCallbackImpl
    Provided by the product to perform a token-based login. With this API, an application can pass a token-byte array to the LoginModules interface.
  - **javax.security.auth.spi.LoginModule interface**

    WebSphere Application Server provides a LoginModules implementation for client and server-side login. Refer to the *Securing applications and their environment* PDF for details.
- javax.security.Subject:
  com.ibm.websphere.security.auth.WSSubject
  An extension provided by the product to invoke remote J2EE resources using the credentials in the javax.security.Subject
  com.ibm.websphere.security.cred.WSCredential
  After a successful JAAS login with the WebSphere Application Server LoginModules interfaces, a com.ibm.websphere.security.cred.WSCredential credential is created and stored in the Subject.
  com.ibm.websphere.security.auth.WSPrincipal
  An authenticated principal that is created and stored in a Subject that is authenticated by the WebSphere Application Server LoginModules interface.

Procedure

1. Use the following as an example of how to perform programmatic login using the CORBA-based programmatic login APIs: The CORBA-based programmatic login APIs are replaced by JAAS login.

   Note: The LoginHelper application programming interface (API) that is used in the following example is deprecated in WebSphere Application Server Version 8.0 and will be removed in a future release. It is recommended that you use the JAAS programmatic login APIs that are shown in the next step.

```
public class TestClient {
...
private void performLogin() {
// Get the ID and password of the user.
String userid = customGetUserid();
String password = customGetPassword();

// Create a new security context to hold authentication data.
LoginHelper loginHelper = new LoginHelper();
try {
// Provide the ID and password of the user for authentication.
org.omg.SecurityLevel2.Credentials credentials =
loginHelper.login(userid, password);

// Use the new credentials for all future invocations.
loginHelper.setInvocationCredentials(credentials);
// Retrieve the name of the user from the credentials
// so we can tell the user that login succeeded.

String username = loginHelper.getUserName(credentials);
System.out.println("Security context set for user: "+username);
} catch (org.omg.SecurityLevel2.LoginFailed e) {
// Handle the LoginFailed exception.
}
}
...
}
```

2. Use the following example to migrate the CORBA-based programmatic login APIs to the JAAS programmatic login APIs.

   The following example assumes that the application code is granted for the required Java 2 security permissions. For more information, see the *Securing applications and their environment* PDF and the JAAS documentation located at http://www.ibm.com/developerworks/java/jdk/security/.

```
public class TestClient {
...
private void performLogin() {
// Create a new JAAS LoginContext.
javax.security.auth.login.LoginContext lc = null;

try {
// Use GUI prompt to gather the BasicAuth data.
lc = new javax.security.auth.login.LoginContext("WSLogin",
new com.ibm.websphere.security.auth.callback.WSGUICallbackHandlerImpl());

// create a LoginContext and specify a CallbackHandler implementation
// CallbackHandler implementation determine how authentication data is collected
// in this case, the authentication date is collected by  login prompt
//   and pass to the authentication mechanism implemented by the LoginModule.
} catch (javax.security.auth.login.LoginException e) {
System.err.println("ERROR: failed to instantiate a LoginContext and the exception: "
+ e.getMessage());
e.printStackTrace();

// may be javax.security.auth.AuthPermission "createLoginContext" is not granted
//   to the application, or the JAAS Login Configuration is not defined.
}

if (lc != null)
try {
lc.login();  // perform login
javax.security.auth.Subject s = lc.getSubject();
// get the authenticated subject

// Invoke a J2EE resources using the authenticated subject
com.ibm.websphere.security.auth.WSSubject.doAs(s,
new java.security.PrivilegedAction() {
public Object run() {
try {
bankAccount.deposit(100.00);  // where bankAccount is an protected EJB
} catch (Exception e) {
System.out.println("ERROR: error while accessing EJB resource, exception: "
+ e.getMessage());
e.printStackTrace();
```

```
}
return null;
}
}
);

// Retrieve the name of the principal from the Subject
// so we can tell the user that login succeeded,
// should only be one WSPrincipal.
java.util.Set ps =
s.getPrincipals(com.ibm.websphere.security.auth.WSPrincipal.class);
java.util.Iterator it = ps.iterator();
while (it.hasNext()) {
com.ibm.websphere.security.auth.WSPrincipal p =
(com.ibm.websphere.security.auth.WSPrincipal) it.next();
System.out.println("Principal: " + p.getName());
}
} catch (javax.security.auth.login.LoginException e) {
System.err.println("ERROR: login failed with exception: " + e.getMessage());
e.printStackTrace();

// login failed, might want to provide relogin logic
}
}
...
}
```

Migrating from the CustomLoginServlet class to servlet filters

Use this topic to allow migration in an application that uses form-based login and servlet filters without the use of the CustomLoginServlet class.

Before you begin

The CustomLoginServlet class is deprecated in WebSphere Application Server Version 5. Those applications using the CustomLoginServlet class to perform authentication now need to use form-based login. Using the form-based login mechanism, you can control the look and feel of the login screen. In form-based login, a login page is specified and displays when retrieving the user ID and password information. You also can specify an error page that displays when authentication fails.

If login and error pages are not enough to implement the CustomLoginServlet class, use servlet filters. Servlet filters can dynamically intercept requests and responses to transform or use the information that is contained in the requests or responses. One or more servlet filters attach to a servlet or a group of servlets. Servlet filters also can attach to JavaServer Pages (JSP) files and HTML pages. All the attached servlet filters are called before invoking the servlet.

Both form-based login and servlet filters are supported by any Servlet 2.3 specification-compliant web container. A form login servlet performs the authentication and servlet filters can perform additional authentication, auditing, or logging tasks.

To perform pre-login and post-login actions using servlet filters, configure these servlet filters for either form login page or for /j_security_check URL. The j_security_check is posted by the form login page with the j_username parameter that contains the user name and the j_password parameter that contains the password. A servlet filter can use user name and password information to perform more authentication or meet other special needs.

Procedure

1. Develop a form login page and error page for the application.
   Refer to the *Securing applications and their environment* PDF for details.
2. Configure the form login page and the error page for the application.
   Refer to the *Securing applications and their environment* PDF for details.
3. Develop servlet filters if additional processing is required before and after form login authentication.

Refer to the *Securing applications and their environment* PDF for details.

4. Configure the servlet filters that are developed in the previous step for either the form login page URL or for the /j_security_check URL. Use an assembly tool or development tools like Rational Application Developer to configure filters. After configuring the servlet filters, the `web-xml` file contains two stanzas. The first stanza contains the servlet filter configuration, the servlet filter, and its implementation class. The second stanza contains the filter mapping section and a mapping of the servlet filter to the URL.

   For more information, see the *Securing applications and their environment* PDF.

Results

This migration results in an application that uses form-based login and servlet filters without the use of the CustomLoginServlet class.

What to do next

The new application uses form-based login and servlet filters to replace the CustomLoginServlet class. Servlet filters also are used to perform additional authentication, auditing, and logging.

Migrating Java 2 security policy

Use this topic for guidance pertaining to migrating Java 2 security policy.

About this task

Previous WebSphere Application Server releases

WebSphere Application Server uses the Java 2 security manager in the server runtime to prevent enterprise applications from calling the System.exit and the System.setSecurityManager methods. These two Java application programming interfaces (API) have undesirable consequences if called by enterprise applications. The System.exit API, for example, causes the Java virtual machine (application server process) to exit prematurely, which is not a beneficial operation for an application server.

To support Java 2 security properly, all the server runtime must be marked as `privileged` (with doPrivileged API calls inserted in the correct places), and identify the default permission sets or policy. Application code is not privileged and subject to the permissions that are defined in the policy files. The doPrivileged instrumentation is important and necessary to support Java 2 security. Without it, the application code must be granted the permissions that are required by the server runtime. This situation is due to the design and algorithm that is used by Java 2 security to enforce permission checks. Refer to the Java 2 security check permission algorithm.

The following two permissions are enforced by the Java 2 security manager (hard coded) for WebSphere Application Server:

- java.lang.RuntimePermission(exitVM)
- java.lang.RuntimePermission(setSecurityManager)

Application code is denied access to these permissions regardless of what is in the Java 2 security policy. However, the server runtime is granted these permissions. All the other permission checks are not enforced.

Only two permissions are supported:

- java.net.SocketPermission
- java.net.NetPermission

However, not all the product server runtime is properly marked as privileged. You must grant the application code all the other permissions besides the two listed previously or the enterprise application can potentially fail to run. This Java 2 security policy for enterprise applications is liberal.

What changed

Java 2 Security is fully supported in WebSphere Application Server, which means that all permissions are enforced. The default Java 2 security policy for an enterprise application is the recommended permission set defined by the Java Platform, Enterprise Edition (Java EE) Version 1.4 specification. Refer to the *profile_root*/config/cells/*cell_name*/nodes/*node_name*/app.policy file for the default Java 2 security policy that is granted to enterprise applications. This policy is a much more stringent compared to previous releases.

All policy is declarative. The product security manager honors all policy that is declared in the policy files. There is an exception to this rule: enterprise applications are denied access to permissions that are declared in the *profile_root*/config/cells/*cell_name*/filter.policy file.

Note: The default Java 2 security policy for enterprise applications is much more stringent and all the permissions are enforced in WebSphere Application Server Version 8.0. The security policy might fail because the application code does not have the necessary permissions granted where system resources, such as file I/O, can be programmatically accessed and are now subject to the permission checking.

In application code, do not use the setSecurityManager permission to set a security manager. When an application uses the setSecurityManager permission, there is a conflict with the internal security manager within WebSphere Application Server. If you must set a security manager in an application for RMI purposes, you also must enable the **Use Java 2 security to restrict application access to local resources** option on the Global security page within the WebSphere Application Server administrative console. WebSphere Application Server then registers a security manager. The application code can verify that this security manager is registered by using System.getSecurityManager() application programming interface (API).

Migrating system properties

The following system properties are used in previous releases in relation to Java 2 security:

- **java.security.policy**. The absolute path of the policy file (action required). This system property contains both system permissions (permissions granted to the Java virtual machine (JVM) and the product server runtime) and enterprise application permissions. Migrate the Java 2 security policy of the enterprise application to Version 8.0. For Java 2 security policy migration, see the steps for migrating Java 2 security policy.
- **enableJava2Security**. Used to enable Java 2 security enforcement (no action required). This system property is deprecated; a flag in the WebSphere configuration application programming interface (API) is used to control whether to enable Java 2 security. Enable this option through the administrative console.
- **was.home**. Expanded to the installation directory of WebSphere Application Server (action might be required). This system property is deprecated; superseded by the ${user.install.root} and ${was.install.root} properties. If the directory contains instance-specific data then ${user.install.root} is used; otherwise ${was.install.root} is used. Use these properties interchangeably for the WebSphere Application Server or the WebSphere Application Server, Network Deployment environments. See the steps for migrating Java 2 security policy.

Migrating the Java 2 Security Policy

No easy way exists to migrate the Java policy file to Version 8.0 automatically because of a mixture of system permissions and application permissions in the same policy file. Manually copy the Java 2 security policy for enterprise applications to a was.policy or app.policy file. However, migrating the Java 2 security policy to a was.policy file is preferable because symbols or relative code base is used instead of an absolute code base. This process has many advantages. Grant the permissions that are defined in the was.policy to the specific enterprise application only, while permissions in the app.policy file apply to all the enterprise applications that run on the node where the app.policy file belongs.

Refer to the *Securing applications and their environment* PDF for more details on policy management.

The following example illustrates the migration of a Java 2 security policy from a previous release. The contents include the Java 2 security policy file for the `app1.ear` enterprise application and the system permissions, which are permissions that are granted to the Java virtual machine (JVM) and the product server runtime.

The default location for the Java 2 security policy file is *profile_root*`/properties/java.policy`. Default permissions are omitted for clarity:

```
// For product Samples
   grant codeBase "file:${app_server_root}/installedApps/app1.ear/-" {
     permission java.security.SecurityPermission "printIdentity";
     permission java.io.FilePermission "${app_server_root}${/}temp${/}somefile.txt",
       "read";
   };
```

For clarity of illustration, all the permissions are migrated as the application level permissions in this example. However, you can grant permissions at a more granular level at the component level (Web, enterprise beans, connector or utility Java archive (JAR) component level) or you can grant permissions to a particular component.

Procedure

1. Ensure that Java 2 security is disabled on the application server.
2. Create a new `was.policy` file, if the file is not present, or update the `was.policy` file for migrated applications in the configuration repository with the following contents:

   ```
   grant codeBase "file:${application}" {
        permission java.security.SecurityPermission "printIdentity";
        permission java.io.FilePermission "
                ${user.install.root}${/}temp${/}somefile.txt", "read";
      };
   ```

   The third and fourth lines in the previous code sample are presented on two lines for illustrative purposes only.

   The `was.policy` file is located in the *profile_root*`/config/cells/`*cell_name*`/applications/app.ear/deployments/app/META-INF/` directory.
3. Use an assembly tool to attach the `was.policy` file to the enterprise archive (EAR) file.

   You also can use an assembly tool to validate the contents of the `was.policy` file. For more information, see the *Securing applications and their environment* PDF.
4. Validate that the enterprise application does not require additional permissions to the migrated Java 2 security permissions and the default permissions set declared in the `${user.install.root}/config/cells/`*cell_name*`/nodes/`*node_name*`/app.policy` file. This validation requires code review, code inspection, application documentation review, and sandbox testing of migrated enterprise applications with Java 2 security enabled in a preproduction environment. Refer to developer kit APIs protected by Java 2 security for information about which APIs are protected by Java 2 security. If you use third-party libraries, consult the vendor documentation for APIs that are protected by Java 2 security. Verify that the application is granted all the required permissions, or it might fail to run when Java 2 security is enabled.
5. Perform preproduction testing of the migrated enterprise application with Java 2 security enabled. Enable trace for the WebSphere Application Server Java 2 security manager in a preproduction testing environment with the following trace string: `com.ibm.ws.security.core.SecurityManager=all=enabled`. This trace function can be helpful in debugging the AccessControlException exception that is created when an application is not granted the required permission or some system code is not properly marked as privileged. The trace dumps the stack trace and permissions that are granted to the classes on the call stack when the exception is created.

   For more information, see the *Securing applications and their environment* PDF.

Note: Because the Java 2 security policy is much more stringent compared with previous releases, the administrator or deployer must review their enterprise applications to see if extra permissions are required before enabling Java 2 security. If the enterprise applications are not granted the required permissions, they fail to run.

Migrating with Tivoli Access Manager for authentication enabled

When Tivoli Access Manager security is configured for your existing environment and security is enabled, you can migrate to WebSphere Application Server, Version 8.0.

Before you begin

Your profiles must be migrated using the migration tools to migrate product configurations.

Important: Do not restart the WebSphere Application Server Version 8.0 server until after performing the following procedure. The migration tools omit some files that enable the server to start correctly.

About this task

After migrating your profiles, additional steps are required when Tivoli Access Manager security is configured.

Note: WebSphere Application Server Version 8.0 hosts Tivoli Access Manager specific files under the `%WAS_HOME%/tivoli/tam` directory. In previous versions, these files were hosted under the `%WAS_HOME%/java/jre/` hierarchy.

Procedure

1. Copy the `profile_root1/PolicyDirector` directory and it's contents to `profile_root2/PolicyDirector`. For this example:
   - *profile_root1* is the root directory of the profile being migrated.
   - *profile_root2* is the root directory of the version 6.1 profile.
   a. From an IBM i command line, type **STRQSH** and press **Enter**.
   b. Type `cp -R profile_root1/PolicyDirector profile_root2` and press **Enter**.
2. Copy the key file of the profile being migrated to the version 8.0 profile. The location of the key file is defined in `profile_root1/PolicyDirector/PdPerm.properties`. For this example:
   - The `PdPerm.properties` file contains *pdcert-url=file\:/QIBM/UserData/WebAS51/Base/AppSvr1/etc/AppSvr1.kdb*.
   - `/QIBM/UserData/WebAS51/Base/AppSvr1` is the root directory of a Version 6.1 profile.
   a. From an IBM i command line type **STRQSH** and press **Enter**.
   b. Type `cp /QIBM/UserData/WebAS51/Base/AppSvr1/etc/AppSvr1.kdb profile_root2/etc/AppSvr1.kdb` and press **Enter**.
3. Edit the property values in `profile_root2/PolicyDirector/PdPerm.properties` and in `profile_root2/PolicyDirector/Pd.properties` to replace occurrences of *profile_root1* with *profile_root2* in the file path name values.

Migrating Java thin clients that use the password encoding algorithm

To migrate Java thin clients that are enabled for OS400 password encoding, use the following information to modify the Java client invocation so that the os400.security.password properties are no longer set on the invocation.

About this task

The password encoding feature offers the following encoding algorithms:

- XOR, which is the default
- OS400

In Version 5 and later, the value of the os400.security.password.validation.list.object property is dependant upon the property value passed to the thin client using the JAVA_FLAGS environment variable. The JAVA_FLAGS environment variable is set by the **setupClient** script. The **setupClient** script calls the **setupCmdLine** script, which is where the value for the os400.security.password.validation.list.object property is set. For example, if a Version 6.*x* Base Edition Java client is passed **-profileName default**, then the **setupClient** script calls the *profile_root*/default/bin/setupCmdLine file.

To migrate Java thin clients that are enabled for OS400 password encoding, modify the Java client invocation so that the os400.security.password properties are no longer set on the invocation. The following code sample does not contain the os400.security.password properties:

```
java -classpath $MY_CLIENT_CLASSES:app_server_root/classes/wsa400.jar:$WAS_CLASSPATH \
  $CLIENTSAS $JAVA_FLAGS \
  -Djava.naming.factory.initial=com.ibm.websphere.naming.WsnInitialContextFactory \
  -Djava.naming.provider.url=iiop://server1:10151 \
  MyClientClass $*
```

Perform the following steps if the following condition is true:

- If the passwords in the sas.client.props file for that profile are encoded with the OS400 password encoding algorithm

Procedure

1. Replace all of the OS400 encoded passwords, which have {OS400}) prefixes in the sas.client.props file for the Application Server profile, with the clear text values of the passwords.
2. Encode the passwords using the **PropFilePasswordEncoder** Qshell command.

   For more information, see PropFilePasswordEncoder command reference.

Results

Attention: You can configure a WebSphere Application Server profile to encode passwords with the XOR algorithm even though the profile is enabled to decode passwords that were encoded with either the OS400 algorithm or the XOR algorithm. If you encode these passwords with the XOR algorithm, then the passwords in the sas.client.props file are encoded with the XOR algorithm.

Enabling security

The following provides information on how to configure security when security was not enabled during the WebSphere Application Sever profile creation.

Before you begin

When you are installing WebSphere Application Server, it is recommended that you install with security enabled. By design, this option ensures that everything has been properly configured. By enabling security, you protect your server from unauthorized users and are then able to provide application isolation and requirements for authenticating application users.

It is helpful to understand security from an infrastructure perspective so that you know the advantages of different authentication mechanisms, user registries, authentication protocols, and so on. Picking the right security components to meet your needs is a part of configuring security. The following sections help you make these decisions.

Read the following articles before continuing with the security configuration:
- Server and administrative security
- Security

After you understand the security components, you can proceed to configure security in WebSphere Application Server.

Procedure

1. Start the WebSphere Application Server administrative console.

   If security is currently disabled, you are prompted for a user ID. Log in with any user ID. However, if security is currently enabled, you are prompted for both a user ID and a password. Log in with a predefined administrative user ID and password.

2. Click **Security > Global security**.

   Use the Security Configuration Wizard, or configure security manually. The configuration order is not important.

   gotcha: You must separately enable administrative security, and application security. Because of this split, WebSphere Application Server clients must know whether application security is disabled at the target server. Administrative security is enabled, by default. Application security is disabled, by default. Before you attempt to enable application security on the target server, verify that administrative security is enabled on that server. Application security can be in effect only when administrative security is enabled.

   For more information on manual configuration, see “Authenticating users” on page 1254.

3. Configure the user account repository. For more information, see “Selecting a registry or repository” on page 1254. On the Global security panel, you can configure user account repositories such as federated repositories, local operating system, stand-alone Lightweight Directory Access Protocol (LDAP) registry, and stand-alone custom registry.

   Note: You can choose to specify either a server ID and password for interoperability or enable a WebSphere Application Server installation to automatically generate an internal server ID. For more information about automatically generating server IDs, see “Local operating system settings” on page 1259.

   One of the details common to all user registries or repositories is the *Primary administrative user name*. This ID is a member of the chosen repository, but also has special privileges in WebSphere Application Server. The privileges for this ID and the privileges that are associated with the administrative role ID are the same. The Primary administrative user name can access all of the protected administrative methods.

   In stand-alone LDAP registries, verify that the Primary administrative user name is a member of the repository and not just the LDAP administrative role ID. The entry must be searchable.

   The Primary administrative user name does **not** run WebSphere Application Server processes. Rather, the process ID runs the WebSphere Application Server processes.

   In the default configuration, WebSphere Application Server processes run under the QEJBSVR system-provided user profile.

4. Select the **Set as current** option after you configure the user account repository. When you click **Apply** and the Enable administrative security option is set, a verification occurs to see if an administrative user ID has been configured and is present in the active user registry. The administrative user ID can be specified at the active user registry panel or from the console users link. If you do not configure an administrative ID for the active user registry, the validation fails.

   Note: When you switch user registries, the `admin-authz.xml` file should be cleared of existing administrative ids and application names. Exceptions will occur in the logs for ids that exist in the `admin-authz.xml` file but do not exist in the current user registry.

5. Configure the authentication mechanism.

Configure Lightweight Third-Party Authentication (LTPA) or Kerberos, which is new to this release of WebSphere Application Server, under Authentication mechanisms and expiration. LTPA credentials can be forwarded to other machines. For security reasons, credential expire; however, you can configure the expiration dates on the console. LTPA credentials enable browsers to visit different product servers, which means you do not have to authenticate multiple times. For more information, see Configuring the Lightweight Third Party Authentication mechanism

Note: You can configure Simple WebSphere Authentication Mechanism (SWAM) as your authentication mechanism. However, SWAM was deprecated in WebSphere Application Server Version 8.0 and will be removed in a future release. SWAM credentials are not forwardable to other machines and for that reason do not expire.

6. Optional: Import and export the LTPA keys for cross-cell single Sign-on (SSO) between cells. For more information, see the following articles:
   - Exporting Lightweight Third Party Authentication keys.
   - Importing Lightweight Third Party Authentication keys

   gotcha: If one of the cells you are connecting to resides on a Version 6.0.x system, see the topic Configuring Lightweight Third Party Authentication keys in the Version 6.0.x Information Center for more information.
7. Configure the authentication protocol for special security requirements from Java clients, if needed.

   You can configure Common Secure Interoperability Version 2 (CSIv2) through links on the Global security panel. The Security Authentication Service (SAS) protocol is provided for backwards compatibility with previous product releases, but is deprecated. Links to the SAS protocol panels display on the Global security panel if your environment contains servers that use previous versions of WebSphere Application Server and support the SAS protocol. For details on configuring CSIv2 or SAS, see the article, “Configuring Common Secure Interoperability Version 2 (CSIV2) inbound and outbound communication settings” on page 1561.

   Attention: IBM no longer ships or supports the Secure Authentication Service (SAS) IIOP security protocol. It is recommended that you use the Common Secure Interoperability version 2 (CSIv2) protocol.
8. Click **Security > Global security** to configure the rest of the security settings and enable security. For information about these settings, see “Global security settings” on page 1187.
9. Validate the completed security configuration by clicking **OK** or **Apply**. If problems occur, they display at the top of the console page in red type.
10. If there are no validation problems, click **Save** to save the settings to a file that the server uses when it restarts. Saving writes the settings to the configuration repository.

    Important: If you do not click **Apply** or **OK** in the Global security panel before you click **Save**, your changes are not written to the repository. The server must be restarted for any changes to take effect when you start the administrative console.
11. Start the WebSphere Application Server administrative console.

    If security is currently disabled, log in with any user ID. If security is currently enabled, log in with a predefined administrative ID and password. This ID is typically the server user ID that is specified when you configured the user registry.

Administrative security

Administrative security determines whether security is used at all, the type of registry against which authentication takes place, and other values, many of which act as defaults. Proper planning is required because incorrectly enabling administrative security can lock you out of the administrative console or cause the server to end abnormally.

Note: It is strongly recommended that you allow the default installation to install administrative security as on by default.

Administrative security can be thought of as a "big switch" that activates a wide variety of security settings for WebSphere Application Server. Values for these settings can be specified, but they will not take effect until administrative security is activated. The settings include the authentication of users, the use of Secure Sockets Layer (SSL), and the choice of user account repository. In particular, application security, including authentication and role-based authorization, is not enforced unless administrative security is active. Administrative security is enabled by default.

Note: Administrative security need not be activated in order for WebSphere applications to make use of JSSE methods to encrypt communication to remote sites.

Administrative security represents the security configuration that is effective for the entire security domain. A *security domain* consists of all of the servers that are configured with the same user registry *realm* name. In some cases, the realm can be the machine name of a local operating system registry. In this case, all of the application servers must reside on the same physical machine. In other cases, the realm can be the machine name of a stand-alone Lightweight Directory Access Protocol (LDAP) registry.

The basic requirement for a security domain is that the access ID that is returned by the registry or repository from one server within the security domain is the same access ID as that returned from the registry or repository on any other server within the same security domain. The *access ID* is the unique identification of a user and is used during authorization to determine if access is permitted to the resource.

The administrative security configuration applies to every server within the security domain.

Why turn on administrative security?

Turning on administrative security activates the settings that protect your server from unauthorized users. Administrative security is enabled by default during the profile creation time. There might be some environments where no security is needed such as a development system. On these systems you can elect to disable administrative security. However, in most environments you should keep unauthorized users from accessing the administrative console and your business applications. Administrative security must be enabled to restrict access.

What does administrative security protect?

The configuration of administrative security for a security domain involves configuring the following technologies:

- Authentication of HTTP clients
- Authentication of IIOP clients
- Administrative console security
- Naming security
- Use of SSL transports
- Role-based authorization checks of servlets, enterprise beans, and mbeans
- Propagation of identities (RunAs)
- The common user registry
- The authentication mechanism
- Other security information that defines the behavior of a security domain includes:
  - The authentication protocol (Remote Method Invocation over the Internet Inter-ORB Protocol (RMI/IIOP) security)
  - Other miscellaneous attributes

Note: It is recommended that before registering a node with an administrative agent process, that you first have administrative security enabled in the administrative agent and base profile. Once you register a profile with the administrative agent, the state of administrative security enablement cannot be changed.

Application security

Application security enables security for the applications in your environment. This type of security provides application isolation and requirements for authenticating application users

In previous releases of WebSphere Application Server, when a user enabled global security, both administrative and application security were enabled. In WebSphere Application Server Version 6.1, the previous notion of global security is split into administrative security and application security, each of which you can enable separately.

As a result of this split, WebSphere Application Server clients must know whether application security is disabled at the target server. Administrative security is enabled, by default. Application security is disabled, by default. Before you can enable application security, you must verify that administrative security is enabled. Application security is in effect only when administrative security is enabled.

An Application Server Enablement Tag, which is specific to WebSphere Application Server, is imported into the Interoperable Object Reference (IOR) to indicate if application security is disabled for the server where the object lives. This tag is server-specific and enables clients to know when application security is disabled at the target server of its request.

For web resources, when application security is enabled, security constraints on those resources in web.xml are enforced. When accessing a protected resource, a web client is prompted for authentication.

For enterprise bean resources, when application security is disabled, the client Common Secure Interoperability version 2 (CSIv2) code ignores the CSIv2 security tags for objects that are unknown system objects. When pure clients see that application security is disabled, these clients prompt for naming lookups, but do not prompt for enterprise bean operations.

Java 2 security

Java 2 security provides a policy-based, fine-grain access control mechanism that increases overall system integrity by checking for permissions before allowing access to certain protected system resources. Java 2 security guards access to system resources such as file I/O, sockets, and properties. Java 2 Platform, Enterprise Edition (J2EE) security guards access to web resources such as servlets, JavaServer Pages (JSP) files and Enterprise JavaBeans (EJB) methods.

Because Java 2 security is relatively new, many existing or even new applications might not be prepared for the very fine-grain access control programming model that Java 2 security is capable of enforcing. Administrators need to understand the possible consequences of enabling Java 2 security if applications are not prepared for Java 2 security. Java 2 security places some new requirements on application developers and administrators.

Important: Java 2 security only restricts Java programs that run in a Java virtual machine that has Java 2 security enabled. It does not protect system resources if Java 2 Security is disabled or if system resources are accessed from other programs or commands. Therefore, if you want to protect your system resources, you need to use operating system security.

Note: The application server does not support a custom Java security manager implementation.

Java 2 security for deployers and administrators

Although Java 2 security is supported, it is disabled by default. You can configure Java 2 security and administrative security independently of one another. Disabling administrative security does not disable Java 2 security automatically. You need to explicitly disable it.

If your applications, or third-party libraries are not ready, having Java 2 security enabled causes problems. You can identify these problems as Java 2 security AccessControlExceptions in the system log or trace files. If you are unsure about the Java 2 security readiness of your applications, disable Java 2 security initially to get your application installed and verify that it is working properly.

The policy embodied by these policy files cannot be made more restrictive because the product might not have the necessary Java 2 security doPrivileged APIs in place. The restrictive policy is the default policy. You can grant additional permissions, but you cannot make the default more restrictive because AccessControlExceptions exceptions are generated from within WebSphere Application Server. The product does not support a more restrictive policy than the default that is defined in the policy files previously mentioned.

Several policy files are used to define the security policy for the Java process. These policy files are static (code base is defined in the policy file) and in the default policy format provided by the IBM Developer Kit, Java Technology Edition. For enterprise application resources and utility libraries, WebSphere Application Server provides dynamic policy support. The code base is dynamically calculated based on deployment information and permissions are granted based on template policy files during runtime. Refer to the “Java 2 security policy files” on page 1181 for more information.

Syntax errors in the policy files cause the application server process to fail, so edit these policy files carefully.

Note: Edit these policy files using the Policy Tool that is provided by the IBM Developer Kit, Java Technology Edition. See Using PolicyTool to edit policy files for Java 2 security for more information.

If an application is not prepared for Java 2 security, if the application provider does not provide a `was.policy` file as part of the application, or if the application provider does not communicate the expected permissions the application is likely to cause Java 2 security access control exceptions at runtime. It might not be obvious that an application is not prepared for Java 2 security. Several run-time debugging aids help troubleshoot applications that might have access control exceptions. See the Java 2 security debugging aids for more details. See “Handling applications that are not Java 2 security ready” on page 1179 for information and strategies for dealing with such applications.

It is important to note when Java Security is enabled in the administrative security settings, the installed security manager does not currently check modifyThread and modifyThreadGroup permissions for non-system threads. Allowing web and Enterprise JavaBeans (EJB) application code to create or modify a thread can have a negative impact on other components of the container and can affect the capability of the container to manage enterprise bean life cycles and transactions.

Java 2 security for application developers

Application developers must understand the permissions that are granted in the default WebSphere policy and the permission requirements of the SDK APIs that their application calls to know whether additional permissions are required. The Permissions in the Java 2 SDK reference in the resources section describes which APIs require which permission.

Application providers can assume that applications have the permissions granted in the default policy previously mentioned. Applications that access resources not covered by the default WebSphere policy are required to grant the additional Java 2 security permissions to the application.

While it is possible to grant the application additional permissions in one of the other dynamic WebSphere policy files or in one of the more traditional `java.policy` static policy files, the `was.policy` file, which is embedded in the EAR file ensures the additional permissions are scoped to the exact application that requires them. Scoping the permission beyond the application code that requires it can permit code that normally does not have permission to access particular resources.

If an application component is being developed, like a library that might actually be included in more than one `.ear` file, then the library developer needs to document the required Java 2 permissions that are required by the application assembler. There is no `was.policy` file for library-type components. The developer must communicate the required permissions through application programming interface (API) documentation or some other external documentation.

If the component library is shared by multiple enterprise applications, the permissions can be granted to all enterprise applications on the node in the `app.policy` file.

Note: Updates to the `app.policy` file only apply to the enterprise applications on the node to which the `app.policy` file belongs.

If the permission is only used internally by the component library and the application is never granted access to resources that are protected by the permission, it might be necessary to mark the code as **privileged**. Refer to the, AccessControlException, topic for more details. However, improperly inserting a doPrivileged call might open up security holes. Understand the implication of doPrivileged call to make a correct judgement.

The section on Dynamic policy files in “Java 2 security policy files” on page 1181 describes how the permissions in the `was.policy` files are granted at runtime.

Developing an application to use with Java 2 security might be a new skill and impose a security awareness not previously required of application developers. Describing the Java 2 security model and the implications on application development is beyond the scope of this section. The following URL can help you get started: http://java.sun.com/j2se/1.5.0/docs/guide/security/index.html.

Debugging Aids

The WebSphere Application Server SYSOUT file and the com.ibm.websphere.java2secman.norethrow property are the two primary aids for debugging.

The WebSphere System Log or Trace Files

The AccessControl exception that is logged in the system log or trace files contains the permission violation that causes the exception, the exception call stack, and the permissions granted to each stack frame. This information is usually enough to determine the missing permission and the code requiring the permission.

The com.ibm.websphere.java2secman.norethrow property

When Java 2 security is enabled in WebSphere Application Server, the security manager component creates a java.security.AccessControl exception when a permission violation occurs. This exception, if not handled, often causes a run-time failure. This exception is also logged in the SYSOUT file.

However, when the Java virtual machine com.ibm.websphere.java2secman.norethrow property is set and has a value of `true`, the security manager does not create the AccessControl exception. This information is logged.

This property is intended for a sandbox or debug environment because it instructs the security manager not to create the AccessControl exception. Java 2 security is not enforced. Do not use this property in a production environment where a relaxed Java 2 security environment weakens the integrity that Java 2 security is intended to produce.

This property is valuable in a sandbox or test environment where the application can be thoroughly tested and where the system log or trace files can be inspected for AccessControl exceptions. Because this property does not create the AccessControl exception, it does not propagate the call stack and does not cause a failure. Without this property, you have to find and fix AccessControl exceptions one at a time.

Handling applications that are not Java 2 security ready

If the increased system integrity that Java 2 security provides is important, then contact the application provider to have the application support Java 2 security or at least communicate the required additional permissions beyond the default WebSphere Application Server policy that must be granted.

The easiest way to deal with such applications is to disable Java 2 security in WebSphere Application Server. The downside is that this solution applies to the entire system and the integrity of the system is not as strong as it might be. Disabling Java 2 security might not be acceptable depending on the organization security policies or risk tolerances.

Another approach is to leave Java 2 security enabled, but to grant either just enough additional permissions or grant all permissions to just the problematic application. Granting permissions however, might not be a trivial thing to do. If the application provider has not communicated the required permissions in some way, no easy way exists to determine what the required permissions are and granting all permissions might be the only choice. You minimize this risk by locating this application on a different node, which might help isolate it from certain resources. Grant the java.security.AllPermission permission in the `was.policy` file that is embedded in the application `.ear` file, for example:

```
grant codeBase "file:${application}" {
            permission java.security.AllPermission;
       };
```

The server.policy file

The `server.policy` file is located in the *profile_root*`/properties` directory.

This policy defines the policy for the WebSphere Application Server classes. At present, all the server processes on the same installation share the same `server.policy` file. However, you can configure this file so that each server process can have a separate `server.policy` file. Define the policy file as the value of the java.security.policy Java system properties . For details of how to define Java system properties, refer to the Process definition section of the Manage application servers file.

The `server.policy` file is not a configuration file managed by the repository and the file replication service. Changes to this file are local and do not get replicated to other machines. Use the `server.policy` file to define Java 2 security policy for server resources. Use the `app.policy` file (per node) or the `was.policy` file (per enterprise application) to define Java 2 security policy for enterprise application resources.

Note: Updates to the `app.policy` file only apply to the enterprise applications on the node to which the app.policy file belongs.

The java.policy file

The file represents the default permissions that are granted to all classes. The policy of this file applies to all the processes launched by the Java Virtual Machine in the WebSphere Application Server.

The java.policy file is located in the${java.home}/lib/security/ directory where ${java.home} is the path to the Software Development Kit (SDK) that you are using. The policy file is used throughout the operating system. Do not edit the java.policy file.

Troubleshooting

Error message CWSCJ0314E

Symptom:

Error message CWSCJ0314E: Current Java 2 security policy reported a potential violation of Java 2 security permission. Refer to Problem Determination Guide for further information.{0}Permission\ :{1}Code\:{2}{3}Stack Trace\:{4}Code Base Location\:{5} Current Java 2 security policy reported a potential violation of Java 2 Security Permission. Refer to Problem Determination Guide for further information.{0}Permission\:{1}Code\:{2}{3}Stack Trace\:{4}Code Base Location\:{5}

Problem:

The Java security manager checkPermission method reported a security exception on the subject permission with debugging information. The reported information can be different with respect to the system configuration. This report is enabled by either configuring a Reliability Availability Service Ability (RAS) trace into debug mode or specifying a Java property.

See Enabling trace for information on how to configure RAS trace in debug mode.

Specify the following property in the JVM Settings panel from the administrative console:
java.security.debug. Valid values include:

access
: Print all debug information including: required permission, code, stack, and code base location.

stack Print debug information including: required permission, code, and stack.

failure Print debug information including: required permission and code.

Recommended response:

The reported exception might be critical to the secure system. Turn on security trace to determine the potential code that might have violated the security policy. After the violating code is determined, verify if the attempted operation is permitted with respect to Java 2 security, by examining all applicable Java 2 security policy files and the application code.

If the application is running with Java Mail, this message might be benign. You can update the was.policy file to grant the following permissions to the application:

```
permission  java.io.FilePermission  "${user.home}${/}.mailcap",  "read";
permission  java.io.FilePermission  "${user.home}${/}.mime.types",  "read";
permission  java.io.FilePermission  "${java.home}${/}lib${/}mailcap",  "read";
permission  java.io.FilePermission  "${java.home}${/}lib${/}mime.types",  "read";
```

SecurityException - Access denied

Symptom:

If Java security is enabled, and permissions to read the jaxm.properties file is not granted, when a SOAPFactory instance is created through a call to javax.xml.soap.SOAPFactory.newInstance(), or a MessageFactory instance is created through a call to MessageFactory.newInstance(), a SecurityException exception occurs, and the following exception is written to the system log:

```
Permission:

      /opt/IBM/WebSphere/AppServer/java/jre/lib/jaxm.properties : access denied
(java.io.FilePermission /opt/IBM/WebSphere/AppServer/java/jre/lib/jaxm.properties
read)

Code:

     com.ibm.ws.wsfvt.test.binding.addr1.binder.AddressBinder
in  {file:/opt/IBM/WebSphere/AppServer/profiles/AppSrv01/installedApps/
```

```
ahp6405Node01Cell/DataBinding.ear/address1.war/WEB-INF/lib
/addressbinder1.jar}

Stack Trace:

java.security.AccessControlException: access denied (java.io.FilePermission
/opt/IBM/WebSphere/AppServer/java/jre/lib/jaxm.properties read)
.
```

Problem:

The Java 2 Security policy reports a potential violation of Java 2 Security permission.

Recommended response:

The SOAPFactory ignores the exception, and continues on to the next means of determining which implementation to load. Therefore, you can ignore the log entry for this security exception.

Because this product uses the SOAPFactory to support other web services technologies, such as WS-Addressing (WS-A), WS-Atomic Transaction (WS-AT), and WS-Notification, you can ignore this SecurityException in any web services application where Java security is enabled.

Messages

Message:	CWSCJ0313E: Java 2 security manager debug message flags are initialized\: TrDebug: {0}, Access: {1}, Stack: {2}, Failure: {3}
Problem:	Configured values of the valid debug message flags for security manager.

Message:	CWSCJ0307E: Unexpected exception is caught when trying to determine the code base location. Exception: {0}
Problem:	An unexpected exception is caught when the code base location is determined.

Java 2 security policy files:

The Java 2 Platform, Enterprise Edition (J2EE) Version 1.3 and later specifications have a well-defined programming model of responsibilities between the container providers and the application code. Using Java 2 security manager to help enforce this programming model is recommended. Certain operations are not supported in the application code because such operations interfere with the behavior and operation of the containers. The Java 2 security manager is used in the product to enforce responsibilities of the container and the application code.

Note: The application server does not support a custom Java security manager implementation.

This product provides support for policy file management. A number of policy files in the product are either static or dynamic. *Dynamic policy* is a template of permissions for a particular type of resource. No relative code base is defined in the dynamic policy template. The code base is dynamically calculated from the deployment and run-time data.

Static policy files

Table 76. Static policy files.

This table lists the location of the static policy files.

Policy file	Location
java.policy	
server.policy	*profile_root*/properties/server.policy. Default permissions are granted to all the product servers.

Table 76. Static policy files (continued).

This table lists the location of the static policy files.

Policy file	Location
client.policy	*profile_root*/properties/client.policy. Default permissions are granted for all of the product client containers and applets on a node.

The static policy files are not managed by configuration and file replication services. Changes made in these files are local and are not replicated to other nodes in the WebSphere Application Server, Network Deployment cell.

Dynamic policy files

Table 77. Dynamic policy files.

This table lists the location of the dynamic policy files.

Policy file	Location
spi.policy	*profile_root*/config/cells/*cell_name*/nodes/*node_name*/spi.policy This template is for the Service Provider Interface (SPI) or the third-party resources that are embedded in the product. Examples of SPI are the Java Message Service (JMS) in MQ Series and Java database connectivity (JDBC) drivers. The code base for the embedded resources are dynamically determined from the configuration (resources.xml file) and run-time data, and permissions that are defined in the spi.policy files are automatically applied to these resources and JAR files that are specified in the class path of a resource adapter. The default permission of the spi.policy file is java.security.AllPermissions.
library.policy	*profile_root*/config/cells/*cell_name*/nodes/*node_name*/library.policy This template is for the library (Java library classes). You can define a shared library to use in multiple product applications. The default permission of the library.policy file is empty.
app.policy	*profile_root*/config/cells/*cell_name*/nodes/*node_name*/app.policy The app.policy file defines the default permissions that are granted to all of the enterprise applications running on *node_name* in *cell_name*. **Note:** Updates to the app.policy file only apply to the enterprise applications on the node to which the app.policy file belongs.
was.policy	*profile_root*/config/cells/*cell_name*/applications/*ear_file_name*/deployments/*application_name*/META-INF/was.policy This template is for application-specific permissions. The was.policy file is embedded in the enterprise archive (EAR) file.
ra.xml	*rar_file_name*/META-INF/was.policy.RAR. This file can have a permission specification that is defined in the ra.xml file. The ra.xml file is embedded in the RAR file.

Grant entries that are specified in the app.policy and was.policy files must have a code base defined. If grant entries are specified without a code base, the policy files are not loaded properly and the application can fail. If the intent is to grant the permissions to all applications, use *file:${application}* as a code base in the grant entry.

Syntax of the policy file

A policy file contains several policy entries. The following example depicts each policy entry format:

```
grant [codebase <Codebase>] {
permission <Permission>;
 permission <Permission>;
permission <Permission>;
};

<CodeBase>:  A URL.
   For example,  "file:${java.home}/lib/tools.jar"
      When [codebase <Codebase>] is not specified, listed
               permissions are applied to everything.
```

```
      If URL ends with a JAR file name,  only the classes in the
               JAR file belong to the codebase.
               If URL ends with "/", only the class files in the specified
               directory belong to the codebase.
               If URL ends with "*", all JAR and class files in the specified
               directory belong to the codebase.
               If URL ends with "-", all JAR and class files in the specified
               directory and its subdirectories belong to the codebase.
<Permissions>: Consists from
       Permission Type   : class name of the permission
          Target Name       : name specifying the target
          Actions           : actions allowed on target
   For example,
         java.io.FilePermission "/tmp/xxx", "read,write"
```

Refer to developer kit specifications for the details of each permission.

Syntax of dynamic policy

You can define permissions for specific types of resources in dynamic policy files for an enterprise application. This action is achieved by using *product-reserved symbols*. The reserved symbol scope depends on where it is defined. If you define the permissions in the `app.policy` file, the symbol applies to all the resources on all of the enterprise applications that run on *node_name*. If you define the permissions in the `META-INF/was.policy` file, the symbol applies only to the specific enterprise application. Valid symbols for the code base are listed in the following table:

Table 78. Dynamic policy syntax.

This table describes valid symbols for the code base for dynamic policy files.

Symbol	Meaning
file:${application}	Permissions apply to all the resources within the application
file:${jars}	Permissions apply to all the utility Java archive (JAR) files within the application
file:${ejbComponent}	Permissions apply to the Enterprise JavaBeans (EJB) resources within the application
file:${webComponent}	Permissions apply to the web resources within the application
file:${connectorComponent}	Permissions apply to the connector resources within the application

You can specify the module name for a granular setting, except for these entries that are specified by the code base symbols. For example:

```
grant codeBase "file:DefaultWebApplication.war" {
   permission java.security.SecurityPermission "printIdentity";
 };

grant codeBase "file:IncCMP11.jar" {
permission java.io.FilePermission
"${user.install.root}${/}bin${/}DefaultDB${/}-",
"read,write,delete";
};
```

The sixth and seventh lines in the previous code sample are one continuous line. You can use a relative code base only in the `META-INF/was.policy` file. Several product-reserved symbols are defined to associate the permission lists to a specific type of resources.

Table 79. Dynamic policy syntax.

This table describes several product-reserved symbols that are defined to associate the permission lists to a specific type of resource.

Symbol	Meaning
file:${application}	Permissions apply to all the resources within the application
file:${jars}	Permissions apply to all the utility JAR files within the application
file:${ejbComponent}	Permissions apply to the enterprise beans resources within the application
file:${webComponent}	Permissions apply to the web resources within the application

Table 79. Dynamic policy syntax (continued).

This table describes several product-reserved symbols that are defined to associate the permission lists to a specific type of resource.

Symbol	Meaning
file:${connectorComponent}	Permissions apply to the connector resources both within the application and in the standalone connector resources.

Five embedded symbols are provided to specify the path and the name for the java.io.FilePermission permission. These symbols enable flexible permission specification. The absolute file path is fixed after the installation of the application.

Table 80. Dynamic policy syntax.

This table describes the embedded symbols that are provided to specify the path and name for the java.io.FilePermission permission.

Symbol	Meaning
${app.installed.path}	Path where the application is installed
${was.module.path}	Path where the module is installed
${current.cell.name}	Current cell name
${current.node.name}	Current node name
${current.server.name}	Current server name

Attention: Do not use the `${was.module.path}` in the `${application}` entry.

Carefully determine where to add a new permission. An incorrectly specified permission causes an AccessControlException exception. Because dynamic policy resolves the code base at runtime, determining which policy file has a problem is difficult. Add a permission only to the necessary resources. For example, `use ${ejbcomponent}`, and `etc` instead of `${application}`, and update the `was.policy` file instead of the `app.policy` file, if possible.

Static policy filtering

Limited static policy filtering support exists. If the `app.policy` file and the `was.policy` file have permissions that are defined in the `filter.policy` file with thefilterMask keyword, the runtime removes the permissions from the applications and an audit message is logged. However, if the permissions that are defined in the `app.policy` and the `was.policy` files are compound permissions, for example, java.security.AllPermission, the permission is not removed, but a warning message is written to the log file. The policy filtering only supports Developer Kit permissions; the permissions package name begins with `java` or `javax`.

Run-time policy filtering support is provided to force stricter filtering. If the `app.policy` file and the `was.policy` file have permissions that are defined in the `filter.policy` file with the runtimeFilterMask keyword, the runtime removes the permissions from the applications no matter what permissions are granted to the application. For example, even if a `was.policy` file has the java.security.AllPermission permission granted to one of its modules, specified permissions such as the runtimeFilterMask permission are removed from the granted permission during runtime.

Policy file editing

Using the policy tool that is provided by the Developer Kit (*app_server_root*`/java/jre/bin/policytool`), to edit the previous policy files is recommended. For WebSphere Application Server, Network Deployment, extract the policy files from the repository before editing. After the policy file is extracted, use the policy tool to edit the file. Check the modified policy files into the repository and synchronize them with other nodes.

Troubleshooting

To debug the dynamic policy, choose one of three ways to generate the detail report of the AccessControlException exception.

- **Trace** (Configured by RAS trace). Enables traces with the trace specification:

  Attention: The following command is one continuous line

```
com.ibm.ws.security.policy.*=all=enabled:
com.ibm.ws.security.core.SecurityManager=all=enabled
```

- **Trace** (Configured by property). Specifies a Java java.security.debug property. Valid values for the java.security.debug property are as follows:
  - Access. Print all debug information including required permission, code, stack, and code base location.
  - Stack. Print debug information including, required permission, code, and stack.
  - Failure. Print debug information including required permission and code.
- **ffdc**. Enable `ffdc`, modify the `ffdcRun.properties` file by changing `Level=4` and `LAE=true`. Look for an Access Violation keyword in the log file.

Access control exception for Java 2 security:

The Java 2 security behavior is specified by its *security policy*. The security policy is an access-control matrix that specifies which system resources certain code bases can access and who must sign them. The Java 2 security policy is declarative and it is enforced by the java.security.AccessController.checkPermission method.

The following example depicts the algorithm for the java.security.AccessController.checkPermission method. For the complete algorithm, refer to the Java 2 security check permission algorithm in the Security: Resources for learning article.

```
i = m;
while (i > 0) {
 if (caller i's domain does not have the permission)
  throw AccessControlException;
 else if (caller i is marked as privileged)
  return;
 i = i - 1;
};
```

The algorithm requires that all the classes or callers on the call stack have the permissions when a java.security.AccessController.checkPermission method is performed or the request is denied and a java.security.AccessControlException exception is created. However, if the caller is marked as *privileged* and the class (caller) is granted these permissions, the algorithm returns and does not traverse the entire call stack. Subsequent classes (callers) do not need the required permission granted.

A java.security.AccessControlException exception is created when certain classes on the call stack are missing the required permissions during a java.security.AccessController.checkPermission method. Two possible resolutions to the java.security.AccessControlException exception are as follows:

- If the application is calling a Java 2 security-protected application programming interface (API), grant the required permission to the application Java 2 security policy. If the application is not calling a Java 2 security-protected API directly, the required permission results from the side-effect of the third-party APIs accessing Java 2 security-protected resources.
- If the application is granted the required permission, it gains more access than it needs. In this case, it is likely that the third party code that accesses the Java 2 security-protected resource is not properly marked as privileged.

Example call stack

This example of a call stack indicates where application code is using a third-party API utility library to update the password. The following example is presented to illustrate the point. The decision of where to mark the code as privileged is application-specific and is unique in every situation. This decision requires great depth of domain knowledge and security expertise to make the correct judgement. A number of well written publications and books are available on this topic. Referencing these materials for more detailed information is recommended.

You can use the **PasswordUtil** utility to change the password of a user. The utility types in the old password and the new password twice to ensure that the correct password is entered. If the old password matches the one stored in the password file, the new password is stored and the password file updates. Assume that none of the stack frame is marked as privileged. According to the java.security.AccessController.checkPermission algorithm, the application fails unless all the classes on the call stack are granted write permission to the password file. The client application does not have permission to write to the password file directly and to update the password file at will.

However, if the PasswordUtil.updatePasswordFile method marks the code that accesses the password file as privileged, then the check permission algorithm does not check for the required permission from classes that call thePasswordUtil.updatePasswordFile method for the required permission as long as the **PasswordUtil** class is granted the permission. The client application can successfully update a password without granting the permission to write to the password file.

The ability to mark code privileged is very flexible and powerful. If this ability is used incorrectly, the overall security of the system can be compromised and security holes can be exposed. Use the ability to mark code privileged carefully.

Resolution to the java.security.AccessControlException exception

As described previously, you have two approaches to resolve a java.security.AccessControlException exception. Judge these exceptions individually to decide which of the following resolutions is best:
1. Grant the missing permission to the application.
2. Mark some code as privileged, after considering the issues and risks.

Enabling security for the realm

Use this topic to enable IBM WebSphere Application Server security. You must enable administrative security for all other security settings to function.

About this task

WebSphere Application Server uses cryptography to protect sensitive data and to ensure confidentiality and integrity of communications between WebSphere Application Server and other components in the network. Cryptography is also used by Web Services Security when certain security constraints are configured for the web services application.

Attention: Fix packs that include updates to the Software Development Kit (SDK) might overwrite unrestricted policy files. Back up unrestricted policy files before you apply a fix pack and reapply these files after the fix pack is applied.

Note: Fix packs that include updates to the Software Development Kit (SDK) might overwrite unrestricted policy files. Back up unrestricted policy files before you apply a fix pack and reapply these files after the fix pack is applied.

Important: Your country of origin might have restrictions on the import, possession, use, or re-export to another country, of encryption software. Before downloading or using the unrestricted policy files, you must check the laws of your country, its regulations, and its policies concerning the import, possession, use, and re-export of encryption software, to determine if it is permitted.

Complete the following steps to download and install the new policy files:

1. Click **Java SE 6**
2. Scroll down the page then click **IBM SDK Policy files**.

   The Unrestricted JCE Policy files for SDK 6 website displays.
3. Click **Sign in** and provide your IBM.com ID and password.
4. Select **Unrestricted JCE Policy files for SDK 6** and click **Continue**.
5. View the license and click **I Agree** to continue.
6. Click **Download Now**.
7. Extract the unlimited jurisdiction policy files that are packaged in the compressed file. The compressed file contains a `US_export_policy.jar` file and a `local_policy.jar` file.
8. In your WebSphere Application Server installation, go to the `$JAVA_HOME/jre/lib/security` directory and back up your `US_export_policy.jar` and `local_policy.jar` files.
9. Replace your `US_export_policy.jar` and `local_policy.jar` files with the two files that you downloaded from the IBM.com website.

Complete the following steps to enable security for the realm:

Procedure

1. Enable security in the WebSphere Application Server. Make sure that all node agents within the cell are active beforehand.

   For more information, see “Enabling security” on page 1172. It is important to click **Security > Global security**. Select an available realm definition from the list, and then click **Set as current** so that security is enabled upon a server restart.

   Note: In previous releases of WebSphere Application Server, the **Set as current** option is known as the **Enable global security** option.
2. Before restarting the server, log off the administrative console. You can log off by clicking **Logout** at the top menu bar.
3. Stop the server by going to the command line in the WebSphere Application Server *app_server_root*`/bin` directory and issue a `stopServer` *server_name* command.
4. Restart the server in secure mode by issuing the command `startServer` *server_name*. Once the server is secure, you cannot stop the server again without specifying an administrative user name and password. To stop the server once security is enabled, issue the command, `stopServer` *server_name* `-username` *user_id* `-password` *password*. Alternatively, you can edit the `soap.client.props` file in the *profile_root*`/properties` directory, and edit the `com.ibm.SOAP.loginUserid` or `com.ibm.SOAP.loginPassword` properties to contain these administrative IDs.

   If you have any problems restarting the server, review the output logs in the *profile_root*`/logs/server_name` directory. Check the Troubleshooting security configurations article for any common problems.

   The *app_server_root* variable refers to the *app_server_root*`/bin/` default directory.

Global security settings:

Use this panel to configure administration and the default application security policy. This security configuration applies to the security policy for all administrative functions and is used as a default security policy for user applications. Security domains can be defined to override and customize the security policies for user applications.

To view this administrative console page, click **Security > Global security**.

Security has some performance impacts on your applications. The performance impacts can vary depending upon the application workload characteristics. You must first determine that the needed level of security is enabled for your applications, and then measure the impact of security on the performance of your applications.

When security is configured, validate any changes to the user registry or authentication mechanism panels. Click **Apply** to validate the user registry settings. An attempt is made to authenticate the server ID or to validate the admin ID (if internalServerID is used) to the configured user registry. Validating the user registry settings after enabling administrative security can avoid problems when you restart the server for the first time.

Security configuration wizard:

Launches a wizard that enables you to configure the basic administrative and application security settings. This process restricts administrative tasks and applications to authorized users.

Using this wizard, you can configure application security, resource or Java 2 Connector (J2C) security, and a user registry. You can configure an existing registry and enable administrative, application, and resource security.

When you apply changes made by using the security configuration wizard, administrative security is turned on by default.

Security configuration report:

Launches a report that gathers and displays the current security settings of the application server. Information is gathered about core security settings, administrative users and groups, CORBA naming roles, and cookie protection. When multiple security domains are configured the report displays the security configuration associated with each domain.

A current limitation to the report is that it does not display application level security information. The report also does not display information on Java Message Service (JMS) security, bus security, or Web Services Security.

Enable administrative security:

Specifies whether to enable administrative security for this application server domain. Administrative security requires users to authenticate before obtaining administrative control of the application server.

For more information, see the related links for administrative roles and administrative authentication.

When enabling security, set the authentication mechanism configuration and specify a valid user ID and password (or a valid admin ID when internalServerID feature is used) in the selected registry configuration.

Note: There is a difference between the user ID (which is normally called the admin ID), which identifies administrators who manage the environment, and a server ID, which is used for server-to-server communication. You do not need to enter a server ID and password when you are using the internal server ID feature. However, optionally, you can specify a server ID and password. To specify the server ID and password, complete the following steps:

1. Click **Security > Global security**.
2. Under User accounts repository, select the repository and click **Configure**.
3. Specify the server ID and password in the Server user identity section.

Default: Enabled

Enable application security:

Enables security for the applications in your environment. This type of security provides application isolation and requirements for authenticating application users

In previous releases of WebSphere Application Server, when a user enabled global security, both administrative and application security were enabled. In WebSphere Application Server Version 6.1, the previous notion of global security is split into administrative security and application security, each of which you can enable separately.

As a result of this split, WebSphere Application Server clients must know whether application security is disabled at the target server. Administrative security is enabled, by default. Application security is disabled, by default. To enable application security, you must enable administrative security. Application security is in effect only when administrative security is enabled.

Default: Disabled

Use Java 2 security to restrict application access to local resources:

Specifies whether to enable or disable Java 2 security permission checking. By default, access to local resources is not restricted. You can choose to disable Java 2 security, even when application security is enabled.

When the **Use Java 2 security to restrict application access to local resources** option is enabled and if an application requires more Java 2 security permissions than are granted in the default policy, the application might fail to run properly until the required permissions are granted in either the `app.policy` file or the `was.policy` file of the application. AccessControl exceptions are generated by applications that do not have all the required permissions. See the related links for more information about Java 2 security.

Default: Disabled

Warn if applications are granted custom permissions:

Specifies that during application deployment and application start, the security runtime issues a warning if applications are granted any custom permissions. Custom permissions are permissions that are defined by the user applications, not Java API permissions. Java API permissions are permissions in the `java.*` and `javax.*` packages.

The application server provides support for policy file management. A number of policy files are available in this product, some of them are static and some of them are dynamic. Dynamic policy is a template of permissions for a particular type of resource. No code base is defined and no relative code base is used in the dynamic policy template. The real code base is dynamically created from the configuration and run-time data. The `filter.policy` file contains a list of permissions that you do not want an application to have according to the J2EE 1.4 specification. For more information on permissions, see the related link about Java 2 security policy files.

Important: You cannot enable this option without enabling the **Use Java 2 security to restrict application access to local resources** option.

Default: Disabled

Restrict access to resource authentication data:

Enable this option to restrict application access to sensitive Java Connector Architecture (JCA) mapping authentication data.

Consider enabling this option when both of the following conditions are true:

- Java 2 security is enforced.
- The application code is granted the accessRuntimeClasses WebSphereRuntimePermission permission in the `was.policy` file found within the application enterprise archive (EAR) file. For example, the application code is granted the permission when the following line is found in your `was.policy` file:

```
permission com.ibm.websphere.security.WebSphereRuntimePermission "accessRuntimeClasses";
```

The **Restrict access to resource authentication data** option adds fine-grained Java 2 security permission checking to the default principal mapping of the WSPrincipalMappingLoginModule implementation. You must grant explicit permission to Java 2 Platform, Enterprise Edition (J2EE) applications that use the WSPrincipalMappingLoginModule implementation directly in the Java Authentication and Authorization Service (JAAS) login when **Use Java 2 security to restrict application access to local resources** and the **Restrict access to resource authentication data** options are enabled.

Default: Disabled

Current realm definition:

Specifies the current setting for the active user repository.

This field is read-only.

Available realm definitions:

Specifies the available user account repositories.

The selections appear in a drop-down list containing:

- Local operating system
- Standalone LDAP registry
- Stand-alone custom registry

Configure...:

Select to configure the global security settings.

Web and SIP security:

Under Authentication, expand Web and SIP security to view links to:

- General settings
- Single sign-on (SSO)
- SPNEGO web authentication
- Trust association

General settings:

Select to specify the settings for web authentication.

Single sign-on (SSO):

Select to specify the configuration values for single sign-on (SSO).

With SSO support, web users can authenticate once when accessing both WebSphere Application Server resources, such as HTML, JavaServer Pages (JSP) files, servlets, enterprise beans, and Lotus Domino® resources.

SPNEGO web authentication:

Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) provides a way for web clients and the server to negotiate the web authentication protocol that is used to permit communications.

Trust association:

Select to specify the settings for the trust association. Trust association is used to connect reversed proxy servers to the application servers.

You can use the global security settings or customize the settings for a domain.

Note: The use of trust association interceptors (TAIs) for SPNEGO authentication is now deprecated. The SPNEGO web authentication panels now provide a much easier way to configure SPNEGO.

RMI/IIOP security:

Under Authentication, expand RMI/IIOP security to view links to:
- CSIv2 inbound communications
- CSIv2 outbound communications

CSIv2 inbound communications:

Select to specify authentication settings for requests that are received and transport settings for connections that are accepted by this server using the Object Management Group (OMG) Common Secure Interoperability (CSI) authentication protocol.

Authentication features include three layers of authentication that you can use simultaneously:
- **CSIv2 attribute layer**. The attribute layer might contain an identity token, which is an identity from an upstream server that already is authenticated. The identity layer has the highest priority, followed by the message layer, and then the transport layer. If a client sends all three, only the identity layer is used. The only way to use the SSL client certificate as the identity is if it is the only information that is presented during the request. The client picks up the interoperable object reference (IOR) from the namespace and reads the values from the tagged component to determine what the server needs for security.
- **CSIv2 transport layer**. The transport layer, which is the lowest layer, might contain a Secure Sockets Layer (SSL) client certificate as the identity.
- **CSIv2 message layer**. The message layer might contain a user ID and password or an authenticated token with an expiration.

CSIv2 outbound communications:

Select to specify authentication settings for requests that are sent and transport settings for connections that are initiated by the server using the Object Management Group (OMG) Common Secure Interoperability (CSI) authentication protocol.

Authentication features include three layers of authentication that you can use simultaneously:
- **CSIv2 attribute layer**. The attribute layer might contain an identity token, which is an identity from an upstream server that already is authenticated. The identity layer has the highest priority, followed by the message layer, and then the transport layer. If a client sends all three, only the identity layer is used.

The only way to use the SSL client certificate as the identity is if it is the only information that is presented during the request. The client picks up the interoperable object reference (IOR) from the namespace and reads the values from the tagged component to determine what the server needs for security.

- **CSIv2 transport layer**. The transport layer, which is the lowest layer, might contain a Secure Sockets Layer (SSL) client certificate as the identity.
- **CSIv2 message layer**. The message layer might contain a user ID and password or an authenticated token with an expiration.

Java authentication and authorization service:

Under Authentication, expand Java authentication and authorization service to view links to:

- Application logins
- System logins
- J2C authentication data

Application logins:

Select to define login configurations that are used by JAAS.

Do not remove the ClientContainer, DefaultPrincipalMapping, and WSLogin login configurations because other applications might use them. If these configurations are removed, other applications might fail.

System logins:

Select to define the JAAS login configurations that are used by system resources, including the authentication mechanism, principal mapping, and credential mapping.

J2C authentication data:

Select to specify the settings for the Java Authentication and Authorization Service (JAAS) Java 2 Connector (J2C) authentication data.

You can use the global security settings or customize the settings for a domain.

LTPA:

Select to encrypt authentication information so that the application server can send the data from one server to another in a secure manner.

The encryption of authentication information that is exchanged between servers involves the Lightweight Third-Party Authentication (LTPA) mechanism.

Kerberos and LTPA:

Select to encrypt authentication information so that the application server can send the data from one server to another in a secure manner.

The encryption of authentication information that is exchanged between servers involves the Kerberos mechanism.

Note: Kerberos must be configured before this option can be selected.

Kerberos configuration:

Select to encrypt authentication information so that the application server can send data from one server to anther in a secure manner.

The encryption of the authentication information that is exchanged between servers involves the KRB5 of LTPA mechanism.

Authentication cache settings:

Select to set your authentication cache settings.

Enable Java Authentication SPI (JASPI):

Select to enable the use of Java Authentication SPI (JASPI) authentication.

You can then click **Providers** to create or edit a JASPI authentication provider and associated authentication modules in the global security configuration.

Use realm-qualified user names:

Specifies that user names that are returned by methods, such as the getUserPrincipal() method, are qualified with the security realm in which they reside.

Security domains:

Use the Security Domain link to configure additional security configurations for user applications.

For example, if you want use a different user registry for a set of user applications than the one used at the global level, you can create a security configuration with that user registry and associate it with that set of applications. These additional security configurations can be associated with various scopes (cell, clusters/servers, SIBuses). Once the security configurations have been associated with a scope all of the user applications in that scope use this security configuration. Read about “Multiple security domains” on page 1222 for more detailed information.

For each security attribute, you can use the global security settings or customize settings for the domain.

External authorization providers:

Select to specify whether to use the default authorization configuration or an external authorization provider.

The external providers must be based on the Java Authorization Contract for Containers (JACC) specification to handle the Java(TM) 2 Platform, Enterprise Edition (J2EE) authorization. Do not modify any settings on the authorization provider panels unless you have configured an external security provider as a JACC authorization provider.

Custom properties:

Select to specify name-value pairs of data, where the name is a property key and the value is a string.

Specify extent of protection wizard settings:

Use this security wizard page to determine whether to enable application security and restrict access to local resources. When you use the wizard, admin security is enabled by default.

To view this security wizard page, click **Security > Global security > Security configuration wizard**.

Enable application security:

Enables security for the applications in your environment. This type of security provides application isolation and requirements for authenticating application users

In previous releases of WebSphere Application Server, when a user enabled global security, both administrative and application security were enabled. In WebSphere Application Server Version 6.1, the previous notion of global security is split into administrative security and application security, each of which you can enable separately.

As a result of this split, WebSphere Application Server clients must know whether application security is disabled at the target server. Administrative security is enabled, by default. Application security is disabled, by default. To enable application security, you must enable administrative security. Application security is in effect only when administrative security is enabled.

Default: Disabled

Use Java 2 security to restrict application access to local resources:

Specifies whether to enable or disable Java 2 security permission checking. By default, access to local resources is not restricted. You can choose to disable Java 2 security, even when application security is enabled.

When the **Use Java 2 security to restrict application access to local resources** option is enabled and if an application requires more Java 2 security permissions than are granted in the default policy, the application might fail to run properly until the required permissions are granted in either the `app.policy` file or the `was.policy` file of the application. AccessControl exceptions are generated by applications that do not have all the required permissions. See the related links for more information about Java 2 security.

Default: Disabled

Security custom properties:

Use this page to understand the psecurity.allowCustomHTTPMethodsredefined custom properties that are related to security.

To view this administrative console page, click **Security > Global security > Custom properties**. Then click **New** to add a new custom property and its associated value.

The custom properties in this topic are set in the administrative console through the previously listed path unless otherwise stated in the description.

You can use the custom properties page to define the following security custom properties:

- “com.ibm.audit.report.granularity” on page 1196
- “com.ibm.CSI.disablePropagationCallerList” on page 1196
- “com.ibm.CSI.propagateFirstCallerOnly” on page 1197
- “com.ibm.CSI.rmiInboundLoginConfig” on page 1197
- “com.ibm.CSI.rmiOutboundLoginConfig” on page 1197

com.ibm.audit.report.granularity:

This property enables you to specify how much auditing data is recorded for each event type. If you only need to record basic information about an event, such as who did what action to what resource, and when, setting this property to `high`, might improve your application server performance.

You can specify values of `high`, `medium`, or `low` for this property. The default value is `low`.

Table 81. Type of data that is recorded for each event type based on the setting for com.ibm.audit.report.granularity. The following table indicates the type of data that is recorded for each event type based on the setting for this property.

Event type	`high` setting	`medium` setting	`low` setting
SessionContext	sessionId	sessionId, remoteHost	sessionId, remoteHost, remoteAddr, remotePort
PropagationContext (is only reported if SAP is enabled)	firstCaller (as part of the who)	firstCaller, and if verbose mode is enabled, the callerList	firstCaller, and if verbose mode is enabled, the callerList
RegistryContext	nothing is recorded	registry type	registry type
ProcessContext	nothing is recorded	realm	realm, and domain if verbose is enabled
EventContext	creationTime	creationTime, globalInstanceId	creationTime, globalInstanceId, eventTrailId, and lastTrailId if verbose mode is enabled
DelegationContext	identityName	delegationType, and identityName	delegationType, roleName, and identityName
AuthnContext	nothing is recorded	authn type	authn type
ProviderContext	nothing is recorded	provider	provider, and providerStatus
AuthnMappingContext	mappedUserName	mappedUserName, and mappedSecurityRealm	mappedUserName, mappedSecurityRealm, and mappedSecurityDomain
AuthnTermContext	terminateReason	terminateReason	terminateReason
AccessContext	progName, action, appUserName, and resourceName	progName, action, appUserName, resourceName, registryUserName, and accessDecision	progName, action, appUserName, resourceName, registryUserName, accessDecision, resourceType, permissionsChecked, permissionsGranted, rolesChecked, and rolesGranted
PolicyContext	nothing is recorded	policyName	policyName, and policyType
KeyContext	keyLabel	keyLabel, and keyLocation	keyLabel, keyLocation, and certificateLifetime
MgmtContext	nothing is recorded	mgmtType, and mgmtCommand	mgmtType, mgmtCommand, and targetInfoAttributes

com.ibm.CSI.disablePropagationCallerList:

This property completely disables the caller list and will not allow the caller list to change. This property prevents the creation of multiple sessions.

This property completely disables adding a caller or host list in the propagation token. Setting this property can be a benefit when the caller or host list in the propagation token is not needed in the environment.

Note: If this property is set to **true** as well as **com.ibm.CSI.propagateFirstCallerOnly**, then **com.ibm.CSI.disablePropagationCallerList** takes precedence.

Default false

com.ibm.CSI.propagateFirstCallerOnly:

This property will not allow the caller list to change and thus prevent the creation of multiple session entries. This property specifically limits the caller list to the first caller only.

This property logs the first caller in the propagation token that stays on the thread when security attribute propagation is enabled. Without setting this property, all caller switches get logged, which affects performance. Typically, only the first caller is of interest.

Note: If this property is set to **true** as well as **com.ibm.CSI.disablePropagationCallerList**, then **com.ibm.CSI.disablePropagationCallerList** takes precedence.

Default true

Note: New for this release, the default value of the com.ibm.CSI.propagateFirstCallerOnly security custom property is set to `true`. When this custom property is set to `true`, the first caller in the propagation token that stays on the thread is logged when security attribute propagation is enabled. When this property is set to `false`, all of the caller switches are logged, which can affect performance.

com.ibm.CSI.rmiInboundLoginConfig:

This property specifies the Java Authentication and Authorization Service (JAAS) login configuration that is used for Remote Method Invocation (RMI) requests that are received inbound.

By knowing the login configuration, you can plug in a custom login module that can handle specific cases for RMI logins.

Default system.RMI_INBOUND

com.ibm.CSI.rmiOutboundLoginConfig:

This property specifies the JAAS login configuration that is used for RMI requests that are sent outbound.

Primarily, this property prepares the propagated attributes in the Subject to be sent to the target server. However, you can plug in a custom login module to perform outbound mapping.

Default system.RMI_OUTBOUND

com.ibm.CSI.supportedTargetRealms:

This property enables credentials that are authenticated in the current realm to be sent to any realm that is specified in the Trusted target realms field. The Trusted target realms field is available on the CSIv2 outbound authentication panel. This property enables those realms to perform inbound mapping of the data from the current realm.

It is not recommended that you send authentication information to an unknown realm. Thus, this provides a way to specify that the alternate realms are trusted. To access the CSIv2 outbound authentication panel, complete the following steps:

1. Click **Security > Global security**.
2. Under RMI/IIOP security, click **CSIv2 outbound authentication**.

com.ibm.security.multiDomain.setNamingReadUnprotected:

This property can be set to true or false to determine if the CosNamingRead role protects all naming read operations. Setting this property to true is the equivalent of assigning the CosNamingRead role the Everyone special subject. If this propert is set, then it will override any assignments made to the CosNamingRead role.

Default none

com.ibm.security.useFIPS:

Specifies that Federal Information Processing Standard (FIPS) algorithms are used. The application server uses the IBMJCEFIPS cryptographic provider instead of the IBMJCE cryptographic provider.

Default false

com.ibm.websphere.crypto.config.certexp.notify.fromAddress:

This security property is used to customize the "from address" of certificate expiration notification email.

The value you assigned to this property should be an internet address, for example "Notification@abc-company.com" If this property is not set, WebSphere uses its email fromAddress: "WebSphereNotification@ibm.com" .

Default None

com.ibm.websphere.crypto.config.certexp.notify.textEncoding:

This security property is used to customize the text encoding character set for certificate expiration notification email.

WebSphere Application Server sends notification email for certificate expiration in either US-English or the machine default character set (if non-English locale is specified). If you want a different text encoding character set for the certificate expiration notification email, you can use this property to customize the text encoding character set.

Default None

com.ibm.websphere.lookupRegistryOnProcess:

This property can be set when realm registry lookups are performed via an MBean on a remote server if the realm is local OS security.

By default, the user registry tasks listRegistryUsers and listRegistryGroups perform lookups from the current process. In the case of Network Deployment (ND), that is the dmgr.

When dealing with a local OS user registry, lookup should occur on the actual server where the registry resides. In an ND environment that could be a remote machine. To perform lookup on the server process where the registry resides, the com.ibm.websphere.lookupRegistryOnProcess custom property should be set to `true`.

If com.ibm.websphere.lookupRegistryOnProcess is not set, or set to `false`, then the lookup is performed on the current process. The custom property can be set using the setAdminActiveSecuritySettings task for global security or the setAppActiveSecuritySettings task for a security domain.

com.ibm.websphere.security.allowAnyLogoutExitPageHost:

When you are using application form login and logout you can provide a URL for a custom logout page. By default, the URL must point to the host to which the request is made or to its domain. If this is not done, then a generic logout page is displayed rather than a the custom logout page. If you want to be able to point to any host, then you need to set this property in the `security.xml` file to a value of true. There is a risk that setting this property to have a value of true may open your systems to potential URL redirect attacks.

Default false

com.ibm.websphere.security.alwaysRestoreOriginalURL:

Use this property to indicate whether a cookie with the value WASReqURL is honored when the custom form login processor is used.

When this property is set to `true`, the value of WASReqURL takes precedence over the current URL, and the WASReqURL cookie is removed from subsequent requests.

When this property is set to `false`, the value of the current URL takes precedence, and the WASReqURL cookie is not removed from subsequent requests.

Default false

com.ibm.websphere.security.config.inherit.trustedRealms:

This property is used to inherit the global trusted realm settings from the global security configuration in the domain.

Security configuration trusted inbound and outbound realms are not inherited by default. However, there are some cases where the configuration might want to use (inherit) the settings from the global security configuration in the domain.

The value of this property can be either `true` or `false`.

com.ibm.websphere.security.console.noSSLTreePortEndpoints:

This property is used to improve the response time for large topology configurations.

When this property is set to `true` the status of the of the SSL port endpoints does not display on the Manage endpoint security configurations page in the administrative console. Displaying the status of the SSL port endpoints sometimes makes the administrative console seem like it is no longer functioning because of a longer than expected response time.

Default false

com.ibm.websphere.security.customLTPACookieName:

This property is used to customize the name of the cookies used for Lightweight Third Party Authentication (LTPA) tokens.

WebSphere Application Server Version 8.0 enables you to customize the name of the cookies used for LTPA and LTPA2 tokens. Custom cookie names allow you to logically separate authentication between Single Sign-On (SSO) domains and to enable customized authentication to a particular environment.

To take advantage of this functionality, a custom property must be set. For LTPA tokens, the custom property com.ibm.websphere.security.customLTPACookieName can be set to any valid string (special characters and spaces are not permitted) for the LTPA token cookie, and com.ibm.websphere.security.customSSOCookieName for the LTPA2 (SSO) token cookie. Each property is case-sensitive.

The value for this property is a valid string.

Note: Before you set this custom property, consider the following:

- This property, as with most custom properties, can be set at the security domain level. In this manner, a separate login can be forced between an administrative console login and an application login.
- The original default LTPAToken or LTPAToken2 cookie names are accepted and trusted by WebSphere Application Server Version 8.0. This enables compatibility with products such as Lotus Domino and WebSphere Portal which both utilize the default cookie name.
- Setting a custom cookie name can cause an authentication failure. For example, a connection to a server that has a custom cookie property set sends this custom cookie to the browser. A subsequent connection to a server that uses either the default cookie name or a different cookie name is not able to authenticate the request via a validation of the inbound cookie.
- This property does not function properly in a mixed-cell environment. For example, a deployment manager in WebSphere Application Server Version 8.0 might be able to create custom cookies. However, a WebSphere Application Server Version 7.0 node or server existing in this same cell does not understand what to do with this cookie and subsequently rejects it.
- If you utilize a product interacting with WebSphere Application Server that generates LTPA tokens, such as Lotus Domino or WebSphere Portal, be aware that these products might not be able to handle custom LTPA cookie names. Please consult the documentation for your product regarding its handling of custom LTPA cookie names.

Note: To activate this property, a restart of WebSphere Application Server is necessary.

com.ibm.websphere.security.customSSOCookieName:

This property is used to customize the name of the cookies used for Lightweight Third Party Authentication Version 2 (LTPA2) tokens.

WebSphere Application Server Version 8.0 enables you to customize the name of the cookies used for LTPA and LTPA2 tokens. Custom cookie names allow you to logically separate authentication between Single Sign-On (SSO) domains and to enable customized authentication to a particular environment.

To take advantage of this functionality, a custom property must be set. For LTPA tokens, the custom property com.ibm.websphere.security.customLTPACookieName can be set to any valid string (special characters and spaces are not permitted) for the LTPA token cookie, and com.ibm.websphere.security.customSSOCookieName for the LTPA2 (SSO) token cookie. Each property is case-sensitive.

The value for this property is a valid string.

Note: Before you set this custom property, consider the following:

- This property, as with most custom properties, can be set at the security domain level. In this manner, a separate login can be forced between an administrative console login and an application login.
- The original default LTPAToken or LTPAToken2 cookie names are accepted and trusted by WebSphere Application Server Version 8.0. This enables compatibility with products such as Lotus Domino and WebSphere Portal which both utilize the default cookie name.

- Setting a custom cookie name can cause an authentication failure. For example, a connection to a server that has a custom cookie property set sends this custom cookie to the browser. A subsequent connection to a server that uses either the default cookie name or a different cookie name is not able to authenticate the request via a validation of the inbound cookie.
- This property does not function properly in a mixed-cell environment. For example, a deployment manager in WebSphere Application Server Version 8.0 might be able to create custom cookies. However, a WebSphere Application Server Version 7.0 node or server existing in this same cell does not understand what to do with this cookie and subsequently rejects it.
- If you utilize a product interacting with WebSphere Application Server that generates LTPA tokens, such as Lotus Domino or WebSphere Portal, be aware that these products might not be able to handle custom LTPA cookie names. Please consult the documentation for your product regarding its handling of custom LTPA cookie names.

Note: To activate this property, a restart of WebSphere Application Server is necessary.

com.ibm.websphere.security.displayRealm:

This property specifies whether the HTTP basic authentication login window displays the realm name that is not defined in the application `web.xml` file.

Note: If the realm name is defined in the application `web.xml` file, this property is ignored.

If the realm name is not defined in the `web.xml` file, one of the following occurs:

- If the property is set to `false`, the WebSphere realm name display is Default Realm.
- If this property is set to `true`, the WebSphere realm name display is the user registry realm name for the LTPA authentication mechanism or the Kerberos realm name for the Kerberos authentication mechanism.

Important: If this property is set to `true`, and the user registry's realm name contains sensitive information, it is displayed to the user. For example, if standalone LDAP configuration is used, the LDAP server hostname and port are displayed. For LocalOS, the hostname is displayed.

Default	false
Type	string

com.ibm.websphere.security.disableGetTokenFromMBean:

Use this property to disables the outbound SOAP call to retrieve the subject from the originating server when Single Sign-On is enabled.

Typically, when Single Sign-On is enabled, and an inbound request needs to be authenticated, the receiving server attempts to retrieve the authentication from the originating server. The connection between the sending and receiving servers never times out during this callback process.

When this property is set to `true`, the receiving server does not attempt to authenticate the inbound request.

Default	false

com.ibm.websphere.security.enableAuditForIsCallerInRole:

Use this property to enable audit for the isCallerInRole method call.

If you set this property to `false`, it disables auditing for the invocation of isCallerInRole. In z/OS, SMF records are not issued for the invocation.

Default true

com.ibm.websphere.security.InvokeTAIbeforeSSO:

Default invocation order of Trust Association Interceptors (TAIs) in relation to Single Sign On (SSO) user authentication can be changed using this property. The default order is to invoke Trust Association Interceptors after SSO. This property is used to change the default order of TAI invocation with SSO. The property value is a comma (,) separated list of TAI class names to be invoked before SSO.

Default com.ibm.ws.security.spnego.TrustAssociationInterceptorImpl
Type string

com.ibm.websphere.security.JAASAuthData.addNodeNameSecDomain:

By default, when JAAS authentication data entries are created at the domain security level, the alias name for the entry will be in the format *aliasName.* . You can enable the addition of the node name to the alias name in order to create the alias name in the format `nodeName/aliasName` for the entry, by setting the following property at the domain security level.

Note: You can set com.ibm.websphere.security.JAASAuthData.addNodeNameSecDomain=true at the global security level, to enable the addition of the node name to the alias name of JAAS authentication data entries for all security domains.

Default false

com.ibm.websphere.security.JAASAuthData.removeNodeNameGlobal:

By default, when JAAS authentication data entries are created at the global security level, the alias name for the entry will be in the format *nodeName/aliasName*. You can disable the addition of the node name to the alias name for the entry, by setting a value of `true` for this property at the global security level.

Default false

com.ibm.websphere.security.krb.canonical_host:

This custom property specifies whether the application server uses the canonical form of the URL/HTTP host name in authenticating a client. This property can be used for both SPNEGO TAI and SPNEGO Web.

If you set this custom property to `false`, a Kerberos ticket can contain a host name that differs from the HTTP host name header and the application server might issue the following message:

```
CWSPN0011E: An invalid SPNEGO token has been encountered while authenticating a HttpServletRequest
```

If you set this custom property to `true`, you can avoid this error message and allow the application server to authenticate using the canonical form of the URL/HTTP host name.

Default true

com.ibm.websphere.security.ldap.logicRealm:

This custom property enables you to change the name of the realm that is placed in the token.

This custom property enables you to configure each cell to have its own LDAP host for interoperability and backward compatibility. Also, it provides flexibility for adding or removing the LDAP host dynamically. If you are migrating a previous installation, this modified realm name does not take effect until administrative security is re-enabled. To be compatible with a previous release that does not support the logic realm, the name must be the same name that is used by the previous installation. You must use the LDAP host name, including a trailing colon and port number.

Type String

This property must be set as the custom property of a stand-alone LDAP registry. To set this custom property, in the administrative console:

1. Click **Security > Global security**.
2. Under User account repository, expand the Available realm definitions list, and select **Standalone LDAP registry**, and then click **Configure**.
3. Under Custom properties, click **New** , and then enter `com.ibm.websphere.security.ldap.logicRealm` in the **Name** field, and the new name of the realm that is placed in the token in the **Value** field.
4. Select this custom property and then click **Apply** or **OK**.

com.ibm.websphere.security.ldapSSLConnectionTimeout:

Use this property, when SSL is enabled on the LDAP server, to specify, in milliseconds, the maximum amount of time the JVM waits for a socket connection before issuing a timeout.

If one or more standalone LDAP servers are offline when a server process starts, and LDAP-SSL is enabled, there might be a delay of up to 3 minutes in the startup procedure even if you specify a value for the com.sun.jndi.ldap.connect.timeout custom property. When LDAP-SSL is enabled, any value specified for the com.sun.jndi.ldap.connect.timeout property is ignored.

When a value is specified for this property, the JVM tries to uses this connection timeout value when attempting to complete a socket connection, instead of trying to establish a directory context. When no value is specified for this property, the JVM tries to establish a directory context.

There will be no default value for this property.

com.ibm.websphere.security.logoutExitPageDomainList:

When you are using application form login and logout you can provide a URL for a custom logout page. By default, the URL must point to the host to which the request is made or to its domain. If this is not done, then a generic logout page is displayed rather than a the custom logout page. If you need to point to a different host, then you can populate this property in `security.xml` with a pipe (|) separated list of URLs that are allowed for the logout page.

Default none

com.ibm.websphere.security.performTAIForUnprotectedURI:

This property is used to specify TAI invocation behavior when **Use available authentication data when an unprotected URI is accessed** is selected in the administrative console.

Default false

com.ibm.websphere.security.rsaCertificateAliasCache:

This property is used to control the size of the alias cache.

The default value is 5000 and can be increased for larger deployments.

The value must be entered into the range of 1 - N, where `N` is a valid positive integer that is greater than or equal to the number of nodes registered with the Job Manager. You do not need to add this property unless your Job Manager topology exceeds 5000 registered nodes.

Default 5000

com.ibm.websphere.security.strictCredentialExpirationCheck:

Specifies whether credential expiration check occurs for a local EJB call. Typically, when an EJB invokes another EJB that is located in a local machine, a direct method invocation occurs even if the credentials of the original invoker expire before the local EJB call occurs.

If this property is set to `true`, a credential expiration check occurs on a local EJB call before the EJB is invoked on the local machine. If the credentials have expired, the EJB call is rejected.

If this property is set to false, a credential expiration check does not occur for a local EJB call.

Default false

com.ibm.websphere.security.tokenFromMBeanSoapTimeout:

Use this property to specify the amount of time the receiving server waits for an outbound SOAP call to retrieve the proper authentication from the originating server when Single Sign-On is enabled.

There is no default value for this property. If no value is specified, the global SOAP timeout value is used as the timeout value for the SOAP connection.

com.ibm.websphere.security.useLoggedSecurityName:

This is a custom property of user registries. This property alters the behavior of creating WSCredential.

A setting of `false` indicates that the security name returned by a user registry is always used to construct WSCredential.

A setting of `true` indicates that either a security name that is supplied by login module is used or a display name that was supplied by a user registry is used. This setting is compatible with WebSphere Application Server version 6.1 and older releases.

Default false

com.ibm.websphere.security.util.csiv2SessionCacheIdleTime:

This property specifies the time in milliseconds that a CSIv2 session can remain idle before being deleted. The session is deleted if the com.ibm.websphere.security.util.csiv2SessionCacheLimitEnabled custom property is set to a true value and the maximum size of the CSIv2 session cache is exceeded.

This custom property only applies if you enable stateful sessions, set the com.ibm.websphere.security.util.csiv2SessionCacheLimitEnabled custom property to true, and set a value for the com.ibm.websphere.security.util.csiv2SessionCacheMaxSize custom property. Consider decreasing the value for this custom property if your environment uses Kerberos authentication and has a short clock skew for the configured key distribution center (KDC). In this scenario, a short clock skew is defined as less than 20 minutes.

Important: Do not set a value for this function through the custom property panel because the value is not validated against the expected range of values. Instead, set the value on the CSIv2 outbound communications panel, which is available in the administrative console by completing the following steps:

1. Expand the **Security** section and click **Global security**.
2. Expand the **RMI/IIOP security** section and click **CSIv2 outbound communications**

You can set the value in the **Idle session timeout** field. However, when you specify this value on the CSIv2 outbound communications panel, the administrative console value is expected in seconds and not milliseconds.

The range of values for this custom property is 60,000 to 86,400,000 milliseconds. By default, the value is not set.

com.ibm.websphere.security.util.csiv2SessionCacheLimitEnabled:

This custom property specifies whether to limit the size of the CSIv2 session cache.

When you set this custom property value to `true`, you must set values for the com.ibm.websphere.security.util.csiv2SessionCacheIdleTime and com.ibm.websphere.security.util.csiv2SessionCacheMaxSize custom properties. When you set this custom property to `false`, the CSIv2 session cache is not limited. The default property value is false.

Consider setting this custom property to `true` if your environment uses Kerberos authentication and has a small clock skew for the configured key distribution center (KDC). In this scenario, a small clock skew is defined as less than 20 minutes. A small clock skew can result in a larger number of rejected CSIv2 sessions. However, with a smaller value for the com.ibm.websphere.security.util.csiv2SessionCacheIdleTime custom property, the application server can clean out these rejected sessions more frequently and potentially reduce the resource shortages.

Important: This custom property only applies if you enable the stateful sessions.

Important: Although you can enable the CSIv2 session cache limit option as a custom property, it is advisable that you enable the option on the CSIv2 outbound communications panel, which is available in the administrative console by completing the following steps:

1. Expand the **Security** section and click **Global security**.
2. Expand the **RMI/IIOP security** section and click **CSIv2 outbound communications**

You can enable the **Enable CSIv2 session cache limit** option. The default value is false.

com.ibm.websphere.security.util.csiv2SessionCacheMaxSize:

This property specifies the maximum size of the session cache after which expired sessions are deleted from the cache.

Expired sessions are defined as sessions that are idle longer than the time that is specified by the com.ibm.websphere.security.util.csiv2SessionCacheIdleTime custom property. When you use the com.ibm.websphere.security.util.csiv2SessionCacheMaxSize custom property, consider setting its value between 100 and 1000 entries.

Consider specifying a value for this custom property if your environment uses Kerberos authentication and has a small clock skew for the configured key distribution center (KDC). In this scenario, a small clock skew is defined as less than 20 minutes. Consider increasing the value of this custom property if the small cache size causes the garbage collection to run so frequently that it impacts the performance of the application server.

This custom property only applies if you enable stateful sessions, set the com.ibm.websphere.security.util.csiv2SessionCacheLimitEnabled custom property to true, and set a value for the com.ibm.websphere.security.util.csiv2SessionCacheIdleTime custom property.

Important: Do not set a value for this function through the custom property panel because the value is not validated against the expected range of values. Instead, set the value on the CSIv2 outbound communications panel, which is available in the administrative console by completing the following steps:

1. Expand the **Security** section and click **Global security**.
2. Expand the **RMI/IIOP security** section and click **CSIv2 outbound communications**

You can set the value in the **Maximum cache size** field.

The range of values for this custom property is 100 to 1000 entries. By default, the value is not set.

com.ibm.websphere.security.webAlwaysLogin:

This property specifies whether the login() method will throw an exception if an identity had already been authenticated. You can overwrite this behavior by setting this property to `true`.

Default	false
Type	string

Note: The login() method always uses the user ID and password to authenticate to the WebSphere application server irrespective of the presence of the SSO information in the HttpServletRequest.

com.ibm.ws.security.addHttpOnlyAttributeToCookies:

This custom property enables you to set the HTTPOnly attribute for single sign-on (SSO) cookies.

You can use the com.ibm.ws.security.addHttpOnlyAttributeToCookies custom property to protect cookies that contain sensitive values. When you set this custom property value to `true`, the application server sets the HTTPOnly attribute for SSO cookies whose values are set by the server. The HTTPOnly attribute enables the protection of sensitive values in cookies.

Also, a true value enables the application server to properly recognize, accept, and process inbound cookies with HTTPOnly attributes and inhibit any *cross-site scripting* from accessing sensitive cookie information.

A common security problem, which impacts web servers, is cross-site scripting. Cross-site scripting is a server-side vulnerability that is often created when user input is rendered as HTML. Cross-site scripting attacks can expose sensitive information about the users of the website. Most modern web browsers honor the HTTPOnly attribute to prevent this attack. A cookie with this attribute is called an *HTTPOnly cookie*. Information that exists in an HTTPOnly cookie is less likely to be disclosed to a hacker or a malicious website. For more information about the HTTPOnly attribute, see the Open Web Application Security Project (OWASP) website.

Important: When you use this custom property, HTTPOnly attribute is not added to every cookie that passes through the application server. Also, the attribute is not added to other non-secure cookies that are created by the application server. A list of non-HTTPOnly cookies includes:

- JSESSIONID cookies
- SSO cookies that are created by authenticators or providers from another software vendor
- Client or browser cookies that do not already contain the HTTPOnly attribute

You can set or remove this custom property from the Single sign-on panel in the administrative console by doing the following:

1. Click **Security > Global security**.
2. Under Authentication, click **Web and SIP security > Single sign-on (SSO)**.

Default true **Type** Boolean

com.ibm.ws.security.allowNonAdminToSecurityXML:

This property specifies whether the non-admin security roles are allowed the ability to modify the security.xml file. Setting this property to `true` gives non-admin security roles the ability to modify the security.xml file. In Version 6.1 and above, by default, non-admin security roles have the ability to modify the security.xml file.

Default false
Type Boolean

com.ibm.ws.security.config.SupportORBConfig:

Specifies whether to check or not check the object request broker (ORB) for properties. This property needs to be set as a system property. You set this property to `true` or `yes` so that the ORB is checked for properties. For any other setting, the ORB is completely ignored.

The property is to be used when a pluggable application client connects to the WebSphere Application Server. Specifically, this property is used whenever a hashmap containing security properties is passed in a hashmap on a new InitialContext(env) call.

com.ibm.ws.security.createTokenSubjectForAsynchLogin:

In this release, the actual LTPA token data is not available from a WSCredential.getCredentialToken() call when called from an asynchronous bean. For an existing configuration, you can add the `com.ibm.ws.security.createTokenSubjectForAsynchLogin` custom property and a `true` value to allow the LTPAToken to be forwarded to asynchronous beans. This property allows portlets to successfully perform LTPA token forwarding. This custom property is case sensitive. You must restart the application server after you add this custom property.

Note: This custom property applies only to system conditions where Server A makes EJB calls from asynchronous beans to Server B. This property does not apply for JAAS login situations.

Default not applicable

com.ibm.ws.security.defaultLoginConfig:

This property is the JAAS login configuration that is used for logins that do not fall under the WEB_INBOUND, RMI_OUTBOUND, or RMI_INBOUND login configuration categories.

Internal authentication and protocols that do not have specific JAAS plug points call the system login configuration that is referenced by com.ibm.ws.security.defaultLoginConfig configuration.

Default system.DEFAULT

com.ibm.ws.security.failSSODuringCushion:

Use the com.ibm.ws.security.failSSODuringCushion custom property to update custom JAAS Subject data for the LTPA token.

When you do not set this custom property to true, new JAAS Subjects might not contain the custom JAAS Subject data.

The default value is true.

com.ibm.ws.security.ltpa.forceSoftwareJCEProviderForLTPA:

Use the com.ibm.ws.security.ltpa.forceSoftwareJCEProviderForLTPA custom property to correct an "invalid library name" error when you attempt to use a PKCS11 type keystore with a Java client.

The `ssl.client.props` file points to a configuration file, which in turn, points to the library name for the cryptographic device. The code for the Java client looks for a keystore type for the correct provider name. Without this custom property, the keystore type constant for PKCS11 is not specified correctly as it references the IBMPKCS11Impl provider instead. Also, the Lightweight Third Party Authentication (LTPA) code uses the provider list to determine the Java Cryptography Extension (JCE) provider. This approach causes a problem when Secure Sockets Layer (SSL) acceleration is attempted because the IBMPKCS11Impl provider needs to be listed before the IBMJCE provider within the `java.security` file.

This custom property corrects both issues so that SSL and other cryptographic mechanisms can use hardware acceleration.

Note: LTPA cannot use hardware acceleration because the software keys for LTPA do not implement the java.security.interfaces.RSAPrivateCrtKey interface, which is required by many accelerator cards.

Set this custom property to true when you want to use a PKCS11 type keystore with a Java client.

Default false

com.ibm.ws.security.ltpa.useCRT:

Use this property to improve the CPU utilization during the sign() operation that occurs when a new LTPA2 (SSO) token is created. When this property is set to `true`, the product implements the Chinese Remainder Theorem (CRT) algorithm when signing the new token. This property has no effect on the old style LTPA token.

Default false

com.ibm.ws.security.ssoInteropModeEnabled:

This property determines whether to send LtpaToken2 and LtpaToken cookies in the response to a web request (interoperable).

When this property value is false, the application server just sends the new LtpaToken2 cookie which is stronger, but not interoperable with some other products and Application Server releases prior to Version 5.1.1. In most cases, the old LtpaToken cookie is not needed and you can set this property to false.

Default true

com.ibm.ws.security.unprotectedUserRegistryMethods:

Specifies the method names on the UserRegistry interface, such as getRealm, getUsers, and isValidUser, that you do not want protected from remote access. If you specify multiple method names, separate the

names with either a space, a comma, a semi-colon, and a separator bar. See your implementation of the UserRegistry interface file for a complete list of valid method names.

If you specify an * as the value for this property, all methods are unprotected from remote access.

If a value is not specified for this property, all methods are protected from remote access.

If an attempt is made to remotely access a protected UserRegistry interface method, the remote process receives a CORBA NO_PERMISSION exception with minor code 49421098.

There is no default value for this property.

com.ibm.ws.security.webChallengeIfCustomSubjectNotFound:

This property determines the behavior of a single sign-on LtpaToken2 login.

If the token contains a custom cache key and the custom Subject cannot be found, then the token is used to log in directly as the custom information needs to be regathered if this property value is set to true. A challenge also occurs so that the user is required to login again. When this property value is set to false and the custom Subject is not found, the LtpaToken2 is used to login and gather all of the registry attributes. However, the token might not obtain any of the special attributes that downstream applications might expect.

Default true

com.ibm.ws.security.webInboundLoginConfig:

This property is the JAAS login configuration that is used for web requests that are received inbound.

By knowing the login configuration, you can plug in a custom login module that can handle specific cases for web logins.

Default system.WEB_INBOUND

com.ibm.ws.security.webInboundPropagationEnabled:

This property determines whether a received LtpaToken2 cookie should search for the propagated attributes locally before searching the original login server that is specified in the token. After the propagated attributes are received, the Subject is regenerated and the custom attributes are preserved.

Default true

com.ibm.wsspi.security.ltpa.tokenFactory:

This property specifies the Lightweight Third Party Authentication (LTPA) token factories that can be used to validate the LTPA tokens.

Validation occurs in the order in which the token factories are specified because LTPA tokens do not have object identifiers (OIDs) that specify the token type. The Application Server validates the tokens using each token factory until validation is successful. The order that is specified for this property is the most likely order of the received tokens. Specify multiple token factories by separating them with a pipe (|) without spaces before or following the pipe.

Default com.ibm.ws.security.ltpa.LTPATokenFactory |
com.ibm.ws.security.ltpa.LTPAToken2Factory |
com.ibm.ws.security.ltpa.AuthzPropTokenFactory

com.ibm.wsspi.security.token.authenticationTokenFactory:

This property specifies the implementation that is used for an authentication token in the attribute propagation framework. The property provides an old LTPA token implementation for use as the authentication token.

Default com.ibm.ws.security.ltpa.LTPATokenFactory

com.ibm.wsspi.security.token.authorizationTokenFactory:

This property specifies the implementation that is used for an authorization token. This token factory encodes the authorization information.

Default com.ibm.ws.security.ltpa.AuthzPropTokenFactory

com.ibm.wsspi.security.token.propagationTokenFactory:

This property specifies the implementation that is used for a propagation token. This token factory encodes the propagation token information.

The propagation token is on the thread of execution and is not associated with any specific user Subjects. The token follows the invocation downstream wherever the process leads.

Default com.ibm.ws.security.ltpa.AuthzPropTokenFactory

com.ibm.wsspi.security.token.singleSignonTokenFactory:

This property specifies the implementation that is used for a Single Sign-on (SSO) token. This implementation is the cookie that is set when propagation is enabled regardless of the state of the com.ibm.ws.security.ssoInteropModeEnabled property.

By default, this implementation is the LtpaToken2 cookie.

Default com.ibm.ws.security.ltpa.LTPAToken2Factory

com.ibm.wsspi.wssecurity.kerberos.failAuthForExpiredKerberosToken:

Use this property to specify how you want the system to handle authentication for a request after the Kerberos token for the request expires.

When this property is set to `true`, if a Kerberos token cannot be refreshed after it expires, authentication for the request fails.

When this property is set to `false`, authentication for the request does not fail even if the token has expired.

The default value for this property is false.

security.allowCustomHTTPMethods:

Use this custom property to permit custom HTTP methods. The custom HTTP methods are other than the standard HTTP methods, which are: DELETE, GET, HEAD, OPTIONS, POST, PUT or TRACE.

When this property is set to `false`, which is the default, if a combination of a URI pattern and a custom HTTP method are not listed in the security-constraint element, a search of the security constraint is performed using an URI pattern only. If there is a match, the value of the <auth-constraints> element is enforced. This behavior minimizes a potential security exposure.

When this property is set to `true`, the custom HTTP methods are treated as the standard HTTP methods. An authorization decision is made by both the URI pattern and the HTTP method. To properly protect a target URI, make sure that the proper HTTP methods are listed in the <web-resource-collection> element.

security.enablePluggableAuthentication:

This property is no longer used. Instead, use WEB_INBOUND login configuration.

Complete the following steps to modify the WEB_INBOUND login configuration:

1. Click **Security > Global security**.
2. Under Java Authentication and Authorization Service, click **System logins**.

Default true

security.useDefaultPolicyWhenJ2SDisabled:

The NullDynamicPolicy.getPermissions method provides an option to delegate a default policy class to construct a Permissions object when the `security.useDefaultPolicyWhenJ2SDisabled` custom property is set to `true`. When this property is set to `false`, an empty Permissions object is returned.

Default false

Security custom property collection:

Use this page to view and manage arbitrary name-value pairs of data, where the name is a property key and the value is a string value that can be used to set internal system configuration properties.

The administrative console contains several custom properties pages that work similarly. To view one of these administrative pages, click a **Custom properties** link.

Name:

Specifies the name (or key) for the property.

Each property name must be unique. If the same name is used for multiple properties, the value specified for the first property is used.

Do not start your property names with `was.` because this prefix is reserved for properties that are predefined in the application server.

Value:

Specifies the value paired with the specified name.

Description:

Provides information about the name-value pair.

Security custom property settings:

Use this page to configure arbitrary name-value pairs of data, where the name is a property key and the value is a string value that can be used to set internal system configuration properties. Defining a new property enables you to configure a setting beyond that which is available in the administrative console.

The administrative console contains several custom property settings pages that work similarly. To view one of these administrative pages, click **Custom properties**.

Name:

Specifies the name (or key) for the property.

Each property name must be unique. If the same name is used for multiple properties, the value specified for the first property is used.

Do not start your property names with `was.` because this prefix is reserved for properties that are predefined in the product.

Data type String

Value:

Specifies the value paired with the specified name.

Data type String

Description:

Provides information about the name and value pair.

Data type String

Testing security after enabling it

Basic tests are available that show whether the fundamental security components are working properly. Use this task to validate your security configuration.

Before you begin

After configuring administrative security and restarting all of your servers in a secure mode, validate that security is properly enabled.

There are a few techniques that you can use to test the various security login types. For example, you can test the Web-based BasicAuth login, Web-based form login, and the Java client BasicAuth login.

Basic tests are available that show whether the fundamental security components are working properly. Complete the following steps to validate your security configuration:

Procedure

1. After enabling security, verify that your system comes up in secure mode.
2. Test the Web-based BasicAuth with *Snoop*, by accessing the following URL: `http://hostname.domain:9080/snoop`.

3. Test the Web-based form login by starting the administrative console: `http://hostname.domain:port_number/ibm/console`. A form-based login page is displayed. If a login page does not appear, try accessing the administrative console by typing `https://myhost.domain:9043/ibm/console`.

   Type in the administrative user ID and password that are used for configuring your user registry when configuring security.
4. Test Java Client BasicAuth with *dumpNameSpace*.

   Use the `app_server_root/bin/dumpNameSpace` file. A login panel appears. If a login panel does not appear, there is a problem. Type in any valid user ID and password in your configured user registry.
5. Test all of your applications in secure mode.
6. If all the tests pass, proceed with more rigorous testing of your secured applications. If you have any problems, review the SYSOUT and SYSPRINT logs. For more information on common problems, see Troubleshooting security configurations.

Results

The results of these tests, if successful, indicate that security is fully enabled and working properly.

Security Configuration Wizard

The Security Configuration Wizard guides you through the process of completing the basic requirements to secure your application serving environment.

This wizard is available from the Security menu from the left pane of the admin console. To get to the wizard, navigate to **Security** > **Global security** > **Security Configuration Wizard**.

Step one of the configuration wizard allows you to choose the level of security desired. application-level security is selected by default. You also have the option of selecting Java 2 security.

Step two of the configuration wizard allows you to select a user repository. You have the following options:

- “Federated repository wizard settings” on page 1327
- “Local operating system wizard settings” on page 1260
- “Stand-alone custom registry wizard settings” on page 1291
- “Standalone LDAP registry wizard settings” on page 1267

Step three of the configuration wizard allows you to specify the local operating system user and group definitions as the repository, and, if necessary, to provide the name of a user with administrator privileges.

Step four of the configuration wizard provides a summary of the results of the configuration process.

Security configuration report

The security configuration report gathers and displays the current security settings of the application server. Information is gathered about core security settings, administrative users and groups, CORBA naming roles, and cookie protection. When multiple security domains are configured, each security domain has it's own report with a subset of the sections shown in the global security report that apply to the domain.

Note: The security configuration report now includes information about session security, web Attributes, and the HttpOnly setting to enable you to get a more complete view of your server security settings.

The report is a table with four columns: **Console Name**, **Security Configuration Name**, **Value** and **Console Path Name**. The security information gathered is divided into sections, and groups common security information. A row highlighted in blue with a title in the first column starts a new section.

The Security Configuration Report can be run from the administrative console by selecting **Security > Global Security** and then clicking **Security Configuration Report**. A new window displays the report information.

The columns

Console Name
Contains the name of the security attribute as found in the administrative console. If the value in this column is on a row highlighted in blue, and is the only entry on the row, then it is the start of a new section.

Security Configuration Name
Contains the security attribute as found in the configuration file.

Value Contains the value of the security attribute.

Console Path Name
Contains the path where the attribute is found on the console.

The sections

Security Settings
Displays information about the top-level security attributes. These attributes set the default for administrative security for the server, such as whether security is enabled, the default user registry, or if Java security is enabled.

For more information, read the Global security settings article.

Authentication Mechanisms and expirations
Contains all the attributes associated with each authentication mechanisms and trust associations as defined in the configuration.

User Registry
Displays the attributes for the default user registry for the server.

Authorization configuration
Displays attributes configured for an external Java Authorization Contract for Containers (JACC) provider.

Application login configuration
Displays application JAAS login entries and their login modules attributes.

For more information, read the SSL configurations collection article.

CSI Displays the attributes that define the inbound and outbound information for the Common Secure Interoperability (CSI) protocol.

SSL configuration repertoires
Displays the attributes that make up the Secure Sockets Layer (SSL) configuration used by the server. There can be multiple SSL configurations defined, and information about each is displayed. This object is often referenced by an SSL configuration group object used to associate it with an inbound or an outbound connection.

For more information, read the SSL configurations collection article.

Key stores
Displays the keystore attributes for each keystore in the configuration. Keystore objects in the configuration are often referenced by an SSL configuration object in the configuration.

For more information, read the Personal certificates collection article.

Trust managers
Displays the attributes that make up trust managers that can be used by the server. Trust manager objects in the configuration are typically referenced by an SSL configuration object.

For the more information, read the Trust managers collection article.

Key managers
Displays the attributes that make up the key managers that are used by the server. Key manager objects in the configuration are typically referenced by an SSL configuration object.

For more information, read the Key managers collection article.

SSL configuration group
Displays the attributes that make up an SSL configuration that are used for an outbound or an inbound connection.

Management scope
Displays the attributes that make up a management scope. The SSL configuration-related objects in the security configuration are defined within a management scope to reference the management scope object.

For more information, read the Management scope configurations article.

Key set groups
Displays the attributes that make up a group of key sets, which are used to manage public, private and shared keys.

For more information, read the Key set groups collection article.

Key set
Displays the attributes that make up the key set, which is used to manage public, private, and shared keys.

For more information, read the Key sets collection article.

Schedules
Displays the attributes that make up the scheduled process in the security configuration.

Notifications
Displays the attributes that make up notification objects in the security configuration.

Manage certificate expiration
Displays the attributes that define how startCertificateExpMonitor is run on the server.

System login configuration
Displays the attributes that define the System login entries and their login modules.

For more information, read the System login configuration entry settings for Java Authentication and Authorization Service article.

Custom properties
Displays all the custom properties that are defined in the security configuration.

For more information, read the Custom properties article.

Web Authentication
Displays properties that are used to define web authentication used by the server.

For more information, read the web authentication settings article.

Administrative Users and Groups
Displays the attributes that define roles and the users and groups associated with them as found in the `admin-authz.xml` file. The column titled **Administrative Role Name** contains the name of the administrative role. A column titled **Administrative Role Value** contains the user ID associated with the role (if one exists).

For more information, read the Administrative roles article.

Corba Naming Console Names
Displays the defined CORBA naming roles and the users that are assigned to the roles.

For more information, read the Administrative group roles and CORBA naming service groups article.

Console Name for Certificate Management
Lists all the certificate in keystore that are defined in the security configuration. There is also information about the certificates location and their validity period.

Cookie Protection
Displays attributes that pertain to HTTP Cookies. This section differs from other sections since information is gathered from different configuration files. The HttpOnly custom property, the web authentication com.ibm.wsspi.security.web.webAuthReq property, and the session security setting on each server are displayed on the report.

Java Authorization SPI Configuration
Displays the attributes that are defined for the Java Authorization SPI (JASPI) configuration. If there is a JASPI configuration object in the security configuration, information is included concerning whether JASPI is enabled, the name of the default JASPI provider, and a list of defined providers and their authentication modules.

Note: If JASPI has not been configured, this section is not shown in the security configuration report.

Adding a new custom property in a global security configuration or in a security domain configuration

Custom properties are arbitrary name-value pairs of data, where the name is a property key and the value is a string value that can be used to set internal system configuration properties. Defining a new property enables you to configure settings beyond those that are available in the administrative console. You can add new security custom properties in a security configuration or in a security domain configuration.

About this task

Adding a new custom property in a global security configuration using the administrative console

1. Click **Security > Global security > Custom properties**.
2. Click **New**,
3. Enter the property key name in the **Name** field.

   Each property key name must be unique. If the same name is used for multiple properties, the value specified for the first property is used.

   Do not start your property names with `was`, because this prefix is reserved for properties that are predefined in the application server.
4. Enter the property value in the **Value** field.
5. Click **Apply** or **Save**.

You can also use the -customProperties flag in the setAdminActiveSecuritySettings wsadmin command to add a new custom property in a global security configuration. See the SecurityConfigurationCommands command group for the AdminTask object article for more information about this command. For example:

```
wsadmin>AdminTask.setAdminActiveSecuritySettings('[-customProperties
["com.ibm.websphere.security.test=false"]]')
```

Adding a new custom property in a security domain configuration using the administrative console

1. Click **Security > Security domains**.
2. Select the global security domain you want to add a new custom property to.
3. Click **Custom properties**.
4. Click **New**.
5. Enter the property key name in the **Name** field.

Each property key name must be unique. If the same name is used for multiple properties, the value specified for the first property is used.

Do not start your property names with `was`, because this prefix is reserved for properties that are predefined in the application server.

6. Enter the property value in the **Value** field
7. Click **Apply** or **Save**.

You can also use the -customProperties flag in the setAppActiveSecuritySettings wsadmin command to add a new custom property in a global security domain configuration. See the SecurityConfigurationCommands command group for the AdminTask object article for more information about this command. Use the -securityDomainName flag to specify the security domain where the custom property is located. For example:

```
wsadmin>AdminTask.setAppActiveSecuritySettings('[ -securityDomainName testDomain
-customProperties ["com.ibm.websphere.security.test=false"]]')
```

Modifying an existing custom property in a global security configuration or in a security domain configuration

Custom properties are arbitrary name-value pairs of data, where the name is a property key and the value is a string value that can be used to set internal system configuration properties. Defining a new property enables you to configure settings beyond those that are available in the administrative console. You can modify existing security custom properties in a global security configuration or in a security domain configuration.

About this task

Modifying an existing custom property in a global security configuration using the administrative console

1. Click **Security > Global security > Custom properies**.
2. Select the custom property you want to modify.
3. Click **Edit** In the **Value** field, and then enter the value you want to modify.
4. Click **Apply** or **Save**.

You can also use the -customProperties flag in the setAdminActiveSecuritySettings wsadmin command to modify an existing custom property in a global security configuration. See the SecurityConfigurationCommands command group for the AdminTask object article for more information about this command. For example:

```
wsadmin>AdminTask.setAdminActiveSecuritySettings('[-customProperties
["com.ibm.websphere.security.test=false"]]')
```

Modifying an existing custom property in a security domain configuration using the administrative console

1. Click **Security > Security domains**.
2. Select the global security domain you want to modify.
3. Click **Custom properties**.
4. Select the custom property you want to modify.
5. Click **Edit**.In the **Value** field, and then enter the value you want to modify.
6. Click **Apply** or **Save**.

You can also use the -customProperties flag in the setAppActiveSecuritySettings wsadmin command to modify an existing custom property in a global security domain configuration. See the SecurityConfigurationCommands command group for the AdminTask object article for more information about this command. Use the -securityDomainName flag to specify the security domain where the custom property is located. For example:

```
wsadmin>AdminTask.setAppActiveSecuritySettings('[ -securityDomainName
testDomain -customProperties ["com.ibm.websphere.security.test=false"]]'
```

Deleting an existing custom property in a global security configuration or in a security domain configuration

Custom properties are arbitrary name-value pairs of data, where the name is a property key and the value is a string value that can be used to set internal system configuration properties. Defining a new property enables you to configure settings beyond those that are available in the administrative console. You can delete existing security custom properties in a global security configuration or in a security domain configuration.

About this task

Deleting an existing custom property in a global security configuration using the administrative console

1. Click **Security > Global security > Custom properties**.
2. Select the custom property you want to delete.
3. Click **Delete**.
4. Click **Apply** or **Save**.

You can also use the -customProperties flag in the setAdminActiveSecuritySettings wsadmin command to delete an existing custom property in a global security configuration. See the SecurityConfigurationCommands command group for the AdminTask object article for more information about this command. For example:

```
wsadmin>AdminTask.setAdminActiveSecuritySettings('[-customProperties
["com.ibm.websphere.security.test="]]')
```

Deleting an existing custom property in a security domain configuration using the administrative console

1. Click **Security > Security domains**.
2. Click **Custom properties**.
3. Select the custom property you want to delete.
4. Click **Delete**.
5. In the **Value** field, enter the value you want to delete.
6. Click **Apply** or **Save**.

You can also use the -customProperties flag in the setAppActiveSecuritySettings wsadmin command to delete an existing custom property in a global security domain configuration. See the SecurityConfigurationCommands command group for the AdminTask object article for more information about this command. Use the -securityDomainName flag to specify the security domain where the custom property is located. .For example:

```
wsadmin>AdminTask.setAppActiveSecuritySettings('[ -securityDomainName testDomain
-customProperties ["com.ibm.websphere.security.test="]]')
```

Configuring multiple security domains

By default, all administrative and user applications in WebSphere Application Server use the global security configuration. For example, a user registry defined in global security is used to authenticate users for every application in the cell. Out-of-the-box, this behavior is the same as it was in previous releases of WebSphere Application Server. You can create additional WebSphere security domains if you want to specify different security attributes for some or all of your user applications. This section describes how to configure a security domain by using the administrative console.

Before you begin

Only users assigned to the administrator role can configure or create new multiple security domains. Enable global security in your environment before configuring multiple security domains.

Read about “Multiple security domains” on page 1222 for a better understanding of what multiple security domains are and how they are supported in this version of WebSphere Application Server.

About this task

Security domains enable you to define multiple security configurations for use in your environment. For example, you can define different security (such as a different user registry) for user applications than for administrative applications. You can also define separate security configurations for user applications deployed to different servers and clusters.

Perform the following steps to configure a new security domain by using the administrative console:

Procedure

1. Click **Security > Security domains**.
2. If you are creating a new multiple security domain, click **New**. Supply a unique name and description for the domain and click **Apply**. If you want to configure an existing multiple security domain, select one to edit. Once you click **Apply** the domain name and additional sections are displayed. One section enables you to define the security attributes for the domain, and another section enables you to select the scopes to which the domain applies.
3. Under Assigned Scopes, select whether you want to assign the security domain to the entire cell or if you want to select the specific servers, clusters, and service integration buses to be included in the security domain. The Assigned Scopes section has two views. The default view is a cell topology. To assign the security domain to the entire cell, click the check box for the cell and then click **Apply** or **OK**.

   The name of the security domain appears next to the cell name, which indicates that the domain is now assigned to the cell. You can expand the topology and assign the domain to one or more servers and clusters. When an item in the topology is already assigned to another security domain, the check box is disabled and the name of the assigned domain is displayed to the right of the scope name. If you want to assign one of these scopes to the domain, you must first disassociate it with its current domain.

   Select **All assigned scopes** to view a list of only those resources that are currently assigned to the security domain.
4. Customize your security configuration by specifying security attributes for your new domain. Attributes that are not listed can not be customized at the domain level. Domains inherit attributes from the global security configuration.

   There are twelve individually configurable security attribute sections. You can expand and collapse each section. In the collapsed state, the name and a summary value for the section are displayed. Additionally, the summary value text indicates whether the attribute is defined in global security and is reused by the domain (as indicated by gray text) or if it is customized for the domain (as indicated by black text prefixed by the word “Customized”).

   Initially, each security attribute is set to use the global security settings. When an attribute is set to use global security, there is no domain-specific configuration for that attribute. Applications that use the domain use the global configuration for these security attributes.

   Only configure the security attributes that you want to change. To configure a security attribute for a domain, expand the security attribute section. The key properties of the global configuration display beneath the **Use global security** option. These properties are provided for convenience.

   To customize the configuration for the domain, select **Customize for this domain**. Configure the property and then click **OK** or **Apply**.

Note: In general, when you select **Customize for this domain**, you override all of the security configurations that are defined for that section in global security. Application logins, system logins, and J2C authentication data entries are some exceptions. When you define entries for a domain, applications in the domain are able to access the global entries in addition to the domain-specific entries.

For example, you might want to use a different user registry for applications that use the security domain but also want to use the global security configuration for all of the other security properties. In this case, expand the User Realm section and select **Customize for this domain**. Select a user registry type, click **Configure**, and provide the appropriate configuration details on the subsequent panel.

You can change security attributes such as the following:

Application Security

Specifies the settings for application security and Java 2 security. You can use the global security settings or customize the settings for a domain.

Select **Enable application security** to enable or disable security this choice for user applications. When this selection is disabled, all of the EJBs and web applications in the security domain are no longer protected. Access is granted to these resources without user authentication. When you enable this selection, the J2EE security is enforced for all of the EJBs and web applications in the security domain. The J2EE security is only enforced when Global Security is enabled in the global security configuration, (that is, you cannot enable application security without first enabling Global Security at the global level).

Java 2 Security

Select **Java 2 security** to enable or disable Java 2 security at the domain level. This choice enables or disables Java 2 security at the process (JVM) level so that all applications (both administrative and user) can enable or disable Java 2 security.

User realm

This section enables you to configure the user registry for the security domain. You can separately configure any registry that is used at the domain level. Read about “Multiple security domains” on page 1222 for more information.

Trust association

When you configure the trust association interceptor (TAI) at a domain level, the interceptors configured at the global level are copied to the domain level for convenience. You can modify the interceptor list at the domain level to fit your needs. Only configure those interceptors that are to be used at the domain level.

SPNEGO Web Authentication

The SPNEGO web authentication, which enables you to configure SPNEGO for web resource authentication, can be configured at the domain level.

Note: In WebSphere Application Server Version 6.1, a TAI that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. This function was deprecated in WebSphere Application Server 7.0. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

RMI/IIOP Security

The RMI/IIOP security attribute refers to the CSIv2 (Common Secure Interoperability version 2) protocol properties. When you configure these attributes at the domain level, the RMI/IIOP security configuration at the global level is copied for convenience.

You can change the attributes that need to be different at the domain level. The Transport layer settings for CSIv2 inbound communications should be the same for both the global and the domain levels. If they are different, the domain level attributes are applied to all of the application in the process.

JAAS application logins

Specifies the configuration settings for the Java Authentication and Authorization Service (JAAS) application logins. You can use the global security settings or customize the settings for a domain.

Note: The JAAS application logins, the JAAS system logins, and the JAAS J2C authentication data aliases can all be configured at the domain level. By default, all of the applications in the system have access to the JAAS logins configured at the global level. The security runtime first checks for the JAAS logins at the domain level. If it does not find them, it then checks for them in the global security configuration. Configure any of these JAAS logins at a domain only when you need to specify a login that is used exclusively by the applications in the security domain.

JAAS system logins

Specifies the configuration settings for the JAAS system logins. You can use the global security settings or customize the configuration settings for a domain.

JAAS J2C authentication

Specifies the configuration settings for the JAAS J2C authentication data. You can use the global security settings or customize the settings for a domain.

Java Authentication SPI (JASPI)

Specifies the configuration settings for a Java Authentication SPI (JASPI) authentication provider and associated authentication modules. You can use the global security settings or customize the settings for a domain. To configure JASPI authentication providers for a domain, select **Customize for this domain** and then enable JASPI. Select **Providers** to define providers for the domain.

Note: The JASPI authentication provider can be enabled with providers configured at the domain level. By default, all of the applications in the system have access to the JASPI authentication providers configured at the global level. The security runtime first checks for the JASPI authentication providers at the domain level. If it does not find them, it then checks for them in the global security configuration. Configure JASPI authentication providers at a domain only when the provider is to be used exclusively by the applications in that security domain.

Authentication Mechanism Attributes

Specifies the various cache settings that need to applied at the domain level.

Select **Authentication cache settings** to specify your authentication cache settings. The configuration specified on this panel is applied only to this domain.

Select **LTPA Timeout** to configure a different LTPA timeout value at the domain level. The default timeout value is 120 minutes, which is set at the global level. If the LTPA timeout is set at the domain level, any token that is created in the security domain when accessing user applications is created with this expiration time.

When **Use realm-qualified user names** is enabled, user names returned by methods such as `getUserPrincipal( )` are qualified with the security realm (user registry) used by applications in the security domain.

Authorization Provider

You can configure an external third party JACC (Java Authorization Contract for Containers) provider at the domain level. Tivoli Access Manager's JACC provider can only be configured at

the global level. Security domains can still use it if they do not override the authorization provider with another JACC provider or with the built-in native authorization.

On z/OS, you can enable or disable the System Authorization Facility (SAF) based authorization at the domain level.

Custom properties

Set custom properties at the domain level that are either new or different from those at the global level. By default, all of the custom properties at the global security configuration can be accessed by all of the applications in the cell. The security runtime code first checks for the custom property at the domain level. If it does not find it, it then attempts to obtain the custom property from the global security configuration.

5. Once you have configured the security attributes and assigned the domain to one or more scopes, click **Apply** or **OK**.
6. Restart all servers and clusters for your changes to take effect.

Multiple security domains

The WebSphere Security Domains (WSD) provide the flexibility to use different security configurations in WebSphere Application Server. The WSD is also referred to as multiple security domains, or simply, security domains. You can configure different security attributes, such as the UserRegistry, for different applications.

Note: Multiple security domain support was introduced in WebSphere Application Server Version 7.0. You can create different security configurations and assign them to different applications in WebSphere Application Server processes. By creating multiple security domains, you can configure different security attributes for both administrative and user applications within a cell environment. You can configure different applications to use different security configurations by assigning the servers or clusters or service integration buses that host these applications to the security domains. Only users assigned to the administrator role can configure multiple security domains.

The following sections describe multiple security domains in more detail:

- “Why security domains are useful”
- “Relationship between global security and security domains” on page 1223
- “Contents of a security domain” on page 1224
- “Creating security domains” on page 1225
- “Configuring attributes for security domains” on page 1226
- “Associating scopes to security domains” on page 1227
- “Relationship between old server level security and the new security domains” on page 1228
- “How domain level security attributes are used by security runtime and applications” on page 1228
- “Client and application security programming model when using security domains” on page 1232
- “Application deployment in multiple domains configurations” on page 1233
- “Cross realm communication” on page 1234
- “Federating a node with security domains” on page 1236
- “Security domains in a mixed-version environment” on page 1237
- “Modifying security domains” on page 1237

Why security domains are useful

WebSphere Security Domains provide two major benefits:

- WebSphere Application Server administrative applications can be configured with a different set of security configurations from those for user applications.

- They enable one set of applications to have a different set of security configurations from another set of applications.

  For example, WebSphere Application Server administration can be configured to a user registry of federated repository while the applications can be configured to a user registry of LDAP.

In previous versions of WebSphere Application Server, all administrative and user applications use security attributes different from those attributes that are defined in global security. All administrative and user applications in WebSphere Application Server use global security attributes by default. For example, a user registry defined in global security is used to authenticate a user for every application in the cell.

In this release of WebSphere Application Server, however, you can use multiple security attributes for user applications other than the global security attributes, create a security domain for those security attributes that must differ, and associate them with the servers and clusters that host those user applications. You also can associate a security domain with the cell. All of the user applications in the cell use this security domain if they do not have a domain previously associated with them. However, global security attributes are still required for administrative applications such as the administrative console, naming resources and MBeans.

If you have used server level security in previous releases of WebSphere Application Server, you should now use multiple security domains since they are more flexible and easier to configure.

Server level security is deprecated in this release. Read “Relationship between global security and security domains” for more information.

Relationship between global security and security domains

Global Security applies to all administrative functions and the default security configuration for user applications. Security domains can be used to define a customized configuration for user applications.

You must have a global security configuration defined before you can create security domains. The global security configuration is used by all of the administrative applications such as the administrative console, naming resources, and Mbeans. If no security domains are configured, all of the applications use information from the global security configuration. User applications such as Enterprise JavaBeans (EJBs), servlets and administrative applications use the same security configuration.

When you create a security domain and associate it with a scope, only the user applications in that scope use the security attributes that are defined in the security domain. The administrative applications as well as the naming operations in that scope use the global security configuration. Define the security attributes at the domain level that need to be different from those at the global level. If the information is common, the security domain does not need to have the information duplicated in it. Any attributes that are missing in the domain are obtained from the global configuration. The global security configuration data is stored in the `security.xml` file, which is located in the `$WAS_HOME/profiles/$ProfileName/cells/$CellName` directory.

The following figure provides an example of a security multiple domain where the cell, a server and a cluster are associated with different security domains. As shown in the figure, the user applications in server `S1.1` as well as the cluster use security attributes that are defined in `Domain2` and `Domain3` respectively (since these scopes are associated with these domains). Server `S2.2` is not associated with a domain. As a result, the user application in `S2.2` uses the domain that is associated with the cell (`Domain1`) by default . Security attributes that are missing from the domain level are obtained from the global configuration.

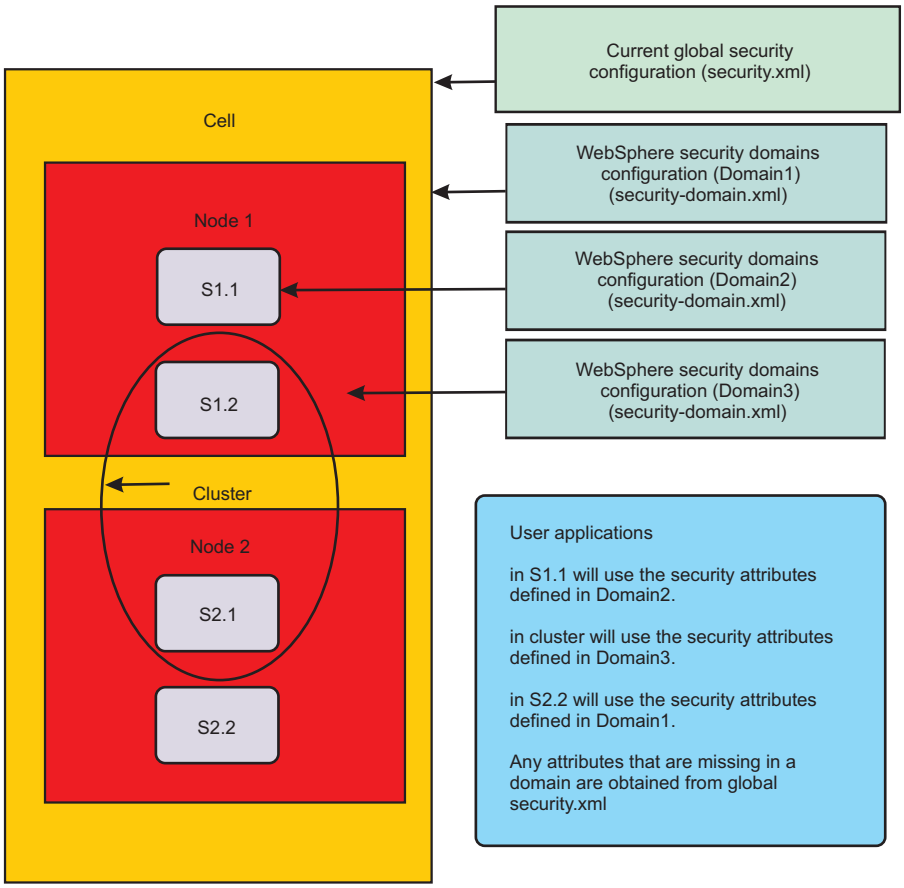

Figure 4. Scopes that can be associated to a security domain

The following figure shows the various high-level security attributes that can be defined at the global security configuration and those that can be overridden at the domain level.

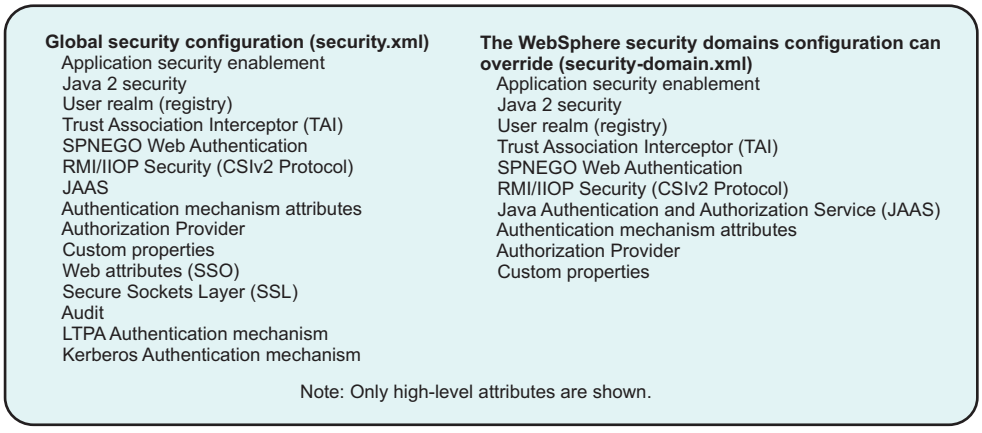

Figure 5. Security attributes that can be configured at the security domain

Contents of a security domain

A security domain is represented by two configuration files. One configuration file contains the list of attributes that are configured in the security domain. The other configuration file contains the scopes that use the security domain. The security domain information is stored in the `$WAS_HOME/profiles/`

$ProfileName/config/waspolicies/default/securitydomains/$SecurityDomainName directory. For every security domain that is configured, a $SecurityDomainName directory is created with two files in it: the security-domain.xml file contains the list of security attributes configured for the security domain, and the security-domain-map.xml file contains the scopes that use the security domain.

The following figure indicates the location of the main security domain related files and the contents of those files.

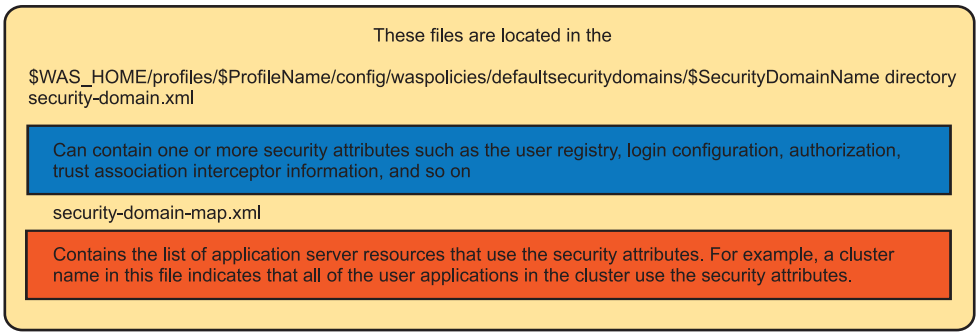

Figure 6. Location and contents of the main security domain related files

Note: You should not modify these files manually. Use administrative console tasks or scripting commands to modify the files instead. For a complete list of administrative tasks and scripting commands, see the links in "Related tasks" at the bottom of this document.

Creating security domains

Use the administrative console tasks or scripting commands to create security domains. In the administrative console, access security domains by clicking **Security > Security domains**. Help is available for each administrative console panel.

For a complete list of administrative console tasks and scripting commands, see the links in "Related tasks" at the bottom of this document.

When you create a security domain you must supply a unique name for the domain, the security attributes you want to configure for the security domain, and the scopes that need to use the security domain. Once configured, the servers that use the security domain must be restarted. The user applications in those scopes then use the attributes that are defined in the security domain. Any attributes that are not configured at the domain level are obtained from the global security configuration. Administrative applications and naming operations in the scopes always use the security attributes from the global security configuration. You must actively manage these attributes.

Any new security domain attributes must be compatible with those global security attributes that are inherited by the user applications that are assigned to the domain.

Other than for JAAS and custom properties, once global attributes are customized for a domain they are no longer used by user applications.

The security domains panel in the administrative console enables you to assign resources and to select the appropriate security attributes for your domain. The panel displays the key security attributes at the global configuration; you can make the decision to override them at the domain level if necessary. Once you have configured and saved the attributes at the domain level, the summary value on the panel displays the customized value for the domain (tagged with the word "customized" in black text).

A scope (a server, cluster, service integration bus or a cell) can be associated with only one domain. For example, you cannot define two domains that both have the cell-wide scope. Multiple scopes, however, can be defined in the same security domain. For example, a domain can be scoped to `Server1` and to `Server2` only within the cell.

The assigned scopes section on the security domain panel displays two views: one view that enables you to select and assign scopes to the domain, and another view that enables you to see a list of the currently assigned scopes. For convenience, you also have the flexibility to copy all of the security attributes from an existing security domain or the global configuration into a new security domain, and then modify only those attributes that must be different. You must still associate the scopes to these copied domains.

Scripting commands also provide you with the ability to create, copy and modify security domains. Once you create a domain, you must run the appropriate commands to associate security attributes and scopes to it.

Configuring attributes for security domains

Security attributes that can be configured at the domain level in WebSphere Application Server Version 8.0 are:

- Application security
- Java 2 security
- User realm (registry)
- Trust association
- Simple and Protected GSS-API Negotiation (SPNEGO) web authentication
- RMI/IIOP security (CSIv2)
- JAAS logins (Application, System and J2C Authentication Data)
- Java Authentication SPI
- Authentication mechanism attributes
- Authorization provider
- Federated repositories
- Custom properties

The security domains panels in the administrative console display all of these security attributes.

Some of the other well-known attributes that you cannot override at the domain level are Kerberos, Audit, Web Single Sign-on (SSO) and Tivoli Access Manager (TAM). The Secure Socket Layer (SSL) attribute already supports different scopes, but it is not part of the domain configuration. For all of the attributes that are not supported at the domain level, user applications in a domain share their configuration from the global level.

Any new security domain attributes must be compatible with those global security attributes that are inherited by the user applications that are assigned to the domain. You must actively manage these attributes. For example, if you customize only a JAAS configuration at the domain level you must make sure that it works with the user registry configured at the global level (if the user registry is not customized at the domain level).

Other than for JAAS and custom properties, once global attributes are customized for a domain they are no longer used by user applications.

The Tivoli Access Manager client runtime is used to provide authentication (used by TrustAssociationInterceptor and PDLoginModule) and authorization (used for JACC) by contacting TAM servers. There is only one Tivoli Access Manager runtime shared by all servers in a cell. Read the Tivoli Access Manager JACC provider configuration topic for more information.

You cannot have a different Tivoli Access Manager configuration at the security domain level to override the configuration at the cell level. However, you can to some degree specify Trust Association Interceptor (TAI) and JACC configuration at the security domain level. For example, you can use a different TAI or a different authorization provider. Since TAM server connectivity can only be defined at the global level, you can have a variety of TAIs defined and configured at the security domain level. Some of these TAIs might not use the TAM user repository, while others do. The TAIs that do need to connect to TAM will also connect to the globally-defined TAM server. Similarly, for authorization, you can have a variety of external authorization providers configured at the domain level. However, if any of these external authorization providers require connection to TAM they end up talking to the singular globally-configured TAM server.

Associating scopes to security domains

In WebSphere Application Server Version 8.0, you can associate a security domain at the cell level, the server level, the cluster level and the service integration bus level.

Note: For more information about the service integration bus and bus security in multiple security domains for WebSphere Application Server Version 8.0, see ../ae/cjr_sec_dom.dita.

When a security domain is associated with a server that is not part of a cluster, all user applications in that server use the attributes from the security domain. Any missing security attributes are obtained from the global security configuration. If the server is part of a cluster, you can associate the security domain with the cluster but not with the individual members in that cluster. The security behavior then remains consistent across all of the cluster members.

If a server is to be part of a cluster, create a cluster first and associate the security domain to it. You might have associated a domain to a server before it was a member of a cluster. If so, even though the domain is associated with the server directly, the security runtime code does not look at the domain. When a server is a cluster member, the security runtime disregards any security domains associated directly to the server. Remove the server scope from the security domain and associate the cluster scope to it instead.

A security domain can also be associated to the cell. This is usually done when you want to associate all user applications in WebSphere Application Server to a security domain. In this scenario, all of the administrative applications and the naming operations use the global security configuration while all of the user applications use the domain level configuration. If you want to split the security configuration information for administrative and user applications, this is all that is needed.

If you have a mixed-version environment, or plan to have one in future, and you want to associate security domains at the cell level, read “Security domains in a mixed-version environment” on page 1237 for more information.

If you are on a base profile server that has its own security domain defined, which is then federated to a deployment manager, associate the server scope to the security domain and not the cell scope. When you federate that node, the security domain information is propagated to the deployment manager. If the cell scope is associated to it, the network deployment configuration uses this security configuration, which might impact existing applications. During federation, the cell scope is changed to the server scope that is being federated. If the server scope is associated with the security domain, only that server uses the security domain after the federation. Other applications in other servers and clusters are not impacted. However, if this base profile server is registered to the Administrative Agent process you can associate the cell scope to the security domain if you want all of the servers from the base profile to use the same security domain for all of their user applications. Read about “Federating a node with security domains” on page 1236 for more information.

You can have a security domain associated at the cell level and also other security domains associated to various clusters or individual servers (those that are not part of any clusters). In this case, the security runtime first checks if any security domains are associated with the server or a cluster. If there is a security domain associated with the server or a cluster, the security attributes defined in it are used for all

of the applications in that server or cluster. Any security attributes missing from this server or cluster domain are obtained from the global security configuration, and not from the domain configuration associated with the cell.

If the server or cluster does not have its own domain defined, the security runtime code uses the security attributes from the domain associated with the cell (if one is defined). Any security attributes missing from the cell domain are inherited from the global security configuration.

Relationship between old server level security and the new security domains

In previous releases of WebSphere Application Server, you could associate a small set of security attributes at a server level. These attributes were used by all of the applications at the server level. The previous way of configuring the security attributes was deprecated in WebSphere Application Server 7.0, and will be removed in a future release.

You should now use the new security domains support starting in WebSphere Application Server 7.0, as these security domains are more easily managed and much more flexible. For example, in previous versions of WebSphere Application Server, you must manually associate the same security configuration to all of the cluster members by configuring the same security attributes for every server in a cluster.

The migration tool migrates the existing server level security configuration information to the new security domain configuration when the script compatibility mode is `false` (`-scriptCompatibility="false"`). A new security domain is created for every server security configuration if it is not part of a cluster. If it is part of a cluster, a security domain is associated with the cluster instead of with all of the servers in that cluster. In both cases, all of the security attributes that were configured at the server level in previous releases are migrated to the new security domain configuration, and the appropriate scope is assigned to the security domains.

If the script compatibility mode is set to `true`, the server level security configuration is not migrated to the new security domains configuration. The old server security configuration is migrated without any changes. The security runtime detects that the old security configuration exists and uses that information, even if a security domain is associated either directly or indirectly to the server. If the script compatibility mode is set to `true`, remove the security configuration from the server level and then create a security domain with the same set of security attributes.

How domain level security attributes are used by security runtime and applications

This section describes how the individual attributes at the domain level are used by the security runtime and how that impacts the user application security. Since all of these security attributes are also defined at the global level, more information about these attributes can be obtained elsewhere. For the purposes of this section, the emphasis is on domain level behavior.

1. **Application Security:**

   Select **Enable application security** to enable or disable security for user applications. When this selection is disabled, all of the EJBs and web applications in the security domain are no longer protected. Access is granted to these resources without user authentication. When you enable this selection, the J2EE security is enforced for all of the EJBs and web applications in the security domain. The J2EE security is only enforced when Global Security is enabled in the global security configuration, (that is, you cannot enable application security without first enabling Global Security at the global level).

2. **Java 2 Security:**

   Select **Use Java 2 security** to enable or disable Java 2 security at the domain level or to assign or add properties related to Java 2 security. This choice enables or disables Java 2 security at the process (JVM) level so that all applications (both administrative and user) can enable or disable Java 2 security.

3. **User Realm (User Registry):**

   This section enables you to configure the user registry for the security domain. You can separately configure any registry that is used at the domain level. Read about “Configuring attributes for security domains” on page 1226 for more information.

   When configuring a registry at the domain level you can choose to define your own realm name for the registry. The realm name distinguishes one user registry from another. The realm name is used in multiple places – in the Java client login panel to prompt the user, in the authentication cache, and when using native authorization.

   At the global configuration level, the system creates the realm for the user registry. In previous releases of WebSphere Application Server, only one user registry is configured in the system. When you have multiple security domains you can configure multiple registries in the system. For the realms to be unique in these domains, configure your own realm name for a security domain. You also can choose the system to create a unique realm name if it is certain to be unique. In the latter case, the realm name is based on the registry that is being used.

   For LDAP registries, the host:port of the LDAP server is the system-generated realm name. For localOS, the name of the localOS machine is the realm name. For custom user registries, the realm is the one returned by the `getRealm ( )` method of the custom registry implementation.

   If the system generated realm names are unique enough, you can choose the option for the system to generate the realm name. If not, choose a unique realm name for each security domain where you have the user registry configured. If the underlying user repository is the same, use the same realm name in different domains. From a security runtime perspective, same realm names have the same set of users and groups information. For example, when users and groups information is required from a realm, the first user repository that matches the realm is used.

   If a localOS registry that is not centralized is configured for any domain, and that domain is associated with servers or clusters in nodes not on the same system as the deployment manager, the realm name has to be provided. This realm name has to be the same as it would be if it were generated on the node. This realm name can be obtained by calling the `getRealm()` method on the SecurityAdmin MBean on that node. Typically, the realm name for localOS registries is the hostname of the machine. In this case, you should not let the system generate the realm name but rather get the realm name that is used by the processes in the node.

   If you select the system to generate the realm for the localOS registry at the time of the user registry configuration, it chooses the localOS registry that is used by the deployment manager. If the realm configured does not match the realm used by the servers then there are authorization issues. Also note that in this case, the domain using this local registry can only be associated with servers and clusters that belong to nodes on the same machine.

   Note: In WebSphere Application Server Version 7.0, the federated repositories user registry can only be configured at the global level and have only one instance per cell, but any domain can use it by configuring it as the active registry. In WebSphere Application Server Version 8.0, you can configure a unique instance of a federated repository at the domain level in a multiple security domain environment.

   When a security domain is copied from the global level, the users and groups defined at the global level are also copied to the security domain. This is also true when copying from an existing domain. A newly-created security domain that uses the file-based VMM repository requires that the user populate the repository with users and groups.

   Also new in this release of WebSphere Application Server, a new checkbox on the Realm configurations settings administrative console page, Use global schema for model, sets the global schema option for the data model in a multiple security domain environment. Global schema refers to the schema of the admin domain.

   When more than one user registry is in a process, the naming lookup that uses “UserRegistry” as the lookup name returns the user registry that is used by user applications. The user registry used by administrative applications is bound by the lookup name, “AdminUserRegistry”.

As described in “Cross realm communication” on page 1234, when an application in one realm communicates with an application in another realm using LTPA tokens, the realms have to be trusted. The trust relationship can be established using the **Trusted authentication realms – inbound** link in the user registry panel or by using the **addTrustedRealms** command. You can establish trust between different realms. A user logged into one realm can access resources in another realm. If no trust is established between the two realms the LTPA token validation fails.

Note: The realm name used in the web.xml file is not related to the user registry realm.

4. **Trust Association:**

   When you configure the trust association interceptor (TAI) at a domain level, the interceptors configured at the global level are copied to the domain level for convenience. You can modify the interceptor list at the domain level to fit your needs. Only configure those interceptors that are to be used at the domain level.

   Tivoli Access Manager's trust association interceptors can only be configured at the global level. The domain configuration can also use them, but cannot have a different version of the trust association interceptor. Only one instance of Tivoli Access Manager's trust association interceptors can exist in the cell.

5. **SPNEGO web authentication:**

   The SPNEGO web authentication, which enables you to configure SPNEGO for web resource authentication, can be configured at the domain level.

   Note: In WebSphere Application Server Version 6.1, a TAI that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function was deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

6. **RMI/IIOP Security (CSIv2):**

   The RMI/IIOP security attribute refers to the CSIv2 (Common Secure Interoperability version 2) protocol properties. When you configure these attributes at the domain level, the RMI/IIOP security configuration at the global level is copied for convenience.

   You can change the attributes that need to be different at the domain level. The Transport layer settings for CSIv2 inbound communications should be the same for both the global and the domain levels. If they are different, the domain level attributes are applied to all of the application in the process.

   When a process communicates with another process with a different realm, the LTPA authentication and the propagation tokens are not propagated to the downstream server unless that server is listed in the outbound trusted realms list. This can be done using the **Trusted authentication realms – outbound** link on the **CSIv2 outbound communication** panel, or by using the **addTrustedRealms** command task. Read about “Cross realm communication” on page 1234 for more information.

7. **JAAS (Java Authentication and Authorization Service):**

   The JAAS application logins, the JAAS system logins, and the JAAS J2C authentication data aliases can all be configured at the domain level. By default, all of the applications in the system have access to the JAAS logins configured at the global level. The security runtime first checks for the JAAS logins at the domain level. If it does not find them, it then checks for them in the global security configuration. Configure any of these JAAS logins at a domain only when you need to specify a login that is used exclusively by the applications in the security domain.

   For JAAS and custom properties only, once global attributes are customized for a domain they can still be used by user applications.

8. **Java Authentication SPI (JASPI)**

   Specifies the configuration settings for a Java Authentication SPI (JASPI) authentication provider and associated authentication modules to be applied at the domain level.

   Select **Providers** to create or to edit a JASPI authentication provider.

Note: The JASPI authentication provider can be enabled with providers configured at the domain level. By default, all of the applications in the system have access to the JASPI authentication providers configured at the global level. The security runtime first checks for the JASPI authentication providers at the domain level. If it does not find them, it then checks for them in the global security configuration. Configure JASPI authentication providers at a domain only when the provider is to be used exclusively by the applications in that security domain.

9. **Authentication Mechanism Attributes:**

   Specifies the various cache settings that must be applied at the domain level.

   a. Authentication cache settings - use to specify your authentication cache settings. The configuration specified on this panel is applied only to this domain.

   b. LTPA Timeout - You can configure a different LTPA timeout value at the domain level. The default timeout value is 120 minutes, which is set at the global level. If the LTPA timeout is set at the domain level, any token that is created in the security domain when accessing user applications is created with this expiration time.

   c. Use realm-qualified user names - When this selection is enabled, user names returned by methods such as `getUserPrincipal( )` are qualified with the security realm (user registry) used by applications in the security domain.

10. **Authorization Provider:**

    You can configure an external third party JACC (Java Authorization Contract for Containers) provider at the domain level. Tivoli Access Manager's JACC provider can only be configured at the global level. Security domains can still use it if they do not override the authorization provider with another JACC provider.

    The JACC attributes, for example the Policy object, are based at the JVM level. This implies that there can be only be one JACC policy object in a JVM process. However, when you have multiple JACC providers configured, the deployment manager process has to handle all these providers in the same JVM because it has to propagate the authorization policy of applications to the respective provider based on the application name.

    If your JACC provider can handle propagating the authorization policy to multiple providers, you can configure it at the global level. In this case, when an application is installed, this JACC provider is called in the deployment manager process and it is the responsibility of this JACC provider to propagate the information to the corresponding JACC provider based on the application name passed in the contextID.

    Another way to achieve this is to set the custom property, `com.ibm.websphere.security.allowMultipleJaccProviders=true`, at the global security level. When this property is set, WebSphere Application Server propagates the authorization policy information to the JACC provider associated with the domain that corresponds to the target server where the application is installed. This property is only used at the deployment manager process since the managed servers do not host multiple JACC providers.

    On z/OS, you can enable or disable the System Authorization Facility (SAF) based authorization at the domain level.

11. **z/OS options:**

    You can set z/OS specific security options at the process (JVM) level so that all applications (both administrative and user) can enable or disable these options. These properties are:

    - Enabling application server and z/OS thread identity synchronization
    - Enabling the connection manager RunAs thread identity.

    For more information, read about z/OS security options.

12. **Custom properties:**

    Set custom properties at the domain level that are either new or different from those at the global level. By default, all of the custom properties at the global security configuration can be accessed by

all of the applications in the cell. The security runtime code first checks for the custom property at the domain level. If it does not find it, it then attempts to obtain the custom property from the global security configuration.

For JAAS and custom properties only, once global attributes are customized for a domain they can still be used by user applications.

Client and application security programming model when using security domains

A Java client or an application acting as a client that accesses an EJB typically does a naming lookup first. The naming resource, which is used by both administrative and the user applications, is considered an administrative resource. It is protected by the global security configuration information. In a multiple domain setup where the global security is using one realm (the *user registry*) and a domain is using a different realm, the Java client must authenticate to two different realms. The first authentication is required for the realm in the global security configuration for the naming operation to succeed, and the second authentication is required to access the EJB, which uses a different realm.

The `CosNamingRead` role protects all naming read operations. This role is usually assigned the **Everyone** special subject. This implies that any user, valid or not, can look up the name space. When a multiple domain is defined, if the `CosNamingRead` role has the **Everyone** special subject the security runtime code in the client side does not prompt you to log in. It uses the UNAUTHENTICATED subject to access the naming operation instead. Once the naming lookup operation is completed, when the client attempts to access the EJB it is prompted with a login panel that indicates the realm that is currently used by that EJB application (that is, the realm used in the domain). The client then presents the appropriate user credentials for that realm, which can then access the EJB. This logic applies to all variations of login source, including `properties` and `stdin`, not just when the login source is set to `prompt`.

If the **Everyone** special subject is removed from the `CosNamingRead` role, you are prompted twice. If the login source is `properties`, you can uncomment the com.ibm.CORBA.loginRealm property in the `$WAS_HOME/profiles/$ProfileName/properties/sas.client.props` file and add the appropriate realms using “|” as the separator. You must also enter the corresponding users and passwords in the com.ibm.CORBA.loginUserid and com.ibm.CORBA.loginPassword properties respectively. When you are using the programmatic logon in the Java client code you must authenticate twice with different user credentials; once prior to do a naming lookup for the EJB (the user should be in the global realm), and later prior to calling any method in the EJB (the user should be in the EJB domain's realm).

In general, when a Java client needs to authenticate to multiple and different realms it has to provide the credential information for all of those realms. If the login source is `prompt` or `stdin` it is prompted to login multiple times, once for each realm. If the login source is set to `properties`, the appropriate properties in the **sas.client.props** file (or any related file) are used for authenticating to different realms.

In certain scenarios, a client might make multiple calls to the same realm. For example, the Java client can access a resource using `realm1` followed by access to a resource using `realm2`, and then come back to access a resource in `realm1` again. In this case, the client is prompted three times; first for `realm1`, secondly for `realm2` and finally for `realm1` again.

By default, the subject that is used to login at a realm is not cached by the client side code. If you have this scenario, and you want the client to cache the subject based on the realm, set the com.ibm.CSI.isRealmSubjectLookupEnabled property to `true` in the **sas.client.props** file. If the com.ibm.CSI.isRealmSubjectLookupEnabled property is set, the client code caches the subject based on the realm name. The next time the Java client needs to authenticate to this realm, the cache is located to obtain the subject and the client is not prompted. Also, when the com.ibm.CSI.isRealmSubjectLookupEnabled property is set, the same subject that was logged in the first time is used for subsequent logins. If the subject information needs to change then this property should not be set.

If the client is doing a programmatic login it can pass the realm along with the user and password that it needs to authenticate. In this case, when the com.ibm.CORBA.validateBasicAuth property is set to `true` (the default value) in the **sas.client.props** file, the registry that matches the realm name is used for login. That realm must be supported in the process where the authentication takes place.

When using the WSLogin JAAS configurations, you also must set the `use_realm_callback` option in the **wsjaas_client.config** file in `$WAS_HOME/profiles/$ProfileName/properties` for the realm name to be passed to the call back handler. If you want to specify a different provider URL for the name server, set the `use_appcontext_callback` option and pass in the provider URL properties in a hash map to WSLogin.

If you do not know the realm name, use <*default*> as the realm name. The authentication is performed against the application realm. If the naming read operation does not have the **Everyone** special subject assigned, you must provide the realm that is used by the administrative applications (the registry used in the global security configuration), as well as the appropriate user and password information in that registry for the lookup operation to succeed.

After the lookup operation succeeds, perform another programmatic login by providing the application realm (or <*default*>) and the user and password information for the appropriate user in the registry that is used by the application. This is similar to the case where the login source is `prompt`. You must authenticate twice, once for the registry used by the global security configuration (for the naming lookup operation) and again for the registry used by the application to access the EJB.

If com.ibm.CORBA.validateBasicAuth is set to `false` in the `$WAS_HOME/profiles/$ProfileName/properties/sas.client.props` file then the programmatic login can use <*default*> as the realm name for both the lookup and the EJB operations. The actual authentication occurs only when the resource is accessed on the server side, in which case the realm is calculated based on the resource that is accessed.

The new security domain support starting in WebSphere Application Version 7.0 does not change the current application security programming model. However, it provides more flexibility and capabilities such as the following:

- User applications can still find the user registry object by using the naming lookup for “UserRegistry”. For the registry object used by administrative applications, the naming lookup for “AdminUserRegistry” can be used.
- The application usage of the JAAS login configuration does not change in a multiple domain setup. However, if an application must refer to the JAAS configuration that is specified at the domain level, the administrator and the deployer of that application must make sure that this domain is configured with the JAAS configurations that are required by the application.
- If an application needs to communicate with other applications using different realms, trust relationship should be established for both inbound and outbound communications when using the LTPA tokens. Read about “Cross realm communication” on page 1234 for more information.
- When using programmatic login in the applications, if you want to login to the realm used by the application, use <*default*> as the realm name or provide the realm name that the application is using. If you need to login to the global realm, you must provide the global realm name. If you provide any other realm, only a basic authentication subject is created. When the request actually flows to the server hosting that realm, the actual authentication of the user occurs if that server hosts the realm. If the server does not host the realm, the login fails.

Application deployment in multiple domains configurations

When deploying an application in a multiple domain setup, all of the modules in the application should be installed in the servers or clusters that belong to the same security domain. If not, depending on the security attributes configured in these security domains, inconsistent behavior can result. For example, if the domains contain different user registries, the users and groups information can be different, which can cause inconsistent behavior when accessing the modules. Another example is when the JAAS data is

different between the security domains. The JAAS configurations is not accessible from all of the modules in the application. The security runtime code and the command tasks rely on one domain being associated with an application when dealing with attributes such as user registry, JAAS login configurations, J2C authentication data, and authorization.

In most cases, application deployment fails when an application is deployed across different domains. However, since this was possible in earlier releases of WebSphere Application Server when only a few attributes were supported at the server level, the deployment tool first checks for attributes that are configured at the domains. If the attributes in the domain are the same as those supported in previous releases, the administrative console requests confirmation to ensure that you want to deploy application modules across multiple security domains. Unless there is an absolute requirement to deploy the applications across different domains, stop the deployment and select the servers and clusters in the same security domain.

Cross realm communication

When applications communicate using the RMI/IIOP protocol and LTPA is the authentication mechanism, the LTPA token is passed between the servers involved. The LTPA token contains the realm-qualified uniqueId, (also called the *accessId*), of the user who is logging into the front-end application. When this token is received by the downstream server it attempts to decrypt the token. If the LTPA keys are shared between the two servers, decryption succeeds and the accessId of the user is obtained from the token. The realm in the accessId is checked with the current realm that is used by the application. If the realms match, the LTPA token validation succeeds and it proceeds with the authorization. If the realms do not match, the token validation fails since the user from the foreign realm cannot be validated in the current realm of the application. If applications are not supposed to communicate with each other when using RMI/IIOP and the LTPA authentication mechanism, you do not to have to do anything further.

If you do want the cross realm communication to succeed when using RMI/IIOP and LTPA tokens, you must first establish trust between the realms involved, both for inbound and outbound communications.

For the server originating the request, its realm must have the realms that it can trust to send the token to. This is referred to as outboundTrustedRealms. For the server receiving the request, its realm needs to trust the realms that it can receive LTPA tokens from. This is referred to as inboundTrustedRealms.

Outbound trusted realms can be established using the addTrustedRealms command with the –communicationType option set to `outbound`. It can also be established in the administrative console by clicking **Trusted authentication realms - outbound** on the**CSIv2 outbound communications** panel.

Inbound trusted realms can be established using the same addTrustedRealms command task with the –communicationType option set to `inbound`. It can also be established by using the administrative console.

The figure below shows the communication between applications that use different user realms (registries) using RMI/IIOP. In this example, application `app1` (for example, a servlet) is configured to use the `realm1` user registry. The `app2` application (for example, an EJB) is configured to use the `realm2` user registry. The user (`user1`) initially logs into the servlet in `app1`, which then attempts to access an EJB in *app2*. The following must be set:

- In Domain1, `realm1` should trust `realm2` for the outbound communication.
- In Domain2, `realm2` should trust `realm1` for the inbound communication.
- The accessId for `user1` should be configured in the authorization table for `app2`.

When the LTPA token that contains the accessId of `user1` is received by `app2`, it decrypts the token. Both of the servers share the same LTPA keys. The LTPA token then ensures that the foreign realm is a trusted realm, and performs the authorization based on the accessId of `user1`. If security attribute propagation is not disabled, then the group information of `user1` is also propagated to `app2`. The groups can be used for

the authorization check, provided that the authorization table contains the group information. You can associate a special subject, AllAuthenticatedInTrustedRealms, to the roles instead of adding individual users and groups to the authorization table.

If the applications in the above example are deployed in different cells, you must do the following:

- Share the LTPA keys between the cells.
- Update the authorization table for `app2` with foreign users and groups accessIds by using the **wsadmin** utility. The administrative console does not have access to the realms outside of the scope of the cell.

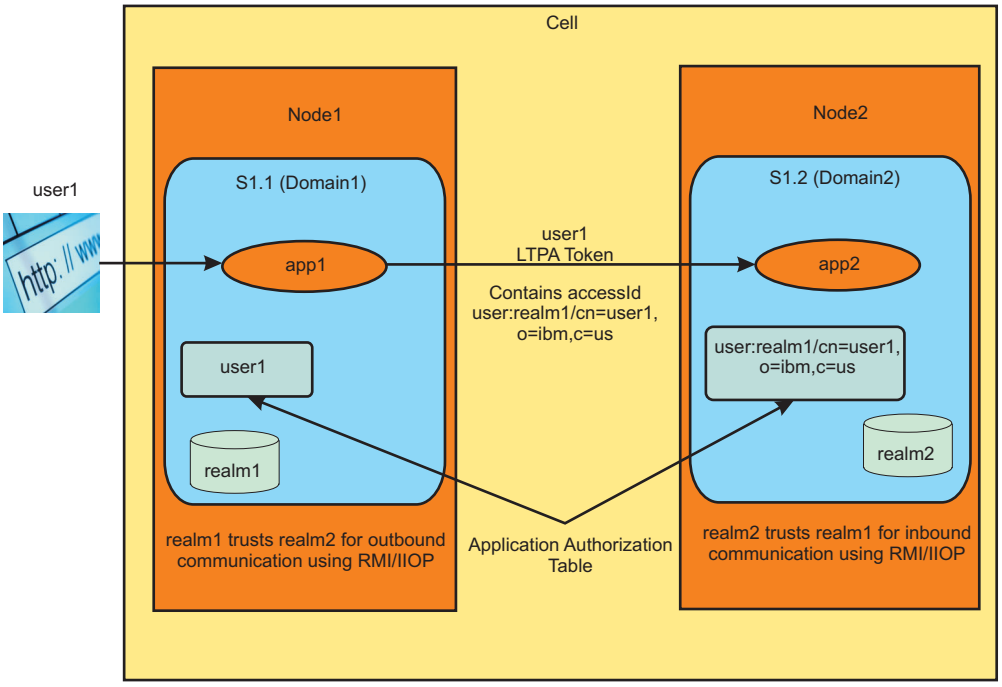

Figure 7. Cross realm communication in a multiple realm environment

Once trust has been established between the realms, when the server receives the LTPA token and the token is decrypted, it checks to see if the foreign realm is in its inbound trusted realms list. If it is trusted, the authentication succeeds. However, since it is a foreign realm, it does not go search the user registry to gather information about the user. Whatever information is in the LTPA token is used to authorize the user.

The only information in the LTPA token is the unique id of the user. This unique id of the user should exist in the authorization table for this application. If it does, authorization succeeds. However, if attribute propagation is enabled, additional authorization attributes (groups that this user belongs to) for the user are sent from the originating server to the receiving server. These additional attributes are used to make the access decisions. If the groups information exists in the propagation tokens it is used when making the authorization decision.

As previously mentioned, the information about the users and or the groups from the trusted realms should exist in the authorization table of the receiving application. Specifically, the accessId of the users and or groups should exist in the binding file of the application. This must be the case when the application is deployed. In the administrative console, when an application is deployed in a domain you can add the accessIds of the users and groups from any of its trusted realms to the authorization table.

You also have an option to associate a special subject, AllAuthenticatedInTrustedRealms, to the roles instead of adding individual users and groups. This is similar to the AllAuthenticated special subject that is currently supported. The difference is that the AllAuthenticated special subject refers to users in the same

realm as the application while the AllAuthenticatedInTrustedRealms special subject applies to all of the users in the trusted realms and in the realm of the application.

You can associate the accessId by using the $AdminApp install script. Because the accessId takes a unique format, use the command task listRegistryUsers with displayAccessIds set to `true`. If an invalid name or format is entered in this field, the authorization fails.

User and group information from the trusted realms is obtained by the deployment manager since it has access to all of the user registry configurations in all domains. However, in certain situations it is not possible to obtain the users and group information.

For example, if a server hosted on an external node is using localOS as the registry for its domain, the deployment manager cannot obtain the users and groups information unless it is running in the same operating system setup. The external operating system should be contacted to obtain this information. This can be done by directly invoking the registry in the server associated with that domain. The servers associated with the domain have to be started for this to work. You also must set the property, com.ibm.websphere.allowRegistryLookupOnProcess, to `true` in the top-level security custom properties. When this property is set, the deployment manager code searches one of the servers that is associated with the security domain and obtains the users and groups information directly from it. This is possible by calling an MBean in one of the servers.

If the MBean in any of the servers that are using that domain cannot be accessed, the administrative console displays a panel where you can enter the user and accessId information manually for each user and group. It is important that the correct accessId format be entered in this field. The accessId format for the user is `user:realmName/userUniqueId`. The realmName is the name of the realm where the user resides, and the userUniqueId is the uniqueId that represents the user, depending on the registry that is used.

For example, for LDAP, the uniqueUserId is the Distinguished Name (DN), for the Windows localOS registry and is the SID of the user. For Unix platforms, it is the UID. For custom registries, it depends on the implementation.

Similarly, for groups, the accessId format is group:realmName/groupUniqueId. As previously mentioned, use the listRegistryUsers and listRegistryGroups command with the –displayAccessIds option set to `true` so that you can obtain the correct format for the domain or realm that you are interested in.

Once users and groups from the trusted realms or the AllAuthenticatedInTrustedRealms special subject is added to the authorization table of the application, it is ready to accept requests from other applications that are using any of its trusted realms. The LTPA token validation on the receiving server first checks to make sure that the realm is trusted. The authorization engine then checks to see if the external user and/or the groups or the AllAuthenticatedInTrustedRealms special subject are given access to the roles needed to access the resource. If true, access is granted.

Cross realm communication is only applicable when using the WebSphere built-in authorization. If you are using other authorization engines including SAF for z/OS, any cross realm authorization can be achieved by implementing custom login modules that map external users to users in its own repository.

Federating a node with security domains

When a security domain is configured in the base version and is federated to a cell, the security domain configured at the base version is also configured for that server in the cell. The same domain security configuration can be used by the server before and after the federation. If a base server is to be federated to a cell, the resource assigned to the security domain should be the server scope instead of the cell scope.

If the base server is expected to be registered with an Administrative Agent process, use the cell scope as the resource if the intention is to have all of the servers in the base profile use this security domain.

If during federation the security domain at the base already exists at the cell level, the **addNode** command fails. You can use the –excludesecuritydomains option not to include the security domain during federation.

When the federated node is removed from a cell, the resources in that node should be removed from the security domains. If security domains have clusters associated with them that span nodes, the nodes are not removed. You can always remove resources from the security domains or any domains that are not used by using scripting commands or the administrative console.

Security domains in a mixed-version environment

You should create security domains once all of the nodes have been migrated to the latest version. This is especially true if there is a need to associate the cell with a domain. However, if you want to create security domains in a mixed- version environment, be aware of the following:

- If a cell-wide domain is created in a mixed version setup, a domain called *PassThroughToGlobalSecurity* is created automatically. All mixed clusters are assigned to this domain at the time of the creation of the cell-wide domain. This PassThroughToGlobalSecurity domain is special in the sense that attributes cannot be added to it, only resources can be assigned to it.

  All resources assigned to the PassThroughToGlobalSecurity domain use the global security configuration information. Whenever a node in the mixed version setup is migrated to the latest version, the servers and clusters in these nodes are added to this domain. Applications in all of the servers and clusters in these nodes do not use the cell-wide domain; they instead use the global security configuration before and after migration.

  If any of these servers need to use the cell-wide domain, you must remove these resources from this PassThroughToGlobalSecurity domain. New servers and clusters that are created in the migrated node use the cell-wide domain, not the PassThroughToGlobalSecurity domain. As a result, you have a mix of servers and clusters, some of them using global security configuration and some using the cell-wide domain.
- Once a cell-wide domain is created, adding any old version cluster members to a WebSphere Application Server Version 8.0 cluster is restricted since this action makes it a mixed cluster. This restriction also holds true when a WebSphere Application Server Version 8.0 cluster is associated with a domain. and a previous version cluster member is added to this cluster. This restriction is needed to avoid associating a security domain to a mixed cluster.
- If possible, you should create a cell-wide domain after all of the nodes have been migrated. In this case, the cell-wide domain is applicable to the entire cell and not just to parts of it. This also eliminates the need to create the PassThroughToGlobalSecurity domain and the mixed cluster scenario with security domains.

Modifying security domains

Use the administrative console tasks or scripting commands to modify security domains. For a complete list of administrative tasks and scripting commands, see the links in "Related tasks" at the bottom of this document.

Once a security domain is created and associated to a set of scopes, the servers associated with this new domain must be restarted. After the restart, the applications in the scopes associated with the new domain use the security attributes defined in the domain.

Changes to any of the domain attributes requires the restart of all of the scopes assigned to it. If new scopes are added they also need to be restarted. Any modifications to the domain configuration, either to the security attributes or to the scopes, has impacts on those applications that are using the domain configuration.

Before you make modifications to an existing domain, consider the following potential impacts. For example, if a user registry that is configured at a domain is removed, and the servers restarted, the user registry from the cell-wide domain (if one is defined), or the global security configuration is then used. This can impact application authentication and authorization. Users and groups associated with an application might no longer be valid in the new registry. Another example to consider is when JAAS configurations are removed from a domain. Applications that rely on this are no longer be able to use the JAAS configurations. Whenever a security configuration is changed it might impact your applications, so all security configuration changes should be made with the utmost care.

Creating new multiple security domains

You can create multiple security domains in your configuration. By creating multiple security domains, you can configure different security attributes for administrative and user applications within a cell environment.

Before you begin

Only users assigned to the administrator role can create new multiple security domains. Enable global security in your environment before creating new multiple security domains.

Read about "Multiple security domains" on page 1222 for a better understanding of what multiple security domains are and how they are supported in this version of WebSphere Application Server.

About this task

Security domains provide a mechanism to use different security settings for administrative applications and user applications. They also provide the ability to support multiple security settings so different applications can use different security attributes like user registry or login configurations.

Use multiple security domains to achieve the following goals:

- Configure different security attributes for administrative and user applications within a cell
- Consolidate server configurations by managing different security configurations within a cell
- Restrict access between applications with different user registries, or configure trust relationships between applications to support communication across registries

Perform the following steps to create a new security domain using the administrative console:

Procedure

1. Click **Security > Security domains**.
2. On the Security domains collection page, click **New**.
3. Specify a unique name for the domain. A domain name must be unique within a cell and cannot contain an invalid character. This field is required.
4. Specify a unique description for the domain. After you click **Apply** you are returned to the Security domains detail page
5. Under Assigned Scopes, assign the security domain to the entire cell or select the specific servers, clusters, and service integration buses to include in the security domain.
6. Customize your security configuration by specifying security attributes for your new domain and by assigning it to cell resources.

   You can change security attributes such as the following:

   Application Security

   Specifies the settings for application security and Java 2 security. You can use the global security settings or customize the settings for a domain.

   Select **Enable application security** to enable or disable security this choice for user applications. When this selection is disabled, all of the EJBs and web applications in the

security domain are no longer protected. Access is granted to these resources without user authentication. When you enable this selection, the J2EE security is enforced for all of the EJBs and web applications in the security domain. The J2EE security is only enforced when Global Security is enabled in the global security configuration, (that is, you cannot enable application security without first enabling Global Security at the global level).

Java 2 Security

Select **Java 2 security** to enable or disable Java 2 security at the domain level. This choice enables or disables Java 2 security at the process (JVM) level so that all applications (both administrative and user) can enable or disable Java 2 security.

User realm

This section enables you to configure the user registry for the security domain. You can separately configure any registry that is used at the domain level. Read about “Multiple security domains” on page 1222 for more information.

Trust association

When you configure the trust association interceptor (TAI) at a domain level, the interceptors configured at the global level are copied to the domain level for convenience. You can modify the interceptor list at the domain level to fit your needs. Only configure those interceptors that are to be used at the domain level.

SPNEGO Web Authentication

The SPNEGO web authentication, which enables you to configure SPNEGO for web resource authentication, can be configured at the domain level.

Note: In WebSphere Application Server Version 6.1, a TAI that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. This function was deprecated in WebSphere Application Server Version 7.0. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

RMI/IIOP Security

The RMI/IIOP security attribute refers to the CSIv2 (Common Secure Interoperability version 2) protocol properties. When you configure these attributes at the domain level, the RMI/IIOP security configuration at the global level is copied for convenience.

You can change the attributes that need to be different at the domain level. The Transport layer settings for CSIv2 inbound communications should be the same for both the global and the domain levels. If they are different, the domain level attributes are applied to all of the application in the process.

JAAS application logins

Specifies the configuration settings for the Java Authentication and Authorization Service (JAAS) application logins. You can use the global security settings or customize the settings for a domain.

The JAAS application logins, the JAAS system logins, and the JAAS J2C authentication data aliases can all be configured at the domain level. Be default, all of the applications in the system have access to the JAAS logins configured at the global level. The security runtime first checks for the JAAS logins at the domain level. If it does not find them, it then checks for them in the global security configuration. Configure any of these JAAS logins at a domain only when you need to specify a login that is used exclusively by the applications in the security domain.

JAAS system logins

Specifies the configuration settings for the JAAS system logins. You can use the global security settings or customize the configuration settings for a domain.

The JAAS application logins, the JAAS system logins, and the JAAS J2C authentication data aliases can all be configured at the domain level. Be default, all of the applications in the system have access to the JAAS logins configured at the global level. The security runtime first checks for the JAAS logins at the domain level. If it does not find them, it then checks for them in the global security configuration. Configure any of these JAAS logins at a domain only when you need to specify a login that is used exclusively by the applications in the security domain.

Note: For both JAAS application logins and JAAS system logins, the collections are not populated until one is created first. You can do this by selecting **customize for this domain** under JAAS application logins or JAAS system logins and then by selecting **Apply** or **OK**.

JAAS J2C authentication

Specifies the configuration settings for the JAAS J2C authentication data. You can use the global security settings or customize the settings for a domain.

The JAAS application logins, the JAAS system logins, and the JAAS J2C authentication data aliases can all be configured at the domain level. Be default, all of the applications in the system have access to the JAAS logins configured at the global level. The security runtime first checks for the JAAS logins at the domain level. If it does not find them, it then checks for them in the global security configuration. Configure any of these JAAS logins at a domain only when you need to specify a login that is used exclusively by the applications in the security domain.

Java Authentication SPI (JASPI)

Specifies the configuration settings for a Java Authentication SPI (JASPI) authentication provider. You can use the global security settings or customize the settings for a domain. To configure JASPI authentication providers for a domain, select **Customize for this domain** and then enable JASPI. Select **Providers** to define providers for the domain.

Note: The JASPI authentication provider can be enabled with providers configured at the domain level. By default, all of the applications in the system have access to the JASPI authentication providers configured at the global level. The security runtime first checks for the JASPI authentication providers at the domain level. If it does not find them, it then checks for them in the global security configuration. Configure JASPI authentication providers at a domain only when the provider is to be used exclusively by the applications in that security domain.

Authentication Mechanism Attributes

Specifies the various cache settings that need to applied at the domain level.

Select **Authentication cache settings** to specify your authentication cache settings. The configuration specified on this panel is applied only to this domain.

Select **LTPA Timeout** to configure a different LTPA timeout value at the domain level. The default timeout value is 120 minutes, which is set at the global level. If the LTPA timeout is set at the domain level, any token that is created in the security domain when accessing user applications is created with this expiration time.

When **Use realm-qualified user names** is enabled, user names returned by methods such as `getUserPrincipal( )` are qualified with the security realm (user registry) used by applications in the security domain.

Authorization Provider

You can configure an external third party JACC (Java Authorization Contract for Containers) provider at the domain level. Tivoli Access Manager's JACC provider can only be configured at

the global level. Security domains can still use it if they do not override the authorization provider with another JACC provider or with the built-in native authorization.

On z/OS, you can enable or disable the System Authorization Facility (SAF) based authorization at the domain level.

Custom properties

Set custom properties at the domain level that are either new or different from those at the global level. By default, all of the custom properties at the global security configuration can be accessed by all of the applications in the cell. The security runtime code first checks for the custom property at the domain level. If it does not find it, it then attempts to obtain the custom property from the global security configuration.

7. Click **Apply**.
8. After you have saved your configuration changes, restart the server for your changes to take effect.

Deleting multiple security domains

You can delete multiple security domains from your configuration. You must remove the resources assigned to the security domains before deleting them. Only remove those security domains that are not needed in your security configuration.

Before you begin

Only users assigned to the administrator role can delete security domains. Enable global security in your environment before deleting security domains.

Read about “Multiple security domains” on page 1222 for a better understanding of what multiple security domains are and how they are supported in this version of WebSphere Application Server.

About this task

Security domains provide a mechanism to use different security settings for administrative applications and user applications. They also provide the ability to support multiple security settings so different applications can use different security attributes like user registry or login configurations.

Perform the following steps to delete an existing security domain using the administrative console:

Note: Only delete the security domains after first removing any resources associated with them. The servers impacted should be restarted.

Procedure

1. Click **Security > Security domains**.
2. On the Security domains collection page, select a domain to delete.
3. Click **Delete**.

Copying multiple security domains

You can copy selected multiple security domains from the domain collection to create a new domain. This is useful if you want to create a domain that is similar to a previous domain. However, you might want to make a few slight adjustments. When copying an existing domain, you must supply a unique domain name for the new one.

Before you begin

Only users assigned to the administrator role can copy or create new multiple security domains. Enable global security in your environment before copying multiple security domains.

Read about “Multiple security domains” on page 1222 for a better understanding of what multiple security domains are and how they are supported in this version of WebSphere Application Server.

About this task

Security domains provide a mechanism to use different security settings for administrative applications and user applications. They also provide the ability to support multiple security settings so different applications can use different security attributes like user registry or login configurations.

Use multiple security domains to achieve the following goals:

- Configure different security attributes for administrative and user applications within a cell
- Consolidate server configurations by managing different security configurations within a cell
- Restrict access between applications with different user registries, or configure trust relationships between applications to support communication across registries

Perform the following steps to copy an existing security domain using the administrative console:

Procedure

1. Click **Security > Security domains**.
2. Optional: From Preferences, you can select the maximum number of rows to display when the domain collection is large. The default number of rows is 20. Rows that exceed that number appear on subsequent pages.
3. Select a domain to copy.
4. Click **Copy Selected Domain...** to copy an existing domain from the collection. You can optionally select **Copy Global Security..** to copy an existing domain and have it maintain its global security settings (collection selections are ignored). A new domain name is also required if you choose this option.
5. Specify a unique name for the domain. This field is required. A domain name must be unique within a cell and cannot contain an invalid character.
6. Specify a unique description for the domain.
7. Click **Apply**. After you click **Apply** you are returned to the Security domains detail page
8. Under Assigned Scopes, assign the security domain to the entire cell or select the specific servers, clusters, and service integration buses to include in the security domain.
9. Customize your security configuration by specifying security attributes for your new domain and by assigning it to cell resources.

   You can change security attributes such as the following:

   Application Security

   Specifies the settings for application security and Java 2 security. You can use the global security settings or customize the settings for a domain.

   Select **Enable application security** to enable or disable security this choice for user applications. When this selection is disabled, all of the EJBs and web applications in the security domain are no longer protected. Access is granted to these resources without user authentication. When you enable this selection, the J2EE security is enforced for all of the EJBs and web applications in the security domain. The J2EE security is only enforced when Global Security is enabled in the global security configuration, (that is, you cannot enable application security without first enabling Global Security at the global level).

   Java 2 Security

   Select **Java 2 security** to enable or disable Java 2 security at the domain level. This choice enables or disables Java 2 security at the process (JVM) level so that all applications (both administrative and user) can enable or disable Java 2 security.

   User realm

This section enables you to configure the user registry for the security domain. You can separately configure any registry that is used at the domain level. Read about “Multiple security domains” on page 1222 for more information.

Trust association

When you configure the trust association interceptor (TAI) at a domain level, the interceptors configured at the global level are copied to the domain level for convenience. You can modify the interceptor list at the domain level to fit your needs. Only configure those interceptors that are to be used at the domain level.

SPNEGO Web Authentication

The SPNEGO web authentication, which enables you to configure SPNEGO for web resource authentication, can be configured at the domain level.

Note: In WebSphere Application Server Version 6.1, a TAI that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. This function was deprecated in WebSphere Application Server 7.0. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

RMI/IIOP Security

The RMI/IIOP security attribute refers to the CSIv2 (Common Secure Interoperability version 2) protocol properties. When you configure these attributes at the domain level, the RMI/IIOP security configuration at the global level is copied for convenience.

You can change the attributes that need to be different at the domain level. The Transport layer settings for CSIv2 inbound communications should be the same for both the global and the domain levels. If they are different, the domain level attributes are applied to all of the application in the process.

JAAS application logins

Specifies the configuration settings for the Java Authentication and Authorization Service (JAAS) application logins. You can use the global security settings or customize the settings for a domain.

The JAAS application logins, the JAAS system logins, and the JAAS J2C authentication data aliases can all be configured at the domain level. Be default, all of the applications in the system have access to the JAAS logins configured at the global level. The security runtime first checks for the JAAS logins at the domain level. If it does not find them, it then checks for them in the global security configuration. Configure any of these JAAS logins at a domain only when you need to specify a login that is used exclusively by the applications in the security domain.

JAAS system logins

Specifies the configuration settings for the JAAS system logins. You can use the global security settings or customize the configuration settings for a domain.

The JAAS application logins, the JAAS system logins, and the JAAS J2C authentication data aliases can all be configured at the domain level. Be default, all of the applications in the system have access to the JAAS logins configured at the global level. The security runtime first checks for the JAAS logins at the domain level. If it does not find them, it then checks for them in the global security configuration. Configure any of these JAAS logins at a domain only when you need to specify a login that is used exclusively by the applications in the security domain.

JAAS J2C authentication

Specifies the configuration settings for the JAAS J2C authentication data. You can use the global security settings or customize the settings for a domain.

The JAAS application logins, the JAAS system logins, and the JAAS J2C authentication data aliases can all be configured at the domain level. Be default, all of the applications in the system have access to the JAAS logins configured at the global level. The security runtime first checks for the JAAS logins at the domain level. If it does not find them, it then checks for them in the global security configuration. Configure any of these JAAS logins at a domain only when you need to specify a login that is used exclusively by the applications in the security domain.

Java Authentication SPI (JASPI)

Specifies the configuration settings for a Java Authentication SPI (JASPI) authentication provider. You can use the global security settings or customize the settings for a domain. To configure JASPI authentication providers for a domain, select **Customize for this domain** and then enable JASPI. Select **Providers** to define providers for the domain.

Note: The JASPI authentication provider can be enabled with providers configured at the domain level. By default, all of the applications in the system have access to the JASPI authentication providers configured at the global level. The security runtime first checks for the JASPI authentication providers at the domain level. If it does not find them, it then checks for them in the global security configuration. Configure JASPI authentication providers at a domain only when the provider is to be used exclusively by the applications in that security domain.

Authentication Mechanism Attributes

Specifies the various cache settings that need to applied at the domain level.

Select **Authentication cache settings** to specify your authentication cache settings. The configuration specified on this panel is applied only to this domain.

Select **LTPA Timeout** to configure a different LTPA timeout value at the domain level. The default timeout value is 120 minutes, which is set at the global level. If the LTPA timeout is set at the domain level, any token that is created in the security domain when accessing user applications is created with this expiration time.

When **Use realm-qualified user names** is enabled, user names returned by methods such as `getUserPrincipal( )` are qualified with the security realm (user registry) used by applications in the security domain.

Authorization Provider

You can configure an external third party JACC (Java Authorization Contract for Containers) provider at the domain level. Tivoli Access Manager's JACC provider can only be configured at the global level. Security domains can still use it if they do not override the authorization provider with another JACC provider or with the built-in native authorization.

On z/OS, you can enable or disable the System Authorization Facility (SAF) based authorization at the domain level.

Custom properties

Set custom properties at the domain level that are either new or different from those at the global level. By default, all of the custom properties at the global security configuration can be accessed by all of the applications in the cell. The security runtime code first checks for the custom property at the domain level. If it does not find it, it then attempts to obtain the custom property from the global security configuration.

10. Click **Apply**.
11. After you have saved your configuration changes, restart the server for your changes to take effect.

Configuring inbound trusted realms for multiple security domains

You can configure which realms to grant inbound trust to for multiple security domains. The trust relationship between realms is used when communicating with Lightweight Third-Party Authentication (LTPA) tokens. Once a LTPA token is decrypted by the receiving server, the realm in the token is checked to see if it is trusted. If it is not, the validation of the token fails. A *realm* represents a user registry in WebSphere Application Server.

Before you begin

For information on cross realm communications, read the section in “Multiple security domains” on page 1222.

Only users assigned to the administrator role can configure multiple security domains. Enable global security in your environment before configuring multiple security domains.

Perform the following steps to grant inbound trusted realms for multiple security domains using the administrative console:

Procedure

1. Click **Security > Security domains**.
2. Select a domain to edit or create a new one. Under Security Attributes, click **User realm**.
3. Click **Customize for this domain**.
4. Under Related Items, select **Trusted authentication realms - inbound**.
5. Select **Trust all realms (including those external to this cell)** or **Trust realms as indicated below**. If Kerberos authentication is enabled, and you have cross realms or trusted realms, you must add the Kerberos trusted realm by selecting **Trust realms as indicated below**.
6. Click **Apply.**

What to do next

The realms you selected to trust accept messages from other trusted realms but do not accept messages from untrusted realms. Select **Add External Realm** to add trust for realms that are external to this cell.

Configure security domains

Use this page to configure the security attributes of a domain and to assign the domain to cell resources. For each security attribute, you can use the global security settings or customize settings for the domain.

To view this administrative console page, click **Security > Security domains**. On the Security domains collection page, select an existing domain to configure, create a new one, or copy an existing domain.

Read about “Multiple security domains” on page 1222 for a better understanding of what multiple security domains are and how they are supported in this version of WebSphere Application Server.

Name

Specifies a unique name for the domain. This name can not be edited after the initial submission.

A domain name must be unique within a cell and cannot contain an invalid character.

Description

Specifies a description for the domain.

Assigned Scopes

Select to display the cell topology. You can assign the security domain to the entire cell or select the specific clusters, nodes and service integration buses to include in the security domain.

If you select **All scopes**, the entire cell topology is displayed.

If you select **Assigned scopes**, the cell topology is displayed with those servers and clusters that are assigned to the current domain.

The name of an explicitly assigned domain appears next to any resource. Checked boxes indicate resources that are currently assigned to the domain. You also can select other resources and click **Apply** or **OK** to assign them to the current domain.

A resource that is not checked (disabled) indicates that it is not assigned to the current domain and must be removed from another domain before it can be enabled for the current domain.

If a resource does not have an explicitly-assigned domain, it uses the domain assigned to the cell. If no domain is assigned to the cell, then the resource uses global settings.

Cluster members cannot be individually assigned to domains; the enter cluster uses the same domain.

Application Security:

Select **Enable application security** to enable or disable security for user applications. You can use the global security settings or customize the settings for a domain.

When this selection is disabled, all of the EJBs and web applications in the security domain are no longer protected. Access is granted to these resources without user authentication. When you enable this selection, the J2EE security is enforced for all of the EJBs and web applications in the security domain. The J2EE security is only enforced when Global Security is enabled in the global security configuration, (that is, you cannot enable application security without first enabling Global Security at the global level).

Enable application security

Enables security for the applications in your environment. This type of security provides application isolation and requirements for authenticating application users

In previous releases of WebSphere Application Server, when a user enabled global security, both administrative and application security were enabled. In WebSphere Application Server Version 6.1, the previous notion of global security were split into administrative security and application security, each of which you can enable separately.

As a result of this split, WebSphere Application Server clients must know whether application security is disabled at the target server. Administrative security is enabled, by default. Application security is disabled, by default. To enable application security, you must enable administrative security. Application security is in effect only when administrative security is enabled.

When this selection is disabled, all of the EJBs and web applications in the security domain are no longer protected. Access is granted to these resources without user authentication. When you enable this selection, the J2EE security is enforced for all of the EJBs and web applications in the security domain. The J2EE security is only enforced when Global Security is enabled in the global security configuration, (that is, you cannot enable application security without first enabling Global Security at the global level).

Java 2 security:

Select **Use Java 2 security** to enable or disable Java 2 security at the domain level or to assign or add properties related to Java 2 security. You can use the global security settings or customize the settings for a domain.

This choice enables or disables Java 2 security at the process (JVM) level so that all applications (both administrative and user) can enable or disable Java 2 security.

Use global security settings
Select to specify the global security settings that are being used.

Customize for this domain
Select to specify the settings that are defined in the domain, such as options to enable application and Java 2 security and to use realm-qualified authentication data.

Use Java 2 security to restrict application access to local resources
Select to specify whether to enable or disable Java 2 security permission checking. By default, access to local resources is not restricted. You can choose to disable Java 2 security, even when application security is enabled.

When the **Use Java 2 security to restrict application access to local resources** option is enabled and if an application requires more Java 2 security permissions than are granted in the default policy, the application might fail to run properly until the required permissions are granted in either the `app.policy` file or the `was.policy` file of the application. AccessControl exceptions are generated by applications that do not have all the required permissions.

Warn if applications are granted custom permissions
Specifies that during application deployment and application start, the security runtime issues a warning if applications are granted any custom permissions. Custom permissions are permissions that are defined by the user applications, not Java API permissions. Java API permissions are permissions in the `java.*` and `javax.*` packages.

The application server provides support for policy file management. A number of policy files are available in this product, some of them are static and some of them are dynamic. Dynamic policy is a template of permissions for a particular type of resource. No code base is defined and no relative code base is used in the dynamic policy template. The real code base is dynamically created from the configuration and run-time data. The `filter.policy` file contains a list of permissions that you do not want an application to have according to the J2EE 1.4 specification.

Important: You cannot enable this option without enabling the **Use Java 2 security to restrict application access to local resources** option.

Restrict access to resource authentication data
This option is disabled if Java 2 security has not been enabled.

Consider enabling this option when both of the following conditions are true:

- Java 2 security is enforced.
- The application code is granted the accessRuntimeClasses WebSphereRuntimePermission permission in the `was.policy` file found within the application enterprise archive (EAR) file. For example, the application code is granted the permission when the following line is found in your `was.policy` file:

```
permission com.ibm.websphere.security.WebSphereRuntimePermission "accessRuntimeClasses";
```

The **Restrict access to resource authentication data** option adds fine-grained Java 2 security permission checking to the default principal mapping of the WSPrincipalMappingLoginModule implementation. You must grant explicit permission to Java 2 Platform, Enterprise Edition (J2EE) applications that use the WSPrincipalMappingLoginModule implementation directly in the Java Authentication and Authorization Service (JAAS) login when **Use Java 2 security to restrict application access to local resources** and the **Restrict access to resource authentication data** options are enabled.

Default: Disabled

User Realm:
This section enables you to configure the user registry for the security domain. You can separately configure any registry that is used at the domain level.

When configuring a registry at the domain level you can choose to define your own realm name for the registry. The realm name distinguishes one user registry from another. The realm name is used in multiple places – in the Java client login panel to prompt the user, in the authentication cache, and when using native authorization.

At the global configuration level, the system creates the realm for the user registry. In previous releases of WebSphere Application Server, only one user registry is configured in the system. When you have multiple security domains you can configure multiple registries in the system. For the realms to be unique in these domains, configure your own realm name for a security domain. You also can choose the system to create a unique realm name if it is certain to be unique. In the latter case, the realm name is based on the registry that is being used.

Trust Association:
Select to specify the settings for the trust association. Trust association is used to connect reversed proxy servers to the application servers.

Trust association enables the integration of IBM WebSphere Application Server security and third-party security servers. More specifically, a reverse proxy server can act as a front-end authentication server while the product applies its own authorization policy onto the resulting credentials that are passed by the proxy server.

Tivoli Access Manager's trust association interceptors can only be configured at the global level. The domain configuration can also use them, but cannot have a different version of the trust association interceptor. Only one instance of Tivoli Access Manager's trust association interceptors can exist in the system.

Note: The use of trust association interceptors (TAIs) for Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) authentication is deprecated. The SPNEGO web authentication panels provide a much easier way to configure SPNEGO.

Interceptors
Select to access or to specify the trust information for reverse proxy servers.

Enable trust association
Select to enable the integration of IBM WebSphere Application Server security and third-party security servers. More specifically, a reverse proxy server can act as a front-end authentication server while the product applies its own authorization policy onto the resulting credentials that are passed by the proxy server.

SPNEGO Web Authentication:
Specifies the settings for Simple and Protected GSS-API Negotiation (SPNEGO) as the web authentication mechanism.

The SPNEGO web authentication, which enables you to configure SPNEGO for web resource authentication, can be configured at the domain level.

Note: In WebSphere Application Server Version 6.1, a TAI that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

RMI/IIOP Security:

Specifies the settings for Remote Method Invocation over the Internet Inter-ORB Protocol (RMI/IIOP).

An Object Request Broker (ORB) manages the interaction between clients and servers, using the Internet InterORB Protocol (IIOP). It enables clients to make requests and receive responses from servers in a network-distributed environment.

When you configure these attributes at the domain level, the RMI/IIOP security configuration at the global level is copied for convenience. You can change the attributes that need to be different at the domain level. The Transport layer settings for CSIv2 inbound communications should be the same for both the global and the domain levels. If they are different, the domain level attributes are applied to all of the applications in the process.

When a process communicates with another process with a different realm, the LTPA authentication and the propagation tokens are propagated to the downstream server unless that server is listed in the outbound trusted realms list. This can be done using the **Trusted authentication realms – outbound** link on the **CSIv2 outbound communication** panel.

CSIv2 inbound communications

Select to specify authentication settings for requests that are received and transport settings for connections that are accepted by this server using the Object Management Group (OMG) Common Secure Interoperability (CSI) authentication protocol.

WebSphere Application Server enables you to specify Internet Inter-ORB Protocol (IIOP) authentication for both inbound and outbound authentication requests. For inbound requests, you can specify the type of accepted authentication, such as basic authentication.

CSIv2 outbound communications

Select to specify authentication settings for requests that are sent and transport settings for connections that are initiated by the server using the Object Management Group (OMG) Common Secure Interoperability (CSI) authentication protocol.

WebSphere Application Server enables you to specify Internet Inter-ORB Protocol (IIOP) authentication for both inbound and outbound authentication requests. For outbound requests, you can specify properties such as type of authentication, identity assertion or login configurations that are used for requests to downstream servers.

JAAS Application logins

Select to define login configurations that are used by JAAS.

The JAAS application logins, the JAAS system logins, and the JAAS J2C authentication data aliases can all be configured at the domain level. By default, all of the applications in the system have access to the JAAS logins configured at the global level. The security runtime first checks for the JAAS logins at the domain level. If it does not find them, it then checks for them in the global security configuration. Configure any of these JAAS logins at a domain only when you need to specify a login that is used exclusively by the applications in the security domain.

For JAAS and custom properties only, once global attributes are customized for a domain they can still be used by user applications.

Do not remove the ClientContainer, DefaultPrincipalMapping, and WSLogin login configurations because other applications might use them. If these configurations are removed, other applications might fail.

Use global and domain-specific logins

Select to specify the settings that are defined in the domain, such as options to enable application and Java 2 security and to use realm-qualified authentication data.

JAAS System Logins:
Specifies the configuration settings for the JAAS system logins. You can use the global security settings or customize the configuration settings for a domain.

System Logins
Select to define the JAAS login configurations that are used by system resources, including the authentication mechanism, principal mapping, and credential mapping

JAAS J2C Authentication Data:
Specifies the settings for the JAAS J2C authentication data. You can use the global security settings or customize the settings for a domain.

Java 2 Platform, Enterprise Edition (J2EE) Connector authentication data entries are used by resource adapters and Java DataBase Connectivity (JDBC) data sources.

Use global and domain-specific entries
Select to specify the settings that are defined in the domain, such as options to enable application and Java 2 security and to use realm-qualified authentication data.

Java Authentication SPI (JASPI)
Specifies the configuration settings for a Java Authentication SPI (JASPI) authentication provider and associated authentication modules. You can use the global security settings or customize the settings for a domain. To configure JASPI authentication providers for a domain, select **Customize for this domain** and then you can enable JASPI. Select **Providers** to create or to edit a JASPI authentication provider.

Note: The JASPI authentication provider can be enabled with providers configured at the domain level. By default, all of the applications in the system have access to the JASPI authentication providers configured at the global level. The security runtime first checks for the JASPI authentication providers at the domain level. If it does not find them, it then checks for them in the global security configuration. Configure JASPI authentication providers at a domain only when the provider is to be used exclusively by the applications in that security domain.

Authentication Mechanism Attributes:
Specifies the various cache settings that must be applied at the domain level.

- Authentication cache settings - use to specify your authentication cache settings. The configuration specified on this panel is applied only to this domain.
- LTPA Timeout - You can configure a different LTPA timeout value at the domain level. The default timeout value is 120 minutes, which is set at the global level. If the LTPA timeout is set at the domain level, any token that is created in the security domain when accessing user applications is created with this expiration time.
- Use realm-qualified user names - When this selection is enabled, user names returned by methods such as `getUserPrincipal( )` are qualified with the security realm (user registry) used by applications in the security domain.

Authorization Provider:
Specifies the settings for the authorization provider. You can use the global security settings or customize the settings for a domain.

You can configure an external third party JACC (Java Authorization Contract for Containers) provider at the domain level. Tivoli Access Manager's JACC provider can only be configured at the global level. Security domains can still use it if they do not override the authorization provider with another JACC provider or with the built-in native authorization.

Select either the **Default authorization** or **External authorization using a JAAC provider**. The **Configure** button is only enabled when **External authorization using a JAAC provider** is selected.

z/OS security options:
Specifies the settings for z/OS. You can use the global security settings or customize the settings for a domain.

Custom properties
Select to specify name-value pairs of data, where the name is a property key and the value is a string.

Set custom properties at the domain level that are either new or different from those at the global level. By default, all of the custom properties at the global security configuration can be accessed by all of the applications in the system. The security runtime code first checks for the custom property at the domain level. If it does not find it, it then attempts to obtain the custom property from the global security configuration.

Web Services Bindings
Click **Default policy set bindings** to set the domain default provider and client bindings.

External realm name
Use this page to add a WebSphere Application Server realm that is external to this cell. The realm is initially not trusted. Use the Trusted authentication realms - inbound page to establish trust.

To view this administrative console page, click **Security > Security domains**. Select a domain to edit or create a new one. Under Security Attributes, click **User realm**. Click **Customize for this domain** and then select a **Realm type**. Click **Configure**. Under Related items, click **Trusted authentication realms - inbound** or **Trusted authentication realms - outbound**. Click **Add External Realm...**.

External realm name
Use to specify the name of the realm that is external to the list of realms that are available to receive trust.

Trust all realms
Use this page to configure which realms to grant inbound or outbound trust to.

The inbound trust is required to validate LTPA tokens that contain a foreign realm. The outbound trust is required to send the credential tokens to the trusted realms. For example, if an application using realmA needs to communicate using LTPA with an application using realmB, realmA should have realmB in its outbound trust list and realmB should have realmA in its inbound trust list.

To view this administrative console page, click **Security > Security domains**. Select a domain to edit or create a new one. Under Security Attributes, click **User realm**. Click **Customize for this domain**. Select a realm type and then click **Configure**.

Under Related items, click **Trusted authentication realms - inbound** or **Trusted authentication realms - outbound**.

Trust all realms (including those external to this cell)
Select to trust all of the realms listed on this page, including those external to the cell.

Trust realms as indicated below
Select to trust only those realms that you have selected from the list of realms that are available to receive inbound trust.

Add External Realm...
Select to add realms that are external to this cell to the list of realms that are available to receive inbound trust. When an external realm is added, it is trusted by default. If it is not trusted it is removed from the list.

Security domains collection

Security domains provide a mechanism to use different security settings for administrative applications and user applications. They also provide the ability to support multiple security settings so different application servers can use different security attributes like user registry or login configurations.

To view this administrative console page, click **Security > Security domains**.

Read about “Multiple security domains” on page 1222 for a better understanding of what multiple security domains are and how they are supported in this version of WebSphere Application Server.

Maximum rows

Specifies the maximum number of rows that display when the collection is large. The rows that are not displayed appear on the next page.

The default is 20. Rows that exceed the maximum number display on subsequent pages.

Retain filter criteria

Specifies whether to use the same filter criteria entered in the show filter function to display this page the next time you visit it.

Copy selected domain

Select to copy a selected domain from the collection (a new name is required)

Copy global security

Select to create a domain with a copy of the global security settings (collection selections are ignored). A domain name is required.

Authentication cache settings

Use this page to specify your authentication cache settings.

To view this administrative console page, click **Security > Global security > Authentication cache settings**.

Enable authentication cache

Specifies whether to disable the authentication cache.

Leave the authentication cache enabled for performance reasons. However, you can disable the authentication cache for debug or measurement purposes. When this choice is disabled, the performance is impacted since whenever a user is authenticated the user registry is accessed to gather information about the user. New tokens are then created for the user.

Default: Enabled

Cache timeout:

Specifies the time period at which the authenticated credential in the cache expires. Verify that this time period is less than the value for the **Timeout value for forwarded credentials between servers** field (the LTPA timeout).

If the application server infrastructure security is enabled, the security cache timeout can influence performance. The timeout setting specifies how often to refresh the security-related caches. Security information pertaining to beans, permissions, and credentials is cached. When the cache timeout expires, all cached information not accessed within the timeout period is purged from the cache. Subsequent requests for the information result in a database lookup. On occasion, acquiring the information requires

invoking a Lightweight Directory Access Protocol (LDAP)-bind or native authentication. Both invocations are relatively costly operations for performance. Determine the best trade-off for the application by looking at usage patterns and security needs for the site.

You must consider the following effects of this value on your configuration:

- Larger authentication cache timeout values can increase the security risk. For example, you might revoke a user in the user registry or repository. However, the revoked user can log into the administrative console using the credential that is cached in the authentication cache until the cache is refreshed.
- Smaller authentication cache timeout values can affect performance. When this value is smaller, the application server accesses the user registry or repository more frequently.
- Larger numbers of entries in the authentication cache, which is due to an increased number of users, increases the memory usage by the authentication cache. Thus, the application server might slow down and affect performance.

You can limit the size of the authentication cache by setting the maximum cache size value. Set both the maximum cache size and the authentication cache timeout values to balance your security risk and performance needs.

The LTPA timeout value should not be set lower than the security cache timeout value. The LTPA timeout value should be set higher than the ORB request timeout value. However, there is no relation between the security cache timeout value and the ORB request timeout value. For more information on the LTPA timeout value, see the documentation about authentication mechanisms and expiration. For more information on the ORB request timeout value, see the documentation about the Object Request Broker service settings.

Default: 10 minutes

Initial cache size:

Specifies the initial size of the hash table caches.

A higher number of available hash values might decrease the occurrence of hash collisions. A hash collision results in a linear search for the hash bucket, which might decrease the retrieval time. If several entries compose a hash table cache, create a table with a larger capacity that supports more efficient hash entries instead of allowing automatic rehashing determine the growth of the table. Rehashing causes every entry to move each time.

Default: 50

Maximum cache size

Indicates the maximum size of the cache.

After this limit is reached, the least used entries are removed from the cache to make space for the new entries.

Default: 25000

Use basic authentication cache keys (password one-way hashed):

Caches the userName and the one-way hashed password as the key lookup in the cache.

Disable this only if you do not want this information to be stored in the cache. If this is disabled, every time a user logs in with userName and password, the user registry is accessed, which impacts performance.

Default: True

Authenticating users

The process of authenticating users involves a user registry and an authentication mechanism. Optionally, you can define trust between WebSphere Application Server and a proxy server, configure single sign-on capability, and specify how to propagate security attributes between application servers.

About this task

The following security topics are covered in this section:

User registries
For information on local operating system, Lightweight Directory Access Protocol (LDAP), custom user registries, and user repositories such as virtual member manager, see "Selecting a registry or repository."

Trust associations
For more information on trust associations, see "Trust associations" on page 1433.

Single sign-on
For more information on single sign-on, see "Single sign-on for authentication using LTPA cookies" on page 1438.

Security attribute propagation
For more information on propagation tokens, authorization tokens, single sign-on tokens, and authentication tokens, see "Security attribute propagation" on page 1544.

The following information is covered in this section:

Procedure

- Configure a user registry. For more information, see "Selecting a registry or repository."
- Configure WebSEAL or a custom trust association interceptor. For more information see, "Integrating third-party HTTP reverse proxy servers" on page 1433.
- Configure single sign-on. For more information, see "Implementing single sign-on to minimize web user authentications" on page 1441.
- Propagate security attributes. For more information, see "Propagating security attributes among application servers" on page 1549.
- Configure the authentication cache. For more information, see "Configuring the authentication cache" on page 1560.

What to do next

After completing the configuring the authentication process, you must authorize access to resources. For more information, see "Authorizing access to resources" on page 1614.

Selecting a registry or repository

Information about users and groups reside in a user registry. In WebSphere Application Server, a user registry authenticates a user and retrieves information about users and groups to perform security-related functions, including authentication and authorization.

Before you begin

Note: During profile creation, either during installation or post-installation, administrative security is enabled by default. The file-based federated user repository is configured as the active user registry. Decide if you want a different user registry.

Before configuring the user registry or repository, decide which user registry or repository to use. You can configure one Active default registry for the Cell.

About this task

WebSphere Application Server provides implementations that support multiple types of registries and repositories including the local operating system registry, a stand-alone Lightweight Directory Access Protocol (LDAP) registry, a stand-alone custom registry, and federated repositories.

With WebSphere Application Server, a user registry or a repository, such as a federated repository, authenticates a user and retrieves information about users and groups to perform security-related functions including authentication and authorization.

With WebSphere Application Server, a user registry or repository is used for:

- Authenticating a user using basic authentication, identity assertion, or client certificates
- Retrieving information about users and groups to perform security-related administrative functions, such as mapping users and groups to security roles

In addition to local operating system, LDAP, and Federated repository registries, WebSphere Application Server also provides a plug-in to support any registry by using the custom registry feature. The custom registry feature enables you to configure any user registry that is not made available through the security configuration panels of the WebSphere Application Server.

Configuring the correct registry or repository is a prerequisite to assigning users and groups to roles for applications. When a user registry or repository is not configured, the local operating system registry is used by default. If your choice of user registry is not the local operating system registry, you need to first configure the registry or repository, which is normally done as part of enabling security, restart the servers, and then assign users and groups to roles for all your applications.

WebSphere Application Server supports the following types of user registries:

- Federated repository
- Local operating system
- Standalone Lightweight Directory Access Protocol (LDAP) registry
- Stand-alone custom registry

The UserRegistry interface is used to implement both the custom registry and the federated repository options for the user account repository. The interface is very helpful in situations where the current user and group information exists in some other formats, for example, a database, and cannot move to local operating system or LDAP registries. In such a case, you can implement the UserRegistry interface so that WebSphere Application Server can use the existing registry for all the security-related operations. The process of implementing a custom registry is a software implementation effort, and it is expected that the implementation does not depend on WebSphere Application Server resource management for its operation. For example, you cannot use an Application Server data source configuration; generally you must invoke database connections and dictate their behavior directly in your code.

Note: WebSphere Application Server has implemented a user registry proxy by using the UserRegistry interface. However, the return values are little different from the interface. For example, getUniqueUserId returns the uniqueID with the realm name wrapped. You cannot use the return value to pass to getUserSecurityName, as shown in the following example:

```
// Retrieves the default InitialContext for this server.
javax.naming.InitialContext ctx = new javax.naming.InitialContext();

// Retrieves the local UserRegistry object.
com.ibm.websphere.security.UserRegistry reg =
        (com.ibm.websphere.security.UserRegistry) ctx.lookup("UserRegistry");

// Retrieves the registry uniqueID based on the userName that is specified
```

```
    // in the NameCallback.
String uniqueid = reg.getUniqueUserId(userName);
// Strip the realm name and get real uniqueID
String uid = com.ibm.wsspi.security.token.WSSecurityPropagationHelper.getUserFromUniqueID (uniqueID);

// Retrieves the security name from the user registry based on the uniqueID.
String securityName = reg.getUserSecurityName(uid);
```

You can use a Service Provider Interface (SPI) for this parsing function.

After the applications are assigned users and groups and you need to change the user registries, delete all the users and groups, including any RunAs role, from the applications, and reassign them after changing the registry through the administrative console or by using wsadmin scripting. The following **wsadmin** command, which uses Jacl, removes all of the users and groups from any application:

```
$AdminApp deleteUserAndGroupEntries yourAppName
```

where *yourAppName* is the name of the application. Backing up the old application is advised before performing this operation. However, if both of the following conditions are true, you might be able to switch the registries without having to delete the users and groups information:

- All of the user and group names, including the password for the RunAs role users, in all of the applications match in both user registries.
- The application bindings file does not contain the access IDs which are unique for each user registry even for the same user or group name.

By default, an application does not contain access IDs in the bindings file. These IDs are generated when the applications start. However, if you migrated an existing application from an earlier release, or if you used the wsadmin script to add access IDs for the applications to improve performance, you have to remove the existing user and group information and add the information after configuring the new user registry.

For more information on updating access IDs, see updateAccess IDs in the Commands for the AdminApp object article.

Attention: WebSphere Application Server supports a variety of user registries and repositories on different operating systems. During the user authentication process, you might use non-alphanumeric characters in your user name or password. Restrictions on the use of these non-alphanumeric characters depends on both the underlying operating system and the user registry type. For more information on which non-alphanumeric characters are not supported, see your operating system and user registry or repository documentation.

For a comprehensive list of the non-alphanumeric characters that are not supported, see the IBM AIX operating system documentation.

Complete one of the following steps to configure your user registry:

Procedure

- “Configuring local operating system registries” on page 1257
- “Configuring Lightweight Directory Access Protocol user registries” on page 1260
- “Configuring stand-alone custom registries” on page 1287.
- “Managing the realm in a federated repository configuration” on page 1316

What to do next

1. If you are enabling security, make sure that you complete the remaining steps. Verify that the User account repository on the Global security panel is set to the appropriate registry or repository. As the final step, validate the user ID and the password by clicking **Apply** on the Global security panel. Save, stop and start all WebSphere Application Servers.

2. For any changes in user registry panels to be effective, you must validate the changes by clicking **Apply** on the Global security panel. After validation, save the configuration and stop and start all WebSphere Application Servers, including the cells, nodes and all of the application servers. To avoid inconsistencies between the WebSphere Application Server processes, make sure that any changes to the registry or repository are done when all of the processes are running. If any of the processes are down, force synchronization to make sure that the process can start later.

   If the server or servers start without any problems, the setup is correct.

Configuring local operating system registries

Use these steps to configure local operating system registries.

Before you begin

For detailed information about using the local operating system user registry, see “Local operating system registries” on page 1258. These steps set up security based on the local operating system user registry on which WebSphere Application Server is installed.

In WebSphere Application Server Version 6.1, you can use an internally-generated server ID because the Security WebSphere Common Configuration Model (WCCM) model contains a new tag, internalServerId. You do not need to specify a server user ID and a password during security configuration except in a mixed-cell environment. See “Administrative roles and naming service authorization” on page 1615 for more detailed information about the new internal server ID.

About this task

The following steps are needed to perform this task initially when setting up security for the first time.

Procedure

1. Click **Security > Global security**.
2. Under User account repository, select **Local operating system** and click **Configure**.
3. Enter a valid user name in the **Primary administrative user name** field. This value is the name of a user with administrative privileges that is defined in the registry. This user name is used to access the administrative console or used by wsadmin.
4. Click **Apply**.
5. Select either the **Automatically generated server identity** or **Server identity that is stored in the repository** option. If you select the **Server identity that is stored in the repository** option, enter the following information:

   Server user ID or administrative user on a Version 6.0.x node
   Specify the short name of the account that is chosen in the second step.

   Server user password
   Specify the password of the account that is chosen in the second step.
6. Enter a valid user profile name in the **Primary administrative user name** field.

   The Primary administrative user name specifies the user profile to use when the server authenticates to the underlying operating system. This identity is also the user that has initial authority to access the administrative application through the administrative console. The administrative user ID is common to all user registries. The administrative ID is a member of the chosen registry and it has special privileges in WebSphere Application Server. However, it does not have any special privileges in the registry that it represents. In other words, you can select any valid user ID in the registry to use as the administrative user ID or server user ID.

   For the **Primary administrative user name** field, you can specify any user profile that meets this criteria:

   - The user profile has a status of `*ENABLED`.

- The user profile has a valid password.
- The user profile is not used as a group profile.

  Important: A group profile is assigned a unique group ID number, which is not assigned to a regular user profile. Run the DSPUSRPRF Display User Profile command to determine if the user profile you want to use as the Primary administrative user name has a defined group ID number. If the **Group ID** field is set to *NONE, you can use the user profile as the Primary administrative user name.

7. Click **OK**.

   The administrative console does not validate the user ID and password when you click **OK**. Validation is only done when you click **OK** or **Apply** in the Global security panel. First, make sure that you select **Local operating system** as the available realm definition in the User account repository section, and click **Set as current**. If security was already enabled and you had changed either the user or the password information in this panel, make sure to go to the Global security panel and click **OK** or **Apply** to validate your changes. If your changes are not validated, the server might not start.

   Important: Until you authorize other users to perform administrative functions, you can only access the administrative console with the server user ID and password that you specified. For more information, see “Authorizing access to administrative roles” on page 1679.

Results

For any changes in this panel to be effective, you need to save, stop, and start all the product servers, including nodes and application servers. If the server comes up without any problems, the setup is correct.

After completed these steps, you have configured WebSphere Application Server to use the local operating system registry to identify authorized users.

What to do next

Complete any remaining steps for enabling security. For more information, see “Enabling security” on page 1172.

Local operating system registries:

With the registry implementation for the local operating system, the WebSphere Application Server authentication mechanism can use the user accounts database of the local operating system.

Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using SystemOut.log , SystemErr.log, trace.log, and activity.log files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

If you want to use the local operating system registry to represent the principals who access your WebSphere Application Server resources, you do not have to complete any special user registry setup steps. The local operating system registry is used for authentication and authorization of users who access WebSphere Application Server resources, but not for WebSphere Application Server users who access operating system resources. WebSphere Application Server does not run under the operating system user profile of Application Server users. Instead, WebSphere Application Server runs under the operating system profile that is configured by the Application Server administrator.

If you want to authorize a user for any WebSphere Application Server resource, a user profile for that user must exist in the operating system. Use the Create User Profile (CRTUSRPRF) command to create new user IDs that can be used by WebSphere Application Server

Do not use a local operating system registry in a WebSphere Application Server environment where application servers are dispersed across more than one machine because each machine has its own user registry.

As mentioned previously, the access IDs taken from the user registry are used during authorization checks. Because these IDs are typically unique identifiers, they vary from machine to machine, even if the exact users and passwords exist on each machine.

Web client certificate authentication is not currently supported when using the local operating system user registry. However, Java client certificate authentication does function with a local operating user registry. Java client certificate authentication maps the first attribute of the certificate domain name to the user ID in the user registry.

Even though Java client certificates function correctly, the following error displays in the `SystemOut.log` file:

```
CWSCJ0337E: The mapCertificate method is not supported
```

The error is intended for web client certificates; however, it also displays for Java client certificates. Ignore this error for Java client certificates.

Using either the local or the domain user registry

. If you want to access users and groups from either the local or the domain user registry, instead of both, set the com.ibm.websphere.registry.UseRegistry property. This property can be set to either `local` or `domain`. When this property is set to `local` (case insensitive) only the local user registry is used. When this property is set to domain, (case insensitive) only the domain user registry is used.

Set this property by completing the following steps to access the **Custom Properties** panel in the administrative console:

1. Click **Security > Global security**
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Local operating system**, and click **Configure**.
3. Under Additional properties, click **Custom properties**.

You can also use wsadmin to configure this property. When the property is set, the privilege requirement for the user who is running the product process does not change. For example, if this property is set to `local`, the user that is running the process requires the same privilege, as if the property was not set.

Using system user registries

The following notes apply when you use system user registries:

Local operating system settings:

Use this page to configure local operating system registry settings.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Local operating system**.
3. Click **Configure**.

WebSphere Application Server Version 7.0 distinguishes between the user identities for administrators who manage the environment and server identities for authenticating server to server communications. In most cases, server identities are automatically generated and are not stored in a repository.

Primary administrative user name:

Specifies the name of a user with administrative privileges that is defined in your local operating system.

The user name is used to log on to the administrative console when administrative security is enabled..

Attention: In WebSphere Application Server, Version 6.1 and above, a single user identity is required for both administrative access and internal process communication. When migrating to Version 6.1 and above, this identity is used as the server user identity. You need to specify another user for the administrative user identity.

Automatically generated server identity:

Enables the application server to generate the server identity, which is recommended for environments that contain only Version 6.1 or later nodes. Automatically generated server identities are not stored in a user repository.

Default: Enabled

Server identity that is stored in the repository:

Specifies a user identity in the repository that is used for internal process communication. Cells that contain Version 6.1 or later nodes require a server user identity that is defined in the active user repository.

Default: Enabled

Local operating system wizard settings:

Use this security wizard page to configure local operating system registry settings.

To view this security wizard page, complete the following steps:

1. Click **Security > Global security > Security configuration wizard**.
2. Select your protection settings and click **Next**.
3. Select the **Local operating system** option and click **Next**.

Primary administrative user name:

Specifies the name of a user with administrative privileges that is defined in your local operating system.

The user name is used to log on to the administrative console when administrative security is enabled..

Attention: In WebSphere Application Server, Version 6.1 and above, a single user identity is required for both administrative access and internal process communication. When migrating to Version 6.1 and above, this identity is used as the server user identity. You need to specify another user for the administrative user identity.

Configuring Lightweight Directory Access Protocol user registries

To access a user registry using the Lightweight Directory Access Protocol (LDAP), you must know a valid user name (ID) and password, the server host and port of the registry server, the base distinguished name

(DN) and, if necessary, the bind DN and the bind password. You can choose any valid user in the user registry that is searchable. You can use any user ID that has the administrative role to log in.

Before you begin

Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

There are two different identities that are used for security purposes: the user ID for administrative functions and the server identity. When administrative security is enabled, the user ID and password for administrative functions is authenticated with the registry. If authentication fails, access to the administrative console is not granted or tasks with wsadmin scripts are not completed. It is important to choose an ID and password that do not expire or change often. If this user ID or password need to change in the registry, make sure that the changes are performed when all the application servers are up and running. When changes are to be made in the registry, review the article on “Standalone Lightweight Directory Access Protocol registries” on page 1407 (LDAP) before beginning this task.

The server identity is used for internal process communication. As part of this task, you can change the server identity from the default automatically generated ID to a server ID and password from the LDAP repository.

Procedure

1. In the administrative console, click **Security** > **Global security**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone LDAP registry**, and click **Configure**.
3. Enter a valid user name in the **Primary administrative user name** field. Typically, the user name is the short name of the user and is defined by the user filter in the Advanced LDAP settings panel.
4. Determine whether to specify the user identity that is used for internal process communication. Cells that contain Version 5.1 or 6.x nodes require a server user identity that is defined in the active user repository. By default, the **Automatically generated server identity** option is enabled, and the application server generates the server identity. However, you can select the **Server identity that is stored in the repository** option to specify both the server identity and its associated password.
5. Select the type of LDAP server to use from the **Type** list. The type of LDAP server determines the default filters that are used by WebSphere Application Server. These default filters change the **Type** field to **Custom**, which indicates that custom filters are used. This action occurs after you click **OK** or **Apply** in the Advanced LDAP settings panel. Choose the **Custom** type from the list and modify the user and group filters to use other LDAP servers, if required.

   IBM Tivoli Directory Server users can choose IBM Tivoli Directory Server as the directory type. Use the IBM Tivoli Directory Server directory type for better performance. For a list of supported LDAP servers, see the Supported hardware, software, and APIs website.

   Attention: IBM SecureWay™ Directory Server has been renamed to IBM Tivoli Directory Server in WebSphere Application Server version 6.1.
6. Enter the fully qualified host name of the LDAP server in the **Host** field. You can enter either the IP address or domain name system (DNS) name.
7. Enter the LDAP server port number in the **Port** field. The host name and the port number represent the realm for this LDAP server in the WebSphere Application Server cell. So, if servers in different cells are communicating with each other using Lightweight Third Party Authentication (LTPA) tokens, these realms must match exactly in all the cells.

The default value is 389. If multiple WebSphere Application Servers are installed and configured to run in the same single sign-on domain, or if the WebSphere Application Server interoperates with a previous version of the WebSphere Application Server, then it is important that the port number match all configurations. For example, if the LDAP port is explicitly specified as 389 in a version 5.*x* configuration, and a WebSphere Application Server at version 6.0.*x* is going to interoperate with the version 5.*x* server, then verify that port 389 is specified explicitly for the version 6.0.*x* server.

You can set the com.ibm.websphere.security.ldap.logicRealm custom property to change the value of the realm name that is placed in the token. For more information, see the security custom properties topic.

8. Enter the base distinguished name (DN) in the **Base distinguished name** field. The base DN indicates the starting point for searches in this LDAP directory server. For example, for a user with a DN of cn=John Doe, ou=Rochester, o=IBM, c=US, specify the base DN as any of the following options, assuming a suffix of c=us:
   - ou=Rochester, o=IBM, c=us
   - o=IBM, c=us
   - c=us

   For authorization purposes, this field is case sensitive by default. Match the case in your directory server. If a token is received (for example, from another cell or Lotus Domino) the base DN in the server must match exactly the base DN from the other cell or Domino. If case sensitivity is not a consideration for authorization, enable the **Ignore case for authorization** option.

   In WebSphere Application Server, the distinguished name is normalized according to the Lightweight Directory Access Protocol (LDAP) specification. Normalization consists of removing spaces in the base distinguished name before or after commas and equal symbols. An example of a non-normalized base distinguished name is o = ibm, c = us or o=ibm, c=us. An example of a normalized base distinguished name is o=ibm,c=us.

   To interoperate between WebSphere Application Server Version 6.0 and later versions, you must enter a normalized base distinguished name in the **Base Distinguished Name** field. In WebSphere Application Server, Version 6.0 or later, the normalization occurs automatically during runtime.

   This field is required for all LDAP directories except the Lotus Domino Directory. The **Base Distinguished Name** field is optional for the Domino server.
9. Optional: Enter the bind DN name in the **Bind distinguished name** field. The bind DN is required if anonymous binds are not possible on the LDAP server to obtain user and group information. If the LDAP server is set up to use anonymous binds, leave this field blank. If a name is not specified, the application server binds anonymously. See the **Base Distinguished Name** field description for examples of distinguished names.
10. Optional: Enter the password corresponding to the bind DN in the **Bind password** field.
11. Optional: Modify the Search time out value. This timeout value is the maximum amount of time that the LDAP server waits to send a response to the product client before stopping the request. The default is 120 seconds.
12. Ensure that the **Reuse connection** option is selected. This option specifies that the server should reuse the LDAP connection. Clear this option only in rare situations where a router is used to send requests to multiple LDAP servers and when the router does not support affinity. Leave this option selected for all other situations.
13. Optional: Verify that the **Ignore case for authorization** option is enabled. When you enable this option, the authorization check is case insensitive. Normally, an authorization check involves checking the complete DN of a user, which is unique in the LDAP server and is case sensitive. However, when you use either the IBM Directory Server or the Sun ONE (formerly iPlanet) Directory Server LDAP servers, you must enable this option because the group information that is obtained from the LDAP servers is not consistent in case. This inconsistency affects the authorization check only. Otherwise, this field is optional and can be enabled when a case sensitive authorization check is required. For example, you might select this option when you use certificates and the certificate contents do not match the case of the entry in the LDAP server.

You can also enable the **Ignore case for authorization** option when you are using single sign-on (SSO) between the product and Lotus Domino. The default is enabled.

14. Optional: Select the **SSL enabled** option if you want to use Secure Sockets Layer communications with the LDAP server.

    Important: This step will only be successful provided that the Signer certificate for the LDAP is first added to the truststore that will be eventually used. If the Signer certificate from the LDAP is not added to the truststore, then

    - An error will be issued by the Administrative console.
    - the deployment manager (DMGR) systemout.log will show the **CWPKI0022E: SSL HANDSHAKE FAILURE** message indicating that the Signer certificate needs to be added to the truststore.

    To ensure an error free operation for this step, You need to first extract to a file the Signer certificate of the LDAP and send that file to the WebSphere Application Server machine. You can then add the certificate to the truststore being defined for the LDAP. In this way, you are assured that the remaining actions for this step will be successful.

    If you select the **SSL enabled** option, you can select either the **Centrally managed** or the **Use specific SSL alias** option.

    Centrally managed

    Enables you to specify an SSL configuration for particular scope such as the cell, node, server, or cluster in one location. To use the **Centrally managed** option, you must specify the SSL configuration for the particular set of endpoints. The Manage endpoint security configurations and trust zones panel displays all of the inbound and outbound endpoints that use the SSL protocol. If you expand the Inbound or Outbound section of the panel and click the name of a node, you can specify an SSL configuration that is used for every endpoint on that node. For an LDAP registry, you can override the inherited SSL configuration by specifying an SSL configuration for LDAP. To specify an SSL configuration for LDAP, complete the following steps:

    a. Click **Security > SSL certificate and key management > Manage endpoint security configurations and trust zones**.
    b. Expand **Outbound** > *cell_name* > **Nodes** > *node_name* > **Servers** > *server_name* > **LDAP**.

    Use specific SSL alias

    Select the **Use specific SSL alias** option if you intend to select one of the SSL configurations in the menu below the option.

    This configuration is used only when SSL is enabled for LDAP. The default is *DefaultSSLSettings*. You can click the name of an existing configuration to modify it or complete the following steps to create a new SSL configuration:

    a. Click **Security > SSL certificate and key management**.
    b. Under Configuration settings, click **Manage endpoint security configurations**.
    c. Select a Secure Sockets Layer (SSL) *configuration_name* for selected scopes, such as a cell, node, server, or cluster.
    d. Under Related items, click **SSL configurations**.
    e. Click **New**.

15. Click **OK** and either **Apply** or **Save** until you return to the Global security panel.

Results

This set of steps is required to set up the LDAP user registry. This step is required as part of enabling security in the WebSphere Application Server.

What to do next

1. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1186.
2. Save, stop, and restart all the product servers (deployment managers, nodes and Application Servers) for changes in this panel to take effect. If the server comes up without any problems the setup is correct.

Standalone LDAP registry settings:

Use this page to configure Lightweight Directory Access Protocol (LDAP) settings when users and groups reside in an external LDAP directory.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone LDAP registry**, and click **Configure**.

When security is enabled and any of these properties change, go to the Global security panel and click **Apply** to validate the changes.

WebSphere Application Server Version 7.0 distinguishes between the user identities for administrators who manage the environment and server identities for authenticating server to server communications. In most cases, server identities are automatically generated and are not stored in a repository.

Note: The initial profile creation configures WebSphere Application Server to use a federated repositories security registry option with the file-based registry. This security registry configuration can be changed to use other options, including the stand-alone LDAP registry. Instead of changing from the federated repositories option to the stand-alone LDAP registry option under the User account repository configuration, consider employing the federated repositories option, which provides for LDAP configuration. Federated repositories provide a wide range of capabilities, including the ability to have one or multiple user registries. It supports federating one or more LDAPs in addition to file-based and custom registries. It also has improved failover capabilities, and a robust set of member (user and group) management capabilities. Federated repositories is required when you are using the new member management capabilities in WebSphere Portal 6.1 and above, and Process Server 6.1 and above. The use of federated repositories is required for following LDAP referrals, which is a common requirement in some LDAP server environments (such as Microsoft Active Directory).

It is recommended that you migrate from stand-alone LDAP registries to federated repositories. If you move to WebSphere Portal 6.1 and above, and or WebSphere Process Server 6.1 and above, you should migrate to federated repositories prior to these upgrades. For more information about federated repositories and its capabilities, read the Federated repositories topic. For more information about how to migrate to federated repositories, read the Migrating a stand-alone LDAP repository to a federated repositories LDAP repository configuration topic.

Primary administrative user name:

Specifies the name of a user with administrative privileges that is defined in your user registry.

The user name is used to log onto the administrative console when administrative security is enabled. Versions 6.1 and later require an administrative user that is distinct from the server user identity so that administrative actions can be audited.

Attention: In WebSphere Application Server, Version 6.0.x, a single user identity is required for both administrative access and internal process communication. When you migrate to Version 7.0, this identity is used as the server user identity. You need to specify another user for the administrative user identity.

Automatically generated server identity:

Enables the application server to generate the server identity, which is recommended for environments that contain only Version 6.1 or later nodes. Automatically generated server identities are not stored in a user repository.

Default: Enabled

Server identity that is stored in the repository:

Specifies a user identity in the repository that is used for internal process communication. Cells that contain Version 6.1 or later nodes require a server user identity that is defined in the active user repository.

Default: Enabled

Type of LDAP server:

Specifies the type of LDAP server to which you connect.

IBM SecureWay Directory Server is not supported.

Host:

Specifies the host ID (IP address or domain name service (DNS) name) of the LDAP server.

Port:

Specifies the host port of the LDAP server.

If multiple application servers are installed and configured to run in the same single sign-on domain or if the application server interoperates with a previous version, it is important that the port number match all configurations. For example, if the LDAP port is explicitly specified as `389` in a Version 6.1 configuration, and a WebSphere Application Server at Version 7.0 is going to interoperate with the Version 6.1 server, verify that port `389` is specified explicitly for the Version 7.0 server.

Default: 389
Type: Integer

Base distinguished name (DN):

Specifies the base distinguished name (DN) of the directory service, which indicates the starting point for LDAP searches of the directory service. In most cases, bind DN and bind password are needed. However, when anonymous bind can satisfy all of the required functions, bind DN and bind password are not needed.

For example, for a user with a DN of `cn=John Doe , ou=Rochester, o=IBM, c=US`, specify the Base DN as any of the following options: `ou=Rochester, o=IBM, c=US` or `o=IBM c=US` or `c=US`. For authorization purposes, this field is case sensitive. This specification implies that if a token is received, for example, from another cell or Lotus Domino, the base DN in the server must match the base DN from the other cell or Lotus

Domino server exactly. If case sensitivity is not a consideration for authorization, enable the **Ignore case for authorization** option. This option is required for all Lightweight Directory Access Protocol (LDAP) directories, except for the Lotus Domino Directory, IBM Tivoli Directory Server V6.0, and Novell eDirectory, where this field is optional.

Bind distinguished name (DN):

Specifies the DN for the application server to use when binding to the directory service.

If no name is specified, the application server binds anonymously. See the Base distinguished name (DN) field description for examples of distinguished names.

Bind password:

Specifies the password for the application server to use when binding to the directory service.

Search timeout:

Specifies the timeout value in seconds for a Lightweight Directory Access Protocol (LDAP) server to respond before stopping a request.

Default: 120

Reuse connection:

Specifies whether the server reuses the LDAP connection. Clear this option only in rare situations where a router is used to distribute requests to multiple LDAP servers and when the router does not support affinity.

Default: Enabled
Range: Enabled or Disabled

Important: Disabling the **Reuse connection** option causes the application server to create a new LDAP connection for every LDAP search request. This situation impacts system performance if your environment requires extensive LDAP calls. This option is provided because the router is not sending the request to the same LDAP server. The option is also used when the idle connection timeout value or firewall timeout value between the application server and LDAP is too small.

If you are using WebSphere Edge Server for LDAP failover, you must enable TCP resets with the Edge server. A TCP reset causes the connection to immediately closed and a backup server to failover. For more information, see "Sending TCP resets when server is down" at http://www.ibm.com/software/webservers/appserv/doc/v50/ec/infocenter/edge/LBguide.htm#HDRRESETSERVER and the Edge Server V2 - TCP Reset feature in PTF #2 described in: ftp://ftp.software.ibm.com/software/websphere/edgeserver/info/doc/v20/en/updates.pdf.

Ignore case for authorization:

Specifies that a case insensitive authorization check is performed when using the default authorization.

This option is required when IBM Tivoli Directory Server is selected as the LDAP directory server.

This option is required when Sun ONE Directory Server is selected as the LDAP directory server. For more information, see "Using specific directory servers as the LDAP server" in the documentation.

This option is optional and can be enabled when a case-sensitive authorization check is required. For example, use this option when the certificates and the certificate contents do not match the case that is used for the entry in the LDAP server. You can enable the **Ignore case for authorization** option when using single sign-on (SSO) between the application server and Lotus Domino.

Default: Enabled
Range: Enabled or Disabled

SSL enabled:

Specifies whether secure socket communication is enabled to the Lightweight Directory Access Protocol (LDAP) server.

When enabled, the LDAP Secure Sockets Layer (SSL) settings are used, if specified.

Centrally managed:

Specifies that the selection of an SSL configuration is based upon the outbound topology view for the Java Naming and Directory Interface (JNDI) platform.

Centrally managed configurations support one location to maintain SSL configurations rather than spreading them across the configuration documents.

Default: Enabled

Use specific SSL alias:

Specifies the SSL configuration alias to use for LDAP outbound SSL communications.

This option overrides the centrally managed configuration for the JNDI platform.

Standalone LDAP registry wizard settings:

Use this security wizard page to provide the basic settings to connect the application server to an existing Lightweight Directory Access Protocol (LDAP) registry.

To view this security wizard page, click **Security > Global security > Security configuration wizard**. You can modify your LDAP registry configuration by completing the following steps:

1. Click **Security > Global security**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select**Standalone LDAP registry**, and click **Configure**.

Primary administrative user name:

Specifies the name of a user with administrative privileges that is defined in your user registry.

The user name is used to log onto the administrative console when administrative security is enabled. Versions 6.1 and later require an administrative user that is distinct from the server user identity so that administrative actions can be audited.

Attention: In WebSphere Application Server, Version 6.0.x, a single user identity is required for both administrative access and internal process communication. When you migrate to Version 7.0, this identity is used as the server user identity. You need to specify another user for the administrative user identity.

Type of LDAP server:

Specifies the type of LDAP server to which you connect.

IBM SecureWay Directory Server is not supported.

Host:

Specifies the host ID (IP address or domain name service (DNS) name) of the LDAP server.

Port:

Specifies the host port of the LDAP server.

If multiple application servers are installed and configured to run in the same single sign-on domain or if the application server interoperates with a previous version, it is important that the port number match all configurations. For example, if the LDAP port is explicitly specified as `389` in a Version 6.1 configuration, and a WebSphere Application Server at Version 7.0 is going to interoperate with the Version 6.1 server, verify that port `389` is specified explicitly for the Version 7.0 server.

Default: 389
Type: Integer

Base distinguished name (DN):

Specifies the base distinguished name (DN) of the directory service, which indicates the starting point for LDAP searches of the directory service. In most cases, bind DN and bind password are needed. However, when anonymous bind can satisfy all of the required functions, bind DN and bind password are not needed.

For example, for a user with a DN of `cn=John Doe , ou=Rochester, o=IBM, c=US`, specify the Base DN as any of the following options: `ou=Rochester, o=IBM, c=US` or `o=IBM, c=US` or `c=US`. For authorization purposes, this field is case sensitive. This specification implies that if a token is received, for example, from another cell or Lotus Domino, the base DN in the server must match the base DN from the other cell or Lotus Domino server exactly.

Bind distinguished name (DN):

Specifies the DN for the application server to use when binding to the directory service.

If no name is specified, the application server binds anonymously. See the Base distinguished name (DN) field description for examples of distinguished names.

Bind password:

Specifies the password for the application server to use when binding to the directory service.

Advanced Lightweight Directory Access Protocol user registry settings:

Use this page to configure the advanced Lightweight Directory Access Protocol (LDAP) user registry settings when users and groups reside in an external LDAP directory.

To view this administrative page, complete the following steps:

1. Click **Security > Global security**.

2. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone LDAP registry**, and click **Configure**.
3. Under Additional properties, click **Advanced Lightweight Directory Access Protocol (LDAP) user registry settings**.

Default values for all the user and group related filters are already completed in the appropriate fields. You can change these values depending on your requirements. These default values are based on the type of LDAP server that is selected in the Standalone LDAP registry settings panel. If this type changes, for example from Netscape to Secureway, the default filters automatically change. When the default filter values change, the LDAP server type changes to `Custom` to indicate that custom filters are used. When security is enabled and any of these properties change, go to the Global security panel and click **Apply** or **OK** to validate the changes.

Note: The initial profile creation configures WebSphere Application Server to use a federated repositories security registry option with the file-based registry. This security registry configuration can be changed to use other options, including the stand-alone LDAP registry. Instead of changing from the federated repositories option to the stand-alone LDAP registry option under the User account repository configuration, consider employing the federated repositories option, which provides for LDAP configuration. Federated repositories provide a wide range of capabilities, including the ability to have one or multiple user registries. It supports federating one or more LDAPs in addition to file-based and custom registries. It also has improved failover capabilities, and a robust set of member (user and group) management capabilities. Federated repositories is required when you are using the new member management capabilities in WebSphere Portal 6.1 and above, and Process Server 6.1 and above. The use of federated repositories is required for following LDAP referrals, which is a common requirement in some LDAP server environments (such as Microsoft Active Directory).

It is recommended that you migrate from stand-alone LDAP registries to federated repositories. If you move to WebSphere Portal 6.1 and above, and or WebSphere Process Server 6.1 and above, you should migrate to federated repositories prior to these upgrades. For more information about federated repositories and its capabilities, read the Federated repositories topic. For more information about how to migrate to federated repositories, read the Migrating a stand-alone LDAP repository to a federated repositories LDAP repository configuration topic.

User filter:

Specifies the LDAP user filter that searches the user registry for users.

This option is typically used for security role-to-user assignments and specifies the property by which to look up users in the directory service. For example, to look up users based on their user IDs, specify `(&(uid=%v)(objectclass=inetOrgPerson))`. For more information about this syntax, see the LDAP directory service documentation.

Data type: String

Group filter:

Specifies the LDAP group filter that searches the user registry for groups

This option is typically used for security role-to-group assignments and specifies the property by which to look up groups in the directory service. For more information about this syntax, see the LDAP directory service documentation.

Data type: String

User ID map:

Specifies the LDAP filter that maps the short name of a user to an LDAP entry.

Specifies the piece of information that represents users when users display. For example, to display entries of the `object class = inetOrgPerson` type by their IDs, specify `inetOrgPerson:uid`. This field takes multiple objectclass:property pairs delimited by a semicolon (;).

Data type: String

Group ID map:

Specifies the LDAP filter that maps the short name of a group to an LDAP entry.

Specifies the piece of information that represents groups when groups display. For example, to display groups by their names, specify `*:cn`. The asterisk (`*`) is a wildcard character that searches on any object class in this case. This field takes multiple `objectclass:property` pairs, delimited by a semicolon (;).

Data type: String

Group member ID map:

Specifies the LDAP filter that identifies user-to-group relationships.

For directory types SecureWay, and Domino, this field takes multiple objectclass:property pairs, delimited by a semicolon (;). In an objectclass:property pair, the object class value is the same object class that is defined in the group filter, and the property is the member attribute. If the object class value does not match the object class in the group filter, authorization might fail if groups are mapped to security roles. For more information about this syntax, see your LDAP directory service documentation.

For IBM Directory Server, Sun ONE, and Active Directory, this field takes multiple `group attribute:member attribute` pairs delimited by a semicolon (;). These pairs are used to find the group memberships of a user by enumerating all the group attributes that are possessed by a given user. For example, attribute pair `memberof:member` is used by Active Directory, and ibm-allGroup:member is used by IBM Directory Server. This field also specifies which property of an object class stores the list of members belonging to the group represented by the object class. For supported LDAP directory servers, see "Supported directory services".

Data type: String

Perform a nested group search:

Specifies a recursive nested group search.

Select this option if the Lightweight Directory Access Protocol (LDAP) server does not support recursive server-side group member searches and if recursive group member search is required. It is not recommended that you select this option to locate recursive group memberships for LDAP servers. Application server security leverages the recursive search functionality of the LDAP server to search a user's group memberships, including recursive group memberships. For example:

- IBM Directory Server is preconfigured by the application server security to recursively calculate a user's group memberships using the `ibm-allGroup` attribute.
- SunONE directory server is preconfigured to calculate nested group memberships using the `nsRole` attribute.

Data type: String

Kerberos user filter:

Specifies the Kerberos user filter value. This value can be modified when Kerberos is configured and is active as one of the preferred authentication mechanisms.

Data type: String

Certificate map mode:

Specifies whether to map X.509 certificates into an LDAP directory by EXACT_DN or CERTIFICATE_FILTER. Specify CERTIFICATE_FILTER to use the specified certificate filter for the mapping.

Data type: String

Certificate filter:

Specifies the filter certificate mapping property for the LDAP filter. The filter is used to map attributes in the client certificate to entries in the LDAP registry.

If more than one LDAP entry matches the filter specification at runtime, authentication fails because the result is an ambiguous match. The syntax or structure of this filter is: `(&(uid=${SubjectCN})(objectclass=inetOrgPerson))`. The left side of the filter specification is an LDAP attribute that depends on the schema that your LDAP server is configured to use. The right side of the filter specification is one of the public attributes in your client certificate. The right side must begin with a dollar sign ($) and open bracket ({) and end with a close bracket (}). You can use the following certificate attribute values on the right side of the filter specification. The case of the strings is important:

- `${UniqueKey}`
- `${PublicKey}`
- `${IssuerDN}`
- `${Issuer<xx>}`

  where *<xx>* is replaced by the characters that represent any valid component of the Issuer Distinguished Name. For example, you might use `${IssuerCN}` for the Issuer Common Name.
- `${NotAfter}`
- `${NotBefore}`
- `${SerialNumber}`
- `${SigAlgName}`
- `${SigAlgOID}`
- `${SigAlgParams}`
- `${SubjectDN}`
- `${Subject<xx>}`

  where *<xx>* is replaced by the characters that represent any valid component of the Subject Distinguished Name. For example, you might use `${SubjectCN}` for the Subject Common Name.
- `${Version}`

Data type: String

Configuring Lightweight Directory Access Protocol search filters:

Use this topic to configure the LDAP search filters. These steps are required to modify existing user and group filters for a particular LDAP directory type, and also to set up certificate filters to map certificates to entries in the LDAP server.

Before you begin

WebSphere Application Server uses Lightweight Directory Access Protocol (LDAP) filters to search and obtain information about users and groups from an LDAP directory server. A default set of filters is provided for each LDAP server that the product supports. You can modify these filters to fit your LDAP configuration. After the filters are modified and you click **OK** or **Apply** the directory type in the Standalone LDAP registry panel changes to `custom`, which indicates that custom filters are used. Also, you can develop filters to support any additional type of LDAP server. The effort to support additional LDAP directories is optional and other LDAP directory types are not supported. Complete the following steps in the administrative console.

Procedure

1. Click **Security > Global security**.
2. Under User account repository, select **Standalone LDAP registry** and click **Configure**.
3. Under Additional properties, click **Advanced Lightweight Directory Access Protocol (LDAP) user registry settings**.
4. Modify the user filter, if necessary. The user filter is used for searching the registry for users and is typically used for the security role-to-user assignment. The filter is also used to authenticate a user with the attribute that is specified in the filter. The filter specifies the property that is used to look up users in the directory service.

   In the following example, the property that is assigned to `%v`, which is the short name of the user, must be a unique key. Two LDAP entries with the same object class cannot have the same short name. To look up users based on their user IDs (uid) and to use the inetOrgPerson object class, specify the following syntax:

   ```
   (&(uid=%v)(objectclass=inetOrgPerson)
   ```

   For more information about this syntax, see the “Using specific directory servers as the LDAP server” on page 1275 documentation.
5. Modify the Kerberos user filter, if necessary. The Kerberos user filter name is used for searching the registry for the Kerberos principal name. Specify the LDAP attribute that holds the Kerberos principal name.

   IBM Lotus Domino default krbuser filter:
   (&(krbPrincipalName=%v)(objectcategory=Person))

   IBM SecureWay Directory Server default krbuser filter:
   (&(krbPrincipalName=%v)(objectcategory=ePerson))

   Microsoft Active Directory default krbuser filter:
   (&(userprincipalname=%v)(objectcategory=user))

   Sun Java System Directory Server default krbuser filter:
   (&(krbPrincipalName=%v)(objectcategory=inetOrgPerson))

   Novell eDirectory default krbuser filter:
   (&(krbPrincipalName=%v)(objectcategory=Person))
6. Optional: If your using Federated Repositories, modify the Kerberos attribute name if necessary. The Kerberos attribute name is used for searching the registry for Kerberos principal. Specify the LDAP attribute that holds the Kerberos principal name.

   IBM Lotus Domino default krbuser filter:
   krbPrincipalName

IBM SecureWay Directory Server default krbuser filter:
krbPrincipalName

Microsoft Active Directory default krbuser filter:
userprincipalname

Sun Java System Directory Server default krbuser filter:
krbPrincipalName

Novell eDirectory default krbuser filter:
krbPrincipalName

7. Modify the group filter, if necessary. The group filter is used in searching the registry for groups and is typically used for the security role-to-group assignment. Also, the filter is used to specify the property by which to look up groups in the directory service.

   In the following example, the property that is assigned to `%v`, which is the short name of the group, must be a unique key. Two LDAP entries with the same object class cannot have the same short name. To look up groups based on their common names (CN) and to use either the groupOfNames object class or the groupOfUniqueNames object class, specify the following syntax:

   ```
   (&(cn=%v)(|(objectclass=groupOfNames)(objectclass=groupOfUniqueNames)))
   ```

   For more information about this syntax, see the “Using specific directory servers as the LDAP server” on page 1275 documentation.
8. Modify the user ID map, if necessary. This filter maps the short name of a user to an LDAP entry and specifies the piece of information that represents users when these users are displayed with their short names. For example, to display entries of `object class = inetOrgPerson` by their IDs, specify `inetOrgPerson:uid`. This field takes multiple objectclass:property pairs, delimited by a semicolon (;). To provide a consistent value for methods like the getCallerPrincipal method and the getUserPrincipal method, the short name that is obtained by using this filter is used. For example, the `CN=Bob Smith, ou=austin.ibm.com, o=IBM, c=US` user can log in using any attributes that are defined, for example, email address, social security number, and so on, but when these methods are called, the `bob` user ID is returned no matter how the user logs in.
9. Modify the group ID map filter, if necessary. This filter maps the short name of a group to an LDAP entry and specifies the piece of information that represents groups when groups display. For example, to display groups by their names, specify `*:cn`. The asterisk (*) is a wildcard character that searches on any object class in this case. This field takes multiple objectclass:property pairs, delimited by a semicolon (;).
10. Modify the group member ID map filter, if necessary. This filter identifies user-to-group memberships. For SecureWay, and Domino directory types, this field is used to query all the groups that match the specified object classes to see if the user is contained in the specified attribute. For example, to get all the users that belong to groups with the groupOfNames object class and the users that are contained in the member attributes, specify `groupOfNames:member`. This syntax, which is a property of an object class, stores the list of members that belong to the group that is represented by the object class. This field takes multiple objectclass:property pairs that are delimited by a semicolon (;). For more information about this syntax, see the “Using specific directory servers as the LDAP server” on page 1275.

    For the IBM Tivoli Directory Server, Sun ONE, and Active Directory, this field is used to query all users in a group with the information that is stored in the user object. For example, the memberof:member filter (for Active Directory) is used to get the memberof attribute of the user object to obtain all the groups to which the user belongs. The member attribute is used to get all the users in a group that use the Group object. Using the User object to obtain the group information improves performance.
11. Select the **Perform a nested group search** option if your LDAP server does not support recursive server-side searches.
12. Modify the Certificate map mode, if necessary. You can use the X.590 certificates for user authentication when LDAP is selected as the registry. This field is used to indicate whether to map

the X.509 certificates into an LDAP directory user by **EXACT_DN** or **CERTIFICATE_FILTER**. If **EXACT_DN** is selected, the DN in the certificate must exactly match the user entry in the LDAP server, including case and spaces.

Select the **Ignore case for authorization** option on the Standalone LDAP registry settings to make the authorization case insensitive. To access the Standalone LDAP registry settings panel, complete the following steps:

a. Click **Security > Global security**.

b. Under User account repository, click the **Available realm definitions** drop-down list, select**Standalone LDAP registry**.

13. If you select **CERTIFICATE_FILTER**, specify the LDAP filter for mapping attributes in the client certificate to entries in LDAP. If more than one LDAP entry matches the filter specification at run time, authentication fails because an ambiguous match results. The syntax or structure of this filter is: `LDAP attribute=${Client certificate attribute}` (for example, `uid=${SubjectCN}`).

    The left side of the filter specification is an LDAP attribute that depends on the schema that your LDAP server is configured to use. The right side of the filter specification is one of the public attributes in your client certificate. Note that the right side must begin with a dollar sign ($), open bracket ({), and end with a close bracket (}). Use the following certificate attribute values on the right side of the filter specification. The case of the strings is important.

    - `${UniqueKey}`
    - `${PublicKey}`
    - `${IssuerDN}`
    - `${Issuer<xx>}`

      where *<xx>* is replaced by the characters that represent any valid component of the Issuer Distinguished Name. For example, you might use `${IssuerCN}` for the Issuer Common Name.
    - `${NotAfter}`
    - `${NotBefore}`
    - `${SerialNumber}`
    - `${SigAlgName}`
    - `${SigAlgOID}`
    - `${SigAlgParams}`
    - `${SubjectDN}`
    - `${Subject<xx>}`

      where *<xx>* is replaced by the characters that represent any valid component of the Subject Distinguished Name. For example, you might use `${SubjectCN}` for the Subject Common Name.
    - `${Version}`

    To enable this field, select **CERTIFICATE_FILTER** for the certificate mapping.

14. Click **Apply**.

    When any LDAP user or group filter is modified in the Advanced LDAP Settings panel click **Apply**. Clicking **OK** navigates you to the Standalone LDAP registry panel, which contains the previous LDAP directory type, rather than the custom LDAP directory type. Clicking **OK** or **Apply** in the Standalone LDAP registry panel saves the back-level LDAP directory type and the default filters of that directory. This action overwrites any changes to the filters that you made. To avoid overwriting changes, you can take either of the following actions:

    - Click **Apply** in the Advanced Lightweight Directory Access Protocol (LDAP) user registry settings panel. Click **Security > Global security** and change the User account repository type to `Stand-alone custom registry`.
    - Select **Custom** type from the Standalone LDAP registry panel. Click **Apply** and then change the filters by clicking the Advanced Lightweight Directory Access Protocol (LDAP) user registry settings panel. After you complete your changes, click **Apply** or **OK**.

    The validation of the changes does not take place in this panel. Validation is done when you click **OK** or **Apply** on the Global security panel. If you are in the process of enabling security for the first time, complete the remaining steps and go to the Global security panel. Select **Standalone LDAP registry** as the user account repository. If security is already enabled and any information on this panel

changes, go to the Global security panel and click **OK** or **Apply** to validate your changes. If your changes are not validated, the server might not start.

Results

These steps result in the configuration of the LDAP search filters. These steps are required to modify existing user and group filters for a particular LDAP directory type. The steps are also used to set up certificate filters to map certificates to entries in the LDAP server.

What to do next

1. Validate this setup by clicking **OK** or **Apply** on the Global security panel.
2. Save, stop, and start all the product servers, including the cell, nodes and all of the application servers for any changes in this panel to become effective.
3. After the server starts, go through all the security-related tasks (getting users, getting groups, and so on) to verify that the changes to the filters function.

Using specific directory servers as the LDAP server:

This article provides important information about the directory servers that are supported as Lightweight Directory Access Protocol (LDAP) servers in WebSphere Application Server.

Before you begin

Microsoft Active Directory forests are not supported with the stand-alone LDAP Registry. The Federated Repository Registry, when configured to use an Active Directory LDAP does support the use of forests.

About this task

For a list of supported LDAP servers, refer to the Supported hardware and software website.

It is expected that other LDAP servers follow the LDAP specification. Support is limited to these specific directory servers only. You can use any other directory server by using the custom directory type in the list and by filling in the filters that are required for that directory.

To improve performance for LDAP searches, the default filters for IBM Tivoli Directory Server, Sun ONE, and Active Directory are defined such that when you search for a user, the result contains all the relevant information about the user (user ID, groups, and so on). As a result, the product does not call the LDAP server multiple times. This definition is possible only in these directory types, which support searches where the complete user information is obtained.

If you use the IBM Directory Server, select the **Ignore case for authorization** option. This option is required because when the group information is obtained from the user object attributes, the case is not the same as when you get the group information directly. For the authorization to work in this case, perform a case insensitive check and verify the requirement for the **Ignore case for authorization** option.

- **Using Directory Services as the LDAP server**

  Support for groups that contain other groups or nested groups depends upon the specific versions of WebSphere Application Server and LDAP. For more information, see “Dynamic groups and nested group support for LDAP” on page 1408.
- **Using IBM Tivoli Directory Server as the LDAP server**

  To use IBM Tivoli Directory Server, formerly IBM Directory Server, select **IBM Tivoli Directory Server** as the directory type.

  The difference between these two types is group membership lookup. It is recommended that you choose the IBM Tivoli Directory Server for optimum performance during runtime. In the IBM Tivoli Directory Server, the group membership is an operational attribute. With this attribute, a group

membership lookup is done by enumerating the ibm-allGroups attribute for the entry. All group memberships, including the static groups, dynamic groups, and nested groups, can be returned with the `ibm-allGroups` attribute.

WebSphere Application Server supports dynamic groups, nested groups, and static groups in IBM Tivoli Directory Server using the `ibm-allGroups` attribute. To utilize this attribute in a security authorization application, use a case-insensitive match so that attribute values returned by the ibm-allGroups attribute are all in uppercase.

Important: It is recommended that you do not install IBM Tivoli Directory Server Version 6.0 on the same machine that you install Version 8.0. IBM Tivoli Directory Server Version 6.0 includes WebSphere Application Server, Express Version 5.1.1, which the directory server uses for its administrative console. Install the Web Administration tool Version 6.0 and WebSphere Application Server, ExpressVersion 5.1.1, which are both bundled with IBM Tivoli Directory Server Version 6.0, on a different machine from Version 8.0. You cannot use Version 8.0 as the administrative console for IBM Tivoli Directory Server. If IBM Tivoli Directory Server Version 6.0 and Version 8.0 are installed on the same machine, you might encounter port conflicts.

If you must install IBM Tivoli Directory Server Version 6.0 and Version 8.0 on the same machine, consider the following information:

- During the IBM Tivoli Directory Server installation process, you must select both the **Web Administration tool** and **WebSphere Application Server, Express Version 5.1.1**.
- Install Version 8.0.
- When you install Version 8.0, change the port number for the application server.
- You might need to adjust the WebSphere Application Server environment variables on Version 8.0 for *WAS_HOME* and *WAS_INSTALL_ROOT* (or *APP_SERVER_ROOT* for IBM i). To change the variables using the administrative console, click **Environment > WebSphere Variables**.

- **Using a Lotus Domino Enterprise Server as the LDAP server**

  If you select the Lotus Domino Enterprise Server Version 6.5.4 or Version 7.0 and the attribute short name is not defined in the schema, you can take either of the following actions:
  - Change the schema to add the short name attribute.
  - Change the user ID map filter to replace the short name with any other defined attribute (preferably to UID). For example, change `person:shortname` to `person:uid`.

  The userID map filter is changed to use the uid attribute instead of the shortname attribute as the current version of Lotus Domino does not create the shortname attribute by default. If you want to use the shortname attribute, define the attribute in the schema and change the userID map filter.

  ```
  User ID Map :    person:shortname
  ```

- **Using Sun ONE Directory Server as the LDAP server**

  You can select **Sun ONE Directory Server** for your Sun ONE Directory Server system. In Sun ONE Directory Server, the object class is the default groupOfUniqueName when you create a group. For better performance, WebSphere Application Server uses the User object to locate the user group membership from the nsRole attribute. Create the group from the role. If you want to use the groupOfUniqueName attribute to search groups, specify your own filter setting. Roles unify entries. Roles are designed to be more efficient and easier to use for applications. For example, an application can locate the role of an entry by enumerating all the roles that are possessed by a given entry, rather than selecting a group and browsing through the members list. When using roles, you can create a group using a:
  - Managed role
  - Filtered role
  - Nested role

All of these roles are computable by the nsRole attribute.

- **Using Microsoft Active Directory server as the LDAP server**

  To use Microsoft Active Directory as the LDAP server for authentication with WebSphere Application Server you must take specific steps. By default, Microsoft Active Directory does not permit anonymous LDAP queries. To create LDAP queries or to browse the directory, an LDAP client must bind to the LDAP server using the distinguished name (DN) of an account that has the authority to search and read the values of LDAP attributes, such as user and group information, needed by the Application Server. A group membership search in the Active Directory is done by enumerating the `memberof` attribute for a given user entry, rather than browsing through the member list in each group. If you change the default behavior to browse each group, you can change the **Group Member ID Map** field from `memberof:member` to `group:member`.

The following steps describe how to set up Microsoft Active Directory as your LDAP server.

Procedure

1. Determine the full distinguished name (DN) and password of an account in the administrators group.

   For example, if the Active Directory administrator creates an account in the Users folder of the Active Directory Users and Computers Windows control panel and the DNS domain is `ibm.com`, the resulting DN has the following structure:

```
cn=<adminUsername>, cn=users, dc=ibm,
dc=com
```

2. Determine the short name and password of any account in the Microsoft Active Directory.
3. Use the WebSphere Application Server administrative console to set up the information that is needed to use Microsoft Active Directory.
   a. Click **Security > Global security**.
   b. Under User account repository, select **Standalone LDAP registry** and click **Configure**.
   c. Set up LDAP with Active Directory as the type of LDAP server. Based on the information that is determined in the previous steps, you can specify the following values on the LDAP settings panel:

      Primary administrative user name
      Specify the name of a user with administrative privileges that is defined in the registry. This user name is used to access the administrative console or used by wsadmin.

      Type Specify Active Directory

      Host Specify the domain name service (DNS) name of the machine that is running Microsoft Active Directory.

      Base distinguished name (DN)
      Specify the domain components of the DN of the account that is chosen in the first step. For example: `dc=ibm, dc=com`

      Bind distinguished name (DN)
      Specify the full distinguished name of the account that is chosen in the first step. For example: `cn=adminUsername, cn=users, dc=ibm, dc=com`

      Bind password
      Specify the password of the account that is chosen in the first step.

   d. Click **OK** and **Save** to save the changes to the master configuration.
4. Click **Security > Global security**.
5. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone LDAP registry**, and click **Configure**.
6. Select either the **Automatically generated server identity** or **Server identity that is stored in the repository** option. If you select the **Server identity that is stored in the repository** option, enter the following information:

Server user ID or administrative user on a Version 6.0.x node
Specify the short name of the account that is chosen in the second step.

Server user password
Specify the password of the account that is chosen in the second step.

7. Optional: Set ObjectCategory as the filter in the Group member ID map field to improve LDAP performance.
   a. Under Additional properties, click **Advanced Lightweight Directory Access Protocol (LDAP) user registry settings** .
   b. Add `;objectCategory:group` to the end of the Group member ID map field.
8. Click **OK** and **Save** to save the changes to the master configuration.
9. Stop and restart the administrative server so that the changes take effect.

Adding users to the Lightweight Directory Access Protocol user registry:

You can use the Lightweight Directory Access Protocol (LDAP) user registry with any of the authentication mechanisms supported by WebSphere Application Server. Therefore, it is necessary to add users into the LDAP directory that you want to have authorization to access Application Server resources.

About this task

This information in this article is specific to the iSeries Directory Services product.

A variety of methods are available to add users. However, the easiest way is to create an LDAP Data Interchange Format (LDIF) file. The file contains the set of users to add into the directory. The file is used by the LDAP utilities, such as **idsldapmodify**. You can run these utilities from either the operating system or from a workstation. If you run these LDAP utilities from the operating system, your LDIF file must reside in the integrated file system.

Complete the following steps to add users to the LDAP user registry:

Procedure

1. Create an LDIF file and save it in the integrated file system. Use either the Edit File (EDTF) utility or your workstation text editor to create the file. Save the file in the integrated file system either by mapping a drive or using the file transfer protocol (FTP).

   For WebSphere Application Server and LDAP directory services, create entries in the directory that correspond to the ePerson schema definition.

   A simple ePerson LDIF entry resembles the following example:

```
dn: cn=John Doe, ou=Rochester, o=IBM, c=US
objectclass: person
objectclass: inetOrgPerson
objectclass: top
objectclass: organizationalPerson
objectclass: ePerson
cn: John Doe
sn: Doe
uid: jdoe
userpassword: secretpass
```

   This LDIF entry defines an ePerson for user John Doe. The user identification (uid) for John is set to `jdoe` and his password is set to `secretpass`. This entry resides within the Rochester organizational unit, which is within the IBM organization in the United States. Each of the `ou`, `o`, and `c` containing entries are defined before this ePerson entry is defined. You can define a series of LDIF entries in the same file to define Lightweight Third Party Authentication (LTPA) users for WebSphere Application Server.

   If you do not specify a value for the userpassword attribute, the LDAP server attempts to authenticate LTPA users with the user profile for the local operating system that is identified by the uid attribute value. This action might be desirable if users have user profiles for the operating system and do not want to manage passwords in both the operating system user registry and the LDAP directory.

When you create an ePerson entry, make sure that the `cn` and `uid` attributes each have a unique value. Do not create two entries that have the same value for the `cn` and `uid` attributes.

Important: If you have a large user registry, login performance might be severely impacted if the Group Member ID Map property is left at its default value, which is both groupOfNames:member and groupOfUniqueNames:uniqueMember.

To address this performance problem, specify one of these object classes and not both. You must then exclusively use the selected object class to implement groups in the user registry.

2. Import the LDIF file entries into your directory on the server. Use the LDAP ldapadd utility in Qshell Interpreter (QSH) or from a workstation.

What to do next

For more information on importing LDIF entries, see the Directory Services documentation in the Information Centers for IBM i 6.1 and 7.1.

Locating user group memberships in a Lightweight Directory Access Protocol registry:

You can configure WebSphere Application Server security to use Lightweight Directory Access Protocol (LDAP) servers. The LDAP specifications allow for different mechanisms to define group memberships. Depending on your LDAP server implementation, you can use methods to determine group memberships. WebSphere Application Server can search group memberships directly or indirectly. Also, you can configure the product to search one or more static groups, recursive or nested groups, and dynamic groups for some Lightweight Directory Access Protocol (LDAP) servers.

Procedure

- Evaluate group memberships.
  - **Static group membership:** All LDAP server implementations support static group membership. The group object contains a list of users or groups that are members of the group. To determine the groups in which a user is a member, you must get the list of all groups, and then query each group in turn to see if the user is a member of that group. This operation results in (0)zero groups and does not scale well.

    Several LDAP servers enable user objects in the LDAP server to contain information about the groups to which they belong. Examples of LDAP servers that support direct group searches include Microsoft Active Directory Server and the owner of eDirectory.
  - **Dynamic group memberships**

    Some user group memberships are computable from attributes within the user object. IBM Directory Server and Sun ONE Directory Server are two examples of LDAP servers that support dynamic group membership. In some LDAP servers, you can use an attribute to include a user's dynamic group memberships, nesting group memberships, and static group memberships to determine all the group memberships from a single attribute.

    For example, in IBM Directory Server, you can return all group memberships including the static groups, dynamic groups, and nested groups using the ibm-allGroups attribute. In the Sun ONE directory server you can use the nsRole attribute to calculate, all roles, including managed roles, filtered roles, and nested roles. If an LDAP server has such an attribute in a User object to include dynamic groups, nested groups, and static groups, you can configure WebSphere Application Server security to use this attribute to determine these groups.

    Depending on the implementation, and LDAP server can caluculate dynamic group membership. In this case, this dynamic computation is performed entirely by the LDAP server under a single LDAP query and is invisible to WebSphere Application Server. While this approach is not as efficient as direct groups, server-side dynamic queries are more efficient than determining group membership using static group queries.

    Dynamic group membership, when it is supported by the LDAP server, is frequently reflected back to the LDAP client, which is the WebSphere Application Server. In this configuration, WebSphere

Application Server is required to compose the appropriate dynamic query against LDAP for each group. This operation results in 0(zero) groups and does not scale well.

Tips:

– Use the efficient direct group membership where possible.

– Use the relatively efficient dynamic group membership where the LDAP computes membership within a single query.

– Use static group membership, or client side dynamic group membership as a secondary alternative. This option only performs well on systems where the number of groups within the LDAP server is "small".

The configurations for the supported, listed LDAP servers are pre-defined to use the optimal group membership mechanisms. They assume that the standard object types and schemas for that LDAP vendor are in use on the LDAP server.

• Evaluate the LDAP registry configuration.

– **Standalone LDAP registry**

If you are configuring an LDAP server outside of the list of pre-configured types, you must configure the appropriate value in the Group Member ID map field on the Advanced LDAP Settings panel using the following methods.

- If you use static group membership, you must specifiy objectclass:attribute pairs. If the objectclass for the group object is, **groupOfUniquePersons**, and within that objectclass, members are listed as **persons**, then the static group membership **Group Member ID map** is **groupOfUniquePersons:persons**.
- If direct group membership is used, attributes exist in the objectclass, you must use attribute:attribute pairs. For example, if the objectclass for the user is **user**and the objectclasst contains attributes called **ingroup**, which contains each group membership, then the direct group membership **Group Member ID map** is **ingroup:member**.

– **LDAP Registry within a Federated Repositories Registry**

If you are configuring an LDAP server outside of the list of pre-configured types, you must configure the appropriate value in the **Group attribute definition** properties for the repository.

- If static group membership is used, you must specify the name of the object class, and the attribute that is used for indicating membership in **Group attribute definition -> Member attributes**. If the group objectclass for the user is, **groupOfUniquePersons**, and within that objectclass, members are listed as **persons**, then the static group **Member attributes** property is set follows:
  1. In the administrative console, click **Security > Global security**.
  2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
  3. Under Related items, click **Manage repositories**.
  4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.
  5. Under Additional properties, click **Group attribute definition**.
  6. Under Additional properties, click **Member attributes**.
  7. Click **New** to specify a new member attribute.

  Set the **Name of member attribute** field to `persons`

  Set the **Object class field** to `groupOfUniquePersons`

  When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.
- If direct group membership is used, then attributes exist in the objectclass for the user and you must use the attribute. For example, if the objectclass for the user is **user**, and it contains

attributes called **ingroup** that contain each group membership, then you specify the direct group membership in the **Group attribute definition** property for the repository. Perform the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.
5. Under Additional properties, click **Group attribute definition**.

Set the **Name of group membership attribute** field to `ingroup`.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

- Use the sample entries of objectClass:attribute pairs in the Group member ID map field.
  - dominoGroup:member for Lotus Domino
  - groupOfNames:member for eDirectory
- Evaluate Nested Groups.
  - **Nested Groups**

    Depending on the LDAP server implementation, groups can contain only users, or can contain other groups, which is known as a nested group. You configure WebSphere Application Server to properly discover all groups by following this nesting as it applies to either a stand-alone LDAP registry or a LDAP Registry within a Federated Repositories Registry.

    - **Standalone LDAP Registry** The stand-alone LDAP registry default setting performs only a single group membership query. If the groups returned are in fact subgroups of other groups, you must enable the **Perform a nested group search** property on the Advanced LDAP Settings panel of the LDAP registry as follows:
      1. Click **Security > Global security**.
      2. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone LDAP registry**, and click **Configure**.
      3. Under Additional properties, click **Advanced Lightweight Directory Access Protocol (LDAP) user registry settings**.

      Put a check mark in the **Perform a nested group search** check box.
    - **LDAP Registry within a Federated Repositories Registry** Within Federated repositories, you must configure what you expect the results of the query to return. Based on this information, the Federated repository makes the appropriate calls to establish all group membership. If the LDAP server returns all nested group information within a single direct group query, then you set the **Scope of group membership** attribute property in the group attribute definition to **Nested.** as follows:
      1. In the administrative console, click **Security > Global security**.
      2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
      3. Under Related items, click **Manage repositories**.
      4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.
      5. Under Additional properties, click **Group attribute definition**.

      Set the **Scope of group membership** attribute property in the group attribute definition to **Nested.**

- If the LDAP server returns only the direct membership, then the registry must then make subsequent queries to establish complete membership. To force the Federated Repository to issue subsequent queries, set the **Scope of group membership** attribute property in the **Group attribute definition** for the repository to **Direct**.

Results

While using the direct method, dynamic groups, recursive groups, and static groups can be returned as multiple values of a single attribute. For example, in IBM Directory Server all group memberships, including the static groups, dynamic groups, and nested groups, can be returned using the ibm-allGroups attribute. In Sun ONE, all roles, including managed roles, filtered roles, and nested roles, are calculated using the nsRole attribute. If an LDAP server can use the nsRole attribute, dynamic groups, nested groups, and static groups are all supported by WebSphere Application Server.

Some LDAP servers do not have recursive computing functionality. For example, although Microsoft Active Directory server has direct group search capability using the memberOf attribute, this attribute lists the groups beneath, which the group is directly nested only and does not contain the recursive list of nested predecessors. The Lotus Domino LDAP server only supports the indirect method to locate the group memberships for a user. You cannot obtain recursive group memberships from a Domino server directly. For LDAP servers without recursive searching capability, WebSphere Application Server security provides a recursive function that is enabled by clicking **Perform a Nested Group Search** in the Advanced LDAP user registry settings. Select this option only if your LDAP server does not provide recursive searches and you want a recursive search.

Configuring dynamic and nested group support for the SunONE or iPlanet Directory Server:

Configure dynamic and nested groups to simplify WebSphere Application Server security management and increase its effectiveness and flexibility.

Before you begin

To use dynamic and nested groups with WebSphere Application Server security, you must be running WebSphere Application Server Version 6.1 or later. Refer to “Dynamic groups and nested group support for LDAP” on page 1408 for more information on this topic.

Procedure

1. In the administrative console for WebSphere Application Server, click **Security > Global security**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone LDAP registry**, and click **Configure**.
3. Select `SunONE` for the type of LDAP server.
4. Select the **Ignore case for authorization** option.
5. Under Additional Properties, click **Advanced Lightweight Directory Access Protocol (LDAP) user registry settings**.
6. Change the Group filter setting to `&(cn=%v)(objectclass=ldapsubentry))`.
7. Change the Group member ID map setting to `nsRole:nsRole`.
8. Click **Apply** or **OK** to validate the changes.

Configuring dynamic and nested group support for the IBM Tivoli Directory Server:

Configure dynamic and nested groups to simplify WebSphere Application Server security management and increase its effectiveness and flexibility.

Before you begin

When creating groups, ensure that nested and dynamic group memberships work correctly.

Procedure

1. In the administrative console for WebSphere Application Server, click **Security > Global security**.
2. Under User account repository, click **Standalone LDAP registry**, and click **Configure**.
3. Select `IBM Tivoli Directory Server` for the type of LDAP server.
4. Under Additional properties, click **Advanced Lightweight Directory Access Protocol (LDAP) user registry settings**.
5. Change the Group filter value to `(&(cn=%v)(|(objectclass=groupOfNames)(objectclass=groupOfUniqueNames)(objectclass=groupOfURLs)))`.
6. Change the Group member ID map value to `ibm-allGroups:member;ibm-allGroups:uniqueMember`.
7. Click **Apply** or **OK** to validate the changes.
8. Verify that Auxiliary object class field on the Add an LDAP entry panel for your IBM Tivoli Directory server has the appropriate value. When you create a nested group, the Auxiliary object class value is `ibm-nestedGroup`. When you create a dynamic group, the Auxiliary object class value is `ibm-dynamicGroup`.

Configuring multiple LDAP servers for user registry failover:

WebSphere Application Server security can be configured to attempt failovers between multiple Lightweight Directory Access Protocol (LDAP) hosts.

Before you begin

The multiple LDAP servers involved in the failover can be replicas that are replicated from the same master LDAP server, or they can be any LDAP host with the same schema. That is any LDAP host that contains data that is imported from the same LDAP data interchange format (LDIF) file.

Note: When WebSphere Application Server attempts failovers between multiple Lightweight Directory Access Protocol (LDAP) hosts, system properties are exchanged. WebSphere Application Server Version 6.1.0 manages the SSL configuration and these system properties. You cannot expect to set system properties yourself and expect the failover to succeed.

Procedure

1. Start the deployment manager process.
   a. Start the Command Prompt application.
   b. Change directories to *profile_root*`/bin`.
   c. Enter startManager.
2. Start the wsadmin Command Prompt application.
   a. Start the Command Prompt application.
   b. Change directories to *profile_root*`/bin`.
   c. Enter the following command:
      `wsadmin –user` *username* `–password` *password*
3. Configure a second LDAP server for failover.
   a. Enter the following command to set the failover LDAP server hostname:
      `set ldapServer [`*ldap server hostname*`]`
   b. Enter the following command to set the LDAP server port number:
      `set ldapPort [`*ldap server port*`]`
   c. Enter the following command to set the WebSphere LDAP failover variable:

```
set Attrs2 [list [list hosts [list [list [list host $ldapServer] [list port $ldapPort]]]]]
```

d. Modify the LDAP configuration to add the failover LDAP server by entering the following command:

```
set result [$AdminConfig list LDAPUserRegistry]
```

e. Find the LDAP server configID by entering the following command:

```
$AdminConfig modify $result $Attrs2
```

f. Enter the following command to save the configuration change:

```
$AdminConfig save
```

g. Enter exit to quit the Command Prompt application. The following is an example of the Command Prompt application output:

```
wsadmin>set ldapServer [list xxxx.xxxx.xxx.com]
xxxx.xxxx.xxx.com
wsadmin>set ldapPort [list NNN]
NNN
wsadmin>set Attrs2 [list [list hosts [list [list [list host $ldapServer] [list port $ldapPort]]]]]
{hosts {{{host xxxx.xxxx.xxx.com} {port NNN}}}}
wsadmin> set result [$AdminConfig list LDAPUserRegistry]
(cells/Father2Cell01|security.xml#LDAPUserRegistry_1)
wsadmin>$AdminConfig modify $result $Attrs2

wsadmin>$AdminConfig save
```

4. Review the configuration change by opening the `security.xml` file with a text editor and review the new entry.
5. Stop the deployment manager.
   a. Start the Command Prompt application.
   b. Change directories to *profile_root*/`bin`.
   c. To stop the deployment manager, enter the following command:

```
stopManager –user username –password password
```

Testing an LDAP server for user registry failover:

After configuring a Lightweight Directory Access Protocol (LDAP) host for failover you should test the failover server by stopping the main LDAP server.

Before you begin

This task assumes the following setup:

- Deployment Manager is installed on the primary LDAP server running Application Server version 6.0.2 or higher.
- All other LDAP hosts are Active Directory machines with similar user registry designs.
- Atleast one of the other LDAP hosts has been configured for failover.

Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

Procedure

1. Stop the Active Directory Server on the failover server.
2. Start the deployment manager process.
   a. Start the Command Prompt application.

b. Change directories to *profile_root*/bin.
c. Enter startManager.

3. Review the SystemOut.log file to see if the LDAP failover happened. The sample text is an example of a SystemOut.log file that records a successful failover:

```
[7/11/05 15:38:31:324 EDT] 0000000a LdapRegistryI A   SECJ0418I:
Cannot connect to the LDAP server ldap://xxxx.xxxxx.xxxx.com:NNN. {primary LDAP server}
[7/11/05 15:38:32:486 EDT] 0000000a UserRegistryI A   SECJ0136I:
Custom Registry:com.ibm.ws.security.registry.ldap.LdapRegistryImpl has been initialized
[7/11/05 15:38:53:787 EDT] 0000000a LdapRegistryI A   SECJ0419I:
The user registry is currently connected to the LDAP server ldap://xxxx.xxxxx.xxxx.com:NNN. {failover LDAP server}
...
[7/11/05 15:39:35:667 EDT] 0000000a WsServerImpl  A   WSVR0001I: Server dmgr open for e-business
```

4. Log into the console to see working and non-working cases.
   a. Start a browser.
   b. Browse to http://localhost:9060/admin.
   c. Type in your user ID and password and click **OK**.
   d. Log out of the Administrative Console.
   e. Type in DummyAdmin as the user ID and dummy1admin as your password and click **OK**. This should fail proving WebSphere Application Server is connected to the other LDAP server. Please make sure that on a production system the user registries are identical so this problem does not happen when switching between LDAP servers.
5. Stop the deployment manager.
   a. Start the Command Prompt application.
   b. Change directories to *profile_root*/bin.
   c. To stop the deployment manager, enter the following command:

```
stopManager –user username –password password
```

Deleting LDAP endpoints using wsadmin:

You can delete Lightweight Directory Access Protocol (LDAP) endpoints for a user registry by using the WebSphere Application Server administrative tool (wsadmin).

Procedure

1. Start the wsadmin scripting tool.
2. Set the LDAP variable and display a list of LDAP endpoint objects. Enter the following commands:

   Using Jacl:

```
set ldap [$AdminConfig list LDAPUserRegistry]

$AdminConfig list EndPoint $ldap
```

   Using Jython:

```
ldap=AdminConfig.list["LDAPUserRegistry"]

print AdminConfig.show(ldap)
```

   For the Jython language, you can obtain the endpoint from the host variable after running the previous command.
3. Display a list of LDAP endpoint objects. Enter the following command for each object:

   Using Jacl:

```
$AdminConfig showall End_Point_Object
```

   Using Jython:

```
AdminConfig.showall("End_Point_Object")
```

4. Delete an LDAP endpoint object. Enter the following command:

Using Jacl:

```
$AdminConfig remove End_Point_Object
```

Using Jython:

```
AdminConfig.remove ("End_Point_Object")
```

5. Save your configuration changes: Enter the following command:

   Using Jacl:

   ```
   $AdminConfig save
   ```

   Using Jython:

   ```
   AdminConfig.save()
   ```

Updating LDAP binding information:

Use this information to dynamically update security LDAP binding information by switching to a different binding identity.

About this task

You can dynamically update Lightweight Directory Access Protocol (LDAP) binding information without first stopping and restarting WebSphere Application Server by using the **wsadmin** tool.

The resetLdapBindInfo method in SecurityAdmin MBean is used to dynamically update LDAP binding information at WebSphere Application Server security runtime, and it takes the bind distinguished name (DN) and bind password parameters as input. The resetLdapBindInfo method validates the bind information against the LDAP server. If validation passes, new binding information is stored in `security.xml`, and a copy of the information is placed in WebSphere Application Server security runtime.

If the new binding information is `null`, `null`, the resetLdapBindInfo method first extracts LDAP binding information, including bind DN, bind password, and target binding host from WebSphere Application Server security configuration in `security.xml`. It then pushes the binding information to WebSphere Application Server security runtime.

There are two ways to dynamically update WebSphere Application Server security LDAP binding information using the SecurityAdmin MBean through wsadmin:

- "Switching to a different binding identity"
- "Switching to a failover LDAP host" on page 1287

Switching to a different binding identity:
About this task

To dynamically update security LDAP binding information by switching to a different binding identity:

Procedure

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone LDAP registry**, and click **Configure**.
3. Create a new bind DN. It must have the same access authority as the current bind DN.
4. Run the SecurityAdmin MBean across all of the application server processes to validate the new binding information, to save it to `security.xml`, and to push the new binding information to the runtime.

Example

The following is a sample Jacl file for step 4:

```
proc LDAPReBind {args} {
  global AdminConfig AdminControl ldapBindDn ldapBindPassword
  set ldapBindDn [lindex $args 0]
  set ldapBindPassword [lindex $args 1]
       set secMBeans [$AdminControl queryNames type=SecurityAdmin,*]
       set plist  [list $ldapBindDn $ldapBindPassword]
       foreach secMBean $secMBeans {
            set result [$AdminControl invoke $secMBean resetLdapBindInfo $plist]
       }
 }
```

Switching to a failover LDAP host:
About this task

To dynamically update security LDAP binding information by switching to a failover LDAP host:

Procedure

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Standalone LDAP registry** and click **Configure**.
3. Change the password for bind DN on one LDAP server (it can be the primary or the backup).
4. Update the new bind DN password to WebSphere Application security runtime by calling resetLdapBindInfo with the bind DN and by using its new password as a parameter.
5. Use the new bind DN password for all of the other LDAP servers. The binding information is now consistent across WebSphere Application Server and the LDAP servers.

   If you call resetLdapBindInfo with `null`, `null` as input parameters, WebSphere Application Server security runtime completes the following steps:

   a. Reads the bind DN, bind password, and target LDAP hosts from `security.xml`.

   b. Refreshes the cached connection to the LDAP server.

   If you configure security to use multiple LDAP servers, this MBean call forces WebSphere Application Server security to reconnect to the first available LDAP host in the list. For example, if three LDAP servers are configured in the order of L1, L2, and L3, the reconnection process always starts with the L1 server.

   When LDAP failover is configured by associating a single hostname to multiple IP addresses, entering an invalid password can cause multiple LDAP bind retries. With the default settings, the number of LDAP bind retries is equal to one more than the number of associated IP addresses. This means a single invalid login attempt can cause the LDAP account to be locked. If the com.ibm.websphere.security.ldap.retryBind custom property is set to false, LDAP bind calls are not retried.

   gotcha: Federated repository does not support failover by associating a single hostname to multiple IP addresses. This feature is only available in stand-alone LDAP.

Configuring stand-alone custom registries

Use the following information to configure stand-alone custom registries through the administrative console.

Before you begin

Before you begin this task, implement and build the UserRegistry interface. For more information on developing stand-alone custom registries refer to Developing stand-alone custom registries. The following steps are required to configure stand-alone custom registries through the administrative console.

Procedure

1. Click **Security > Global security**.
2. Under User account repositories, select **Stand-alone custom registry** and click **Configure**.
3. Enter a valid user name in the Primary administrative user name field. This ID is the security server ID, which is only used for WebSphere Application Server security and is not associated with the

system process that runs the server. The server calls the local operating system registry to authenticate and obtain privilege information about users by calling the native APIs in that particular registry.

4. Enter the dot-separated class name that implements the com.ibm.websphere.security.UserRegistry interface in the Custom registry class name field. For the sample, this file name is `com.ibm.websphere.security.FileRegistrySample`.

   Attention: The sample provided is intended to familiarize you with this feature. Do not use this sample in an actual production environment.

5. Add your custom registry class name to the class path.
6. Optional: Select the **Ignore case for authorization** option for the authorization to perform a case insensitive check. Enabling this option is necessary only when your user registry is case insensitive and does not provide a consistent case when queried for users and groups.
7. Click **Apply** if you have any other additional properties to enter for the registry initialization.
8. Optional: Enter additional properties to initialize your implementation.
   a. Click **Custom properties > New**.
   b. Enter the property name and value.

      For the sample, enter the following two properties. It is assumed that the `users.props` file and the `groups.props` file are in the *customer_sample* directory under the product installation directory. You can place these properties in any directory that you choose and reference their locations through custom properties. However, make sure that the directory has the appropriate access permissions.

Table 82. Additional properties.

This table lists additional custom properties when configuring stand-alone custom registries.

Property name	Property value
usersFile	${*USER_INSTALL_ROOT*}/*customer_sample* /users.props
groupsFile	${*USER_INSTALL_ROOT*}/*customer_sample* /groups.props

      Attention: The QEJBSVR user profile must have Execute (*X) authority for the directory that contains `user.props` and `groups.props` files. Additionally, QEJBSVR must have Read and Execute (*RX) authority for the `user.props` and `groups.props` files.

      Samples of these two properties are available in “users.props file” on page 1310 and “groups.props file” on page 1310.

      The **Description**, **Required**, and **Validation Expression** fields are not used and can remain blank.

      WebSphere Application Server version 4-based custom user registry is migrated to the custom user registry based on the com.ibm.websphere.security.UserRegistry interface.

   c. Click **Apply**.
   d. Repeat this step to add other additional properties.
9. Click **Security > Global security**.
10. Under User account repository, click the **Available realm definitions** drop-down list, select **Stand-alone custom registry**, and click **Configure**.
11. Select either the **Automatically generated server identity** or **Server identity that is stored in the repository** option. If you select the **Server identity that is stored in the repository** option, enter the following information:

    Server user ID or administrative user on a Version 6.0.x node
    Specify the short name of the account that is chosen in the second step.

    Server user password
    Specify the password of the account that is chosen in the second step.

12. Click **OK** and complete the required steps to turn on security.

Results

This set of steps is required to set up the stand-alone custom registry and to enable security in WebSphere Application Server.

Note: The security component of WebSphere Application Server expands a selected list of variables when enabling security. See the information about variable settings for more details.

What to do next

1. Complete the remaining steps, if you are enabling security.
2. Validate the user and password. Save and synchronize in the cell environment.
3. After security is turned on, save, stop, and start all the product servers, including cell, nodes, and all of the application servers, for any changes to take effect. If the server comes up without any problems, the setup is correct.

Stand-alone custom registries:

A *stand-alone custom registry* is a customer-implemented registry that implements the UserRegistry Java interface, as provided by the product. A custom-implemented registry can support virtually any type of an account repository from a relational database, flat file, and so on. The custom user registry provides considerable flexibility in adapting product security to various environments where some form of a registry or repository other than federated repositories, stand-alone Lightweight Directory Access Protocol (LDAP) registry or local operating system registry already exists in the operational environment.

WebSphere Application Server security provides an implementation that uses various local operating system-based registries and various stand-alone Lightweight Directory Access Protocol (LDAP)-based registries. However, situations can exist where your user and group data resides in other repositories or custom user registries, such as a database, and moving this information to either a local operating system registry or a stand-alone LDAP registry implementation might not be feasible. For these situations, WebSphere Application Server security provides a service provider interface (SPI) that you can implement to interact with your current registry. The custom registry feature supports any user registry that is not implemented by WebSphere Application Server.

The SPI is the UserRegistry interface. The *UserRegistry interface* is a collection of methods that are required for authorization purposes. These methods authenticate individual users using either a password or certificates and collect information about the user, which are called privilege attributes. This interface also includes methods that obtain user and group information so that they can be given access to resources. When implementing the methods in the interface, you must decide how to map the information that is manipulated by the UserRegistry interface to the information in your registry.

This interface has a set of methods to implement for the product security to interact with your registries for all security-related tasks. The local operating system and LDAP registry implementations that are provided also implement this interface. Custom user registries are sometimes called the *pluggable user registries* or *custom registries* for short. Your custom user registry implementation is expected to be thread-safe.

Building a custom registry is a software implementation effort. The implementation does not depend on other WebSphere Application Server resources, for example, data sources, for its operation.

Make sure that your implementation of the custom registry does not depend on any WebSphere Application Server components such as data sources, enterprise beans, and so on. Do not have this dependency because security is initialized and enabled prior to most of the other WebSphere Application Server components during startup. If your previous implementation used these components, make a change that eliminates the dependency.

The methods in the UserRegistry interface operate on the following information for users:

User security name
The user name is similar to the user profile in the operating system registry.

This name is used to log in when prompted by a secured application. By default, the Enterprise JavaBeans (EJB) getCallerPrincipal method and the getRemoteUser and getUserPrincipal servlet methods return this name. The user security name is also referred to as *userSecurityName*, *userName*, or *user name*.

WAS_UseDisplayName
This is a custom property of User Registries. This property defines the returning value of the getCallerPrincipal(), getUserPrincipal(), and RemoteUser() methods. The following shows acceptable values for WAS_UseDisplayName:
- `false` This is default. Security Name is returned.
- `true` The display name is returned. This setting requires that the custom property **com.ibm.websphere.security.useLoggedSecurityName** be set to true.

Unique user ID
This ID represents a unique identifier for the user, which is required by the UserRegistry interface. The unique ID is similar to the system ID (SID) in Windows systems, the Unique ID (UID) in Linux and UNIX systems, and the distinguished name (DN) in Lightweight Directory Authentication Protocol (LDAP). This ID is also referred to as *uniqueUserId*. The unique ID is used to make the authorization decisions for protected resources.

Display user name
The display name is the text description for the user profile.

Group security name
This name, which represents the security group, is also referred to as *groupSecurityName*, *groupName*, and *group name*.

Unique group ID
The unique ID is the identifier for a group. This name is also referred to as *uniqueGroupId* ID.

Display group name
The display name is an optional string that describes a group.

The topic on UserRegistry interface describes each of the methods in the interface that need implementing. An explanation of each of the methods and their usage in the sample and any changes from the Version 4 interface are provided. The Related references section provides links to all other custom user registries documentation, including a file-based registry sample. The Sample provided is very simple and is intended to familiarize you with this feature. Do not use this sample in an actual production environment.

Stand-alone custom registry settings:

Use this page to configure the stand-alone custom registry.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Stand-alone custom registry**, and click **Configure**.

After the properties are set in this panel, click **Apply**. Under Additional Properties, click **Custom properties** to include additional properties that the custom user registry requires.

Note: Custom properties might include information such as specifying lists of users or groups.

When security is enabled and any of these custom user registry settings change, go to the Global security panel and click **Apply** to validate the changes.

WebSphere Application Server Version 7.0 distinguishes between the user identities for administrators who manage the environment and server identities for authenticating server to server communications. In most cases, server identities are automatically generated and are not stored in a repository.

Primary administrative user name:

Specifies the name of a user with administrative privileges that is defined in your custom user registry.

The user name is used to log onto the administrative console when administrative security is enabled. Version 6.1 requires an administrative user that is distinct from the server user identity so that administrative actions can be audited.

Attention: In WebSphere Application Server, Version 6.0.x, a single user identity is required for both administrative access and internal process communication. When migrating to Version 6.1, this identity is used as the server user identity. You need to specify another user for the administrative user identity.

Automatically generated server identity:

Enables the application server to generate the server identity, which is recommended for environments that contain only Version 6.1 or later nodes. Automatically generated server identities are not stored in a user repository.

Default: Enabled

Server identity that is stored in the repository:

Specifies a user identity in the repository that is used for internal process communication. Cells that contain Version 6.1 or later nodes require a server user identity that is defined in the active user repository.

Default: Enabled

Custom registry class name:

Specifies a dot-separated class name that implements the com.ibm.websphere.security.UserRegistry interface.

Put the custom registry class name in the class path. A suggested location is the following directory.

- *profile_root*/classes

Data type: String
Default: com.ibm.websphere.security.FileRegistrySample

Ignore case for authorization:

Indicates that a case-insensitive authorization check is performed when you use the default authorization.

Default: Disabled
Range: Enabled or Disabled

Stand-alone custom registry wizard settings:

A wizard page exists in the administrative console to aid in viewing the basic settings necessary to connect the application server to an existing stand-alone custom registry. After you have viewed the basic settings, you can also modify the existing stand-alone customer registry configuration using the administrative console.

To view this security wizard page, complete the following steps:

1. Click **Security > Global security > Security configuration wizard**.
2. Select your protection settings and click **Next**.
3. Select the **Stand-alone custom registry** option and click **Next**.

You can modify your stand-alone custom registry configuration by completing the following steps:

1. Click **Security > Global security**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Stand-alone custom registry**, and click **Configure**.
3. Enter additional properties to initialize your implementation
   - Click **Custom properties > New**.
   - Enter the property name and value. For the sample, enter the following two properties. It is assumed that the `users.props` file and the `groups.props` file are in the *customer_sample* directory under the product installation directory. You can place these properties in any directory that you choose and reference their locations through Custom properties. However, make sure that the directory has the appropriate access permissions.

Table 83. Custom properties.

This table lists additional custom properties when changing stand-alone custom registry wizard settings.

Property name	Property value
usersFile	${*USER_INSTALL_ROOT*}/*customer_sample* /users.props
groupsFile	${*USER_INSTALL_ROOT*}/*customer_sample* /groups.props

     Samples of these two properties are available in reference topics for the `users.props` file and the `groups.props` file. See the related links below for more information.

     The Description, Required, and Validation Expression fields are not used and can remain blank.

     WebSphere Application Server Version 4 based custom user registry is migrated to the custom user registry based on the com.ibm.websphere.security.UserRegistry interface.
   - Click **Apply**.

Primary administrative user name:

Specifies the name of a user with administrative privileges that is defined in your custom user registry.

The user name is used to log onto the administrative console when administrative security is enabled. Version 6.1 requires an administrative user that is distinct from the server user identity so that administrative actions can be audited.

Attention: In WebSphere Application Server, Version 6.0.x, a single user identity is required for both administrative access and internal process communication. When migrating to Version 6.1, this identity is used as the server user identity. You need to specify another user for the administrative user identity.

Custom registry class name:

Specifies a dot-separated class name that implements the com.ibm.websphere.security.UserRegistry interface.

Put the custom registry class name in the class path. A suggested location is the following directory.

- *profile_root*/classes

Data type: String
Default: com.ibm.websphere.security.FileRegistrySample

Ignore case for authorization:

Indicates that a case-insensitive authorization check is performed when you use the default authorization.

Default: Disabled
Range: Enabled or Disabled

FileRegistrySample.java file:

This provides an example of the FileRegistrySample.java file.

The user and group information required by this sample is contained in the "users.props file" on page 1310 and "groups.props file" on page 1310 files.

Attention: The samples that are provided are intended to familiarize you with this feature. Do not use these samples in an actual production environment.

* Returns the display name for the user specified by
*  userSecurityName.
*
* This method may be called only when the user information
* is displayed (information purposes only, for example, in
* the administrative console) and hence not used in the actual
* authentication or authorization purposes. If there are no
* display names in the registry return null or empty string.
*
* In WebSphere Application Server 4.x custom registry, if you
* had a display name for the user and if it was different from the
* security name, the display name was returned for the EJB
* methods getCallerPrincipal() and the servlet methods
* getUserPrincipal() and  getRemoteUser().
* In WebSphere Application Server Version 5.x and later, for the
* same methods, the security name will be returned by default.
* This is the recommended way as the display name is not unique
* and might create security holes. However, for backward
* compatibility if you need the display name to be returned
* set the property WAS_UseDisplayName to true.
*
*See the Information Center documentation for more information.
*
* @param     userSecurityName the name of the user.
* @return    the display name for the user. The display
*            name is a registry-specific string that
*            represents a descriptive, not necessarily
*            unique, name for a user. If a display name
*            does not exist return null or empty string.

/**
 * Gets a list of users in a group.
 *
 * The maximum number of users returned is defined by the
 * limit argument.
 *
 * This method is being used by the WebSphere Application Server
 * Enterprise process choreographer (Enterprise) when
 * staff assignments are modeled using groups.
 *
 * In rare situations, if you are working with a registry where
 * getting all the users from any of your groups is not practical
 * (for example if there are a large number of users) you can create
 * the NotImplementedException for that particular group. Make sure
 * that if the process choreographer is installed (or if installed later)
 * the staff assignments are not modeled using these particular groups.
 * If there is no concern about returning the users from groups
 * in the registry it is recommended that this method be implemented
 * without creating the NotImplemented exception.
 * @param         groupSecurityName the name of the group
 * @param         Limits the maximum number of users that should be
 *                returned. This is very useful in situations where there
 *                are lots of users in the registry and getting all of
 *                them at once is not practical. A value of 0 implies
 *                get all the users and hence must be used with care.
 * @return        A Result object that contains the list of users
 *                requested and a flag to indicate if more users exist.
 * @deprecated    This method will be deprecated in future.
 * @exception     NotImplementedException create this exception in rare
```

```
 *                situations if it is not practical to get this information
 *                for any of the group or groups from the registry.
 * @exception     EntryNotFoundException if the group does not exist in
 *                the registry
 * @exception     CustomRegistryException if there is any registry-specific
 *                problem

                if(c == ']')
                    break;
                char c1 = c;
                if(j + 2 < i && s.charAt(j + 1) == '-')
                    c1 = s.charAt(j += 2);
                char ac1[] = {
                    c, c1
                };
                vector1.addElement(ac1);
            }

            char ac[][] = new char[vector1.size()][];
            vector1.copyInto(ac);
            obj = ac;
            break;

        case 92: /* '\\' */
            if(j + 1 < i)
                c = s.charAt(++j);
            break;

        }
        if(obj != null)
        {
            if(stringbuffer != null)
            {
                vector.addElement(stringbuffer.toString());
                stringbuffer = null;
```

```
                }
                vector.addElement(obj);
                obj = null;
            }
            else
            {
                if(stringbuffer == null)
                    stringbuffer = new StringBuffer();
                stringbuffer.append(c);
            }
        }

        if(stringbuffer != null)
            vector.addElement(stringbuffer.toString());
        expr = new Object[vector.size()];
        vector.copyInto(expr);
    }

    static final char NOT[] = new char[2];
    static final Integer ANY = new Integer(0);
    static final Integer STAR = new Integer(1);
    Object expr[];

}

Developing the UserRegistry interface for using custom registries:

Implementing this interface enables WebSphere Application Server security to use custom registries. This capability extends the `java.rmi` file. With a remote registry, you can complete this process remotely.

About this task

Provide implementations of the following methods.

Procedure

- Initialize the UserRegistry method, with initialize(java.util.Properties).

```
public void initialize(java.util.Properties props)
       throws CustomRegistryException,
              RemoteException;
```

  This method is called to initialize the UserRegistry method. All the properties that are defined in the Custom User Registry panel propagate to this method.

  For the `FileRegistrySample.java` sample file, the initialize method retrieves the names of the registry files that contain the user and group information.

  This method is called during server bringup to initialize the registry. This method is also called when validation is performed by the administrative console, when security is on. This method remains the same as in Version 4.x.

- Authenticate users with checkPassword(String,String).

```
public String checkPassword(String userSecurityName, String password)
      throws PasswordCheckFailedException
             CustomRegistryException,
             RemoteException;
```

  The checkPassword method is called to authenticate users when they log in using a name or user ID and a password. This method returns a string which, in most cases, is the user security name. A credential is created for the user for authorization purposes. This user name is also returned for the getCallerPrincipal enterprise bean call and the servlet calls the getUserPrincipal and getRemoteUser methods. See the getUserDisplayName method for more information if you have display names in your registry. In some situations, if you return a user other than the one who is logged in, you must verify that the user is valid in the registry.

  For the `FileRegistrySample.java` sample file, the mapCertificate method gets the distinguished name (DN) from the certificate chain and makes sure it is a valid user in the registry before returning the user. For the sample, the checkPassword method checks the name and password combination in the user registry and, if they match, the method returns the user being authenticated.

  This method is called for various scenarios, for example, by the administrative console to validate the user information after the user registry is initialized. This method is also called when you access protected resources in the product for authenticating the user and before proceeding with the authorization. This method is the same as in Version 4.x.

- Obtain user names from X.509 certificates with mapCertificate(X509Certificate[]).

```
public String mapCertificate(X509Certificate[] cert)
          throws CertificateMapNotSupportedException,
                 CertificateMapFailedException,
                 CustomRegistryException,
                 RemoteException;
```

  The mapCertificate method is called to obtain a user name from an X.509 certificate chain that is supplied by the browser. The complete certificate chain is passed to this method and the implementation can validate the chain if needed and get the user information. A credential is created for this user for authorization purposes. If browser certificates are not supported in your configuration, you can create the CertificateMapNotSupportedException exception. The consequence of not supporting certificates is authentication failure if the challenge type is certificates, even if valid certificates are in the browser.

This method is called when certificates are provided for authentication. For web applications, when the authentication constraints are set to CLIENT-CERT in the `web.xml` file of the application, this method is called to map a certificate to a valid user in the registry. For Java clients, this method is called to map the client certificates in the transport layer, when using transport layer authentication. When the identity assertion token, using the CSIv2 authentication protocol, is set to contain certificates, this method is called to map the certificates to a valid user.

In WebSphere Application Server Version 4.x, the input parameter is the X509Certificate certificate. In WebSphere Application Server Version 5.x and later, this parameter changes to accept an array of X509Certificate certificates such as a certificate chain. In Version 4.x, this parameter is called for web applications only, but in version 5.x and later, you can call this method for both web and Java clients.

- Obtain the security realm name with getRealm.

```
public String getRealm()
       throws CustomRegistryException,
       RemoteException;
```

The getRealm method is called to get the name of the security realm. The name of the realm identifies the security domain for which the registry authenticates users. If this method returns a null value, a customRealm default name is used.

For the `FileRegistrySample.java` sample file, the getRealm method returns the customRealm string. One of the calls to this method occurs when the user registry information is validated. This method is the same method as in Version 4.x.

- Obtain the list of users from the registry with getUsers(String,int).

```
public Result getUsers(String pattern, int limit)
     throws CustomRegistryException,
            RemoteException;
```

The getUsers method returns the list of users from the registry. The names of users depend on the pattern parameter. The number of users are limited by the limit parameter. In a registry that has many users, getting all the users is not practical. So the limit parameter is introduced to limit the number of users retrieved from the registry. A limit of zero (0) indicates to return all the users that match the pattern and might cause problems for large registries. Use this limit with care.

The custom registry implementations are expected to support at least the wildcard search (*). For example, a pattern of asterisk (*) returns all the users and a pattern of (b*) returns the users starting with *b*.

The return parameter is an object with a com.ibm.websphere.security.Result type. This object contains two attributes, a java.util.List and a java.lang.boolean attribute. The list contains the users that are returned and the Boolean flag indicates if more users are available in the user registry for the search pattern. This Boolean flag is used to indicate to the client whether more users are available in the registry.

In the `FileRegistrySample.java` sample file, the getUsers method retrieves the required number of users from the user registry and sets them as a list in the Result object. To find out if more users are presented than requested, the sample gets one more user than requested and if it finds the additional user, it sets the Boolean flag to `true`. For pattern matching, the match method in the RegExpSample class is used, which supports wildcard characters such as the asterisk (*) and the question mark (?).

This method is called by the administrative console to add users to roles in the various map-users-to-roles panels. The administrative console uses the Boolean set in the Result object to indicate that more entries matching the pattern are available in the user registry.

In WebSphere Application Server Version 4.*x*, this method specifies to take only the pattern parameter. The return is a list. In WebSphere Application Server Version 5.x or later, this method is changed to take one additional parameter, the limit. Ideally, your implementation changes to take the limit value and limits the users that are returned. The return is changed to return a Result object, which consists of the list and a flag that indicates if more entries exist. When the list returns, use the Result.setList(List) method to set the list in the Result object. If more entries exist than requested in the limit parameter, set the Boolean attribute to `true` in the result object, using the Result.setHasMore method. The default for the Boolean attribute in the result object is `false`.

- Obtain the display name of a user with getUserDisplayName(String).

```
public String getUserDisplayName(String userSecurityName)
      throws EntryNotFoundException,
             CustomRegistryException,
             RemoteException;
```

  The getUserDisplayName method returns a display name for a user, if one exists. The display name is an optional string that describes the user that you can set in some registries. This descriptive name is for the user and does not have to be unique in the registry.

  For example, in IBM i systems, you can display the text description for the user profile.

  If you do not need display names in your registry, return null or an empty string for this method.

  If display names existed for any user in WebSphere Application Server Version 4.x, these names were useful for the Enterprise JavaBeans (EJB) method call getCallerPrincipal and the servlet calls getUserPrincipal and getRemoteUser. If the display names are not the same as the security name for any user, the display names are returned for the previously mentioned enterprise beans and servlet methods. Returning display names for these methods might become problematic in some situations because the display names might not be unique in the user registry. Avoid this problem by changing the default behavior to return the user security name instead of the user display name in this version of the product. For more information on how to set properties for the custom registry, see the section on *Setting Properties for Custom Registries*.

  In the `FileRegistrySample.java` sample file, this method returns the display name of the user whose name matches the user name that is provided. If the display name does not exist, this method returns an empty string.

  This method can be called by the product to present the display names in the administrative console, or by using the command line and the **wsadmin** tool. Use this method for display purposes only. This method is the same as in Version 4.x.

- Obtain the unique ID of a user with getUniqueUserId(String).

```
public String getUniqueUserId(String userSecurityName)
       throws EntryNotFoundException,
              CustomRegistryException,
              RemoteException;
```

  This method returns the unique ID of the user, given the security name.

  In the `FileRegistrySample.java` sample file, this method returns the uniqueUserId value of the user whose name matches the supplied name. This method is called when forming a credential for a user and also when creating the authorization table for the application.

- Obtain the security name of a user with getUserSecurityName(String).

```
public String getUserSecurityName(String uniqueUserId)
      throws EntryNotFoundException,
             CustomRegistryException,
             RemoteException;
```

  This method returns the security name of a user given the unique ID. In the `FileRegistrySample.java` sample file, this method returns the security name of the user whose unique ID matches the supplied ID.

  This method is called to make sure a valid user exists for a given uniqueUserId. This method is called to get the security name of the user when the uniqueUserId is obtained from a token.

- Check whether a given user is a valid user in the registry with isValidUser(String).

```
public boolean isValidUser(String userSecurityName)
       throws CustomRegistryException,
              RemoteException;
```

  This method indicates whether the given user is a valid user in the registry.

  In the `FileRegistrySample.java` sample file, this method returns `true` if the user is found in the registry, otherwise this method returns `false`. This method is primarily called in situations where knowing if the

user exists in the directory prevents problems later. For example, in the mapCertificate call, when the name is obtained from the certificate if the user is not found as a valid user in the user registry, you can avoid trying to create the credential for the user.

- Return the list of groups from the user registry with getGroups(String,int).

```
public Result getGroups(String pattern, int limit)
      throws CustomRegistryException,
             RemoteException;
```

The getGroups method returns the list of groups from the user registry. The names of groups depend on the pattern parameter. The number of groups is limited by the limit parameter. In a registry that has many groups, getting all the groups is not practical. So, the limit parameter is introduced to limit the number of groups retrieved from the user registry. A limit of zero (0) implies to return all the groups that match the pattern and can cause problems for large user registries. Use this limit with care. The custom registry implementations are expected to support at least the wildcard search (*). For example, a pattern of asterisk (*) returns all the users and a pattern of (b*) returns the users starting with *b*.

The return parameter is an object of the com.ibm.websphere.security.Result type. This object contains the `java.util.List` and `java.lang.boolean` attributes. The list contains the groups that are returned and the Boolean flag indicates whether more groups are available in the user registry for the pattern searched. This Boolean flag is used to indicate to the client if more groups are available in the registry.

In the `FileRegistrySample.java` sample file, the getUsers method retrieves the required number of groups from the user registry and sets them as a list in the Result object. To find out if more groups are presented than requested, the sample gets one more user than requested and if it finds the additional user, it sets the Boolean flag to `true`. For pattern matching, the match method in the RegExpSample class is used, which supports the asterisk (*) and question mark (?) characters.

This method is called by the administrative console to add groups to roles in the various map-groups-to-roles panels. The administrative console uses the boolean set in the Result object to indicate that more entries matching the pattern are available in the user registry.

In WebSphere Application Server Version 4, this method is used to take the pattern parameter only and returns a list. In WebSphere Application Server Version 5.x or later, this method is changed to take the limit parameter. Change to take the limit value and limit the users that are returned. The return is changed to return a Result object, which consists of the list and a flag that indicates whether more entries exist. Use the Result.setList(List) method to set the list in the Result object. If more entries exist than requested in the limit parameter, set the Boolean attribute to `true` in the Result object using the Result.setHasMore method. The default for the Boolean attribute in the Result object is `false`.

- Obtain the display name of a group with getGroupDisplayName(String).

```
public String getGroupDisplayName(String groupSecurityName)
      throws EntryNotFoundException,
             CustomRegistryException,
             RemoteException;
```

The getGroupDisplayName method returns a display name for a group if one exists. The display name is an optional string that describes the group that you can set in some user registries. This name is a descriptive name for the group and does not have to be unique in the registry. If you do not need to have display names for groups in your registry, return null or an empty string for this method.

In the `FileRegistrySample.java` sample file, this method returns the display name of the group whose name matches the group name that is provided. If the display name does not exist, this method returns an empty string.

The product can call this method to present the display names in the administrative console or through the command line using the **wsadmin** tool. This method is used for display purposes only.

- Obtain the unique ID of a group with getUniqueGroupId(String).

```
public String getUniqueGroupId(String groupSecurityName)
        throws EntryNotFoundException,
               CustomRegistryException,
               RemoteException;
```

This method returns the unique ID of the group that is given the security name.

In the FileRegistrySample.java sample file, this method returns the security name of the group whose unique ID matches the supplied ID. This method verifies that a valid group exists for a given uniqueGroupId ID.

- Obtain the unique IDs of all groups to which a user belongs with getUniqueGroupIds(String).

```
public List getUniqueGroupIds(String uniqueUserId)
      throws EntryNotFoundException,
             CustomRegistryException,
             RemoteException;
```

This method returns the unique IDs of all the groups to which a user belongs.

In the FileRegistrySample.java sample file, this method returns the unique ID of all the groups that contain this uniqueUserID ID. This method is called when creating the credential for the user. As part of creating the credential, all the groupUniqueIds IDs in which the user belongs are collected and put in the credential for authorization purposes when groups are given access to a resource.

- Obtain the security name of a group with getGroupSecurityName(String).

```
public String getGroupSecurityName(String uniqueGroupId)
     throws EntryNotFoundException,
            CustomRegistryException,
            RemoteException;
```

This method returns the security name of a group given its unique ID.

In the FileRegistrySample.java sample file, this method returns the security name of the group whose unique ID matches the supplied ID. This method verifies that a valid group exists for a given uniqueGroupId ID.

- Determine whether a group is a valid group in the registry with isValidGroup(String).

```
public boolean isValidGroup(String groupSecurityName)
       throws CustomRegistryException,
              RemoteException;
```

This method indicates if the given group is a valid group in the registry.

In the FileRegistrySample.java sample file, this method returns true if the group is found in the registry, otherwise the method returns false. This method can be used in situations where knowing whether the group exists in the directory might prevent problems later.

- Obtain all groups to which a user belongs with getGroupsForUser(String).

```
public List getGroupsForUser(String userSecurityName)
     throws EntryNotFoundException,
            CustomRegistryException,
            RemoteException;
```

This method returns all the groups to which a user belongs whose name matches the supplied name. This method is similar to the getUniqueGroupIds method with the exception that the security names are used instead of the unique IDs.

In the FileRegistrySample.java sample file, this method returns all the group security names that contain the userSecurityName name.

This method is called by the administrative console or the scripting tool to verify that the users entered for the RunAs roles are already part of that role in the users and groups-to-role mapping. This check is required to ensure that a user cannot be added to a RunAs role unless that user is assigned to the role in the users and groups-to-role mapping either directly or indirectly through a group that contains this user. Because a group in which the user belongs can be part of the role in the users and groups-to-role mapping, this method is called to check if any of the groups that this user belongs to mapped to that role.

- Retrieve users from a specified group with getUsersForGroup(String,int).

```
public Result getUsersForGroup(String groupSecurityName, int limit)
     throws NotImplementedException,
            EntryNotFoundException,
            CustomRegistryException,
            RemoteException;
```

This method retrieves users from the specified group. The number of users returned is limited by the limit parameter. A limit of zero (0) indicates to return all of the users in that group. This method is not directly called by the WebSphere Application Server security component. However, this method can be called by other components. In rare situations, if you are working with a user registry where getting all the users from any of your groups is not practical, you can create the NotImplementedException exception for the particular groups. In this case, verify that if the process choreographer is installed the staff assignments are not modeled using these particular groups. If no concern exists about returning the users from groups in the user registry, it is recommended that you do not create the NotImplemented exception when implementing this method.

The return parameter is an object with a com.ibm.websphere.security.Result type. This object contains the java.util.List and java.lang.boolean attributes. The list contains the users that are returned and the Boolean flag, which indicates whether more users are available in the user registry for the search pattern. This Boolean flag indicates to the client whether users are available in the user registry.

In the example, this method gets one user more than the requested number of users for a group, if the limit parameter is not set to zero (0). If the method succeeds in getting one more user, the Boolean flag is set to `true`.

In WebSphere Application Server Version 4, this getUsers method is mandatory for the product. For WebSphere Application Server Version 5.x or later, this method can create the `NotImplementedException` exception in situations where it is not practical to get the requested set of users. However, create this exception in rare situations when as other components can be affected. In Version 4, this method accepts only the pattern parameter and returns a list. In Version 5, this method accepts the limit parameter. Change your implementation to take the limit value and limit the users that are returned. The return changes to return a Result object, which consists of the list and a flag that indicates whether more entries exist. When the list is returned, use the Result.setList(List) method to set the list in the Result object. If more entries than requested are in the limit parameter, set the Boolean attribute to `true` in the Result object using Result.setHasMore method. The default for the Boolean attribute in the Result object is `false`.

- Implement the createCredential(String) method.

  Attention: The first two lines of the following code sample are split for illustrative purposes only.

```
public com.ibm.websphere.security.cred.WSCredential createCredential(String userSecurityName)
 throws NotImplementedException,
           EntryNotFoundException,
           CustomRegistryException,
           RemoteException;
```

  In this release the WebSphere Application Server, the createCredential method is not called. You can return *null*. In the example, a *null* value is returned.

What to do next

Managing the realm in a federated repository configuration

Follow this topic to manage the realm in a federated repository configuration.

Before you begin

The realm can consist of identities in:

- The file-based repository that is built into the system
- One or more external repositories
- Both the built-in, file-based repository and in one or more external repositories

Before you configure your realm, review “Federated repositories limitations” on page 1322.

Procedure

1. Configure your realm by using one of the following topics. You might be configuring your realm for the first time or changing an existing realm configuration.

- "Using a single built-in, file-based repository in a new configuration under Federated repositories" on page 1325
- "Changing a federated repository configuration to include a single built-in, file-based repository only" on page 1330
- "Configuring a single, Lightweight Directory Access Protocol repository in a new configuration under Federated repositories" on page 1331
- "Changing a federated repository configuration to include a single, Lightweight Directory Access Protocol repository only" on page 1333
- "Configuring multiple Lightweight Directory Access Protocol repositories in a federated repository configuration" on page 1334
- "Configuring a single built-in, file-based repository and one or more Lightweight Directory Access Protocol repositories in a federated repository configuration" on page 1335

2. Configure supported entity types using the steps described in "Configuring supported entity types in a federated repository configuration" on page 1377. You must configure supported entity types before you can manage this account with Users and Groups. The Base entry for the default parent determines the repository location where entities of the specified type are placed on a create operation.
3. Optional: Use one or more of the following tasks to extend the capabilities of storing data and attributes in your realm:
   a. Configure an entry mapping repository using the steps described in "Configuring an entry mapping repository in a federated repository configuration" on page 1374. An entry mapping repository is used to store data for managing profiles on multiple repositories.
   b. Configure a property extension repository using the steps described in "Configuring a property extension repository in a federated repository configuration" on page 1353. A property extension repository is used to store attributes that cannot be stored in your Lightweight Directory Access Protocol (LDAP) server.
   a. Set up a database repository using wsadmin commands as described in "Setting up an entry mapping repository, a property extension repository, or a custom registry database repository using wsadmin commands" on page 1359
4. Optional: Use one or more of the following advanced user tasks to extend the capabilities of LDAP repositories in your realm:
   - "Increasing the performance of the federated repository configuration" on page 1382
   - "Configuring Lightweight Directory Access Protocol entity types in a federated repository configuration" on page 1396
   - "Configuring group attribute definition settings in a federated repository configuration" on page 1398
5. Optional: Manage repositories that are configured in your system by following the steps described in "Managing repositories in a federated repository configuration" on page 1380.
6. Optional: Add an external repository into your realm by following the steps described in "Adding an external repository in a federated repository configuration" on page 1352.
7. Optional: Change the password for the repository that is configured under federated repositories by the following steps described in "Changing the password for a repository under a federated repositories configuration" on page 1324.

What to do next

1. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.

2. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1186. As the final step, validate this setup by clicking **Apply** in the Global security panel.
3. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Federated repositories:

Federated repositories enable you to use multiple repositories with WebSphere Application Server. These repositories, which can be file-based repositories, LDAP repositories, or a sub-tree of an LDAP repository, are defined and theoretically combined under a single realm. All of the user repositories that are configured under the federated repository functionality are invisible to WebSphere Application Server.

When you use the federated repositories functionality, all of the configured repositories, which you specify as part of the federated repository configuration, become active. It is required that the user ID, and the distinguished name (DN) for an LDAP repository, be unique in multiple user repositories that are configured under the same federated repository configuration. For example, there might be three different repositories that are configured for the federated repositories configuration: Repository A, Repository B, and Repository C. When user1 logs in, the federated repository adapter searches each of the repositories for all of the occurrences of that user. If multiple instances of that user are found in the combined repositories, an error message displays.

In addition, the federated repositories functionality in WebSphere Application Server supports the logical joining of entries across multiple user repositories when the Application Server searches and retrieves entries from the repositories. For example, when an application calls for a sorted list of people whose age is greater than twenty, WebSphere Application searches all of the repositories in the federated repositories configuration. The results are combined and sorted before the Application Server returns the results to the application.

Unlike the local operating system, stand-alone LDAP registry, or custom registry options, federated repositories provide user and group management with read and write capabilities. When you configure federated repositories, you can use one of the following methods to add, create, and delete users and groups:

Important: If you configure multiple repositories under the federated repositories realm, you must also configure supported entity types and specify a base entry for the default parent. The base entry for the default parent determines the repository location where entities of the specified type are placed on write operations by user and group management. See “Configuring supported entity types in a federated repository configuration” on page 1377 for details.

- Use the user management application programming interfaces (API). For more information, refer to articles under "Developing with virtual member manager" in this information center.
- Use the administrative console. To manage users and groups within the administrative console, click **Users and Groups** > **Manage Users** or **Users and Groups** > **Manage Groups**. For information on user and group management, click the Help link that displays in the upper right corner of the window. From the left navigation pane, click **Users and Groups**.
- Use the wsadmin commands. For more information, see the WIMManagementCommands command group for the AdminTask object topic.

If you do not configure the federated repositories functionality or do not enable federated repositories as the active repository, you cannot use the user management capabilities that are associated with federated repositories. You can configure an LDAP server as the active user registry and configure the same LDAP server under federated repositories, but not select federated repositories as the active user repository. With this scenario, authentication takes place using the LDAP server, and you can use the user management functionality for the LDAP server that is available for federated repositories.

The following table compares the federated repository functionality that is available in WebSphere Application Server Version 8.0 with the registry functionality that remains unchanged from previous versions of the Application Server.

Table 84. Federated repositories versus user registry implementations.

This table lists federated repositories versus user registry implementations.

Federated repositories	User registry
Supports multiple types of repositories such as file-based, LDAP, database, and custom. In WebSphere Application Server Version 8.0, file-based and LDAP repositories are supported by the administrative console. However, the federated repositories functionality does not support local operating system implementations. With this service release, the federated repositories functionality supports local operating system implementations. For database and custom repositories, you can use the wsadmin command-line interface or the configuration application programming interfaces (API).	Supports multiple types of registries such as the local operating system, a stand-alone LDAP registry, and a stand-alone custom registry.
Supports multiple repositories in a realm within a cell.	Supports one registry only in a realm within a cell.
Provides read and write capabilities for the repositories that are defined in the federated repository configuration.	Provides read only capability for the registries.
Provides account and password policy support as defined by the registry type. However, this support is not provided by the federated repository functionality.	Provides account and password policy support as defined by the registry type.
Supports identity profiles.	Does not support identity profiles.
Uses the custom UserRegistry implementation.	Uses the custom UserRegistry implementation.

Realm configuration settings:

Use this page to manage the realm. The realm can consist of identities in the file-based repository that is built into the system, in one or more external repositories, or in both the built-in, file-based repository and one or more external repositories.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Security domains**.
2. Under User realm, select **Customize for this domain**. Select **Federated repositories** from the Realm type field and click **Configure**.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

A single built-in, file-based repository is built into the system and included in the realm by default.

You can configure one or more Lightweight Directory Access Protocol (LDAP) repositories to store identities in the realm. Click **Add base entry to realm** to specify a repository configuration and a base entry into the realm. You can configure multiple different base entries into the same repository.

Click **Remove** to remove selected repositories from the realm. Repository configurations and contents are not destroyed. The following restrictions apply:

- The realm must always contain at least one base entry; therefore, you cannot remove every entry.
- If you plan to remove the built-in, file-based repository from the administrative realm, verify that at least one user in another member repository is a console user with administrative rights. Otherwise, you must disable security to regain access to the administrative console.

WebSphere Application Server Version 7.0 distinguishes between the user identities for administrators who manage the environment and server identities for authenticating server to server communications. In most cases, server identities are automatically generated and are not stored in a repository.

Realm name:

Specifies the name of the realm. You can change the realm name.

Primary administrative user name:

Specifies the name of the user with administrative privileges that is defined in the repository, for example, adminUser.

The user name is used to log on to the administrative console when administrative security is enabled. Version 6.1 requires an administrative user that is distinct from the server user identity so that administrative actions can be audited.

Attention: In WebSphere Application Server, Version 6.0.x, a single user identity is required for both administrative access and internal process communication. When migrating to Version 6.1, this identity is used as the server user identity. You need to specify another user for the administrative user identity.

Automatically generated server identity:

Enables the application server to generate the server identity, which is recommended for environments that contain only Version 6.1 or later nodes. Automatically generated server identities are not stored in a user repository.

Default: Enabled

Server identity that is stored in the repository:

Specifies a user identity in the repository that is used for internal process communication. Cells that contain Version 6.1 or later nodes require a server user identity that is defined in the active user repository.

Default: Enabled

Ignore case for authorization:

Specifies that a case-insensitive authorization check is performed.

If case sensitivity is not a consideration for authorization, enable the **Ignore case for authorization** option.

Allow operations if some of the repositories are down:

Specifies whether operations (such as login, search, or get) are allowed even if the repositories in the realm are down.

Use global schema for model:

Sets the global schema option for the data model in a multiple security domain environment. Global schema refers to the schema of the admin domain.

Note: Application domains that are set to use global schema share the same schema of the admin domain. If you extend the schema for an application in one domain, you must also consider how that might affect applications of other domains, as they are bound by the same schema. For example, adding a mandatory property for one application might cause other applications to fail.

Base entry:

Specifies the base entry within the realm. This entry and its descendents are part of the realm.

Repository identifier:

Specifies a unique identifier for the repository. This identifier uniquely identifies the repository within the cell.

Repository type:

Specifies the repository type, such as File or LDAP.

User attribute mapping for federated repositories:

Use this panel to set or to modify the mapping for a user registry's user or group attribute to a federated repository property.

To view this administrative console page, click **Security > Global security**. Under Available realm definitions, click **Federated repositories**, and then **Configure**. On the next panel and under Additional Properties, click **User repository attribute mapping**.

Attribute mappings:

Select an attribute to set or to modify the mapping for a user registry's user or group attribute to a federated repository property, and then click **Edit**.

Custom properties details for federated repositories:

Use this panel to specify the configuration for access to a custom repository.

To view this administrative console page, click **Security > Global security**. Under Available realm definitions, click **Federated repositories**, and then **Configure**. On the next panel and under Additional Properties, click **Manage repositories**. Under Add, select **Custom repository**.

Repository identifier:

Specifies a unique identifier for the repository. This identifier uniquely identifies the repository within the cell.

Repository adapter class name:

Specifies the implementation class name for the repository adapter. For a User Registry bridge, use com.ibm.ws.wim.adapter.urbridge.URBridge.

Login properties:

Specifies the property names to use to log into the application server.

Custom properties:

Specifies arbitrary name and value pairs of data. The name is a property key and the value is a string value that can be used to set internal system configuration properties.

File details for federated repositories:

Use this panel to specify the configuration for access to a file repository.

To view this administrative console page, click **Security > Global security**. Under Available realm definitions, click **Federated repositories**, and then **Configure**. On the next panel and under Additional Properties, click **Manage repositories**. Under Add, select **File repository**.

Repository identifier:

Specifies a unique identifier for the repository. This identifier uniquely identifies the repository within the cell.

Repository adapter class name:

Specifies the implementation class name for the repository adapter. For a User Registry bridge, use com.ibm.ws.wim.adapter.urbridge.URBridge.

Base directory:

The base directory where the files are to be created. This directory must already exist.

File name:

The file name for the repository.

The default value is `fileRegistry.xml`.

Salt length:

Specifies the salt length of the randomly generated salt for password hashing.

The default value is 12.

Message digest algorithm:

Specifies the message digest algorithm to use for hashing the password.

Select one of the following: SHA-1, SHA-256, SHA-384 or SHA-512.

The default value is SHA-1.

Login properties:

Specifies the property names to use to log into the application server.

Custom properties:

Specifies arbitrary name and value pairs of data. The name is a property key and the value is a string value that can be used to set internal system configuration properties.

Federated repositories limitations:

This topic outlines known limitations and important information for configuring federated repositories.

Configuring federated repositories in a mixed-version environment

In a mixed-version deployment manager cell that contains both Version 6.1.x and Version 5.x or 6.0.x nodes, the following limitations apply for configuring federated repositories:

- You can configure only one Lightweight Directory Access Protocol (LDAP) repository under federated repositories, and the repository must be supported by Version 5.x or 6.0.x.
- You can specify a realm name that is compatible with prior versions only. The host name and the port number represent the realm for the LDAP server in a mixed-version nodes cell. For example, machine1.austin.ibm.com:389.
- You must configure a stand-alone LDAP registry; the LDAP information in both the stand-alone LDAP registry and the LDAP repository under the federated repositories configuration must match. During node synchronization, the LDAP information from the stand-alone LDAP registry propagates to the Version 5.x or 6.0.x nodes.

  Important: Before node synchronization, verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. Do not set the stand-alone LDAP registry as the current realm definition.
- You cannot configure an entry mapping repository or a property extension repository in a mixed-version deployment manager cell.

Configuring LDAP servers in a federated repository

The LDAP connection `connectTimeout` default value is 20 seconds. LDAP should respond within 20 seconds for any request from WebSphere Application Server. If you cannot connect to your LDAP within this time, make sure that your LDAP is running. A connection error displays at the top of the LDAP configuration panel when the connection timeout exceeds 20 seconds.

Coexisting with Tivoli Access Manager

For Tivoli Access Manager to coexist with a federated repositories configuration, the following limitations apply:

- You can configure only one LDAP repository under federated repositories, and that LDAP repository configuration must match the LDAP server configuration under Tivoli Access Manager.
- The distinguished name for the realm base entry must match the LDAP distinguished name (DN) of the base entry within the repository. In WebSphere Application Server, Tivoli Access Manager recognizes the LDAP user ID and LDAP DN for both authentication and authorization. The federated repositories configuration does not include additional mappings for the LDAP user ID and DN.
- The federated repositories functionality does not recognize the metadata that is specified by Tivoli Access Manager. When users and groups are created under user and group management, they are not formatted using the Tivoli Access Manager metadata. The users and groups must be manually imported into Tivoli Access Manager before you use them for authentication and authorization.

Limitation for configuring active directories with their own federated repository realms

In order to use the administrative console to perform a wildcard search for all available users on two Active Directories, and to prevent multiple entries exceptions with all built-in IDs, you must first configure each Active Directory with it's own federated repository realm.

However, you cannot use the administrative console to configure each Active Directory with it's own federated repository realm. You can instead use a wsadmin script similar to the following:

```
$AdminTask createIdMgrRealm {-name AD1realm}
$AdminTask addIdMgrRealmBaseEntry {-name AD1realm -baseEntry o=AD1}

$AdminTask createIdMgrRealm {-name AD2realm}
$AdminTask addIdMgrRealmBaseEntry {-name AD2realm -baseEntry o=AD2}

$AdminConfig save
```

Changing the password for a repository under a federated repositories configuration:

Passwords allow security control over the repositories under a federated repositories configuration. As part of managing the realm in a federated repository configuration, one of the optional tasks you can perform is to change the password of an individual repository that is under a federated repositories configuration.

Before you begin

Before you change the password for the repository that is configured under federated repositories, ensure that the WebSphere Application Server is running and the target repository for the password change is configured under the federated repositories configuration.

Procedure

- Changing the password for a repository using the dynamic **updateIdMgrLDAPBindInfo** command Use the following steps to change the Lightweight Directory Access Protocol (LDAP) bind distinguished name (DN) or bind password of an LDAP repository.

  From a **wsadmin** prompt, you can enter the following command to display a list of arguments for the **updateIdMgrLDAPBindInfo** command: `$AdminTask help updateIdMgrLDAPBindInfo`

  1. Start the wsadmin command-line utility. The wsadmin command is found in the*app_server_root*`/bin` directory. The WebSphere Application Server and wsadmin must remaining running.
  2. Use an LDAP tool to change the password of the LDAP repository. Some LDAP repositories require a stop and start of the LDAP server to change the password.
  3. From the **wsadmin** prompt, enter the **updateIdMgrLDAPBindInfo** command to update the LDAP password under the federated repository. The change is also reflected in the wimconfig.xml file.
- Changing the password for a repository using the **updateIdMgrDBRepository** command
  1. Start the wsadmin command-line utility. The wsadmin command is found in the *app_server_root*`/bin` directory. The wsadmin command session must remain running. If WebSphere Application Server is not started, you need to open a wsadmin command session in local mode. `wsadmin -conntype none`

     gotcha: If you are starting the wsadmin command session in local mode, you must ensure that the location of the database driver is specified in the class path using the –wsadmin_classpath option. For information on using this option, see the topic, *wsadmin scripting tool* in the WebSphere Application Server information center.
  2. Log in to the Administrative Console for WebSphere Application Server.
  3. Change the password for the repository.
  4. From the Administrative Console, change the data source (J2C) password. You access the proper console page by clicking **Resources > JDBC > Data sources >***data_source***> JAAS - J2C authentication data**.
  5. From the Administrative Console, save your changes to the master configuration.
  6. From the **wsadmin** prompt, use the updateIdMgrDBRepository command to update the password in the wimconfig.xml file.
  7. From the **wsadmin** prompt, save your changes to the master configuration. The following command is used to save the master configuration: `$AdminConfig save`.
  8. Restart the WebSphere Application Server.
- Changing the password for a repository using the **setIdMgrPropertyExtensionRepository** command
  1. Start the wsadmin command-line utility. The wsadmin command is found in the*app_server_root*`/bin` directory. The wsadmin command session must remain running. If WebSphere Application Server is not started, you need to open a wsadmin command session in local mode.

     ```
     wsadmin -conntype none
     ```
  2. Log in to the Administrative Console for WebSphere Application Server.
  3. Change the password for the repository.

4. From the Administrative Console, change the data source (J2C) password. You access the proper console page by clicking **Resources > JDBC > Data sources >** *data_source* **> JAAS - J2C authentication data**.
5. From the Administrative Console, save your changes to the master configuration.
6. From the **wsadmin** prompt, use the **setIdMgrPropertyExtensionRepository** command to update the password in the wimconfig.xml file.
7. From the **wsadmin** prompt, save your changes to the master configuration. The following command is used to save the master configuration: `$AdminConfig save`.
8. Restart the WebSphere Application Server.

- Changing the password for a repository using the **setIdMgrEntryMappingRepository** command
  1. Start the wsadmin command-line utility. The wsadmin command is found in the*app_server_root*`/bin` directory. The wsadmin command session must remain running. If WebSphere Application Server is not started, you need to open a wsadmin command session in local mode.

     ```
     wsadmin -conntype none
     ```
  2. Log in to the Administrative Console for WebSphere Application Server.
  3. Change the password for the repository.
  4. From the Administrative Console, change the data source (J2C) password. You access the proper console page by clicking **Resources > JDBC > Data sources >***data_source* **> JAAS - J2C authentication data**.
  5. From the Administrative Console, save your changes to the master configuration.
  6. From the **wsadmin** prompt, use the **setIdMgrEntryMappingRepository** command to update the password in the wimconfig.xml file.
  7. From the **wsadmin** prompt, save your changes to the master configuration. The following command is used to save the master configuration: `$AdminConfig save`.
  8. Restart the WebSphere Application Server.
- Changing the password for a repository using the **updateIdMgrLDAPServer** command
  1. Start the wsadmin command-line utility. The wsadmin command is found in the*app_server_root*`/bin` directory. The wsadmin command session must remain running. If WebSphere Application Server is not started, you need to open a wsadmin command session in local mode.

     ```
     wsadmin -conntype none
     ```
  2. Change the password for the repository.
  3. From the **wsadmin** prompt, use the **updateIdMgrLDAPServer** command to update the password in the wimconfig.xml file.
  4. From the **wsadmin** prompt, save your changes to the master configuration. The following command is used to save the master configuration: `$AdminConfig save`.
  5. Restart the WebSphere Application Server.

Results

The password for the repository has been changed.

Using a single built-in, file-based repository in a new configuration under Federated repositories:

Follow this task to use a single built-in, file-based repository in a new configuration under Federated repositories.

Before you begin

To use the default configuration under Federated repositories that includes a single built-in, file-based repository only, you need to know the primary administrative user name of the user who manages WebSphere Application Server resources and user accounts.

Restriction:

Client certificate login is not supported in a realm that includes a single built-in, file-based repository or a single built-in, file-based repository with other repositories.

Procedure

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Leave the Realm name field value as `defaultWIMFileBasedRealm`.
4. Enter the name of the primary administrative user in the Primary administrative user name field, for example, adminUser.
5. Leave the **Ignore case for authorization** option enabled.
6. Click **OK**.
7. Provide an administrative user password. This panel displays only when a built-in, file-based repository is included in the realm. Otherwise, the panel does not display. If a built-in, file-based repository is included, complete the following steps:
   a. Supply a password for the administrative user in the Password field.
   b. Confirm the password of the primary administrative user in the Confirm password field.
   c. Click **OK**.

Results

After completing these steps, your new configuration under Federated repositories includes a single built-in, file-based repository only.

What to do next

1. Before you can manage this account with Users and Groups, configure supported entity types as described in “Configuring supported entity types in a federated repository configuration” on page 1377.
2. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
3. If you are enabling security, complete the remaining steps, as specified in “Enabling security for the realm” on page 1186. As the final step, validate this setup by clicking **Apply** in the Global security panel.
4. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Administrative user password settings:

Use this page to set a password for the administrative user who manages the product resources and user accounts.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. If your federated repository configuration includes a built-in, file-based repository, then the **Administrative user password** panel displays when changes are applied.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

Password:

Specifies the password of the administrative user who manages the product resources and user accounts.

Confirm password:

Confirms the password of the administrative user who manages the product resources and user accounts.

Federated repository wizard settings:

Use this security wizard page to complete the basic requirements to connect the application server to a federated repository.

To view this security wizard page, complete the following steps

1. Click **Security > Global security > Security configuration wizard**.
2. Select your protection settings and click **Next**.
3. Select the **Federated repositories** option and click **Next**.

You can modify your federated repository configuration by completing the following steps:

1. Click **Security > Global security**.
2. Under User account repository, select Federated repository and click **Configure**.

Note: This wizard is used for the initial configuration of a built-in, file-based repository. The user name and password do not have to be in the federated repository because they will be created. If you have previously configured federated repositories, do not use the Security configuration wizard to modify your configuration. Instead, modify your configuration using the Federated repositories selection under User account repository on the Global security panel.

Primary administrative user name:

Specifies the name of the user with administrative privileges that is defined in the repository, for example, adminUser.

The user name is used to log on to the administrative console when administrative security is enabled. Version 6.1 requires an administrative user that is distinct from the server user identity so that administrative actions can be audited.

Attention: In WebSphere Application Server, Version 6.0.x, a single user identity is required for both administrative access and internal process communication. When migrating to Version 6.1, this identity is used as the server user identity. You need to specify another user for the administrative user identity.

Password:

Specifies the password of the administrative user who manages the product resources and user accounts.

Confirm password:

Confirms the password of the administrative user who manages the product resources and user accounts.

Configuring a single built-in, file-based repository in a new configuration under federated repositories using wsadmin:

You can use the Jython or Jacl scripting language with the wsadmin tool to configure a single built-in, file-based repository in a new configuration under Federated repositories.

Before you begin

Shut down the application server and ensure you have the primary administrator id and password.

About this task

The federated repositories configuration file, `wimconfig.xml`, is supported by WebSphere Application Server 6.1.x and is located in the *app_server_root*/`profiles/profile_name/config/cells/cell_name/wim/config` directory.

Use the following steps to configure for use a single built-in, file-based repository in a new configuration for federated repositories.

Procedure

1. Start the wsadmin scripting tool.
2. Create the `fileRegistry.xml` file, which is the user registry itself, if it does not already exist. If the `fileRegistry.xml` file does exist, this step just adds the user to registry.

   Using Jython:

   ```
   AdminTask.addFileRegistryAccount('-userId isoet01s01 -password oets01')
   ```

   Using Jacl:

   ```
   $AdminTask addFileRegistryAccount {-userId isoet01s01 -password oets01}
   ```

   For more information on the addFileRegistryAccount command, see the documentation about the FileRegistryCommands command group for the AdminTask object.
3. Update the `security.xml` file to enable administrative security, set the activeUserRegistry to use federated repositories, and update the primaryAdmin and its password.

   Using Jython:

   ```
   AdminTask applyWizardSettings('-secureApps false
    -secureLocalResources false
    -userRegistryType WIMUserRegistry
    -customRegistryClass com.ibm.ws.wim.registry.WIMUserRegistry
    -adminName isoet01s01 -adminPassword oets01')
   ```

   Using Jacl:

   ```
   $AdminTask applyWizardSettings {-secureApps false
    -secureLocalResources false
    -userRegistryType WIMUserRegistry
    -customRegistryClass com.ibm.ws.wim.registry.WIMUserRegistry
    -adminName isoet01s01
    -adminPassword oets01}
   ```

   For more information on the applyWizardSettings command, see the documentation about the WizardCommands command group for the AdminTask object.
4. Save your configuration changes. Enter the following commands to save the new configuration and close the wsadmin tool:

   Using Jython:

   ```
   AdminConfig.save()
   ```

   Using Jacl:

   ```
   $AdminConfig save
   ```
5. Restart the application server.

FileRegistryCommands command group for the AdminTask object:

Federated repositories provides a file registry. Use the commands in the FileRegistryCommands command group to administer the file registry using the wsadmin tool.

Note: If the Use global security settings option is selected for the user realm or the Global federated repositories option is selected as the realm type for the specified domain, the user and group management commands are executed on the federated repository of the admin domain. For example, if you run the createUser command for the specified domain, the user is created in the admin domain. However, configuration changes that are performed on the domain are applied to the security domain-specific configuration.

Use the following commands in the FileRegistryCommands group to modify the federated repository file registry:

- "addFileRegistryAccount command"
- "changeFileRegistryAccountPassword command" on page 1330

addFileRegistryAccount command

The addFileRegistryAccount command adds an account to the file registry. You must save your configuration changes after running this command to save the new account to the master repository.

Target object

None

Required parameters

-userId
Specifies the ID of the user to add to the file registry. (String, required)

-password
Specifies the password of the user to add to the file registry. (String, required)

Optional parameters

-securityDomainName
Specifies the name that uniquely identifies the security domain. If you do not specify this parameter, the command uses the global federated repository. (String, optional)

-parent
Specifies the parent of the entity. (String, optional)

.

Return value

This command returns a message that indicates that the command ran successfully, as the following example displays:

```
'CWWIM4544I Account newAcct(uid=newAcct,o=defaultWIMFileBasedRealm) is stored in the
file registry in the temporary workspace. You must use the "$AdminConfig save"
command to save it in the master repository.'
```

Batch mode example usage

- Using Jython string:

```
AdminTask.addFileRegistryAccount('[-userId newAcct -password new22password]')
```

Interactive mode example usage

- Using Jython string:

```
AdminTask.addFileRegistryAccount(['-userId', 'newAcct', '-password', 'new22password'])
```

changeFileRegistryAccountPassword command

The changeFileRegistryAccountPassword changes the password for the file registry account.

Target object

None.

Required parameters

-userId
Specifies the user ID of interest. (String, required)

-password
Specifies the new password. (String, required)

Optional parameters

-securityDomainName
Specifies the name that uniquely identifies the security domain. If you do not specify this parameter, the command uses the global federated repository. (String, optional)

-uniqueName
Specifies the fully-qualified unique name of the administrator. (String, optional)

Return value

This command returns a message that indicates that the command ran successfully, as the following example displays:

```
'CWWIM4545I The password is changed for newAcct(uid=newAcct,o=defaultWIMFileBasedRealm)
in the file registry in the temporary workspace. You must use the "$AdminConfig save"
command to save it in the master repository.'
```

Batch mode example usage

- Using Jython string:

```
AdminTask.changeFileRegistryAccountPassword('[-userId newAcct -password newPassword -uniqueName
uid=newAcct,o=defaultWIMFileBasedRealm]')
```

Interactive mode example usage

- Using Jython string:

```
AdminTask.changeFileRegistryAccountPassword(['-userId', 'newAcct', '-password', 'newPassword',
'-uniqueName', 'uid=newAcct,o=defaultWIMFileBasedRealm'])
```

Changing a federated repository configuration to include a single built-in, file-based repository only:

Follow this task to change your federated repository configuration to include a single built-in, file-based repository only.

Before you begin

To change your federated repository configuration to include a single built-in, file-based repository only, you need to know the primary administrative user name of the user who manages WebSphere Application Server resources and user accounts.

Restriction: Client certificate login is not supported in a realm that includes a single built-in, file-based repository or a single built-in, file-based repository with other repositories.

Procedure

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Enter the name of the realm in the Realm name field. If the realm contains a single built-in, file-based repository only, you must specify `defaultWIMFileBasedRealm` as the realm name.
4. Enter the name of the primary administrative user in the Primary administrative user name field, for example, adminUser.
5. Enable the **Ignore case for authorization** option.
6. Click **Use built-in repository** if the built-in, file-based repository is not listed in the collection.
7. Select all repositories in the collection that are not of type File and click **Remove**.
8. Click **OK**.
9. Provide an administrative user password. This panel displays only when a built-in, file-based repository is included in the realm. Otherwise, it does not display. If a built-in, file-based repository is included, complete the following steps:
   a. Supply a password for the primary administrative user in the Password field.
   b. Confirm the password of the primary administrative user in the Confirm password field.
   c. Click **OK**.

Results

After completing these steps, your federated repository configuration, which includes a single built-in, file-based repository only, is configured.

What to do next

1. Before you can manage this account with Users and Groups, configure supported entity types as described in “Configuring supported entity types in a federated repository configuration” on page 1377.
2. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
3. If you are enabling security, complete the remaining steps, as specified in “Enabling security for the realm” on page 1186. As the final step, validate this setup by clicking **Apply** in the Global security panel.
4. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Configuring a single, Lightweight Directory Access Protocol repository in a new configuration under Federated repositories:

Follow this task to configure a single, Lightweight Directory Access Protocol (LDAP) repository in a new configuration under Federated repositories.

Before you begin

To configure an LDAP repository in a new configuration under Federated repositories, you must know a valid user name (ID), the user password, the server host and port and, if necessary, the bind distinguished name (DN) and the bind password. You can choose any valid user in the repository that is searchable. In some LDAP servers, administrative users are not searchable and cannot be used (for example, cn=root in SecureWay). This user is referred to as the WebSphere Application Server *administrative user name* or

administrative ID in the documentation. Being an administrative ID means a user has special privileges when calling some protected internal methods. Normally, this ID and password are used to log in to the administrative console after you turn on security. You can use other users to log in, if those users are part of the administrative roles.

Procedure

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. On the Federated repositories panel, complete the following steps:
   a. Enter the name of the realm in the Realm name field. You can change the existing realm name.
   b. Enter the name of the primary administrative user in the Primary administrative user name field, for example, adminUser.
   c. Optional: Select the **Ignore case for authorization** option. When you enable this option, the authorization check is case-insensitive. Normally, an authorization check involves checking the complete DN of a user, which is unique in the realm and is case-insensitive. Clear this option when all of the member repositories in the realm are case-sensitive.

      Restriction: Some repositories contain data that is case-sensitive only, and some repositories contain data that is case-insensitive only. Do not include both case-sensitive and case-insensitive repositories in the realm. For example, do not include case-sensitive repositories in the realm with a built-in, file-based repository.
   d. Click **Add base entry to realm** to add a base entry that uniquely identifies the external repository in the realm. Then complete the steps in “Adding an external repository in a federated repository configuration” on page 1352.
4. On the Federated repositories panel, complete the following steps:
   a. Select the built-in, file-based repository in the collection, and click **Remove**.

      Restriction: Before you remove the built-in, file-based repository from the administrative realm, verify that at least one user in another member repository is a console user with administrative rights. Otherwise, you must disable security to regain access to the administrative console.
   b. Click **OK**.

Results

After completing these steps, your new configuration under Federated repositories includes a single, LDAP repository only.

What to do next

1. Before you can manage this account with Users and Groups, configure supported entity types as described in “Configuring supported entity types in a federated repository configuration” on page 1377.
2. After configuring the federated repositories, click **Security > Global secuity** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
3. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1186. As the final step, validate this setup by clicking **Apply** in the Global security panel.

4. Save, stop, and restart all the product servers (deployment managers, nodes and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Changing a federated repository configuration to include a single, Lightweight Directory Access Protocol repository only:

Follow this task to change your federated repository configuration to include a single, Lightweight Directory Access Protocol repository (LDAP) repository only.

Before you begin

To configure an LDAP repository in a federated repository configuration, you must know a valid user name (ID), the user password, the server host and port and, if necessary, the bind distinguished name (DN) and the bind password. You can choose any valid user in the repository that is searchable. In some LDAP servers, administrative users are not searchable and cannot be used (for example, cn=root in SecureWay). This user is referred to as a WebSphere Application Server *administrative user name* or *administrative ID* in the documentation. Being an administrative ID means a user has special privileges when calling some protected internal methods. Normally, this ID and password are used to log into the administrative console after you turn on security. You can use other users to log in if those users are part of the administrative roles.

Procedure

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Enter the name of the realm in the Realm name field. You can change the existing realm name.
4. Enter the name of the primary administrative user in the Primary administrative user name field, for example, adminUser.
5. Optional: Select the **Ignore case for authorization** option. When you enable this option, the authorization check is case-insensitive. Normally, an authorization check involves checking the complete DN of a user, which is unique in the realm and is case-insensitive. Clear this option when all of the member repositories in the realm are case-sensitive.

   Restriction: Some repositories contain data that is case-sensitive only, and some repositories contain data that is case-insensitive only. Do not include both case-sensitive and case-insensitive repositories in the realm. For example, do not include case-sensitive repositories in the realm with a built-in, file-based repository.
6. Optional: Click **Add base entry to realm** if the LDAP repository that you need is not contained in the collection. Then complete the steps in “Adding an external repository in a federated repository configuration” on page 1352.
7. On the Federated repositories panel, complete the following steps:
   a. Optional: Select the repositories in the collection that you do not need in the realm and click **Remove**.

      Restriction: The realm must always contain at least one base entry; therefore, you cannot remove every entry.
   b. Click **OK**.

Results

After completing these steps, your federated repository configuration, which includes a single LDAP repository only, is configured.

What to do next

1. Before you can manage this account with Users and Groups, configure supported entity types as described in “Configuring supported entity types in a federated repository configuration” on page 1377.
2. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
3. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1186. As the final step, validate this setup by clicking **Apply** in the Global security panel.
4. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Configuring multiple Lightweight Directory Access Protocol repositories in a federated repository configuration:

Follow this task to configure multiple Lightweight Directory Access Protocol (LDAP) repositories in a federated repository configuration.

Before you begin

To configure an LDAP repository in a federated repository configuration, you must know a valid user name (ID), the user password, the server host and port and, if necessary, the bind distinguished name (DN) and the bind password. You can choose any valid user in the repository that is searchable. In some LDAP servers, administrative users are not searchable and cannot be used (for example, cn=root in SecureWay). This user is referred to as a WebSphere Application Server *administrative user name* or *administrative ID* in the documentation. Being an administrative ID means a user has special privileges when calling some protected internal methods. Normally, this ID and password are used to log into the administrative console after you turn on security. You can use other users to log in if those users are part of the administrative roles.

Procedure

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Enter the name of the realm in the Realm name field. You can change the existing realm name.
4. Enter the name of the primary administrative user in the Primary administrative user name field, for example, adminUser.
5. Optional: Select the **Ignore case for authorization** option. When you enable this option, the authorization check is case-insensitive. Normally, an authorization check involves checking the complete DN of a user, which is unique in the realm and is case-insensitive. Clear this option when all of the member repositories in the realm are case-sensitive.

   Restriction: Some repositories contain data that is case-sensitive only, and some repositories contain data that is case-insensitive only. Do not include both case-sensitive and case-insensitive repositories in the realm. For example, do not include case-sensitive repositories in the realm with a built-in, file-based repository.
6. Optional: Click **Add base entry to realm** if the LDAP repository that you need is not listed in the collection. Then complete the steps in “Adding an external repository in a federated repository configuration” on page 1352.
7. On the Federated repositories panel, complete the following steps:

a. Optional: Repeat step 6 if the LDAP repository that you need is not listed in the collection.
b. Optional: Select the repositories in the collection that you do not need in the realm and click **Remove**. The following restrictions apply:
   - The realm must always contain at least one base entry; therefore, you cannot remove every entry.
   - If you plan to remove the built-in, file-based repository from the administrative realm, verify that at least one user in another member repository is a console user with administrative rights. Otherwise, you must disable security to regain access to the administrative console.
c. Click **OK**.

Results

After completing these steps, your federated repository configuration, which includes multiple LDAP repositories, is configured.

What to do next

1. Before you can manage this account with Users and Groups, configure supported entity types as described in "Configuring supported entity types in a federated repository configuration" on page 1377.
2. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
3. If you are enabling security, complete the remaining steps as specified in "Enabling security for the realm" on page 1186. As the final step, validate this setup by clicking **Apply** in the Global security panel.
4. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Configuring a single built-in, file-based repository and one or more Lightweight Directory Access Protocol repositories in a federated repository configuration:

Follow this task to configure a single built-in, file-based repository and multiple Lightweight Directory Access Protocol (LDAP) repositories in a federated repository configuration.

Before you begin

To configure a built-in, file-based repository in a federated repository configuration, you must know the primary administrative user name of the user who manages WebSphere Application Server resources and user accounts.

To configure an LDAP repository in a federated repository configuration, you must know a valid user name (ID), the user password, the server host and port and, if necessary, the bind distinguished name (DN) and the bind password. You can choose any valid user in the repository that is searchable. In some LDAP servers, administrative users are not searchable and cannot be used (for example, cn=root in SecureWay). This user is referred to as a WebSphere Application Server *administrative user name* or *administrative ID* in the documentation. Being an administrative ID means a user has special privileges when calling some protected internal methods. Normally, this ID and password are used to log in to the administrative console after you turn on security. You can use other users to log in if those users are part of the administrative roles.

Restriction: Client certificate login is not supported in a realm that includes a single built-in, file-based repository or a single built-in, file-based repository with other repositories.

Procedure

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Enter the name of the realm in the Realm name field. You can change the existing realm name.
4. Enter the name of the primary administrative user in the Primary administrative user name field, for example, adminUser.

   Restriction: When you configure multiple repositories that includes a single built-in, file-based repository, the primary administrative user name must exist in the file-based repository. If the primary administrative user name does not exist in the file-based repository, then the name is created in the file-based repository. The primary administrative user name cannot exist in other repositories.
5. Select the **Ignore case for authorization** option.

   Attention: When the realm includes a built-in, file-based repository, you must enable the **Ignore case for authorization** option.
   When you enable this option, the authorization check is case-insensitive. Normally, an authorization check involves checking the complete DN of a user, which is unique in the realm and is case-insensitive. Clear this option when all of the member repositories in the realm are case-sensitive.

   Restriction: Some repositories contain data that is case-sensitive only, and some repositories contain data that is case-insensitive only. Do not include both case-sensitive and case-insensitive repositories in the realm. For example, do not include case-sensitive repositories in the realm with a built-in, file-based repository.
6. Optional: Click **Add base entry to realm** if the LDAP repository that you need is not contained in the collection. Then complete the steps in “Adding an external repository in a federated repository configuration” on page 1352.
7. On the Federated repositories panel, complete the following steps:
   a. Optional: Repeat step 6 if the LDAP repository that you need is not listed in the collection.
   b. Click **Use built-in repository** if the built-in, file-based repository is not listed in the collection.
   c. Optional: Select the repositories in the collection that you do not need in the realm and click **Remove**.

      Restriction: The realm must always contain at least one base entry; therefore, you cannot remove every entry.
   d. Click **OK**.
8. Provide an administrative user password. This panel displays only when a built-in, file-based repository is included in the realm. Otherwise, the panel does not display. If a built-in, file-based repository is included, complete the following steps:
   a. Supply a password for the administrative user in the Password field.
   b. Confirm the password of the primary administrative user in the Confirm password field.
   c. Click **OK**.

Results

After completing these steps, your federated repository configuration, which includes a single built-in, file-based repository and one or more LDAP repositories, is configured.

What to do next

1. Before you can manage this account with Users and Groups, configure supported entity types as described in “Configuring supported entity types in a federated repository configuration” on page 1377.

2. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
3. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1186. As the final step, validate this setup by clicking **Apply** in the Global security panel.
4. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Manually configuring an Lightweight Directory Access Protocol repository in a federated repository configuration:

Follow this topic to manually configure Lightweight Directory Access Protocol (LDAP) repository in a federated repository configuration.

Before you begin

As a prerequisite, you need to add a LDAP repository to your WebSphere Application Server configuration, where you define the following information:

Table 85. Prerequisite LDAP repository information.

This table lists prerequisite LDAP repository information,

Item Name	Example
Repository identifier	`ldaprepo1`
Directory type	IBM Tivoli Directory Server
Primary host name	`localhost`
Port	`389`
Bind distinguished name	`cn=ldapadmin`
Bind password	`yourpwd`
Login properties	`uid` (a property containing login information)

See “Lightweight Directory Access Protocol repository configuration settings” on page 1343 for the specific steps you must perform to establish this LDAP repository.

About this task

At this point, you have a valid LDAP repository ready to be manually configured in a federated repository configuration.

Procedure

1. Map the federated repository entity types to the LDAP object classes.
   a. Configure the LDAP repository to match the used LDAP object class for users.
      1) In the administrative console, click **Security > Global security**.
      2) Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
      3) Under Related items, click **Manage repositories**.
      4) Select the repository (for example, `ldaprepo1`).
      5) Click **LDAP entity types**.

6) Click **PersonAccount**.
7) Insert the *objectclass* name used in our LDAP server, for example, `inetOrgPerson`.
8) Click **Apply**.
9) Click **Save**.

See “Configuring supported entity types in a federated repository configuration” on page 1377 for an explanation of the supported entity types.

See http://publib.boulder.ibm.com/infocenter/wasinfo/v6r1/topic/com.ibm.websphere.wim.doc.en/ldap.html for a description of the LDAP default mappings.

b. Configure the LDAP repository to match the used LDAP *objectclass* for groups
1) In the administrative console, click **Security > Global security**.
2) Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3) Under Related items, click **Manage repositories**.
4) Select `ldaprepo1`.
5) Click **LDAP entity types**.
6) Click **Group**.
7) Insert the objectclass name used for your LDAP server, for example, `groupOfUniqueNames`.
8) Click **Apply**.
9) Click **Save**.

See “Group attribute definition settings” on page 1400 for an explanation of group attribute definitions.

2. Map the federated repository property names to the LDAP attribute names.
a. Configure the LDAP repository to match the used LDAP attributes for a user.
1) Edit the file

```
{WAS_HOME}\profiles\{profileName}\config\cells\{cellName}\wim\config\wimconfig.xml
```

2) Look for the section in this file containing the LDAP repository configuration, For example,
a)

```
<config:repositories
xsi:type="config:LdapRepositoryType"
adapterClassName="com.ibm.ws.wim.adapter.ldap.LdapAda
pter" id="ldaprepo1" ...>
```

b)

```
<config:attributeConfiguration>
```

c)

```
...
```

d)

```
<config:attributes name="anLDAPattribute"
propertyName="aVMMattribute"/>
```

e)

```
...
<config:attributeConfiguration>
```

3) Add an element of type `config:attributes` to define the mapping between a given federated depository property name, such as `departmentNumber`, to a desired LDAP attribute name, such as `warehouseSection`.

Note: For all given federated depository properties, a one-to-one mapping is assumed. If no explicit mapping of the above type is defined, for example the federated repository property `departmentNumber`, the underlying LDAP attribute name, `departmentNumber` is assumed.

b. Configure the unsupported properties of the federated repository.

To indicate that a given federated repository property, such as `departmentNumber` is not supported by any LDAP attributes, you need to define the following type of element:

```
<config:repositories xsi:type="config:LdapRepositoryType"
adapterClassName="com.ibm.ws.wim.adapter.ldap.LdapAdapter"
id="ldaprepo1" ...>
<config:attributeConfiguration>
...
<config:propertiesNotSupported name=" departmentNumber"/>
...
<config:attributeConfiguration>
```

c. Configure the LDAP repository to match the used LDAP user membership attribute in the groups.
   1) In the administrative console, click **Security > Global security**.
   2) Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
   3) Under Related items, click **Manage repositories**.
   4) Select `ldaprepo1`
   5) Click **Group attribute defintions**.
   6) Click **Member attributes**.
   7) Check if your LDAP attributes (for example, `uniqueMember`) is specified for your LDAP objectclass (for example, `groupOfUniqueNames`).
      - If not specified, click **New** and add the pair (*objectclass / member attribute name*) that applies to your LDAP schema (for example, `uniqueMember / groupOfUniqueNames`
      - If specified, proceed.
   8) Click **Apply**.
   9) Click **Save**.

3. Map other LDAP settings by configuring a new base entry for the new LDAP repository.
   a. In the administrative console, click **Security > Global security**.
   b. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
   c. Click **Add Base Entry to Realm**.
   d. Select `ldaprepo1`.
   e. Specifiy:
      - The base entry within the federated repository realm, for example, `o=Default Organization`
      - The base entry within the LDAP repository, for example, `o=Default Organization`
   f. Click **Apply**.
   g. Click **Save**.

   For an explanation of base entries, see the Configuring supported entity types in a federated repository configuration topic.

Results

After completing these steps, your federated repository matches the LDAP server settings.

What to do next

Configuring Lightweight Directory Access Protocol in a federated repository configuration:

Follow this topic to configure Lightweight Directory Access Protocol (LDAP) settings in a federated repository configuration.

Before you begin

You have chosen among various ways to configure LDAP:

- "Configuring a single, Lightweight Directory Access Protocol repository in a new configuration under Federated repositories" on page 1331

- “Changing a federated repository configuration to include a single, Lightweight Directory Access Protocol repository only” on page 1333
- “Configuring multiple Lightweight Directory Access Protocol repositories in a federated repository configuration” on page 1334
- “Configuring a single built-in, file-based repository and one or more Lightweight Directory Access Protocol repositories in a federated repository configuration” on page 1335
- “Managing repositories in a federated repository configuration” on page 1380

About this task

At this point, you are viewing the LDAP repository configuration page of the administrative console.

Procedure

1. Enter a unique identifier for the repository in the Repository identifier field. This identifier uniquely identifies the repository within the cell, for example: LDAP1.
2. Select the type of LDAP server that is used from the Directory type list. The type of LDAP server determines the default filters that are used by WebSphere Application Server.

   IBM Tivoli Directory Server users can choose either IBM Tivoli Directory Server or SecureWay as the directory type. Use the IBM Tivoli Directory Server directory type for better performance. For a list of supported LDAP servers, see “Using specific directory servers as the LDAP server” on page 1275.
3. Enter the fully qualified host name of the primary LDAP server in the Primary host name field. You can enter either the IP address or the domain name system (DNS) name.
4. Enter the server port of the LDAP directory in the Port field. The host name and the port number represent the realm for this LDAP server in a mixed version nodes cell. If servers in different cells are communicating with each other using Lightweight Third Party Authentication (LTPA) tokens, these realms must match exactly in all the cells.

   The default value is 389, which is not a Secure Sockets Layer (SSL) connection. Use port 636 for a Secure Sockets Layer (SSL) connection. For some LDAP servers, you can specify a different port for a non-SSL or SSL connection. If you do not know the port to use, contact your LDAP server administrator.

   If multiple WebSphere Application Servers are installed and configured to run in the same single sign-on domain, or if WebSphere Application Server interoperates with a previous version of WebSphere Application Server, then it is important that the port number match all configurations. For example, if the LDAP port is explicitly specified as 389 in a Version 5.x or 6.0.x configuration, and WebSphere Application Server at Version 6.1 is going to interoperate with the Version 5.x or 6.0.x server, then verify that port 389 is specified explicitly for the Version 6.1 server.
5. Optional: Enter the host name of the failover LDAP server in the Failover host name field. You can specify a secondary directory server to be used in the event that your primary directory server becomes unavailable. After switching to a secondary directory server, LDAP repository attempts to reconnect to the primary directory server every 15 minutes.
6. Optional: Enter the port of the failover LDAP server in the Port field and click **Add**. The default value is 389, which is not a Secure Sockets Layer (SSL) connection. Use port 636 for a Secure Sockets Layer (SSL) connection. For some LDAP servers, you can specify a different port for a non-SSL or SSL connection. If you do not know the port to use, contact your LDAP server administrator.
7. Optional: Select the type of *referral*. A referral is an entity that is used to redirect a client request to another LDAP server. A referral contains the names and locations of other objects. It is sent by the server to indicate that the information that the client requested can be found at another location, possibly at another server or several servers. The default value is ignore.

   ignore
   Referrals are ignored.

   follow Referrals are followed automatically.

8. Optional: Enter the bind DN name in the Bind distinguished name field, for example, cn=root. The bind DN is required if anonymous binds are not possible on the LDAP server to obtain user and group information or for write operations. In most cases, bind DN and bind password are needed. However, when anonymous bind can satisfy all of the required functions, bind DN and bind password are not needed. If the LDAP server is set up to use anonymous binds, leave this field blank. If a name is not specified, the application server binds anonymously.

   Note: To create LDAP queries or to browse, an LDAP client must bind to the LDAP server using the distinguished name (DN) of an account that has the authority to search and read the values of LDAP attributes, such as user and group information. The LDAP administrator ensures that **read access privileges** are set for the bind DN. Read access privileges allow access to the subtree of the base DN and ensure that searches of user and group information are successful.

   The directory server provides an operational attribute in each directory entry (for example, the IBM Directory Server uses ibm-entryUuid as the operational attribute). The value of this attribute is a universally unique identifier (UUID), which is chosen automatically by the directory server when the entry is added, and is expected to be unique: no other entry with the same or different name would have this same value. Directory clients may use this attribute to distinguish objects identified by a distinguished name or to locate an object after renaming. **Ensure that the bind credentials have the authority to read this attribute.**
9. Optional: Enter the password that corresponds to the bind DN in the Bind password field.
10. Optional: Enter the property names to use to log into WebSphere Application Server in the Login properties field. This field takes multiple login properties, delimited by a semicolon (;). For example, `uid;mail`.

    All login properties are searched during login. If multiple entries or no entries are found, an exception is thrown. For example, if you specify the login properties as `uid;mail` and the login ID as Bob, the search filter searches for uid=Bob or mail=Bob. When the search returns a single entry, then authentication can proceed. Otherwise, an exception is thrown.

    Note: If you define multiple login properties, then the first login property is programmatically mapped to the federated repositories principalName property. For example, if you set `uid;mail` as the login properties, the LDAP attribute uid value is mapped to the federated repositories principalName property. If you define multiple login properties, after login, the first login property is returned as the value of the principalName property. For example, if you pass `joe@yourco.com` as the principalName value and the login properties are configured as uid;mail, the principalName is returned as joe.
11. Optional: Select the certificate map mode in the Certificate mapping field. You can use the X.590 certificates for user authentication when LDAP is selected as the repository. The Certificate mapping field is used to indicate whether to map the X.509 certificates into an LDAP directory user by EXACT_DN or CERTIFICATE_FILTER. If EXACT_DN is selected, the DN in the certificate must exactly match the user entry in the LDAP server, including case and spaces.
12. If you select **CERTIFICATE_FILTER** in the Certificate mapping field, specify the LDAP filter for mapping attributes in the client certificate to entries in LDAP.

    If more than one LDAP entry matches the filter specification at run time, authentication fails because the result is an ambiguous match. The syntax or structure of this filter is:

    ```
    LDAP attribute=${Client certificate attribute}
    ```

    For example, `uid=${SubjectCN}`.

    The left side of the filter specification is an LDAP attribute that depends on the schema that your LDAP server is configured to use. The right side of the filter specification is one of the public attributes in your client certificate. The right side must begin with a dollar sign ($) and open bracket ({) and end with a close bracket (}). You can use the following certificate attribute values on the right side of the filter specification. The case of the strings is important:
    - `${UniqueKey}`

- ${PublicKey}
- ${PublicKey}
- ${Issuer}
- ${NotAfter}
- ${NotBefore}

- ${SigAlgName}
- ${SigAlgOID}
- ${SigAlgParams}
- ${SubjectCN}
- ${Version}

13. Optional: Select the **Require SSL communications** option if you want to use Secure Sockets Layer communications with the LDAP server.

    If you select the **Require SSL communications** option, you can select either the **Centrally managed** or **Use specific SSL alias** option.

    Centrally managed

    Enables you to specify an SSL configuration for a particular scope, such as the cell, node, server, or cluster in one location. To use the Centrally managed option, you must specify the SSL configuration for the particular set of endpoints. The Manage endpoint security configurations and trust zones panel displays all of the inbound and outbound endpoints that use the SSL protocol. If you expand the Inbound or Outbound section of the panel and click the name of a node, you can specify an SSL configuration that is used for every endpoint on that node. For an LDAP registry, you can override the inherited SSL configuration by specifying an SSL configuration for LDAP. To specify an SSL configuration for LDAP, complete the following steps:

    a. Click **Security > SSL certificate and key management > Manage endpoint security configurations and trust zones**.

    b. Expand **Outbound >** *cell_name* **> Nodes >** *node_name* **> Servers >** *server_name* **> LDAP**.

    Use specific SSL alias

    Select the **Use specific SSL alias** option if you intend to select one of the SSL configurations in the menu that follows the option.

    This configuration is used only when SSL is enabled for LDAP. The default is *DefaultSSLSettings*. To modify or create a new SSL configuration, complete the following steps:

    a. Click **Security > SSL certificate and key management**.

    b. Under Configuration settings, click **Manage endpoint security configurations and trust zones >** *configuration_name*.

    c. Under Related items, click **SSL configurations**.

14. Click **OK**.

Results

After completing these steps, your LDAP repository settings are configured.

What to do next

Return to the appropriate task to complete the steps for your federated repository configuration:
- “Configuring a single, Lightweight Directory Access Protocol repository in a new configuration under Federated repositories” on page 1331
- “Changing a federated repository configuration to include a single, Lightweight Directory Access Protocol repository only” on page 1333

- “Configuring multiple Lightweight Directory Access Protocol repositories in a federated repository configuration” on page 1334
- “Configuring a single built-in, file-based repository and one or more Lightweight Directory Access Protocol repositories in a federated repository configuration” on page 1335
- “Managing repositories in a federated repository configuration” on page 1380

Lightweight Directory Access Protocol repository configuration settings:

Use this page to configure secure access to a Lightweight Directory Access Protocol (LDAP) repository with optional failover servers.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

Repository identifier:

Specifies a unique identifier for the LDAP repository. This identifier uniquely identifies the repository within the cell, for example: LDAP1.

Directory type:

Specifies the type of LDAP server to which you connect.

Expand the drop-down list to display a list of LDAP directory types.

Primary host name:

Specifies the host name of the primary LDAP server. This host name is either an IP address or a domain name service (DNS) name.

Port:

Specifies the LDAP server port.

The default value is 389, which is not a Secure Sockets Layer (SSL) connection. Use port 636 for a Secure Sockets Layer (SSL) connection. For some LDAP servers, you can specify a different port for a non-SSL or SSL connection. If you do not know the port to use, contact your LDAP server administrator.

Data type:	Integer	
Default:	389	
Range:	389, which is not a Secure Sockets Layer (SSL) connection	636, which is a Secure Sockets Layer (SSL) connection

Failover host name:

Specifies the host name of the failover LDAP server.

You can specify a secondary directory server to be used in the event that your primary directory server becomes unavailable. After switching to a secondary directory server, the LDAP repository attempts to reconnect to the primary directory server every 15 minutes.

Port:

Specifies the port of the failover LDAP server.

The default value is 389, which is not a Secure Sockets Layer (SSL) connection. Use port 636 for a Secure Sockets Layer (SSL) connection. For some LDAP servers, you can specify a different port for a non-SSL or SSL connection. If you do not know the port to use, contact your LDAP server administrator.

Data type:	Integer	
Range:	389, which is not a Secure Sockets Layer (SSL) connection	636, which is a Secure Sockets Layer (SSL) connection

Support referrals to other LDAP servers:

Specifies how referrals that are encountered by the LDAP server are handled.

A referral is an entity that is used to redirect a client request to another LDAP server. A referral contains the names and locations of other objects. It is sent by the server to indicate that the information that the client requested can be found at another location, possibly at another server or several servers. The default value is ignore.

Default:	ignore
Range:	**ignore** Referrals are ignored.
	follow Referrals are followed automatically.

Support for repository change tracking:

Specifies the type of support for repository change tracking, wih is one of the following:

none Specifies there is no change tracking support for this repository.

native Specifies that the repository's native change tracking mechanism is used by virtual member manager to return changed entities.

Custom properties:

Specifies arbitrary name and value pairs of data. The name is a property key and the value is a string value that can be used to set internal system configuration properties.

Defining a new property enables you to configure a setting beyond that which is available in the administrative console.

Bind distinguished name:

Specifies the distinguished name (DN) for the application server to use when binding to the LDAP repository.

If no name is specified, the application server binds anonymously. In most cases, bind DN and bind password are needed. However, when anonymous bind can satisfy all of the required functions, bind DN and bind password are not needed.

Bind password:

Specifies the password for the application server to use when binding to the LDAP repository.

Login properties:

Specifies the property names to use to log into the application server.

This field takes multiple login properties, delimited by a semicolon (;). For example, `uid;mail`. All login properties are searched during login. If multiple entries or no entries are found, an exception is thrown. For example, if you specify the login properties as `uid;mail` and the login ID as Bob, the search filter searches for uid=Bob or mail=Bob. When the search returns a single entry, then authentication can proceed. Otherwise, an exception is thrown.

Note: If you define multiple login properties, then the first login property is programmatically mapped to the federated repositories principalName property. For example, if you set `uid;mail` as the login properties, the LDAP attribute uid value is mapped to the federated repositories principalName property. If you define multiple login properties, after login, the first login property is returned as the value of the principalName property. For example, if you pass `joe@yourco.com` as the principalName value and the login properties are configured as uid;mail, the principalName is returned as joe.

LDAP attribute for Kerberos principal name:

Specifies the LDAP attribute for Kerberos principal name. This field can be modified when Kerberos is configured and it is one of the active or preferred authentication mechanisms.

Certificate mapping:

Specifies whether to map X.509 certificates into an LDAP directory by EXACT_DN or CERTIFICATE_FILTER. Specify CERTIFICATE_FILTER to use the specified certificate filter for the mapping.

Certificate filter:

Specifies the filter certificate mapping property for the LDAP filter. The filter is used to map attributes in the client certificate to entries in the LDAP repository.

If more than one LDAP entry matches the filter specification at run time, authentication fails because the result is an ambiguous match. The syntax or structure of this filter is:

```
LDAP attribute=${Client certificate attribute}
```

An example of a simple certificate filter is: `uid=${SubjectCN}`.

You can also specify multiple properties and values as part of the certificate filter. Two examples of complex certificate filters are:

```
(&(cn=${IssuerCN}) (employeeNumber=${SerialNumber})

(& (issuer=${IssuerDN}) (serial=${SerialNumber}) (subjectdn=${SubjectDN}))
```

The left side of the filter specification is an LDAP attribute that depends on the schema that your LDAP server is configured to use. The right side of the filter specification is one of the public attributes in your client certificate. You can also use the **UniqueKey** certificate variable, which consists of the base64-encoding of the MD5 hash of the subject DN and issuer DN. The right side must begin with a

dollar sign ($) and open bracket ({) and end with a close bracket (}). You can use the following certificate attribute values on the right side of the filter specification. The case of the strings is important:
- `${UniqueKey}`
- `${PublicKey}`
- `${IssuerDN}`
- `${Issuer`*xx*`}` where *xx* is replaced by the characters that represent any valid component of the Issuer Distinguished Name. For example, you might use `${IssuerCN}` for the Issuer Common Name.
- `${NotAfter}`
- `${NotBefore}`
- `${SerialNumber}`
- `${SigAlgName}`
- `${SigAlgOID}`
- `${SigAlgParams}`
- `${SubjectDN}`
- `${Subject`*xx*`}` where *xx* is replaced by the characters that represent any valid component of the Subject Distinguished Name. For example, you might use `${SubjectCN}` for the Subject Common Name.
- `${Version}`

Require SSL communications:

Specifies whether secure socket communication is enabled to the LDAP server.

When enabled, the Secure Sockets Layer (SSL) settings for LDAP are used, if specified.

Centrally managed:

Specifies that the selection of an SSL configuration is based upon the outbound topology view for the Java Naming and Directory Interface (JNDI) platform.

Centrally managed configurations support one location to maintain SSL configurations, rather than spreading them across the configuration documents.

Default:	Enabled
Range:	Enabled or Disabled

Use specific SSL alias:

Specifies the SSL configuration alias to use for LDAP outbound SSL communications.

This option overrides the centrally managed configuration for the JNDI platform.

Migrating a stand-alone LDAP repository to a federated repositories LDAP repository configuration:

When configuring the security for your application server, you might need to migrate a stand-alone LDAP registry to a federated repositories LDAP repository configuration.

Before you begin

Note the specifications of your stand-alone LDAP repository that you want to migrate, for reference when configuring the LDAP repository in federated repositories. To access these fields, on the administrative console, click **Security > Global security**. To access these fields in a multiple security domain environment, click **Security > Security domains > DomainName**, and then, under Security Attributes, expand User Realm, and click **Customize for this domain**. Select a Realm type. and then click **Configure**.

The following table shows the administrative console panels and fields of the stand-alone LDAP repository configuration and their corresponding fields in a federated repositories LDAP repository configuration for mapping.

Table 86. Mapping between a stand-alone LDAP repository configuration and a federated repositories LDAP repository configuration. This table illustrates the mapping between a stand-alone LDAP repository configuration and a federated repositories LDAP repository configuration.

Stand-alone LDAP repository configuration	**LDAP repository in a federated repositories configuration**
Global security > Standalone LDAP registry General properties – Primary administrative user name	Global security > Federated repositories General properties – Primary administrative user name
Global security > Standalone LDAP registry LDAP server – Type of LDAP server	Global security > Federated repositories > Manage repositories > *repository_ID* LDAP server – Directory Type
Global security > Standalone LDAP registry LDAP server – Host	Global security > Federated repositories > Manage repositories > *repository_ID* LDAP server – Primary host name
Global security > Standalone LDAP registry LDAP server – Port	Global security > Federated repositories > Manage repositories > *repository_ID* LDAP server – Port
Global security > Standalone LDAP registry LDAP server – Failover hosts	Global security > Federated repositories > Manage repositories > *repository_ID* LDAP server – Failover server used when primary is not available
Global security > Standalone LDAP registry LDAP server – Base distinguished name (DN)	Global security > Federated repositories > Repository reference (Click Add Base entry to realm) General properties – Distinguished name of a base entry that uniquely identifies this set of entries in the realm and General properties – Distinguished name of a base entry in this repository
Global security > Standalone LDAP registry LDAP server – Search timeout	Global security > Federated repositories > Manage repositories > *repository_ID* > Performance General properties - Limit search time
Global security > Standalone LDAP registry LDAP server – Custom properties	Global security > Federated repositories > Custom properties
Global security > Standalone LDAP registry LDAP server – Server user identity	Global security > Federated repositories General properties – Server user identity
Global security > Standalone LDAP registry Security – Bind distinguished name (DN)	Global security > Federated repositories > Manage repositories > *repository_ID* Security – Bind distinguished name
Global security > Standalone LDAP registry Security – Bind password	Global security > Federated repositories > Manage repositories > *repository_ID* Security – Bind password

Table 86. Mapping between a stand-alone LDAP repository configuration and a federated repositories LDAP repository configuration (continued). This table illustrates the mapping between a stand-alone LDAP repository configuration and a federated repositories LDAP repository configuration.

Stand-alone LDAP repository configuration	LDAP repository in a federated repositories configuration
Global security > Standalone LDAP registry > Advanced Lightweight Directory Access Protocol (LDAP) user registry settings General properties – Kerberos user filter	Global security > Federated repositories > Manage repositories > *repository_ID* Security – LDAP attribute used for Kerberos principal name
Global security > Standalone LDAP registry > Advanced Lightweight Directory Access Protocol (LDAP) user registry settings General properties – Certificate map mode	Global security > Federated repositories > Manage repositories > *repository_ID* Security – Certificate mapping
Global security > Standalone LDAP registry > Advanced Lightweight Directory Access Protocol (LDAP) user registry settings General properties – Certificate filter	Global security > Federated repositories > Manage repositories > *repository_ID* Security – Certificate filter

The Realm name field under General Properties on the federated repositories LDAP configuration panel is not listed in the previous table because it does not have a one-to-one correspondence with a field in the stand-alone LDAP configuration panel. The host name and the port number represent the realm name for the standalone LDAP server in the WebSphere Application Server cell. For information on changing the realm name, see the topic Realm configuration settings.

The User Filter, Group Filter, User ID map, Group ID map, and Group member ID map fields also are not listed in the previous table as they do not have a one-to-one correspondence with fields in the federated repositories LDAP repository configuration panel. These LDAP attributes are set differently in the federated repositories LDAP repository configuration and involve multiple steps. These settings are explained in detail in the following sections and procedure.

About this task

Migrating from a stand-alone LDAP repository configuration to a federated repositories LDAP repository configuration involves migrating the configuration parameters, most of which are straight forward as shown in Table 1 in the previous section. Migrating the search filters is an important part of migrating a stand-alone LDAP repository configuration to a federated repository LDAP configuration; therefore, the concept and migration of LDAP search filters is described here in detail.

Stand-alone LDAP registry search filters follow the LDAP filter syntax, where you specify the attribute on which the search is based and its value.

The user filter is used for searching the registry for users. It is used to authenticate a user by using the attribute specified in the filter.

The group filter is used for searching the registry for groups. It specifies the property by which to look up groups.

Examples of commonly used LDAP user filters: In the following examples of search filters, %v is replaced with the corresponding search pattern of the user or group at run time.

```
(&(uid=%v)(objectclass=ePerson))
```

Searches for users where the uid attribute matches the specified search pattern of the ePerson object class.

```
(&(cn=%v)(objectclass=user))
```

Searches for users where the cn attribute matches the specified search pattern of the user object class.

```
(&(sAMAccountName=%v)(objectcategory=user))
```

Searches for users where the sAMAccountName attribute matches the specified search pattern of the user object category.

```
(&(userPrincipalName=%v)(objectcategory=user))
```

Searches for users where the userPrinciplalName attribute matches the specified search pattern of the user object category.

```
(&(mail=%v)(objectcategory=user))
```

Searches for users where the mail attribute matches the specified search pattern of the user object category.

```
(&(|(sAMAccountName=%v)(userPrincipalName=%v))(objectcategory=user))
```

Searches for users where the sAMAccountName or the userPrincipalName matches the specified search pattern of the user object category.

Examples of commonly used group filters:

```
(&cn=%v)(objectCategory=group)
```

Looks up groups based on their common names (cn).

```
(&(cn=%v)(|(objectclass=groupOfNames)(objectclass=groupOfUniqueNames)))
```

Looks up groups based on their common names (cn) and by using the object class of either groupOfNames or groupOfUniqueNames.

As shown in these examples, a stand-alone LDAP registry search filter consists of LDAP attributes and object classes, based on which the search or login is performed.

You can also specify the LDAP attributes and object classes in the LDAP adapter configuration of federated repositories, but they are configured differently and provide more flexibility. In federated repositories the user is represented as PersonAccount entity type and group as Group entity type. Each entity type can have its own RDN (Relative Distinguished Name) property (rdnProperties) and object class. For example, the default RDN property of PersonAccount is uid, and the default RDN property of Group is cn. The default object class mapping depends on the LDAP server type. For example, for Tivoli Directory Server, the object class for PersonAccount is inetOrgPerson and object class for Group is groupOfNames. PersonAccount can also have login properties. When a user logs in or a search is performed for a user in a user registry, these login properties are matched with the pattern. For example, if the login properties are uid and mail, then for the search pattern, a*, all the users who match uid=a* or mail=a* are returned.

gotcha: You can specify the value of User ID Map property (userIdMap) of the stand-alone LDAP repository as the RDN property (rdnProperties) or the first login property (loginProperties) in federated repositories. Though you can set both the RDN property and the login property in federated repositories, it is sufficient if you set only the RDN property. The login property is

optional and you need to set it only if the login property is different from RDN property or if there are more than one login properties. If both the RDN property and login property are set, the login property takes precedence over RDN property.

Migrating search filters involves one or more of the following steps: setting the correct login properties, mapping the attributes of the back-end repository to the federated repositories properties, setting the object class, setting the search filter by using object class or object category, and setting the member or membership attribute. This mapping and configuration for federated repositories is maintained in the wimconfig.xml file.

The stand-alone LDAP registry search filter can be split into two parts:

- User or group attributes filter
- User or group object class or object category filter

For example, in the search filter, `(&(cn=%v)(objectclass=user))`:

- The attribute filter is (cn=%v)
- The object class filter is (objectclass=user)

These two filters are mapped separately in a federated repositories configuration:

- The attribute filter is mapped to the RDN properties or login properties configuration for user and to RDN properties configuration for group.
- The object class filter is mapped to the entity type configuration of the LDAP adapter.

The default attribute and object class mapping is set based on the LDAP server type but additional steps might be required to migrate these two filters:

- attribute filter:
  - Setting either or both the RDN property and login properties (if applicable)
  - Mapping the federated repository property to the LDAP attribute (if applicable)
- object class filter:
  - Setting the object class for entity type (if applicable)
  - Setting the search filter of entity type (if applicable)

Some of the steps in the following procedure include two examples. In these steps:

- Example 1 is applicable to the scenario where you are migrating the search filter `(&(cn=%v)(objectclass=ePerson))` from a stand-alone IBM Tivoli Directory Server LDAP repository to a federated repositories LDAP repository with the identifier LDAPTDS.
- Example 2 is applicable to the scenario where you are migrating the search filter `(&(|(sAMAccountName=%v)(userPrincipalName=%v))(objectcategory=user))` from a stand-alone Microsoft Active Directory LDAP repository to a federated repositories LDAP repository with the identifier LDAPAD. sAMAccountName and userPrincipalName attributes are not defined in federated repositories, so these attributes must be mapped to federated repository properties.

Procedure

1. Add the LDAP repository that you want to migrate to the federated repositories configuration.

   See Table 1 in the Before you begin section of this topic, and follow the steps described in the topic *Configuring a single, Lightweight Directory Access Protocol repository in a new configuration under Federated repositories*. These steps include links to other procedures that you must complete such as:

   - Adding an external repository in a federated repository configuration.
   - Configuring supported entity types in a federated repository configuration.
   - Configuring Lightweight Directory Access Protocol in a federated repository configuration.

After you complete these steps, the LDAP repository that you want to migrate will be successfully configured in the federated repository configuration.

2. Set the login properties (if applicable).

   Login properties are the property names that are used to log on to the WebSphere Application Server. You can specify multiple login properties by using the semicolon (;) as a delimiter. The federated repositories properties commonly used as login properties are uid, cn, sn, givenName, mail, and so on.

   To set login properties on the administrative console, follow the steps in the topic *Lightweight Directory Access Protocol repository configuration settings*, and apply the settings under the section, Login properties.

   Example 1: In the **Login properties** field, enter `cn`.

   Example 2: In the **Login properties** field, enter `uid;cn`.

   Complete Step 3 to map these properties to LDAP attributes.

3. Map the federated repository property to the LDAP attribute (if applicable).

   If the LDAP attribute is not a federated repository property, then the login property that you defined must be mapped to the LDAP attribute.

   a. In the administrative console, click **Global security > Federated repositories > Manage repositories >** *repository_ID*, and then, under Additional properties, click the **LDAP attributes** link.

   b. If the attribute mapping exists, you must first delete the existing mapping for the LDAP attribute, and then add a new mapping for the attribute. Select the checkbox next to the LDAP attribute name and click **Delete**.

   c. To add an attribute mapping, click **Add**, and select **Supported** from the drop-down menu. Enter the LDAP attribute name in the **Name** field, the federated repositories property name in the **Property name** field, and the entity type which applies the attribute mapping in the **Entity types** field.

   Example 1: Because the federated repository property cn is implicitly mapped to the cn LDAP attribute, no additional mapping is required.

   Example 2: Here the search filter includes two LDAP attributes, sAMAccountName and userPrincipalName.

   - For the LDAP server type, Active Directory, the LDAP attribute sAMAccountName is mapped by default to the federated repositories property, uid, as shown in the list of attributes on LDAP attributes panel. Therefore, you do not have to execute the addIdMgrLDAPAttr command to add an attribute configuration for sAMAccountName.
   - If an attribute mapping for the LDAP attribute userPrincipalName exists, then delete the existing attribute mapping before adding a new configuration.
     a. Select the checkbox next to **userPrincalName** and click **Delete**.
     b. Click **Add**, and select **Supported** from the drop-down menu.
     c. In the **Name** field, enter `userPrincipalName`.
     d. In the **Property name** field, enter `cn`.
     e. In the **Entity types** field, enter `PersonAccount`.

4. Set the object class for an entity type (if applicable).

   gotcha: Before executing this step, check the current mapping . If the object class mapping is already set, skip this step.

   To set the object class for an entity type on the administrative console, follow the steps in the topic *Lightweight Directory Access Protocol entity types settings*, and apply the following settings under the section, Object classes:

   - Specify `PersonAccount` as the entity type name for user filters
   - Specify `Group` as the entity type name for group filters.

Example 1: In the **Entity type** field, enter `PersonAccount`.

In the **Object classes** field, enter `ePerson`.

Example 2: In the **Entity type** field, enter `PersonAccount`.

In the **Object classes** field, enter `user`.

5. Set the search filter for the entity type (if applicable).

   Federated repositories performs the search based on the object class setting. To change this default setting and use object category as the filter, follow the steps in topic *Lightweight Directory Access Protocol entity types settings*, and apply the settings under the section, Search Filter.

   Example 1: Because the search is based on object class, no additional configuration is required.

   Example 2: In the **Search filter** field, enter `(objectcategory=user)`.

6. To migrate group filters, you must also configure the group attribute definition settings.

   The steps to configure the group attribute definition settings through the administrative console are specified in the topic *Locating user group memberships in a Lightweight Directory Access Protocol registry*, under the section, LDAP Registry within a Federated Repositories Registry. You can also use the wsadmin commands addIdMgrLDAPGroupDynamicMemberAttr or addIdMgrLDAPGroupMemberAttr that are described in the topic *IdMgrRepositoryConfig command group for the AdminTask object*.

7. Save your configuration changes
8. Restart the application server.

Results

After completing these steps, your LDAP repository is configured for use within the federated repositories configuration.

Adding an external repository in a federated repository configuration:

Follow this task to add an external repository into a federated repository configuration.

Procedure

1. If the Lightweight Directory Access Protocol (LDAP) repository that you want to add to your federated repository configuration is previously configured, select the corresponding Repository on the Repository reference panel. To access the Repository reference panel, complete the following steps:
   a. Click **Security > Global security**.
   b. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
   c. Click **Add base entry to realm**.
2. Enter a distinguished name for the realm base entry in the Distinguished name that uniquely identifies... field. This base entry must uniquely identify the external repository in the realm. If multiple repositories are included in the realm, use this field to define an additional distinguished name (DN) that uniquely identifies this set of entries within the realm. For example, repositories LDAP1 and LDAP2 might both use o=ibm,c=us as the base entry in the repository. Use the DN in this field to uniquely identify this set of entries in the realm. For example: o=ibm,c=us for LDAP1 and o=ibm2,c=us for LDAP2. The specified DN in this field maps to the LDAP DN of the base entry within the repository.
3. Enter the LDAP DN of the base entry within the repository in the Distinguished name of a base entry... field. The base entry indicates the starting point for searches in this LDAP directory server. This entry and its descendents are mapped to the subtree that is identified by this unique base name entry field. For example, for a user with a DN of `cn=John Doe, ou=Rochester, o=IBM, c=US`, specify the LDAP base entry as any of the following options:

`ou=Rochester, o=IBM, c=us` or `o=IBM, c=us` or `c=us`

In most cases, this LDAP DN is the same as the distinguished name for the realm base entry.

If this field is left blank, then the subtree defaults to the root of the LDAP repository. Consult your LDAP administrator to determine if your LDAP repository provides support to search from the root, or create users and groups under the root without defining a suffix beforehand.

In WebSphere Application Server, the distinguished name is normalized according to the LDAP specification. Normalization consists of removing spaces in the base distinguished name before or after commas and equal symbols. An example of a non-normalized base distinguished name is o = ibm, c = us or o=ibm, c=us. An example of a normalized base distinguished name is o=ibm,c=us.

4. If the LDAP repository that you want to add to your realm is not previously configured, complete the following steps:
   a. Click **Add Repository** on the Repository reference panel to configure the LDAP repository. See step 1 to access the Repository reference panel.
   b. Configure LDAP on the LDAP configuration panel, as described in “Configuring Lightweight Directory Access Protocol in a federated repository configuration” on page 1339.
   c. Select the new Repository on the Repository reference panel.
5. Click **OK**.

Results

You have added a new or previously configured external repository into your federated repository configuration.

What to do next

1. Before you can manage this account with Users and Groups, configure supported entity types as described in “Configuring supported entity types in a federated repository configuration” on page 1377.
2. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
3. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1186. As the final step, validate this setup by clicking **Apply** in the Global security panel.
4. Save, stop, and restart all the product servers (deployment managers, nodes and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Configuring a property extension repository in a federated repository configuration:

Follow this task to configure a property extension repository to store attributes that cannot be stored in your Lightweight Directory Access Protocol (LDAP) server.

About this task

For security and business reasons, you might want to prohibit write operations to your repositories. However, applications calling the federated repository configuration might need to store additional properties for the entities. A federated repository configuration provides a *property extension repository*, which is a database regardless of the type of main profile repositories, for a propertylevel join configuration. For example, a company that uses an LDAP directory for its internal employees and a database for external customers and business partners might not allow write access to its LDAP and its database. The company can use the *property extension repository* in a federated repository configuration to store additional properties for the people in those repositories, excluding the user ID. When an

application uses the federated repository configuration to retrieve an entry for a person, the federated repository configuration transparently joins the properties of the person that is retrieved from either the LDAP or the customer's database with the properties of the person that is retrieved from the property extension repository into a single logical person entry.

When you configure a property extension repository, you can supply a valid data source, a direct connection configuration, or both. The system first tries to connect by way of the data source. If the data source is not available, then the system uses the direct access configuration.

Restriction: You cannot configure a property extension repository in a mixed version deployment manager cell.

Procedure

1. Configure the WebSphere Application Server data source. See “Configuring the WebSphere Application Server data source” on page 1373.
2. If you are adding new properties (including properties that are stored in the property extension repository) to the schema, you must do the following before you create the property extension repository.
   a. Open or create the `wimxmlextension.xml` file under the *profile_root*`\config\cells\`*cell_name*`\wim\model` directory.

      Attention: Make sure the editor is on the deployment manager node.

   b. Add the schema definition of the new property. The following sample `wimxmlextension.xml` file adds a new property called ibmotherEmail to both the Person and PersonAccount entity types. This new property type is "String" and it is multiplevalued.

```
<sdo:datagraph xmlns:sdo="commonj.sdo"
    xmlns:wim="http://www.ibm.com/websphere/wim">
 <wim:schema>
  <wim:propertySchema
   nsURI="http://www.ibm.com/websphere/wim"
   dataType="String"
   multiValued="true"
   propertyName="ibm-otherEmail">
     <wim:applicableEntityTypeNames>Person
    </wim:applicableEntityTypeNames>
    <wim:applicableEntityTypeNames>PersonAccount
    </wim:applicableEntityTypeNames>
  </wim:propertySchema>
  <wim:propertySchema
   nsURI="http://www.ibm.com/websphere/wim"

Available data types are defined in `com.ibm.websphere.wim.SchemaConstants`. For example:

```
/**
  * Instance Class: java.lang.String
  */
 String DATA_TYPE_STRING = "String";
 /**
  * Instance Class: int
  */
 String DATA_TYPE_INT = "Int";
 /**
  * Instance Class: java.lang.Object
  */
 String DATA_TYPE_DATE = "Date";
 /**
  * Instance Class: dobjava.lang.Object
  */
 String DATA_TYPE_ANY_SIMPLE_TYPE = "AnySimpleType";
 /**
  * Instance Class: java.lang.String
  */
 String DATA_TYPE_ANY_URI = "AnyURI";
 /**
  * Instance Class: java.lang.boolean
  */
 String DATA_TYPE_BOOLEAN = "Boolean";
 /**
  * Instance Class: long
  */
 String DATA_TYPE_LONG = "Long";
 /**
  * Instance Class: double
  */
 String DATA_TYPE_DOUBLE = "Double";
 /**
  * Instance Class: short
  */
 String DATA_TYPE_SHORT = "Short";
```

c. Add the new property to the property extension repository. Before running the `setupIdMgrPropertyExtensionRepositoryTables` command, add the new properties into *install_root*`/etc/wim/setup/wimlaproperties.xml`.

d. Follow the example inside this file to define the new property definitions. The schema file for `wimlaproperties.xml` is `wimdbproperty.xsd` and is in the same directory. It can be used for reference.

3. Run the `setupIdMgrPropertyExtensionRepositoryTables` command to create the property extension repository and to add the new properties.
4. Set up the property extension repository using wsadmin by following the procedure discussed in “Setting up an entry mapping repository, a property extension repository, or a custom registry database repository using wsadmin commands” on page 1359; ignore the "Before you begin" options.
5. Configure the property extension repository by completing the following steps:
   a. In the administrative console, click **Security > Global security**.
   b. Under User account repository, select **Federated repositories**, and click **Configure**.
   c. Click **Property extension repository**.
   d. Supply the name of the data source in the Data source name field.
   e. Select the type of database that is used for the property extension repository.
   f. Supply the name of the Java database connectivity (JDBC) driver in the JDBC driver field.

      Values include:

      DB2 `com.ibm.db2.jcc.DB2Driver`

      Oracle
      `oracle.jdbc.driver.OracleDriver`

      Informix
      `com.informix.jdbc.IfxDriver`

Microsoft SQL Server
com.microsoft.jdbc.sqlserver.SQLServerDriver

Derby org.apache.derby.jdbc.EmbeddedDriver

g. Supply the database URL that is used to access the property extension repository with JDBC in the Database URL field. Use an alphanumeric text string that conforms to the standard JDBC URL syntax.

Values include:

DB2 jdbc:db2://<*hostname*>:<*port*>/<*DB2location*>

Oracle
jdbc:oracle:thin:@<*hostname*>:<*port*>:<*dbname*>

Derby jdbc:derby:c:\derby\wim

Microsoft SQL Server
jdbc:microsoft:sqlserver://<*hostname*>:1433;databaseName=wim;selectmethod=cursor;

Informix
jdbc:informixsqli://<*hostname*>:1526/wim:INFORMIXSERVER=<*IFXServerName*>;

h. Supply the user name of the database administrator in the Database administrator user name field.

i. Supply the password of the database administrator in the Password field.

j. Specify the entity retrieval limit in the Entity retrieval limit field. The entity retrieval limit is the maximum number of entities that the system can retrieve from the property extension repository with a single database query. The default value is 200.

k. Click **OK**.

Results

After completing these steps, your federated repository configuration, which includes a property extension repository, is configured.

What to do next

1. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1186. As the final step, validate this setup by clicking **Apply** on the Global security panel.
2. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Property extension repository settings:

Use this page to configure a property extension repository that is used to store attributes that cannot be stored in existing repositories.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Additional properties, click **Property extension repository**.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

Data source name:

Specifies the Java Naming and Directory Interface (JNDI) name of the data source that is used to access the property extension repository.

Default: `jdbc/wimDS`

Database type:

Specifies the type of database that is used for the property extension repository.

Default: `DB2`

JDBC driver:

Specifies the Java Database Connectivity (JDBC) driver that is used to access the entry mapping repository.

Values include:

DB2 `COM.ibm.db2.jcc.DB2Driver`

Oracle
`oracle.jdbc.driver.OracleDriver`

Informix
`com.informix.jdbc.IfxDriver`

DataDirect Connect
`com.ddtek.jdbc.sqlserver.SQLServerDriver`

Derby `org.apache.derby.jdbc.EmbeddedDriver`

Microsoft SQL Server
`com.microsoft.sqlserver.jdbc.SQLServerDriver`

Database URL:

Specifies the web address for the property extension repository.

Values include:

DB2 `jdbc:db2:wim`

Informix
`jdbc:informix-sqli://`*`host_name`*`:`*`port`*`/wim:INFORMIXSERVER=`*`IFXServerName`*`;`

DataDirect Connect
jdbc:datadirect:sqlserver://*host_name*:1433;databaseName=wim;selectMethod=cursor;

Derby `jdbc:derby:c:\derby\wim`

Oracle
`jdbc:oracle:thin:@`*`host_name`*`:`*`port`*`:`*`dbname`*

Microsoft SQL Server
`jdbc:sqlserver://`*`host_name`*`:1433;databaseName=wim;selectMethod=cursor;`

Database administrator user name:

Specifies the user name of the database administrator that is used to access the property extension repository.

Password:

Specifies the password that is used to enable the database administrator to access the property extension repository.

Entity retrieval limit:

Specifies the maximum number of entities that the system can retrieve from the property extension repository with a single database query.

Data type:	Integer
Default:	200

Setting up an entry mapping repository, a property extension repository, or a custom registry database repository using wsadmin commands:

You can set up an entry mapping repository, a property extension repository, or a custom registry database repository using wsadmin commands.

Before you begin

If you are setting up an entry mapping repository, begin with the steps described in “Configuring an entry mapping repository in a federated repository configuration” on page 1374.

If you are setting up a property extension repository, begin with the steps described in “Configuring a property extension repository in a federated repository configuration” on page 1353.

About this task

When you create a repository, use the appropriate wsadmin commands to define the database schema and to populate the database property definitions.

Procedure

1. Create the database. You can use any relational database product. The following examples give you tips for specific vendors.
   a. For **DB2**, open a DB2 command window or command center and enter the following:

```
db2 create database <name> using codeset UTF-8 territory US
```

   Enter the following database tuning commands:

```
db2 update database configuration for <name> using applheapsz 1024
db2 update database configuration for <name> using stmtheap 4096
db2 update database configuration for <name> using app_ctl_heap_sz 2048
db2 update database configuration for <name> using locklist 1024
db2 update database configuration for <name> using indexrec RESTART
db2 update database configuration for <name> using logfilsiz 1000
db2 update database configuration for <name> using logprimary 12
db2 update database configuration for <name> using logsecond 10
db2 update database configuration for <name> using sortheap 2048
db2set DB2_RR_TO_RS=yes
```

   b. Optional: For **Informix** databases using `dbaccess`, enter the following command:

```
CREATE DATABASE <name> WITH BUFFERED LOG
```

   c. Optional: For **Oracle** databases, the database should already exist during Oracle installation (for example, `orcl`).
2. Run the `setupIdMgrEntryMappingRepositoryTables` command, the `setupIdMgrPropertyExtensionRepositoryTables` command, or the `setupIdMgrDBTables` command (for custom registry repositories) by doing the following:
   a. Start WebSphere Application Server.
   b. Open a command window and go to the `<WAS>/Profiles/<PROFILE_NAME>bin` directory.

c. Start wsadmin.
d. Type the necessary commands as described below.

What to do next

Using these commands, you can:
- Specify the arguments on the command line.
- Specify the arguments in a file.

The `-file` option enables you to specify a file in which some or all of the parameters are specified. To use the `-file` argument on the command line, enter the full path to the file. Parameters in the file must be specified in `key=value` pairs and each must be on its own line. If a parameter is specified on both the command line and in the file, the value on the command line takes precedence.

Tips for diagnosing argument errors:
- If an argument is not properly specified on the command line or in the file, a message is returned which states that the argument was not properly specified. This might mean that the argument was not specified at all or was required for a given configuration but was not specified.
- If the argument was not specified at all, check that the parameter is specified on the command line or in the file, and that it is properly spelled and has matching case.
- If the argument was required for a given configuration but was not specified, it is possible that a value is not required solely by the command but is required for the type of database and configuration you are setting.

  For example, if you set the `dn`, `wasAdminId`, or `wasAdminPassword` parameters, you must also specify the `dbDriver` parameter.

  Additionally, if the `dn`, `wasAdminId` or `wasAdminPassword` parameters are specified, and the `databaseType` is not a Apache Derby v10.2 database, then the `dbAdminId` and `dbAdminPassword` parameters must also be specified.

The setupIdMgrDBTables command:

The setupIdMgrDBTables command creates, and populates the tables in the database that you previously created. Arguments are case-sensitive, both through the command line and the file.

Parameters:

schemaLocation (String, Required)
The location of the `<WAS>/etc/wim/setup` directory.

dbPropXML (String)
The location of database repository property definition XML file.

databaseType (String, Required)
The type of database. Supported databases are db2, oracle, informix, derby, sqlserver, db2zos, and db2iseries.

dbURL (String, Required)
The database URL for direct access mode. For example: jdbc:db2:wim.

dbDriver (String)
The name of the database driver. For example: com.ibm.db2.jcc.DB2Driver.

dbAdminId (String)
The database administrator ID for direct access mode. For example: db2admin.

Note: For a Apache Derby v10.2 embedded database, dbAdminId is not required.

dbAdminPassword (String)
The password associated with the dbAdminId.

Note: For a Apache Derby v10.2 embedded database, dbAdminPassword is not required.

dn (String)
The default organization uniqueName to replace. For example: `o=yourco`. If it is not set, `o=Default Organization` is used.

wasAdminId (String)
The WebSphere Application Server admin user ID. The ID should be a short name, not a uniqueName. For example: wasadmin. After creation, the uniqueName is `uid=wasadmin, <defaultOrg>`.

wasAdminPassword (String)
The WebSphere Application Server admin user password. If `wasAdminId` is set, then this parameter is mandatory.

saltLength (Integer)
The salt length of the randomly generated salt for password hashing.

encryptionKey (String)
The password encryption key. Set the password encryption key to match the encryption key in the wimconfig.xml file for the repository. If the encryption key is not set, the default is used.

derbySystemHome (String)
The home location of the Apache Derby v10.2 system if you are setting up a Apache Derby v10.2 database.

reportSqlError (String)
Specifies whether to report SQL errors while setting up databases.

file (String)
The full path to a file containing the input parameters. Each input parameter must match a corresponding parameter as it would be typed on the command line, and it must be placed in a `key=value` pair. Each pair must be on a separate line.

dbSchema (String)
The database schema where you want to create the federated repository tables. The schema should exist in the database. The default value is the default schema of the database according to the database type. Typically, the default schema is the namespace of the current database user.

The deleteIdMgrDBTables command:

The deleteIdMgrDBTables command deletes the tables in the database.

Parameters:

schemaLocation (String, Required)
The location of the `<WAS>/etc/wim/setup` directory.

databaseType (String, Required)
The type of database. Supported databases are db2, oracle, informix, derby, sqlserver, db2zos, and db2iseries.

dbURL (String, Required)
The database URL for direct access mode. For example: jdbc:db2:wim.

dbDriver (String)
The name of the database driver. For example: com.ibm.db2.jcc.DB2Driver.

dbAdminId (String)
The database administrator ID for direct access mode. For example: db2admin.

Note: For a Apache Derby v10.2 embedded database, dbAdminId is not required.

dbAdminPassword (String)
The password associated with the dbAdminId.

Note: For a Apache Derby v10.2 embedded database, dbAdminPassword is not required.

derbySystemHome (String)
The home location of the Apache Derby v10.2 system if you are setting up a Apache Derby v10.2 database.

reportSqlError (String)
Specifies whether to report SQL errors while setting up databases.

file (String)
The full path to a file containing the input parameters. Each input parameter must match a corresponding parameter as it would be typed on the command line, and it must be placed in a `key=value` pair. Each pair must be on a separate line.

dbSchema (String)
The database schema from which you want to delete the federated repository tables. The schema should exist in the database. The default value is the default schema of the database according to the database type. Typically, the default schema is the namespace of the current database user.

The setupIdMgrPropertyExtensionRepositoryTables command:

The setupIdMgrPropertyExtensionRepositoryTables command sets up the property extension repository. The default behavior includes creating and populating the tables in the database.

This command is available in connected or local mode.

Parameters:

schemaLocation (String, Required)
The location of the *app_server_root*`/etc/wim/setup` directory.

laPropXML (String)
The location of the property extension repository definition XML file.

databaseType (String, Required)
The type of database. Supported databases are db2, oracle, informix, derby, sqlserver, db2zos, and db2iseries.

dbURL (String, Required)
The database URL for direct access mode. For example: jdbc:db2:wim.

dbAdminId (String)
The database administrator ID for direct access mode. For example: db2admin.

Note: For a Apache Derby v10.2 embedded database, dbAdminId is not required.

dbAdminPassword (String)
The password associated with the dbAdminId.

Note: For a Apache Derby v10.2 embedded database, dbAdminPassword is not required.

derbySystemHome (String)
The home location of the Apache Derby v10.2 system if you are setting up a Apache Derby v10.2 database.

reportSqlError (String)
Specifies whether to report SQL errors while setting up databases.

skipDBCreation (Boolean)
Specifies whether to create the tables in the property extension repository.

If you set this parameter value to false or do not specify a value, then the command follows the default behavior of creating and populating the tables in the database.

If you set this parameter value to true, manually set up the property extension repository before running this command so that the tables get populated. For more information on this manual process, see the appropriate topic on manually setting up the property extension repository for your database.

file (String)
The full path to a file containing the input parameters. Each input parameter must match a corresponding parameter as it would be typed on the command line, and it must be placed in a `key=value` pair. Each pair must be on a separate line.

dbSchema (String)
The database schema where you want to create the federated repository tables. The schema should exist in the database. The default value is the default schema of the database according to the database type. Typically, the default schema is the namespace of the current database user.

The deleteIdMgrPropertyExtensionRepositoryTables command:

The deleteIdMgrPropertyExtensionRepositoryTables command deletes the tables in the property extension database.

This command is available in the connected or local mode.

Parameters:

schemaLocation (String, Required)
The location of the `<WAS>/etc/wim/setup` directory.

databaseType (String, Required)
The type of database. Supported databases are db2, oracle, informix, derby, sqlserver, db2zos, and db2iseries.

dbURL (String, Required)
The database URL for direct access mode. For example: jdbc:db2:wim.

dbDriver (String)
The name of the database driver. For example: com.ibm.db2.jcc.DB2Driver.

dbAdminId (String)
The database administrator ID for direct access mode. For example: db2admin.

Note: For a Apache Derby v10.2 embedded database, dbAdminId is not required.

dbAdminPassword (String)
The password associated with the dbAdminId.

Note: For a Apache Derby v10.2 embedded database, dbAdminPassword is not required.

derbySystemHome (String)
The home location of the Apache Derby v10.2 system if you are setting up a Apache Derby v10.2 database.

reportSqlError (String)
Specifies whether to report SQL errors while setting up databases.

file (String)
The full path to a file containing the input parameters. Each input parameter must match a

corresponding parameter as it would be typed on the command line, and it must be placed in a `key=value` pair. Each pair must be on a separate line.

dbSchema (String)
The database schema from which you want to delete the federated repository tables. The schema should exist in the database. The default value is the default schema of the database according to the database type. Typically, the default schema is the namespace of the current database user.

The setupIdMgrEntryMappingRepositoryTables command:

The setupIdMgrEntryMappingRepositoryTables command sets up the entry mapping repository, which includes creating and populating the tables of the repository.

Parameters:

schemaLocation (String, Required)
The location of the `<WAS>/etc/wim/setup` directory.

databaseType (String, Required)
The type of database. Supported databases are db2, oracle, informix, derby, sqlserver, db2zos, and db2iseries.

dbURL (String, Required)
The database URL for direct access mode. For example: jdbc:db2:wim.

dbDriver (String)
The name of the database driver. For example: com.ibm.db2.jcc.DB2Driver.

dbAdminId (String)
The database administrator ID for direct access mode. For example: db2admin.

Note: For a Apache Derby v10.2 embedded database, dbAdminId is not required.

dbAdminPassword (String)
The password associated with the dbAdminId.

Note: For a Apache Derby v10.2 embedded database, dbAdminPassword is not required.

derbySystemHome (String)
The home location of the Apache Derby v10.2 system if you are setting up a Apache Derby v10.2 database.

reportSqlError (String)
Specifies whether to report SQL errors while setting up databases.

file (String)
The full path to a file containing the input parameters. Each input parameter must match a corresponding parameter as it would be typed on the command line, and it must be placed in a `key=value` pair. Each pair must be on a separate line.

dbSchema (String)
The database schema where you want to create the federated repository tables. The schema should exist in the database. The default value is the default schema of the database according to the database type. Typically, the default schema is the namespace of the current database user.

The deleteIdMgrEntryMappingRepositoryTables command:

The deleteIdMgrEntryMappingRepositoryTables command deletes the tables in the entry mapping repository.

Parameters:

schemaLocation (String, Required)
The location of the <WAS>/etc/wim/setup directory.

databaseType (String, Required)
The type of database. Supported databases are db2, oracle, informix, derby, sqlserver, db2zos, and db2iseries.

dbURL (String, Required)
The database URL for direct access mode. For example: jdbc:db2:wim.

dbDriver (String)
The name of the database driver. For example: com.ibm.db2.jcc.DB2Driver.

dbAdminId (String)
The database administrator ID for direct access mode. For example: db2admin.

Note: For a Apache Derby v10.2 embedded database, dbAdminId is not required.

dbAdminPassword (String)
The password associated with the dbAdminId.

Note: For a Apache Derby v10.2 embedded database, dbAdminPassword is not required.

derbySystemHome (String)
The home location of the Apache Derby v10.2 system if you are setting up a Apache Derby v10.2 database.

reportSqlError (String)
Specifies whether to report SQL errors while setting up databases.

file (String)
The full path to a file containing the input parameters. Each input parameter must match a corresponding parameter as it would be typed on the command line, and it must be placed in a key=value pair. Each pair must be on a separate line.

dbSchema (String)
The database schema from which you want to delete the federated repository tables. The schema should exist in the database. The default value is the default schema of the database according to the database type. Typically, the default schema is the namespace of the current database user.

Sample command line usage:

To set up a database using the command line, enter the following:

```
$AdminTask setupIdMgrDBTables {-schemaLocation "C:/WAS/etc/wim/setup" -dbPropXML
"C:/WAS/etc/wim/setup/wimdbproperties.xml" -databaseType db2
-dbURL jdbc:db2:wim -dbAdminId db2admin
-dbDriver com.ibm.db2.jcc.DB2Driver -dbAdminPassword db2adminPwd
-reportSqlError true}
```

To delete database tables using the command line, enter the following:

```
$AdminTask deleteIdMgrDBTables {-schemaLocation "C:/WAS/etc/wim/setup"
-databaseType db2  -dbURL jdbc:db2:wim -dbAdminId db2admin
-dbDriver com.ibm.db2.jcc.DB2Driver -dbAdminPassword db2adminPwd
-reportSqlError true}
```

To set up a property extension repository using the command line, enter the following:

```
$AdminTask setupIdMgrPropertyExtensionRepositoryTables {-schemaLocation
"C:/WAS/etc/wim/setup"
-laPropXML "C:/WAS/etc/wim/setup/wimlaproperties.xml" -databaseType db2
-dbURL jdbc:db2:wim -dbAdminId db2admin -dbDriver com.ibm.db2.jcc.DB2Driver
-dbAdminPassword db2adminPwd -reportSqlError true}
```

To delete a property extension repository using the command line, enter the following:

```
$AdminTask deleteIdMgrPropertyExtensionRepositoryTables {-schemaLocation "C:/WAS/etc/wim/setup "
-databaseType db2 -dbURL jdbc:db2:wim -dbAdminId db2admin -dbDriver
com.ibm.db2.jcc.DB2Driver -dbAdminPassword db2adminPwd -reportSqlError true}
```

To set up an entry mapping repository using the command line, enter the following:

```
$AdminTask setupIdMgrEntryMappingRepositoryTables {-schemaLocation "C:/WAS/etc/wim/setup"
-databaseType db2 -dbURL jdbc:db2:wim -dbAdminId db2admin -dbDriver
com.ibm.db2.jcc.DB2Driver -dbAdminPassword db2adminPwd -reportSqlError true}
```

To delete an entry mapping repository using the command line, enter the following:

```
$AdminTask deleteIdMgrEntryMappingRepositoryTables {-schemaLocation "C:/WAS/etc/wim/setup"
-databaseType db2 -dbURL jdbc:db2:wim -dbAdminId db2admin -dbDriver
com.ibm.db2.jcc.DB2Driver -dbAdminPassword db2adminPwd -reportSqlError true}
```

Sample CLI Usage using -file option:

To set up a database with the `-file` option using the example `params.txt` file below, enter the following:

```
$AdminTask setupIdMgrDBTables {–file C:/params.txt -dbPropXML
"C:/OverrideDBPropParam/wimdbproperties.xml"}
```

Params.txt

```
schemaLocation=C:/WAS/etc/wim/setup
dbPropXML=C:/Program Files/IBM/WebSphere/AppServer/profiles/default
/config/cells/mycell/wim/config/wimdbproperties.xml
laPropXML=C:/Program Files/IBM/WebSphere/AppServer/profiles/default
/config/cells/mycell/wim/config/wimlaproperties.xml
databaseType=db2
dbURL=jdbc:db2:wim
dbDriver=com.ibm.db2.jcc.DB2Driver
reportSqlError=true
dn=o=db.com
dbAdminId=db2admin
dbAdminPassword=dbPassword
wasAdminId=wasadmin
wasAdminPassword=wasadmin1
```

To set up a database with the `-file` option using a file only, enter the following:

```
$AdminTask setupIdMgrDBTables {-file C:/params.txt}
```

Note: The use of a file only works if `-file` is the only parameter specified on the command line. If other parameters are specified then the file is completely ignored, and only the parameters on the command line are used to execute the command.

Manually setting up the property extension repository for federated repositories:

You can use the createIdMgrPropExtDbTables script to create tables in the property extension repository for federated repositories.

Before you begin

The following databases are supported by the script when the database exists on a distributed operating system:

- IBM DB2
- Apache Derby
- IBM Informix Dynamic Server
- Oracle 11g
- Microsoft SQL Server

For a list of the supported database versions, see the IBM WebSphere Application Server detailed system requirements.

To use the IBM DB2 on z/OS or IBM DB2 on iSeries database, read about manually setting up the property extension repository in DB2.

If you do not have WebSphere Application Server installed on the same system on which you are setting up the database, you must copy the following files from a system where WebSphere Application Server is installed to the system on which you are setting up the database. Ensure that you replicate the same directory structure within the setup directory. The *db_type* variable represents one of the following directory names: `db2`, `oracle`, `informix`, `derby`, or `sqlserver`.

app_server_root\etc\wim\setup\bin\createIdMgrPropExtDbTables.sh
app_server_root\etc\wim\setup\bin\createIdMgrPropExtDbTables.bat
app_server_root\etc\wim\setup\lookaside*db_type*\dbclean.sql
app_server_root\etc\wim\setup\lookaside*db_type*\schema.sql
app_server_root\etc\wim\setup\lookaside*db_type*\primarykeys.sql
app_server_root\etc\wim\setup\lookaside*db_type*\indexes.sql
app_server_root\etc\wim\setup\lookaside*db_type*\references.sql
app_server_root\etc\wim\setup\lookaside\keys.sql
app_server_root\etc\wim\setup\lookaside\bootstrap.sql

Specifying the database schema:

You can specify the database schema where you want to create the federated repository tables when you are manually setting up the property extension repository.

If you want to use the default schema of the database, you must execute the following commands without specifying the DBSCHEMA parameter. Typically, the default schema is the namespace of the current database user.

Complete these steps to replace the schema variable in the SQL files with the actual database schema name. If WebSphere Application Server and the database are not on the same system, set the SCHEMA_LOCATION value to the location where you copied the SQL files.

Windows operating systems:

1. Open a command window.
2. Change to the *app_server_root*\etc\wim\setup directory.
3. Enter the following commands:

```
set SCHEMA_LOCATION=app_server_root\etc\wim\setup\lookaside
set DBTYPE=<db_type>
set DBSCHEMA=dbschemaname
set SCHEMA_DEST_LOCATION=<location where the updated SQL files with replaced variables should be copied>
ws_ant.bat -f app_server_root\etc\wim\setup\filterbuild.xml
```

   where the value of <*db_type*> is db2, derby, informix, oracle, or sqlserver.

Note: : If SCHEMA_DEST_LOCATION is not set, the updated SQL files are copied to a directory with the name as the value not substituted under the current directory. The output shows where the files are copied.

AIX, HP-UX, Linux, and Solaris operating systems:

1. Open a command window
2. Change to the *app_server_root*/etc/wim/setup directory.
3. Enter the following commands:

```
export SCHEMA_LOCATION=app_server_root/etc/wim/setup/lookaside
export DBTYPE=<db_type>
export DBSCHEMA=dbschemaname
export SCHEMA_DEST_LOCATION=<location where the updated SQL files with replaced variables should be copied>
ws_ant.sh -f app_server_root/etc/wim/setup/filterbuild.xml
```

   where the value of <*db_type*> is db2, derby, informix, oracle, or sqlserver.

Note: If SCHEMA_DEST_LOCATION is not set, the updated SQL files are copied to a directory with the name as the value not substituted under the current directory. The output shows where the files are copied.

About this task

The following notes apply to specific databases:

- **Oracle 11g**
  - If you did not create the default database when you installed Oracle product, you must manually create the database before you run the createIdMgrPropExtDbTables script. The value of the *ORACLE_SID* variable is the same value as the name of the database.
  - If you want to create the tables in the schema that you specified using DBSCHEMA (described in the previous section, Specifying the database schema) ensure that you create the specified schema in this database before you run the createIdMgrPropExtDbTables script.
  - On the AIX, HP-UX, Linux, and Solaris operating systems, run the createIdMgrPropExtDbTables script either as an Oracle user or as a root user with database administrator (dba) rights and appropriate permissions to run SQL queries as a system database administrator (sysdba).
- **IBM DB2**
  - On the Windows operating systems, you must initialize the DB2 environment before you run the createIdMgrPropExtDbTables script. At the Windows command prompt, enter db2cmd to open a new DB2 command window and run the createIdMgrPropExtDbTables batch file from this prompt.
- **Microsoft SQL Server**
  - Open a command window, change to the *app_server_root*\bin directory, and enter the following commands to replace the variables in the SQL files. If WebSphere Application Server and the database are not on the same system, set the **SCHEMA_LOCATION** value to the location where you copied the SQL files.

    ```
    set SCHEMA_LOCATION=app_server_root\etc\wim\setup\lookaside
    set DBTYPE=sqlserver
    set SCHEMA_DEST_LOCATION=<location where the updated SQL files with replaced variables should be copied>
    set DBOWNER=dbo
    ws_ant.bat -f app_server_root\etc\wim\setup\filterbuild.xml
    ```

    Note: If SCHEMA_DEST_LOCATION is not set, the updated SQL files are copied to a directory with the name as the value not substituted under the current directory. The output shows where the files are copied.

The following default instance is created as a part of the database installation:

- DB2: *DB2*
- Informix: *demo_on*
- SQL Server: *%computername%*

The Informix database is created with the following environment:

```
CLIENT_LOCALE=EN_US.CP1252
DB_LOCALE=EN_US.8859-1
SERVER_LOCALE=EN_US.CP1252
DBLANG=EN_US.CP125
```

Procedure

Run the createIdMgrPropExtDbTables.sh script or createIdMgrPropExtDbTables.bat script to create the tables in the property extension repository.
Run the script from the following location or from the directory to which you previously copied the script file:

AIX, HP-UX, Linux, and Solaris operating systems

app_server_root/etc/wim/setup/bin/createIdMgrPropExtDbTables.sh

Windows

app_server_root\etc\wim\setup\bin\createIdMgrPropExtDbTables.bat

Use the following parameters to specify the values that you require when you run the script:

-b Use this parameter to specify the home directory of the database.

This value is a string value that is required for all database types.

-d Use this parameter to specify the schema of the database.

The value of this parameter should be the same value that you specified for DBSCHEMA (described in the previous section, Specifying the database schema).

This value is a string value that is optional for DB2, Derby, and SQL Server databases, if you want to specify the database schema where you want to create the federated repository tables. This value is not required for Oracle and Informix databases.

-h Use this parameter to display the help information. (Optional)

-i Use this parameter to specify the home directory of the database instance.

This value is a string value that is required for a DB2 database only; do not specify a value for other database types.

This parameter applies to the AIX, HP-UX, Linux, and Solaris operating systems.

-n Use this parameter to specify the name of the database to which you are connecting.

For an Oracle database, the value of the *ORACLE_SID* variable is the same as the name of the database.

This value is a string value that is required for all database types.

-p Use this parameter to specify the password of the database administrator.

This value is a string value that is required for DB2, Oracle, Informix, and SQL Server databases only; do not specify a value for a Derby database.

-s On AIX, HP-UX, Linux, and Solaris operating systems, this parameter specifies the location of the *app_server_root*/etc/wim/setup directory, or the location to which the updated files are copied according to the steps in the previous section, Specifying the database schema.

On Windows operating systems, this parameter specifies the location of the *app_server_root*\etc\wim\setup directory, or the location to which the updated files are copied according to the steps in the previous section, Specifying the database schema.

This value is a string value that is required for all database types.

-t Use this parameter to specify a database type.

- On the AIX, HP-UX, Linux, and Solaris operating systems, specify one of the following valid values: db2, oracle, informix, derby.
- On the Windows operating systems, specify one of the following valid values: db2, oracle, informix, derby, or sqlserver.

This value is a string value that is required for all database types.

-u Use this parameter to specify the user ID of the database administrator.

This value is a string value that is required for DB2, Oracle, Informix, and SQL Server databases only; do not specify a value for a Derby database.

Example

Run the appropriate script for your database and operating system to create tables in the property extension repository. Use the sample values to specify database parameters. If the database exists on a system where WebSphere Application Server is not installed, the following examples assume that your PATH variable includes an entry for the location to which you copied the script files. For the AIX, HP-UX, Linux, and Solaris operating systems, the entry might be the *app_server_root*/etc/wim/setup/bin/ or the /setup/bin/ directory. For Windows operating systems, the entry might be the *app_server_root*\etc\wim\setup\bin\ or the \setup\bin\ directory.

The examples in the following section are organized into multiple lines for illustration purposes only.

On the AIX, HP-UX, Linux, and Solaris operating systems:

Oracle databases

```
createIdMgrPropExtDbTables.sh
-b /space/oracle/product/10.2.0/Db_1/
-n orcl
-u system
-p manager
-s /opt/IBM/WebSphere/AppServer1/etc/wim/setup
-t oracle
```

Informix databases

```
createIdMgrPropExtDbTables.sh
-b /opt/IBM/informix/
-n demo_on
-u informix
-p informix
-s /opt/IBM/WebSphere/AppServer/etc/wim/setup
-t informix
```

DB2 databases

```
createIdMgrPropExtDbTables.sh
-b /opt/ibm/db2/V9.1/
-n db2inst1
-p db2inst1
-s /opt/IBM/WebSphere/AppServer/etc/wim/setup
-t DB2
-u db2inst1
-i /home/db2inst1/
```

Derby databases

```
createIdMgrPropExtDbTables.sh
-b /opt/ibm/derby/
-n test11
-s /opt/IBM/WebSphere/AppServer/etc/wim/setup
-t derby
```

On the Windows operating systems:

Oracle databases

```
createIdMgrPropExtDbTables.bat
-b "c:\oracle\product\10.2.0\Db_1"
-n orcl
-u system
-p manager
-s "c:\Program Files\IBM\WebSphere\AppServer1\etc\wim\setup"
-t oracle
```

Informix databases

```
createIdMgrPropExtDbTables.bat
-b "c:\Program Files\IBM\informix"
-n demo_on
```

```
-u informix
-p informix
-s "c:\Program Files\IBM\WebSphere\AppServer\etc\wim\setup"
-t informix
```

DB2 databases

```
createIdMgrPropExtDbTables.bat
-t db2
-u db2admin
-p sec001ret#
-n test23
-b "c:\Program Files\IBM\SQLLIB"
-s "c:\Program Files\IBM\WebSphere\AppServer1\etc\wim\setup"
```

Derby databases

```
createIdMgrPropExtDbTables.bat
-t derby
-b "c:\Derby"
-n test11
-s "c:\Program Files\IBM\WebSphere\AppServer1\etc\wim\setup"
```

Microsoft SQL Server databases

```
createIdMgrPropExtDbTables.bat
-t sqlserver
-u sa
-p sec001ret#
-n sqlsrv
-b "c:\Progra~1\Micros~1\90\Tools"
-s "C:\Progra~1\IBM\WebSphere\AppServer1\etc\wim\setup"
```

What to do next

Run the setupIdMgrPropertyExtensionRepositoryTables command with the **skipDBCreation** parameter set to true to populate the tables that are created. For more information, read about setting up an entry mapping repository, a property extension repository, or a custom registry database repository using wsadmin commands.

Manually setting up the property extension repository for DB2 for iSeries or DB2 for z/OS:

Use this task to set up the property extension repository for DB2 for iSeries or DB2 for z/OS.

Before you begin

The information in this topic applies in the following scenarios:

- The application server and the database both exist on the IBM i operating system.
- The application server and the database both exist on the z/OS operating system.
- The application server exists on a distributed operating system, but the database exists on either the IBM i or z/OS operating system.

If you do not have WebSphere Application Server installed in the system on which you are setting up the database, copy the following files from a system where WebSphere Application Server is installed to the system on which you are setting up the database:

DB2 for iSeries

app_server_root/etc/wim/setup/lookaside/db2iseries/dbclean.sql
app_server_root/etc/wim/setup/lookaside/db2iseries/schema.sql
app_server_root/etc/wim/setup/lookaside/db2iseries/primarykeys.sql
app_server_root/etc/wim/setup/lookaside/db2iseries/indexes.sql
app_server_root/etc/wim/setup/lookaside/db2iseries/references.sql
app_server_root/etc/wim/setup/lookaside/keys.sql
app_server_root/etc/wim/setup/lookaside/bootstrap.sql

DB2 for z/OS

app_server_root/etc/wim/setup/lookaside/db2zos/dbclean.sql
app_server_root/etc/wim/setup/lookaside/db2zos/schema.sql
app_server_root/etc/wim/setup/lookaside/db2zos/primarykeys.sql
app_server_root/etc/wim/setup/lookaside/db2zos/indexes.sql
app_server_root/etc/wim/setup/lookaside/db2zos/references.sql
app_server_root/etc/wim/setup/lookaside/keys.sql
app_server_root/etc/wim/setup/lookaside/bootstrap.sql

About this task

For information about how to create a database and run SQL queries in DB2 for iSeries, see the DB2 Universal Database for iSeries in the IBM iSeries Information Center.

For information about how to create a database and run SQL queries in DB2 for z/OS, see the Information Management Software for z/OS Solutions Information Center.

Procedure

1. Open a command window.
2. Change to the *app_server_root*/bin directory
3. Enter the following commands to replace the variables in the SQL files:
   a. `export SCHEMA_LOCATION=`*app_server_root*`/etc/wim/setup/lookaside`

      Set the SCHEMA_LOCATION value to the location where you copied the SQL files if you do not have WebSphere Application Server installed on the same system on which you are setting up the database.

   b. `export DBTYPE=<`*db_type*`>`

      where the value of *<db_type>* is db2iseries or db2zos

   c. To specify the database schema where you want to create the federated repository tables use the DBSCHEMA command. If you want to use the default schema, which is typically the namespace of the current database user, do not specify the DBSCHEMA command.

      ```
      export DBSCHEMA=dbschemaname
      ```

   d. `export TSPREFIX=<`*tsprefix*`>`

      where *<tsprefix>* is the tablespace prefix. The maximum length allowed for this string is 3 characters.

   e. `export SCHEMA_DEST_LOCATION=<`*schema_dest_location*`>`

      where *<schema_dest_location>* is the location where the updated SQL files with replaced variables should be copied. If SCHEMA_DEST_LOCATION is not set, the updated SQL files are copied to a directory with the name as the unsubstituted value under the current directory. The output indicates where the files are copied to.

   f. `./ws_ant.sh -f `*app_server_root*`/etc/wim/setup/filterbuild.xml`
4. Start the DB2 server.
5. Create a database.
6. Run the SQL files, which were previously referenced, to create the tables for the property extension repository. If you are setting up the database on the same system on which the application server is installed, the files are located in the following locations:

   DB2 for iSeries

   app_server_root/etc/wim/setup/lookaside/db2iseries/dbclean.sql
   app_server_root/etc/wim/setup/lookaside/db2iseries/schema.sql
   app_server_root/etc/wim/setup/lookaside/db2iseries/primarykeys.sql
   app_server_root/etc/wim/setup/lookaside/db2iseries/indexes.sql
   app_server_root/etc/wim/setup/lookaside/db2iseries/references.sql
   app_server_root/etc/wim/setup/lookaside/keys.sql
   app_server_root/etc/wim/setup/lookaside/bootstrap.sql

DB2 for z/OS

app_server_root/etc/wim/setup/lookaside/db2zos/dbclean.sql
app_server_root/etc/wim/setup/lookaside/db2zos/schema.sql
app_server_root/etc/wim/setup/lookaside/db2zos/primarykeys.sql
app_server_root/etc/wim/setup/lookaside/db2zos/indexes.sql
app_server_root/etc/wim/setup/lookaside/db2zos/references.sql
app_server_root/etc/wim/setup/lookaside/keys.sql
app_server_root/etc/wim/setup/lookaside/bootstrap.sql

Otherwise, run the SQL files from the location to which you copied the files. If you executed the commands to substitute variables according to the steps in the previous section, Specifying the database schema, the SQL files are copied to the location you specified for SCHEMA_DEST_LOCATION. If SCHEMA_DEST_LOCATION is not set, the updated SQL files are copied to a directory with the name as the unsubstituted value under the current directory. The output shows where the files are copied.

What to do next

Run the setupIdMgrPropertyExtensionRepositoryTables command with the **skipDBCreation** parameter set to true to populate the tables that are created. For more information, read about setting up an entry mapping repository, a property extension repository, or a custom registry database repository using wsadmin commands.

Configuring the WebSphere Application Server data source:

Installed applications use data sources as resources to obtain connection to relational databases. To create these connections between an application and a relational database, WebSphere Application Server uses the driver implementation classes that are encapsulated by the JDBC provider, which is an object that represents vendor-specific JDBC driver classes to WebSphere Application Server. For access to a relational databases, applications use the JDBC drivers and data sources that you configure for WebSphere Application Server.

Procedure

1. Start the WebSphere Application Server administrative console.
2. Click **Security -> Global security**.
3. On the Configuration panel, expand Java Authentication and Authorization Service and click **J2C authentication data**.
4. Click **New** and enter the Alias, User ID and Password.
5. Click **Ok**.
6. On the WebSphere Application Server administrative console, expand **Resources**. Expand **JDBC** then click **JDBC Providers**.
7. In the Scope section, choose the **Node level** from the drop-down list.
8. Click **New** to create a new JDBC driver.
9. Select, in this order, the Database type, Provider type, Implementation type and Name. The Name automatically fills based on the implementation type you choose.
10. Click **Next** and configure the database class path. Click **Next**.
11. On the Summary page, click **Finish**.
12. Click **Save** to save your selections. The JDBC providers page then appears.
13. On the WebSphere Application Server administrative console, click **Data sources**.
14. Click **New** to create a new data source. Enter the Data source name and the JNDI name, and choose the authentication alias from the drop-down list in Component-managed authentication alias. The JNDI name should match the datasourceName value set in `wimconfig.xml`. By default, it is `jdbc/wimDS`.

Note: For Apache Derby v10.2 embedded databases, leave the Component-managed authentication alias field set to `NONE`.

15. Click **Next**.
16. Enter the Database name and deselect the checkbox, **Use this data source in container managed persistence (CMP)**. Click **Next**.
17. On the Summary page, click **Finish**.
18. The Data sources page displays. Click **Save**, Then select the check box for the authentication alias previously created. Click **Test Connection**. The message should indicate that the connection is successful. Ignore any warnings, and then click **Next**.
19. Save the configurations, and restart WebSphere Application Server.

Configuring an entry mapping repository in a federated repository configuration:

Follow this task to configure an entry mapping repository that is used to store data for managing profiles on multiple repositories.

About this task

An *entry-level join* means that the federated repository configuration uses multiple repositories simultaneously and recognizes the entries in the different repositories as entries representing distinct entities. For example, a company might have a Lightweight Directory Access Protocol (LDAP) directory that contains entries for its employees and a database that contains entries for business partners and customers. By configuring an entry mapping repository, a federated repository configuration can use both the LDAP and the database at the same time. The federated repository configuration hierarchy and constraints for identifiers provide the aggregated namespace for both of those repositories and prevent identifiers from colliding.

When you configure an entry mapping repository, you can supply a valid data source, a direct connection configuration, or both. The system first tries to connect by way of the data source. If the data source is not available, then the system uses the direct access configuration.

Restriction: You cannot configure an entry mapping repository in a mixed-version deployment manager cell.

Procedure

1. Configure the WebSphere Application Server data source. See “Configuring the WebSphere Application Server data source” on page 1373.
2. Set up the entry mapping repository using wsadmin. See “Setting up an entry mapping repository, a property extension repository, or a custom registry database repository using wsadmin commands” on page 1359; ignore the "Before you begin" options.
3. Configure the entry mapping repository into the federated repository by doing the following:
   a. In the administrative console, click **Security > Global security**.
   b. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
   c. Click **Entry mapping repository**.
   d. Supply the name of the data source in the Data source name field.
   e. Select the type of database that is used for the property extension repository.
   f. Supply the name of the Java database connectivity (JDBC) driver in the JDBC driver field.
      Values include:

      DB2 `com.ibm.db2.jcc.DB2Driver`

DB2 for iSeries
com.ibm.db2.jcc.DB2Driver

Informix
com.informix.jdbc.IfxDriver

DataDirect Connect
com.ddtek.jdbc.sqlserver.SQLServerDriver

Derby org.apache.derby.jdbc.EmbeddedDriver

Microsoft SQL Server
com.microsoft.sqlserver.jdbc.SQLServerDriver

Oracle
oracle.jdbc.driver.OracleDriver

g. Supply the database URL that is used to access the property extension repository with JDBC in the Database URL field. Use an alphanumeric text string that conforms to the standard JDBC URL syntax.

Values include:

DB2 jdbc:db2:wim

Informix
jdbc:informix-sqli://*host_name*:1526/wim:INFORMIXSERVER=*IFXServerName*;

DataDirect Connect
jdbc:datadirect:sqlserver://*host_name*:1433;databaseName=wim;selectMethod=cursor;

Derby jdbc:derby:c:\derby\wim

Microsoft SQL Server
jdbc:sqlserver://*host_name*:1433;databaseName=wim;selectMethod=cursor;

Oracle
jdbc:oracle:thin:@*host_name*:*port*:*dbname*

h. Supply the user name of the database administrator in the Database administrator user name field.

i. Supply the password of the database administrator in the Password field.

j. Click **OK**.

Results

After completing these steps, your federated repository configuration, which includes an entry mapping repository, is configured.

What to do next

1. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
2. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1186. As the final step, validate this setup by clicking **Apply** in the Global security panel.
3. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Entry mapping repository settings:

Use this page to configure an entry mapping repository that is used to store data for managing profiles on multiple repositories.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Additional properties, click **Entry mapping repository**.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

Data source name:

Specifies the Java Naming and Directory Interface (JNDI) name of the data source that is used to access the entry mapping repository.

Default: `jdbc/wimDS`

Database type:

Specifies the type of database that is used to access the entry mapping repository.

Default: `DB2`

JDBC driver:

Specifies the Java Database Connectivity (JDBC) driver that is used to access the entry mapping repository.

Values include:

DB2 `com.ibm.db2.jcc.DB2Driver`

DB2 for iSeries
`com.ibm.db2.jcc.DB2Driver`

DataDirect Connect
`com.ddtek.jdbc.sqlserver.SQLServerDriver`

Informix
`com.informix.jdbc.IfxDriver`

Oracle
`oracle.jdbc.driver.OracleDriver`

Microsoft SQL Server
`com.microsoft.sqlserver.jdbc.SQLServerDriver`

Derby `org.apache.derby.jdbc.EmbeddedDriver`

Database URL:

Specifies the web address for the entry mapping repository.

Values include:

DB2 `jdbc:db2:wim`

Derby `jdbc:derby:c:\derby\wim`

DataDirect Connect

`datadirect:sqlserver://:host_name1433;databaseName=wim;selectMethod=cursor;`

Oracle

`jdbc:oracle:thin:@host_name:port:dbname`

Microsoft SQL Server

`jdbc:sqlserver://host_name:1433;databaseName=wim;selectMethod=cursor;`

Informix

`jdbc:informix-sqli://host_name:port/wim:INFORMIXSERVER=IFXServerName;`

Database administrator user name:

Specifies the user name of the database administrator that is used to access the entry mapping repository.

Password:

Specifies the password that is used to enable the database administrator to access the entry mapping repository.

Configuring supported entity types in a federated repository configuration:

Follow this task to configure supported entity types for user and group management.

About this task

You must configure the supported entity types before you can manage this account with Users and Groups in the administrative console. The supported entity types are Group, OrgContainer, and PersonAccount. A Group entity represents a simple collection of entities that might not have any relational context. An OrgContainer entity represents an organization, such as a company or an enterprise, a subsidiary, or an organizational unit, such as a division, a location, or a department. A PersonAccount entity represents a human being. You cannot add or delete the supported entity types, because these types are predefined.

The Base entry for the default parent determines the repository location where entities of the specified type are placed on write operations by user and group management.

Note: To manage users and groups, click **Users and Groups** in the console navigation tree. Click either **Manage Users** or **Manage Groups**.

Note: You must restart the server or dmgr if the federated repository has changed before using the Manage Users option. Otherwise, user or group changes made to the repository could be lost after restart.

Procedure

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Click **Supported entity types** to view a list of predefined entity types.
4. Click the name of a predefined entity type to change its configuration.
5. Supply the distinguished name of a base entry in the repository in the Base entry for the default parent field. This entry determines the default location in the repository where entities of this type are placed on write operations by user and group management.

6. Supply the relative distinguished name (RDN®) properties for the specified entity type in the Relative Distinguished Name properties field. Possible values are `cn` for Group, `uid` or `cn` for PersonAccount, and `o`, `ou`, `dc`, and `cn` for OrgContainer. Delimit multiple properties for the OrgContainer entity with a semicolon (;).

   The following list outlines known requirements and limitations that apply to specific Lightweight Directory Access Protocol (LDAP) servers:

   Using Microsoft Active Directory as the LDAP server

   - Unless you modify the LDAP schema to use `uid`, you must specify `cn` in the Relative Distinguished Name (RDN) properties field for the PersonAccount entity type.
   - Secure Sockets Layer communications must be enabled to create users with passwords. To select the **Require SSL communications** option, see the topic "Configuring Lightweight Directory Access Protocol in a federated repository configuration" on page 1339.
   - Typically the value of `user` is specified as the value in the Object classes field for the PersonAccount entity type and the value of `group` is specified as the value in the Object classes field for the Group entity type.

   Using a Lotus Domino Enterprise Server as the LDAP server

   - Typically, the value of `cn` is specified in the Relative Distinguished Name (RDN) properties field for the PersonAccount entity type. The value of `uid` is also acceptable.
   - Typically, both `inetOrgPerson` and `dominoPerson` are used as values in the Object classes field for the PersonAccount entity type.

   Using Sun ONE Directory Server as the LDAP server

   - Typically, `groupOfUniqueNames` is specified as the value in the Object classes field for the Group entity type.
7. Click **OK**.

Results

After completing these steps, your federated repository configuration, which uses supported entity types, is configured.

What to do next

1. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
2. If you are enabling security, complete the remaining steps as specified in "Enabling security for the realm" on page 1186. As the final step, validate this setup by clicking **Apply** on the Global security panel.
3. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Supported entity types collection:

Use this page to list entity types that are supported by the member repositories or to select an entity type to view or change its configuration properties.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.

2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Additional properties, click **Supported entity types**.

You must configure the supported entity types before you can manage this account with Users and Groups in the administrative console. The Base entry for the default parent determines the repository location where entities of the specified type are placed on write operations by user and group management.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

Entity type:

Specifies the entity type name.

Base entry for the default parent:

Specifies the distinguished name of a base entry in the repository.

This entry determines the default location in the repository where entities of this type are placed on write operations by user and group management.

Relative Distinguished Name properties:

Specifies the relative distinguished name (RDN) properties for the specified entity type.

Possible values are `cn` for Group, `uid` or `cn` for PersonAccount, and `o`, `ou`, `dc`, and `cn` for OrgContainer. Delimit multiple properties for the OrgContainer entity with a semicolon (;).

Supported entity types settings:

Use this page to configure entity types that are supported by the member repositories.

To view this administrative console page, complete the following steps:
1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Additional properties, click **Supported entity types**.
4. Click the name of a configured entity type to view or change its configuration.

You must configure the supported entity types before you can manage this account with Users and Groups in the administrative console. The Base entry for the default parent determines the repository location where entities of the specified type are placed on write operations by user and group management.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

Entity type:

Specifies the name of the entity type.

Base entry for the default parent:

Specifies the distinguished name of a base entry in the repository.

This entry determines the default location in the repository where entities of this type are placed on write operations by user and group management.

Relative Distinguished Name properties:

Specifies the relative distinguished name (RDN) properties for the specified entity type.

Possible values are `cn` for Group, `uid` or `cn` for PersonAccount, and `o`, `ou`, `dc`, and `cn` for OrgContainer. Delimit multiple properties for the OrgContainer entity with a semicolon (;).

Managing repositories in a federated repository configuration:

Follow this topic to manage repositories in a federated repository configuration.

Procedure

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**. Repositories that are configured in the system are listed in the collection panel. This list includes repositories that are configured using the federated repository functionality as well as repositories that are created using wsadmin commands described in the topic IdMgrRepositoryConfig command group for the AdminTask object.
4. Optional: Click **Add** to configure a new external repository. The Lightweight Directory Access Protocol (LDAP) repository configuration settings are described in detail in “Configuring Lightweight Directory Access Protocol in a federated repository configuration” on page 1339.

   Restriction: You cannot add a database repository using the administrative console. This repository configuration is supported by using wsadmin commands only.
5. Optional: Click **Delete** to delete a repository that you specified previously using the administrative console or wsadmin commands.

   Restriction: You cannot delete the built-in, file-based repository from the collection panel.
6. Optional: Select one of the LDAP repository identifier entries to view or update an external repository that is configured in the system previously. The steps to configure LDAP settings are described in detail in “Configuring Lightweight Directory Access Protocol in a federated repository configuration” on page 1339.

   Restriction: While database repositories that are configured in the system are listed in the collection panel, you cannot update a database repository using the administrative console. Updates to a database repository are supported by using wsadmin commands only.
7. Click **OK**.

Results

After completing these steps, the collection panel under Managing repositories reflects a current list of repositories that are configured in your system.

What to do next

1. To add one or more external repositories that are listed on this collection panel into the realm, see “Managing the realm in a federated repository configuration” on page 1316.
2. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply**

on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.

3. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1186. As the final step, validate this setup by clicking **Apply** in the Global security panel.
4. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Replicating changes to a built-in, file-based repository:

Changes to built-in, file-based repositories are not automatically replicated to managed nodes in a federated repositories configuration. You need to use the administrative console to replicate the changes you make to a built-in, file-based repository.

About this task

The network deployment support in a federated repositories configuration only updates the in-memory state of the processes that are running on the managed nodes. Because WebSphere Application Server synchronizes the file systems, the network deployment support does not attempt to update the file systems of the managed nodes.

You must synchronize the node configuration to replicate the changes to the built-in, file-based repository.

Procedure

1. In the administrative console, click **System Administration > Nodes**. to access the nodes panel.
2. On the Nodes panel, select all the relevant nodes for which the changes to the built-in, file-based repository need to be made.
3. Click **Full Resynchronize**. The resynchronize operation resolves conflicts among configuration files and can take several minutes to complete.

Results

After completing these steps, your federated repository configuration of managed nodes reflects the changes to the built-in, file-based repository.

Manage repositories collection:

Use this page to list repositories that are configured in the system or to select a repository to view or change its configuration properties. You can add or delete external repositories.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

Repository identifier:

Specifies a unique identifier for the repository. This identifier uniquely identifies the repository within the cell.

Repository type:

Specifies the repository type, such as File or LDAP.

Add:

Select to add a new LDAP, custom or file repository.

Repository reference settings:

Use this page to configure a repository reference. A repository reference is a single repository that contains a set of identity entries that are referenced by a base entry into the directory information tree.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Click **Add base entry to realm**.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

Repository:

Specifies a unique identifier for the repository. This identifier uniquely identifies the repository within the cell.

Expand the drop-down list to display a list of previously defined repository identifiers.

Distinguished name that uniquely identifies this set of entries in the realm:

Specifies the distinguished name (DN) that uniquely identifies this set of entries in the realm.

If multiple repositories are included in the realm, it is necessary to define an additional distinguished name that uniquely identifies this set of entries within the realm. Overlapping base entries are not supported. You should not define two base entries where one is c=us, and the other is o=myorg,c=us in the same realm; otherwise a search returns duplicate results.

Distinguished name of a base entry in this repository:

Specifies the Lightweight Directory Access Protocol (LDAP) distinguished name (DN) of the base entry within the repository. The entry and its descendents are mapped to the subtree that is identified by the unique base name entry field.

If this field is left blank, then the subtree defaults to the root of the LDAP repository.

Increasing the performance of the federated repository configuration:

Follow this page to manage the realm in a federated repository configuration.

Before you begin

The settings that are available on the Performance panel are independent options that pertain specifically to the federated repositories functionality. These options do not affect your entire WebSphere Application Server configuration.

Procedure

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories** > *repository_name*.
4. Under Additional properties, click **Performance**.
5. Optional: Select the **Limit search time** option and enter the maximum number of milliseconds that the Application Server can use to search through your Lightweight Directory Access Protocol (LDAP) entries.
6. Optional: Select the **Limit search returns** option and enter the maximum number of entries to return that match the search criteria.
7. Optional: Select the **Use connection pooling** option to specify whether the Application Server can store separate connections to the LDAP server for reuse.
8. Optional: Select the **Enable context pool** option to specify whether multiple applications can use the same connection to the LDAP server. If you select the option, specify the initial, preferred, and maximum number of entries that can use the same connection. The **Enable context pool** option can be enabled either in conjunction with the **Use connection pool** option or separately. If this option is disabled, a new connection is created for each context. You can also select the **Context pool times out** option and specify the number of seconds after which the entries in the context pool expire.
9. Optional: Set the **Maximum size** value of the context pool to zero (0).
10. Optional: Select the **Cache the attributes** option and specify the maximum number of search attribute entries. This option enables WebSphere Application Server to save the LDAP entries so that it can search the entries locally rather than making multiple calls to the LDAP server. Click the **Cache times out** option that is associated with the **Cache the attributes** option to specify the maximum number of seconds that the Application Server can save these entries.
11. Optional: Select the **Cache the search results** option and specify the maximum number of search result entries. This option enables WebSphere Application Server to save the results of a search inquiry instead of making multiple calls to the LDAP server to search and retrieve the results of that search. Click the **Cache times out** option that is associated with the **Cache the search results** option to specify the maximum number of seconds that the Application Server can save the results.
12. Optional: Create the root DataObject object locally using the com.ibm.websphere.wim.util.SDOHelper.createRootDataObject method instead of the com.ibm.websphere.wim.ServiceProvider.createRootDataObject method.

Results

These options are available to potentially increase the performance of your federated repositories configuration. However, the any increase in performance is dependant upon your specific configuration.

Lightweight Directory Access Protocol performance settings:

Use this page to minimize impacts to performance by adding opened connections and contexts to internally maintained pools and reusing them. Also minimize performance impacts by maintaining internal caches of retrieved data.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.
5. Under Additional properties, click **Performance**.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

Limit search time:

Specifies the timeout value in milliseconds for a Lightweight Directory Access Protocol (LDAP) server to respond before stopping a request.

Data type:	Integer
Units:	Milliseconds
Default:	0
Range:	Equal to or greater than 0. A value of 0 specifies that no search time limit exists.

Limit search returns:

Specifies the maximum number of entries that are returned in a search result.

Data type:	Integer
Units:	Entries
Default:	0
Range:	Equal to or greater than 0. A value of 0 specifies that no search return limit exists.

Use connection pooling:

Specifies whether to utilize the connection pooling function, which is provided in the Software Development Kit (SDK).

Connection pooling is maintained by the Java run time. It is configured by system properties.

Default:	Disabled
Range:	Enabled or Disabled

Enable context pool:

Specifies whether context pooling is enabled to the LDAP server. To improve performance, use the context pool in combination with connection pooling.

Default:	Enabled
Range:	Enabled or Disabled

Initial size:

Specifies the number of context instances in the pool when the pool is initially created by the LDAP repository.

Data type:	Integer
Default:	1
Range:	1 to 50

Preferred size:

Specifies the preferred number of context instances that the context pool maintains. Both in-use and idle context instances contribute to this number.

Data type: Integer
Default: 3
Range: 0 to 100

Maximum size:

Specifies the maximum number of context instances that can be maintained concurrently by the context pool. Both in-use and idle context instances contribute to this number.

When the pool size reaches the maximum size, no new context instances can be created for a new request. The new request is blocked until a context instance is released or removed. The request periodically checks for context instances that are available in the pool. A request for a pooled context instance uses an existing pooled and idle context instance or a newly created pooled context instance.

A maximum pool size of 0 indicates that the context pool can maintain an infinite number of context instances.

Data type: Integer
Default: 0

Context pool times out:

Specifies the number of seconds for the context pool to time out and remove idle context instances.

A timeout value of 0 indicates that the context pool does not time out context instances.

Data type: Integer
Default: 0

Distribution policy:

Specifies the distribution policy for the cache in a clustered environment, which is one of the following:

None Sends out new entries, both ID and data, and updates to those entries.

Push Requests data from other servers in the cluster when that data is not locally present.

Push and pull
Sends out IDs for new entries and requests from other servers in the cluster entries for IDs that were previously broadcast. The dynamic cache always sends out cache entry invalidations.

Cache the attributes:

Specifies whether to cache the attributes that are returned from the LDAP server.

Default: Enabled
Range: Enabled or Disabled

Cache size:

Specifies the maximum size of the cache.

Data type: Integer
Default: 4000
Range: Equal to or greater than 100

Cache times out:

Specifies the maximum number of seconds that the cached search results can stay in the cache.

A timeout value of 0 indicates that the cached search results stay in the cache until update operations are made.

Data type: Integer
Units: Seconds
Default: 1200
Range: Equal to or greater than 0

Cache the search results:

Specifies whether to cache the search results that are returned from the LDAP server.

Default: Enabled
Range: Enabled or Disabled

Cache size:

Specifies the maximum size of the cache.

Data type: Integer
Default: 2000
Range: Equal to or greater than 100

Cache times out:

Specifies the maximum number of seconds that the cached search results can stay in the cache.

A timeout value of 0 indicates that the cached search results stay in the cache until update operations are made.

Data type: Integer
Units: Seconds
Default: 600
Range: Equal to or greater than 0

Using custom adapters for federated repositories:

When the custom adapters for federated repositories are part of the default realm, the users and groups can be managed using wsadmin commands or the administrative console.

About this task

If custom adapters for federated repositories are part of the default realm, you use the administrative console to manage the users and groups in the realm.

Note: The default parent for PersonAccount and Group entities needs to be the same as the base entry of the custom adapter.

To view this administrative console page, complete the following steps:

- In the administrative console, click **Security > Global security**.
- Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
- Under Additional properties, click **Supported entity types**.

You must configure the supported entity types before you can manage this account with Users and Groups in the administrative console. The Base entry for the default parent determines the repository location where entities of the specified type are placed on write operations by user and group management.

Procedure

1. In the administrative console, click **Users and Groups** to access users and groups panel.
2. Click **Manage Groups** to test the basic functions of the custom adapter with respect to custom adapters for federated repositories.
3. Click **Manage Users** to test the basic functions of the custom adapter with respect to custom adapters for federated repositories.

   Note: You must restart the server or dmgr if the federated repository has changed before using the Manage Users option. Otherwise, user or group changes made to the repository could be lost after restart.

Results

After completing these steps, you will have ensured that the custom adapter is being used properly.

What to do next

Adjustments to the custom adapter can be made by using the wsadmin tool to make configuration changes. See “Configuring custom adapters for federated repositories using wsadmin” on page 1389 for more details.

Sample custom adapters for federated repositories examples:

Out of the box adapters for federated repositories provide File, LDAP, and Database adapters for your use. These adapters implement the com.ibm.wsspi.wim.Repository software programming interface (SPI). A virtual member manager custom adapter needs to implement the same SPI.

Developing custom adapters for federated repositories

Out of the box adapters for federated repositories provide File, LDAP and Database adapters for your use. All these adapters implement the `com.ibm.wsspi.wim.Repository` SPI. See the `com.ibm.wsspi.wim.Repository` SPI for more information. As you develop a virtual member manager custom adapter, you need to implement the same SPI.

Custom adapters for federated repositories must not depend on any WebSphere Application Server components, such as data sources and enterprise beans. These WebSphere Application Server components require that security is initialized and enabled prior to startup. If your implementation of custom adapters for federated repositories needs to use data sources to connect to a database, you need to use Java database connectivity (JDBC) to make the connection during server startup. Then, at a later time, switch to using the data sources when the data source is available.

There are examples of suggested behavior and requirements of custom adapters for federated repositories that you can find in the sample code.

A sample custom adapter for federated repositories

A sample custom adapter implementation has been provided as an example. The custom adapter is based on file repository. The sample source code and class files are bundled in vmmsampleadapter.jar. The `vmmsampleadapter.jar` can be downloaded at this location: http://www.ibm.com/developerworks/websphere/downloads/samples/vmmsampleadapter.html.

Contents of the vmmsampleadapter.jar file are as follows:

- Class files for the sample adapter:
  - `com/ibm/ws/wim/adapter/sample/AbstractAdapterImpl.class`
  - `com/ibm/ws/wim/adapter/sample/SampleFileAdapter.class`
  - `com/ibm/ws/wim/adapter/sample/XPathHelper.class`
- Source code for the sample adapter:
  - `src/com/ibm/ws/wim/adapter/sample/AbstractAdapterImpl.java`
  - `src/com/ibm/ws/wim/adapter/sample/SampleFileAdapter.java`
  - `src/com/ibm/ws/wim/adapter/sample/XPathHelper.java`

Note: The sample files should not be used in the production environment. You should make a copy of these files, rename them, and update them based on your specific adapter implementation. Refer to the Javadoc in the source code for more information.

com/ibm/ws/wim/sample/adapter/AbstractAdapterImpl.java
Provides an abstract implementation class which handles most of the repository independent internal operations for the adapter and defines some simple abstract methods that should be implemented by the custom adapter. For most cases, you may not need to change this file.

com/ibm/ws/wim/sample/adapter/SampleFileAdapter.java
Extends from the AbstractAdapterImpl class and implements the abstracts method. This class implements the abstract methods using file as the repository. Adapter providers can use this class as a reference to implement these methods specific to their adapters.

com/ibm/ws/wim/sample/adapter/XPathHelper.java
Defines a helper class to parse the XPath search expression and build the search tree. This helper class also contains the method to evaluate the search expression. If your repository supports a search expression, then you need to convert XPath expression to an expression that your repository can process and let your repository evaluate the expression. This helper class evaluates the search expression based on the use of dataobjects. You can overwrite the `evaluate()` method to perform the evaluation using other objects, such as **java.util.Map**.

Some utility classes have been provided to help adapter providers. Most of these utility methods are used in the sample adapter. Refer to http://publib.boulder.ibm.com/infocenter/wasinfo/v6r1/index.jsp?topic=/com.ibm.websphere.javadoc.doc/vmm/com/ibm/wsspi/wim/package-summary.html for more details.

Establishing custom adapters for federated repositories:

Out of the box adapters for federated repositories provide File, LDAP, and Database adapter for your use. These adapters implement the com.ibm.wsspi.wim.Repository software programming interface (SPI). Custom adapters for federated repositories need to implement the same SPI.

Before you begin

Refer to the Repository SPI implementation information in the related references for information about the custom adapters for federated repositories SPI.

Refer to the sample custom adapter code that is available in the vmmsampleadapter.jar file. The JAR file contains the sample customer adapter code in the src/ directory. The vmmsampleadapter.jar can be downloaded at this location: http://www.ibm.com/developerworks/websphere/library/samples/vmmsampleadapter.html

Note:

- The sample that is provided is intended to familiarize you with the features of custom adapters for federated repositories and the handling of various types of dataobjects. Do not use this sample in an actual production environment.
- Copy the AbstractAdapterImpl class and rename it before making changes. Make sure that the new name is appropriate for your adapter.

Custom adapters for federated repositories must not depend on any WebSphere Application Server components, such as data sources and enterprise beans. These WebSphere Application Server components require that security is initialized and enabled prior to startup. If your implementation of the virtual member manager custom adapter needs to use data sources to connect to a database, you need to use Java database connectivity (JDBC) to make the connection during server startup. Then, at a later time, switch to using the data sources when the data source is available.

Procedure

1. Build your implementation.

   Note: EMF JAR files contain version number in their names, such as v200607270021. Make sure to change the version number to reflect your installation.

   To compile your code, you need the following JAR files in the classpath:

   - *app_server_root*/plugins/com.ibm.ws.runtime_6.1.0.jar
   - *app_server_root*/plugins/org.eclipse.emf.commonj.sdo_2.1.0.v200607270021.jar
   - *app_server_root*/plugins/org.eclipse.emf.ecore_2.2.1.v200607270021.jar
   - *app_server_root*/plugins/org.eclipse.emf.common_2.2.1.v200607270021.jar
   - *app_server_root*/plugins/org.eclipse.emf.ecore.xmi_2.2.0.v200607270021.jar
   - *app_server_root*/plugins/org.eclipse.emf.ecore.sdo_2.2.0.v200607270021.jar

   Here is an example:

   ```
   "${java.home}/bin/javac -classpath
   app_server_root/plugins/com.ibm.ws.runtime_6.1.0.jar;app_server_root/plugins/org.eclipse.emf.commonj.sdo_2.1.0.
   v200607270021.jar;app_server_root/plugins/org.eclipse.emf.ecore_2.2.1.v200607270021.jar;
   app_server_root/plugins/org.eclipse.emf.
   common_2.2.1.v200607270021.jar;app_server_root/plugins/org.eclipse.emf.ecore.xmi_2.2.0.v200607270021.jar;
   app_server_root/plugins/org.eclipse.emf.
   ecore.sdo_2.2.0.v200607270021.jar your_implementation_file.java"
   ```

2. Copy the generated class files or the packaged JAR file to the product classpath. The preferred location is the *app_server_root*/lib/ext directory. This should be copied to the classpaths of all the product processes (cell and all NodeAgents).
3. Configure your custom adapter by following the steps in “Configuring custom adapters for federated repositories using wsadmin.”
4. Test your custom adapter by following the steps in “Using custom adapters for federated repositories” on page 1386

What to do next

“Configuring custom adapters for federated repositories using wsadmin” provides details about configuring your custom adapter with the wsadmin tool.

Configuring custom adapters for federated repositories using wsadmin:

You can use the Jython or Jacl scripting language with the wsadmin tool to define custom adapters in the federated repositories configuration file.

Before you begin

Shut down the WebSphere Application Server and the wsadmin command window.

About this task

The federated repositories configuration file, `wimconfig.xml`, is shipped with WebSphere Application Server 6.1.x and is located in the *app_server_root*/`profiles/`*profile_name*`/config/cells/`*cell_name*`/wim/config` directory.

Note: For additional information about the commands to use for this topic, see the IdMgrRepositoryConfig command group for the AdminTask object topic.

Use the following steps to add a custom adapter to any federated repositories configuration file and to any realm defined within the configuration file.

Procedure

1. Open the `wimconfig.xml` file with a text editor.
2. Add a new config:repositories element to the file. This element should be placed before the config:realmConfiguration element.

   The following example configures a custom repository to use the **com.ibm.ws.wim.adapter.sample.SampleFileAdapter** class and sets the **SampleFileRepository** repository as the identifier:

```
<config:repositories adapterClassName="com.ibm.ws.wim.adapter.sample.SampleFileAdapter"
id="SampleFileRepository"/>
```

3. Save the `wimconfig.xml` file and close the text editor.
4. Copy the `vmmsampleadapter.jar` file that is provided to `app_server_root/lib`.
5. Enter the following command to start the wsadmin tool:

```
wsadmin –conntype none
```

6. Disable paging in the common repository configuration. Set the supportPaging parameter for the updateIdMgrRepository command to false to disable paging.

   Note: You must perform this step because the sample adapter does not support paging.

   The following examples use the **SampleFileRepository** repository as the identifier for the custom repository.

   Using Jython:

```
AdminTask.updateIdMgrRepository('-id SampleFileRepository -supportPaging false')
```

   Using Jacl:

```
$AdminTask updateIdMgrRepository {-id SampleFileRepository -supportPaging
false}
```

   Note: A warning will appear until the configuration of the sample repository is complete.

7. Add the necessary custom properties for the adapter. Use the setIdMgrCustomProperty command repeatedly to add multiple properties. Use this command once per property to add multiple properties to your configuration. You must use both the **name** and **value** parameters to add the custom property for the specified repository. For example, to add a custom property of **fileName**, enter the following command.

   Using Jython:

```
AdminTask.setIdMgrCustomProperty('-id SampleFileRepository -name fileName
-value "c:\sampleFileRegistry.xml"')
```

   Using Jacl:

```
$AdminTask setIdMgrCustomProperty {-id SampleFileRepository -name fileName
-value "c:\sampleFileRegistry.xml"}
```

8. Add a base entry to the adapter configuration. Use the addIdMgrRepositoryBaseEntry command to specify the name of the base entry for the specified repository. For example:

   Using Jython:

```
AdminTask.addIdMgrRepositoryBaseEntry('-id SampleFileRepository -name
o=sampleFileRepository')
```

   Using Jacl:

```
$AdminTask addIdMgrRepositoryBaseEntry {-id SampleFileRepository -name
o=sampleFileRepository}
```

9. Use the addIdMgrRealmBaseEntry command to add the base entry to the realm, which will link the realm with the repository:

   Using Jython:

```
AdminTask.addIdMgrRealmBaseEntry('-name defaultWIMFileBasedRealm -baseEntry o=sampleFileRepository')
```

   Using Jacl:

```
$AdminTask addIdMgrRealmBaseEntry {-name defaultWIMFileBasedRealm -baseEntry o=sampleFileRepository}
```

10. Save your configuration changes. Enter the following commands to save the new configuration and close the wsadmin tool.

    Using Jython:

```
AdminConfig.save()
exit
```

    Using Jacl:

```
$AdminConfig save
exit
```

    The following example displays the complete text of the newly-revised `wimconfig.xml` file:

```

```

11. Restart the application server.

Configuring the user registry bridge for federated repositories using wsadmin scripting:

The user registry bridge is configured like other custom adapters. You can use the Jython or Jacl scripting language with the wsadmin scripting tool to define the user registry bridge in the federated repositories configuration.

Before you begin

Shut down WebSphere Application Server and the wsadmin command window.

Important: If you are migrating from the stand-alone user registry on the local operating system to federated repositories on the local operating system, you must first configure the current user registry under federated repositories. For more information, see Managing the realm in a federated repository configuration.

Authorization failures might occur if users or groups are mapped to roles before migration and you use those users or groups after migrating to user registry bridge. This situation occurs because the mapping contains registry-specific information. After migration, re-map the users or groups to avoid authorization failures.

About this task

For additional information about the commands to use for this topic, see IdMgrRepositoryConfig command group for the AdminTask object.

Use the following steps to add a user registry bridge to any federated repositories configuration and to any realm that is defined within the configuration.

Procedure

1. Start the wsadmin scripting tool. You can use the following command to start the wsadmin scripting tool:

```
wsadmin –conntype none
```

2. Use the createIdMgrCustomRepository command to add a new repository configuration for the user registry bridge.

   The following example configures a custom repository to use the com.ibm.ws.wim.adapter.urbridge.URBridge class and sets urbcustom as the identifier:

   Using Jython:

```
AdminTask.createIdMgrCustomRepository('-id urbcustom
-adapterClassName com.ibm.ws.wim.adapter.urbridge.URBridge')
```

   Using Jacl:

```
$AdminTask createIdMgrCustomRepository {-id urbcustom
-adapterClassName com.ibm.ws.wim.adapter.urbridge.URBridge}
```

   gotcha: The user registry bridge handles requests to one user registry only. Therefore, if you define multiple repositories, each user registry implementation must have a separate instance of the user registry bridge and you must define each implementation as a separate repository with a unique repository ID..

3. Optional: Add the necessary registry-specific properties as custom properties. Use the setIdMgrCustomProperty command repeatedly to add multiple properties. Use this command once per property to add multiple properties to your configuration. You must use both the name and value parameters to add the custom property for the specified repository. For example, to add a custom property of uniqueUserIdProperty, enter the following command:

   Using Jython:

```
AdminTask.setIdMgrCustomProperty('-id urbcustom
-name uniqueUserIdProperty -value "uniqueId"')
```

   Using Jacl:

```
$AdminTask setIdMgrCustomProperty {-id urbcustom
-name uniqueUserIdProperty -value "uniqueId"}
```

   To configure the user registry bridge to use a custom user registry, you must add the registryImplClass property and specify the exact registry implementation class. For example, specify com.xyz.abc.MyCustomRegistry as the value for the property.

   To configure the user registry bridge to use the local operating system user registry, do not specify the registryImplClass property. The user registry bridge identifies the underlying user registry implementation that is provided by WebSphere Application Server for the local operating system.

   You can set other optional properties as custom properties to define the mapping between federated repository properties and user registry properties, such as uniqueUserIdProperty, userSecurityNameProperty, userDisplayNameProperty, uniqueGroupIdProperty, groupSecurityNameProperty, and groupDisplayNameProperty. For more information about the available custom properties and their default values, see Security custom properties. To override any of these properties at the user registry level, configure the property as a custom property.

4. Add a base entry to the user registry bridge configuration. Use the addIdMgrRepositoryBaseEntry command to specify the name of the base entry for the specified repository. For example:

   Using Jython:

```
AdminTask.addIdMgrRepositoryBaseEntry('-id urbcustom
-name o=custom')
```

   Using Jacl:

```
$AdminTask addIdMgrRepositoryBaseEntry {-id urbcustom
-name o=custom}
```

5. Use the addIdMgrRealmBaseEntry command to add the base entry to the realm, which will link the realm with the repository.

   Note: The default realm name is defaultWIMFileBasedRealm. If this realm name was previously renamed, use the new realm name instead of defaultWIMFileBasedRealm. For example, to ensure consistency, you can set the realm name of the federated repository configuration to be the same name as the local operating system user registry as specified in the `security.xml` file. For information about how to set the realm name, see Realm configuration settings.

   Use the following command:

   Using Jython:

```
AdminTask.addIdMgrRealmBaseEntry('-name defaultWIMFileBasedRealm
-baseEntry o=custom')
```

   Using Jacl:

```
$AdminTask addIdMgrRealmBaseEntry {-name defaultWIMFileBasedRealm
-baseEntry o=custom}
```

6. Save your configuration changes. Enter the following commands to save the new configuration and close the wsadmin scripting tool:

   Using Jython:

```
AdminConfig.save()
exit
```

   Using Jacl:

```
$AdminConfig save
exit
```

7. Restart the application server.

Results

The following code is an example of a basic configuration in the `wimconfig.xml` file for a user registry bridge accessing a custom user registry:

```
<config:repositories adapterClassName="com.ibm.ws.wim.adapter.urbridge.URBridge" id="urbcustom">
<config:baseEntries name="o=custom"/>
  <config:CustomProperties name="registryImplClass" value="com.ibm.registry.impl.FileRegistrySample"/>
  <config:CustomProperties name="usersFile" value="${USER_PROPS}"/>
  <config:CustomProperties name="groupsFile" value="${GROUP_PROPS}"/>
</config:repositories>
```

In the previous example, the *${USER_PROPS}* and *${GROUP_PROPS}* variables are used to define the values of the custom properties.

You can use variables to define custom properties. However, these variables are resolved only in the WebSphere Application Server connected mode. For information about how to define environment variables, see Creating, editing, and deleting WebSphere variables.

User registry bridge for federated repositories:

The user registry bridge is a read-only adapter that provides an interface between federated repositories and an underlying user registry implementation, which can be either a local operating system user registry or a custom user registry implementation.

The user registry bridge enables IBM WebSphere Application Server applications to use your user registry implementation. It can work with any user registry that implements the com.ibm.websphere.security.UserRegistry interface, without knowing the details of its implementation. This capability makes the bridge versatile and allows it to connect to, and use, various registries.

The user registry bridge allows access to the same repository information without any platform-specific implementation. Thus, it eliminates the need to have a specialized user registry bridge for each operating system.

You can federate and configure the local operating system user registry, a custom user registry, or both, as a federated repository. The user registry bridge handles user registry-related requests from federated repositories, makes appropriate calls to the underlying user registry implementation, and returns data that is formatted according to the federated repositories specifications.

Therefore, to use the user registry bridge you must configure your user registry under federated repositories. This configuration can map the properties in the underlying user registry to the properties for the federated repository. You can also configure any user registry specific information, if required. For information about how to configure the user registry bridge, see Configuring the user registry bridge for federated repositories using wsadmin scripting.

The following figure illustrates the difference between configuring a federated repository user registry with and without the user registry bridge.

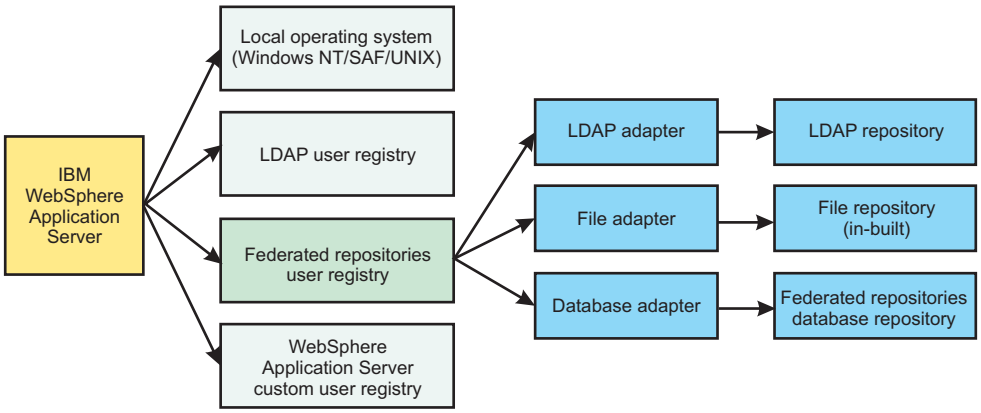

Figure 8. Configuring a federated repository user registry without the user registry bridge

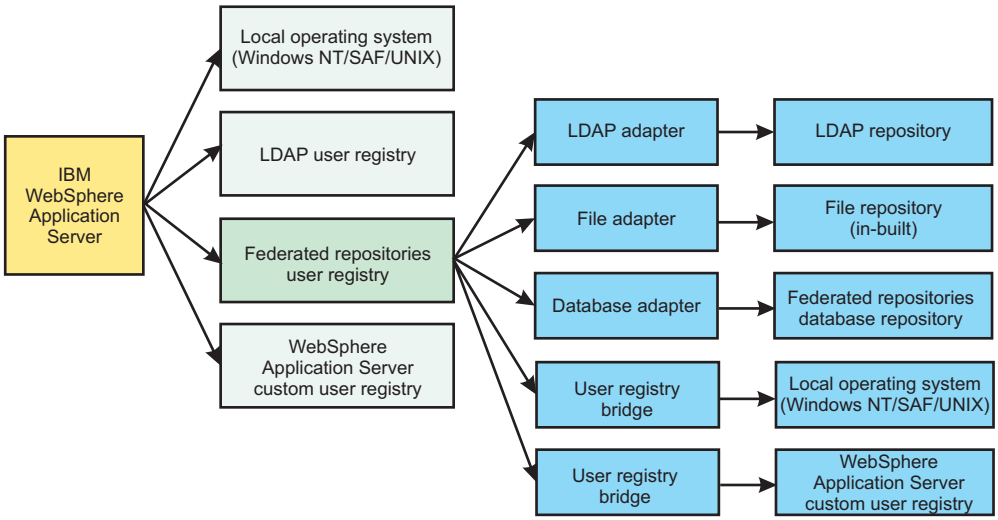

Figure 9. Configuring a federated repository user registry with the user registry bridge

As shown in the previous figure, using the same adapter, which is the user registry bridge, you can configure multiple user registries under federated repositories. For example, you can configure a local operating system user registry and one or more custom user registries.

Limitations

The following limitations exist:

- You can use the user registry bridge only for read-only operations, such as authentication and search functions. You cannot perform write operations such as create, delete, or modify users and groups. An attempt to perform write operations results in an exception, which notifies the user that the operation is not supported by the bridge. This limitation exists because the user registry bridge does not have direct access to the repository. Instead, the bridge uses an underlying existing user registry implementation that is read-only; hence, it might not be able to fulfill requests for certain properties that exist in the federated repositories.
- The user registry bridge does not support a stand-alone Lightweight Directory Access Protocol (LDAP) user registry. LDAP repositories are supported as a standard federated repositories adapter with read and write capabilities.
- Some of the properties that are placed in control data objects are not relevant to the user registry bridge as they are not applicable in the underlying repository.

– The properties ignored for GroupMembershipControl and GroupMemberControl data objects are searchBases, timeLimit, treeView, expression, and level.
– The properties ignored for SearchControl data objects are searchBases and timeLimit. The property part of the expression, such as uid and mail, is ignored as you can search WebSphere Application Server user registry entities with security names only. The expression is parsed to get the entity type and the pattern with which the search must be performed.

Supported user registries

WebSphere Application Server applications can access the user registry properties of the following user registry implementations as a read-only repository:

- Local operating system user registry
- Custom user registry

Configuring Lightweight Directory Access Protocol entity types in a federated repository configuration:

Follow this task to configure Lightweight Directory Access Protocol (LDAP) entity types in a federated repository configuration.

Procedure

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured. During LDAP configuration, based on the selected LDAP server type, some defaults and mappings are set in the configuration. When the selected LDAP server type is custom, no default is set, and you must set all of the mappings manually. To avoid setting all of the mappings manually, choose a non-custom LDAP server type (for example, IBM Directory Server or SunOne) which matches closely to your LDAP server.

   Note:

   - If you click **Add** to specify a new external repository, you must first complete the required fields and click **Apply** before you can proceed to the next step.
   - If you decide to use a custom LDAP server type, you must use the command-line interface to create the entity types. Read about IdMgrRepositoryConfig command group for the AdminTask object for more information.

     After you create the entity types, you can use the administrative console to modify these entities. You cannot use the administrative console to create entity types for a custom LDAP server type.
5. Under Additional properties, click **LDAP entity types**.
6. View the entity types that are supported by the member repositories, or select an entity type to view or change its configuration properties.
7. Supply the object classes that are mapped to this entity type in the Object classes field. LDAP entries that contain one or more of the object classes belong to this entity type.
8. Supply the search bases that are used to search this entity type. The search bases specified must be subtrees of the base entry in the repository. For example, you can specify the following search bases, where `o=ibm,c=us` is the base entry in the repository:

   `o=ibm,c=us` or `cn=users,o=ibm,c=us` or `ou=austin,o=ibm,c=us`

   In the preceding example, you cannot specify search bases `c=us` or `o=ibm,c=uk`.

   Delimit multiple search bases with a semicolon (;). For example:

`ou=austin,o=ibm,c=us;ou=raleigh,o=ibm,c=us`

9. Supply the LDAP search filter that is used to search this entity type.

   For example, use `(objectclass=ePerson)` to search for users or `(|(objectclass=groupOfNames)(objectclass=groupOfUniqueNames)` to search for groups in an external LDAP repository.

   If a search filter is not specified, the object classes and the relative distinguished name (RDN) properties are used to generate the search filter. For information on RDN properties, see “Configuring supported entity types in a federated repository configuration” on page 1377.

Results

After completing these steps, LDAP entity types are configured for your LDAP repository.

What to do next

1. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
2. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1186. As the final step, validate this setup by clicking **Apply** in the Global security panel.
3. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Lightweight Directory Access Protocol entity types collection:

Use this page to list Lightweight Directory Access Protocol (LDAP) entity types that are supported by the member repositories or to select an LDAP entity type to view or change its configuration properties.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.
5. Under Additional properties, click **LDAP entity types**.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

Entity type:

Specifies the entity type name.

Object classes:

Specifies the object classes that are mapped to this entity type. LDAP entries that contain one or more of the object classes belong to this entity type.

You cannot map multiple entity types to the same LDAP object class.

Lightweight Directory Access Protocol entity types settings:

Use this page to configure Lightweight Directory Access Protocol (LDAP) entity types that are supported by the member repositories.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.
5. Under Additional properties, click **LDAP entity types**.
6. Select an entity type to view or change its configuration properties.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

Entity type:

Specifies the entity type.

Object classes:

Specifies the object classes that are mapped to this entity type. LDAP entries that contain one or more of the object classes belong to this entity type.

You cannot map multiple entity types to the same LDAP object class.

Search bases:

Specifies the search bases that are used to search this entity type.

The search bases specified must be subtrees of the base entry in the repository. For example, you can specify the following search bases, where `o=ibm,c=us` is the base entry in the repository:

`o=ibm,c=us` or `cn=users,o=ibm,c=us` or `ou=austin,o=ibm,c=us`

In the preceding example, you cannot specify search bases `c=us` or `o=ibm,c=uk`.

Delimit multiple search bases with a semicolon (;). For example:

```
ou=austin,o=ibm,c=us;ou=raleigh,o=ibm,c=us
```

Search filter:

Specifies the LDAP search filter that is used to search this entity type.

For example, use `(objectclass=ePerson)` to search for users or `(&(cn=%v)(|(objectclass=groupOfNames)(objectclass=groupOfUniqueNames)))` to search for groups in an external LDAP repository.

If a search filter is not specified, the object classes and the relative distinguished name (RDN) properties are used to generate the search filter.

Configuring group attribute definition settings in a federated repository configuration:

Follow this task to configure group definition settings in a federated repository configuration.

Before you begin

Because group attribute definition settings apply only to a Lightweight Directory Access Protocol (LDAP) repository, you must first configure an LDAP repository. For more information, see “Managing repositories in a federated repository configuration” on page 1380.

Procedure

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.

   Note: If you click **Add** to specify a new external repository, you must first complete the required fields and click **Apply** before you can proceed to the next step.
5. Under Additional properties, click **Group attribute definition**.
6. Supply the name of the group membership attribute in the Name of group membership attribute field. Only one membership attribute can be defined for each LDAP repository.

   Every LDAP entry should have this attribute to indicate the groups to which this entry belongs. For example, memberOf is the name of the membership attribute that is used in Active Directory. The group membership attribute contains values that reference groups to which this entry belongs. If UserA belongs to GroupA, then the value of the memberOf attribute of UserA should contain the distinguished name of GroupA.

   If your LDAP server does not support the group membership attribute, then do not specify this attribute. The LDAP repository can look up groups by searching the group member attributes, though the performance might be slower.
7. Select the scope of the group membership attribute. The default value is Direct.

   Direct The membership attribute contains direct groups only. Direct groups are the groups that contain the member. For example, if Group1 contains Group2 and Group2 contains User1, then Group2 is a direct group of User1, but Group1 is not a direct group of User1.

   Nested
   The membership attribute contains both direct groups and nested groups.

   All The membership attribute contains direct groups, nested groups, and dynamic members.

Results

After completing these steps, group attribute definition settings are configured for your LDAP repository.

What to do next

1. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
2. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1186. As the final step, validate this setup by clicking **Apply** in the Global security panel.

3. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Group attribute definition settings:

Use this page to specify the name of the group membership attribute. Every Lightweight Directory Access Protocol (LDAP) entry includes this attribute to indicate the group to which this entry belongs.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.
5. Under Additional properties, click **Group attribute definition**.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

Name of group membership attribute:

Specifies the name of the group membership attribute. Only one membership attribute can be defined for each Lightweight Directory Access Protocol (LDAP) repository.

Every LDAP entry should have this attribute to indicate the groups to which this entry belongs. For example, memberOf is the name of the membership attribute that is used in Active Directory. The group membership attribute contains values that reference groups to which this entry belongs. If UserA belongs to GroupA, then the value of the memberOf attribute of UserA should contain the distinguished name of GroupA.

If your LDAP server does not support the group membership attribute, then do not specify this attribute. The LDAP repository can look up groups by searching the group member attributes, though the performance might be slower.

Scope of group membership attribute:

Specifies the scope of the group membership attribute.

Default: Direct

Range:

Direct The membership attribute contains direct groups only. Direct groups are the groups that contain the member. For example, if Group1 contains Group2 and Group2 contains User1, then Group2 is a direct group of User1, but Group1 is not a direct group of User1.

Nested The membership attribute contains both direct groups and nested groups.

All The membership attribute contains direct groups, nested groups, and dynamic members.

Configuring member attributes in a federated repository configuration:

Follow this task to configure member attributes in a federated repository configuration.

Before you begin

Because member attributes apply only to a Lightweight Directory Access Protocol (LDAP) repository, you must first configure an LDAP repository. For more information, see “Managing repositories in a federated repository configuration” on page 1380.

Procedure

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.

   Note: If you click **Add** to specify a new external repository, you must first complete the required fields and click **Apply** before you can proceed to the next step.
5. Under Additional properties, click **Group attribute definition**.
6. Under Additional properties, click **Member attributes**.
7. Click **New** to specify a new member attribute or **Delete** to remove a preconfigured member attribute.
8. Accept the default, or supply the name of the member attribute in the Name of member attribute field. For example, member and uniqueMember are two commonly used names of member attributes.

   The member attribute is used to store the values that reference members that the group contains. For example, a group type with an object class groupOfNames has a member attribute named member; group type with object class groupOfUniqueNames has a member attribute named uniqueMember. An LDAP repository supports multiple group types if multiple member attributes and their associated group object classes are specified.
9. Supply the object class of the group that uses this member attribute in the Object class field. If this field is not defined, this member attribute applies to all group object classes.
10. Select the scope of the member attribute. The default value is Direct.

    Direct The member attribute contains direct members only. Direct members are members that are directly contained by the group. For example, if Group1 contains Group2 and Group2 contains User1, then User1 is a direct member of Group2, but User1 is not a direct member of Group1.

    Nested
    The member attribute contains both direct members and nested members.

    All The member attribute contains direct members, nested members, and dynamic members.

Results

After completing these steps, member attributes are configured for your LDAP repository.

What to do next

1. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
2. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1186. As the final step, validate this setup by clicking **Apply** in the Global security panel.

3. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Member attributes collection:

Use this page to list Lightweight Directory Access Protocol (LDAP) member attributes or to select a member attribute to view or change its configuration properties.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.
5. Under Additional properties, click **Group attribute definition**.
6. Under Additional properties, click **Member attributes**.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

Name:

Specifies the name of the member attribute in LDAP. For example, member and uniqueMember are two commonly used names of member attributes.

The member attribute is used to store the values that reference members that the group contains. For example, a group type with an object class groupOfNames has a member attribute named member; group type with object class groupOfUniqueNames has a member attribute named uniqueMember. An LDAP repository supports multiple group types if multiple member attributes and their associated group object classes are specified.

Scope:

Specifies the scope of the member attribute.

Default: Direct

Range:

Direct The member attribute contains direct members only. Direct members are members that are directly contained by the group. For example, if Group1 contains Group2 and Group2 contains User1, then User1 is a direct member of Group2, but User1 is not a direct member of Group1.

Nested The member attribute contains both direct members and nested members.

All The member attribute contains direct members, nested members, and dynamic members.

Object class:

Specifies the object class of the group that uses this member attribute. If this field is not defined, this member attribute applies to all group object classes.

Member attributes settings:

Use this page to configure Lightweight Directory Access Protocol (LDAP) member attributes.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is pre-configured.
5. Under Additional properties, click **Group attribute definition**.
6. Under Additional properties, click **Member attributes**.
7. Click **New** to specify a new member attribute.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

Name of member attribute:

Specifies the name of the member attribute in LDAP. For example, member and uniqueMember are two commonly used names of member attributes.

The member attribute is used to store the values that reference members that the group contains. For example, a group type with an object class groupOfNames has a member attribute named member; group type with object class groupOfUniqueNames has a member attribute named uniqueMember. An LDAP repository supports multiple group types if multiple member attributes and their associated group object classes are specified.

Object class:

Specifies the object class of the group that uses this member attribute. If this field is not defined, this member attribute applies to all group object classes.

Scope:

Specifies the scope of the member attribute.

Default: Direct

Range:

Direct The member attribute contains direct members only. Direct members are members that are directly contained by the group. For example, if Group1 contains Group2 and Group2 contains User1, then User1 is a direct member of Group2, but User1 is not a direct member of Group1.

Nested The member attribute contains both direct members and nested members.

All The member attribute contains direct members, nested members, and dynamic members.

Configuring dynamic member attributes in a federated repository configuration:

Follow this task to configure dynamic member attributes in a federated repository configuration.

Before you begin

Because dynamic member attributes apply only to a Lightweight Directory Access Protocol (LDAP) repository, you must first configure an LDAP repository. For more information, see “Managing repositories in a federated repository configuration” on page 1380.

About this task

A dynamic group defines its members differently than a static group. Instead of listing the members individually, the dynamic group defines its members using an LDAP search. The filter for the search is defined in a dynamic member attribute. For example, the dynamic group uses the structural objectclass groupOfURLs, or auxiliary objectclass ibm-dynamicGroup, and the attribute memberURL, to define the search using a simplified LDAP URL syntax:

```
ldap:///<base DN of search> ? ? <scope of search> ? <searchfilter>
```

The following is an example of the LDAP URL that defines all entries that are under `o=Acme` with the `objectclass=person`:

```
ldap:///o=Acme,c=US??sub?objectclass=person
```

If both member and dynamic member attributes are specified for the same group type, this group type is a hybrid group with both static and dynamic members.

Procedure

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select**Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.

   Note: If you click **Add** to specify a new external repository, you must first complete the required fields and click **Apply** before you can proceed to the next step.
5. Under **Additional Properties**, click **LDAP entity types**.
6. Click the link for **Group** entity type.
7. In the **Object Classes** field, add the entry for the object class, for example, groupOfUrls. Delimit multiple entries with a semicolon (;).
8. Click **OK**.
9. Under Additional properties, click **Group attribute definition**.
10. Under Additional properties, click **Dynamic member attributes**.
11. Click **New**to specify a new dynamic member attribute or **Delete** to remove a preconfigured dynamic member attribute.
12. Specify the name of the dynamic member attribute in the Name of dynamic member attribute field. The name of the dynamic member attribute defines the filter for dynamic group members in LDAP, for example, memberURL is the name of a commonly used dynamic member attribute.
13. Specify the object class of the group that contains the dynamic member attribute in the Dynamic object class field, for example, groupOfURLs. If this property is not defined, the dynamic member attribute applies to all group object classes.
14. Save your configuration changes in the administration console: Click **System administration > Save changes to master repository > Save**.
15. This next step involves using a wsadmin command and cannot be done through the administrative console. Start the wsadmin scripting tool and connect to a server, by using the following command:

```
wsadmin –username username –password password
```

16. Use the addIdMgrPropertyToEntityTypes command to add the dynamic member attribute specified in step 12 to the federated repositories schema. The dynamic member attribute needs to be added to the entity type Group in the federated repositories schema otherwise an error occurs while creating a group in an LDAP repository configured under federated repositories using the create() API and specifying the memberURL attribute and its value. The correctness of the value of the memberURL attribute is not validated because LDAP does not validate this.

    In the following example, the memberURL property is added to the entity type Group:

    ```
    $AdminTask addIdMgrPropertyToEntityTypes {-name memberURL -dataType String -entityTypeNames Group -repositoryIds re
    ```

17. Save your configuration changes.

    ```
    $AdminConfig save
    ```

Results

After completing these steps, dynamic member attributes are configured for your LDAP repository.

What to do next

1. After configuring the federated repositories, click **Security > Global security** to return to the Global security panel. Verify that Federated repositories is identified in the Current realm definition field. If Federated repositories is not identified, select **Federated repositories** from the Available realm definitions field and click **Set as current**. To verify the federated repositories configuration, click **Apply** on the Global security panel. If Federated repositories is not identified in the Current realm definition field, your federated repositories configuration is not used by WebSphere Application Server.
2. If you are enabling security, complete the remaining steps as specified in “Enabling security for the realm” on page 1186. As the final step, validate this setup by clicking **Apply** in the Global security panel.
3. Save, stop, and restart all the product servers (deployment managers, nodes, and Application Servers) for changes in this panel to take effect. If the server comes up without any problems, the setup is correct.

Dynamic member attributes collection:

Use this page to manage Lightweight Directory Access Protocol (LDAP) dynamic member attributes.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.
5. Under Additional properties, click **Group attribute definition**.
6. Under Additional properties, click **Dynamic member attributes**.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

Name:

Specifies the name of the attribute that defines the filter for dynamic group members in LDAP. For example, memberURL is the name of a commonly used dynamic member attribute.

If both member and dynamic member attributes are specified for the same group type, this group type is a hybrid group with both static and dynamic members.

A dynamic group defines its members differently than a static group. Instead of listing the members individually, the dynamic group defines its members using an LDAP search. The filter for the search is defined in a dynamic member attribute. For example, the dynamic group uses the structural objectclass groupOfURLs, or auxiliary objectclass ibm-dynamicGroup, and the attribute memberURL, to define the search using a simplified LDAP URL syntax:

```
ldap:///<base DN of search>??<scope of search>?<searchfilter>
```

The following is an example of the LDAP URL that defines all entries that are under `o=Acme` with the `objectclass=person`:

```
ldap:///o=Acme,c=US??sub?objectclass=person
```

Object class:

Specifies the object class of the group that contains this dynamic member attribute, for example, groupOfURLs. If this property is not defined, the dynamic member attribute applies to all group object classes.

Dynamic member attributes settings:

Use this page to configure Lightweight Directory Access Protocol (LDAP) dynamic member attributes.

To view this administrative console page, complete the following steps:

1. In the administrative console, click **Security > Global security**.
2. Under User account repository, select **Federated repositories** from the Available realm definitions field and click **Configure**.
3. Under Related items, click **Manage repositories**.
4. Click **Add** to specify a new external repository or select an external repository that is preconfigured.
5. Under Additional properties, click **Group attribute definition**.
6. Under Additional properties, click **Dynamic member attributes**.
7. Click **New** to specify a new dynamic member attribute.

When you finish adding or updating your federated repository configuration, go to the **Security > Global security** panel and click **Apply** to validate the changes.

Name of dynamic member attribute:

Specifies the name of the attribute that defines the filter for dynamic group members in LDAP. For example, memberURL is the name of a commonly used dynamic member attribute.

If both member and dynamic member attributes are specified for the same group type, this group type is a hybrid group with both static and dynamic members.

A dynamic group defines its members differently than a static group. Instead of listing the members individually, the dynamic group defines its members using an LDAP search. The filter for the search is defined in a dynamic member attribute. For example, the dynamic group uses the structural objectclass groupOfURLs, or auxiliary objectclass ibm-dynamicGroup, and the attribute memberURL, to define the search using a simplified LDAP URL syntax:

```
ldap:///<base DN of search>??<scope of search>?<searchfilter>
```

The following is an example of the LDAP URL that defines all entries that are under `o=Acme` with the `objectclass=person`:

```
ldap:///o=Acme,c=US??sub?objectclass=person
```

Dynamic object class:

Specifies the object class of the group that contains this dynamic member attribute, for example, groupOfURLs. If this property is not defined, the dynamic member attribute applies to all group object classes.

Standalone Lightweight Directory Access Protocol registries

A Standalone Lightweight Directory Access Protocol (LDAP) registry performs authentication using an LDAP binding.

WebSphere Application Server security provides and supports the implementation of most major LDAP directory servers, which can act as the repository for user and group information. These LDAP servers are called by the product processes for authenticating a user and other security-related tasks. For example, the servers are used to retrieve user or group information. This support is provided by using different user and group filters to obtain the user and group information. These filters have default values that you can modify to fit your needs. The custom LDAP feature enables you to use any other LDAP server, which is not in the product-supported list of LDAP servers, for its user registry by using the appropriate filters.

Note: The initial profile creation configures WebSphere Application Server to use a federated repositories security registry option with the file-based registry. This security registry configuration can be changed to use other options, including the stand-alone LDAP registry. Instead of changing from the federated repositories option to the stand-alone LDAP registry option under the User account repository configuration, consider employing the federated repositories option, which provides for LDAP configuration. Federated repositories provide a wide range of capabilities, including the ability to have one or multiple user registries. It supports federating one or more LDAPs in addition to file-based and custom registries. It also has improved failover capabilities, and a robust set of member (user and group) management capabilities. Federated repositories is required when you are using the new member management capabilities in WebSphere Portal 6.1 and above, and Process Server 6.1 and above. The use of federated repositories is required for following LDAP referrals, which is a common requirement in some LDAP server environments (such as Microsoft Active Directory).

It is recommended that you migrate from stand-alone LDAP registries to federated repositories. If you move to WebSphere Portal 6.1 and above, and or WebSphere Process Server 6.1 and above, you should migrate to federated repositories prior to these upgrades. For more information about federated repositories and its capabilities, read the Federated repositories topic. For more information about how to migrate to federated repositories, read the Migrating a stand-alone LDAP repository to a federated repositories LDAP repository configuration topic.

To use LDAP as the user registry, you need to know an administrative user name that is defined in the registry, the server host and port, the base distinguished name (DN) and, if necessary, the bind DN and the bind password. You can choose any valid user in the registry that is searchable and have administrative privileges. In some LDAP servers, the administrative users are not searchable and cannot be used, for example, `cn=root` in SecureWay. This user is referred to as WebSphere Application Server security server ID, server ID, or server user ID in the documentation. Being a server ID means a user has special privileges when calling some protected internal methods. Normally, this ID and password are used to log into the administrative console after security is turned on. You can use other users to log in if those users are part of the administrative roles.

When security is enabled in the product, the primary administrative user name and password are authenticated with the registry during the product startup. If authentication fails, the server does not start. It is important to choose an ID and password that do not expire or change often. If the product server user ID or password need to change in the registry, make sure that the changes are performed when all the product servers are up and running.

When the changes are done in the registry, use the steps that are described in “Configuring Lightweight Directory Access Protocol user registries” on page 1260. Change the ID, password, and other configuration information, save, stop, and restart all the servers so that the new ID or password is used by the product. If any problems occur starting the product when security is enabled, disable security before the server can start up. To avoid these problems, make sure that any changes in this panel are validated in the Global security panel. When the server is up, you can change the ID, password, and other configuration information and then enable security.

You can use the custom Lightweight Directory Access Protocol (LDAP) feature to support any LDAP server by setting up the correct configuration. However, support is not extended to these custom LDAP servers because many configuration possibilities exist.

The users and groups and security role mapping information is used by the configured authorization engine to perform access control decisions.

Dynamic groups and nested group support for LDAP:

Dynamic and nested groups simplify WebSphere Application Server security management and increase its effectiveness and flexibility.

Dynamic groups contain a group name and membership criteria:

- The group membership information is as current as the information on the user object.
- There is no need to manually maintain members on the group object.
- Dynamic groups are designed so an application does not need a large amount of information from the directory to find out if someone is a member of a group.

Nested groups enable the creation of hierarchical relationships that are used to define inherited group membership. A nested group is defined as a child group entry whose distinguished name (DN) is referenced by a parent group entry attribute.

You only need to assign a larger parent group if all nested groups share the same privilege. Assigning a role to a single parent group simplifies the run-time authorization table.

Dynamic groups and nested group support for the IBM Tivoli Directory Server

WebSphere Application Server supports all Lightweight Directory Access Protocol (LDAP) dynamic and nested groups when using IBM Tivoli Directory Server. This function is enabled by default by taking advantage of a new feature in IBM Tivoli Directory Server. IBM Tivoli Directory Server uses the ibm-allGroups forward-reference group attribute that automatically calculates all the group memberships including dynamic and recursive memberships for a user. Security directly locates a user group membership from a user object rather than indirectly search all the groups to match group members.

For more information, see “Configuring dynamic and nested group support for the IBM Tivoli Directory Server” on page 1282.

When you create groups, ensure that nested and dynamic group memberships work correctly.

Dynamic and nested group support for the SunONE or iPlanet Directory Server

The SunONE or iPlanet Directory Server uses two grouping mechanisms:

Groups
Entries that name other entries as a list of members or as a filter for members.

Roles Entries that name other entries as a list of members or as a filter for members. Additional functionality is provided by generating the nsrole attribute on each role member.

Three types of roles are available:

Filtered roles
Depends upon the attributes that are contained in each entry. Entries are members, if they match a specified Lightweight Directory Access Protocol (LDAP) filter. This role is equivalent to a dynamic group.

Nested roles
Creates roles that contain other roles. This role is equivalent to a nested group.

Managed roles
Explicitly assigns a role to member entries. This role is equivalent to a static group.

Refer to "Configuring dynamic and nested group support for the SunONE or iPlanet Directory Server" on page 1282 for more information.

Security failover among multiple LDAP servers:

WebSphere Application Server security can be configured to attempt failovers between multiple Lightweight Directory Access Protocol (LDAP) hosts.

Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

If the current active LDAP server is unavailable, WebSphere Application Server security attempts a failover to the first available LDAP host in the specified host list. The multiple LDAP servers can be replicas of the same master LDAP server, or they can be any LDAP host with the same schema, which contain data that is imported from the same LDAP Data Interchange Format (LDIF) file.

Whenever a failover occurs, WebSphere Application Server security always uses the first available LDAP server in the specified host list. For example, if there are four LDAP servers configured in the order of L1, L2, L3, and L4, L1 is treated as the primary LDAP server. The preference of connection is from L1 to L4. If, for example, WebSphere Application Server security is currently connected to L4, and failover or reconnection is necessary, WebSphere Application Server security first attempts to connect to L1, L2, and then L3 in that order until the connection is successful.

The current LDAP host name is logged in message CWSCJ0419I in the WebSphere Application Server log file, `SystemOut.log`. If you want to reconnect to the primary LDAP host, run the WebSphere Application Server MBean method, resetLDAPBindInfo, with `null,null` as the input.

To configure LDAP failover among multiple LDAP hosts, you must use wsadmin or ConfigService to include the backup LDAP host, which does not have a number limitation. The LDAP host that is displayed in the administrative console is the primary LDAP host, and is the first item listed in the LDAP host list in `security.xml`.

The WebSphere Application Server security realm name defaults to the primary LDAP host name that is displayed in the administrative console. It includes a trailing colon and a port number (if one exists). However, the custom property, com.ibm.websphere.security.ldap.logicRealm, can be added to override the default security realm name. Use the logicRealm name to configure each cell to have its own LDAP host for interoperability and backward compatibility, and to provide flexibility for adding or removing the LDAP host dynamically. If migrating from a previous installation, the new logicRealm name does not take effect until administrative security is enabled again. To be compatible with a previous release that does not

support logic realm, the logicRealm name has to be the same as that used by the previous installation (the LDAP host name, including a trailing colon and port number).

When LDAP failover is configured by associating a single hostname to multiple IP addresses through the use of a load balancer (which does that translation transparently to WebSphere Application Server), entering an invalid password can cause multiple LDAP bind retries. WebSphere Application Server retries and the load balancer routes requests to multiple replicas. With the default settings, the number of LDAP bind retries is equal to one more than the number of associated IP addresses. This means a single invalid login attempt can cause the LDAP account to be locked. If the com.ibm.websphere.security.ldap.retryBind custom property is set to `false`, LDAP bind calls are not retried.

The following Jacl example shows how to use wsadmin to add a backup LDAP host for failover:

```
#--------------------------------------------------------------------
# Main
#  This is a bi-modal script: it can be included in the wsadmin
#  command invocation like this:
#     wsadmin -f LDAPAdd.jacl ldaphost 800
#
#  or the script can be sourced from the wsadmin command line:
#     wsadmin> source LDAPAdd.jacl
#     wsadmin> LDAPAdd ldaphost 800
#
#  The script expects some parameters:
#      arg1 - LDAP Server host name
#      arg2 - LDAP Server port number
#--------------------------------------------------------------------
if { !($argc == 2)} {
   puts ""
   puts "LDAPAdd: This script requires 2 parameters: LDAP server host name and LDAP server port number"
   puts "For example: LDAPAdd ldaphost 389"
   puts ""
   return;
}
else {
   set ldapServer        [lindex $argv 0]
   set ldapPort          [lindex $argv 1]
   LDAPAdd $ldapServer $ldapPort
   return;
}
proc LDAPAdd {ldapServer ldapPort args} {
   global AdminConfig AdminControl ldapServer ldapPort
   set ldapServer  lindex $args 0
   set ldapPort  lindex $args 1
   global ldapUserRegistryId
   # Get the LDAP user registry object from the security configuration
   if { catch {$AdminConfig list LDAPUserRegistry} result } {
      puts stdout "\$AdminConfig list LDAPUserRegistry caught an exception $result\n"
      return
   }
   else {
      if {$result != {}} {
         set ldapUserRegistryId  lindex $result 0
      }
      else {
         puts stdout "\$AdminConfig list LDAPUserRegistry caught an exception $result\n"
         return;
      }
   }
   # Set the host and port values in Attrs2
   set Attrs2  list  list hosts  list  list  list host
   $ldapServer
   list port $ldapPort

   # Modify the LDAP configuration host object
   $AdminConfig modify $ldapUserRegistryId $Attrs2
   $AdminConfig save
}
```

The following Jython example shows how to use wsadmin to add a backup LDAP host for failover:

```
#--------------------------------------------------------------------
# Add ldap hostname and port
#     wsadmin -f LDAPAdd.py arg1 arg2
#
#  The script expects some parameters:
#      arg1 - LDAP Server hostname
#      arg2 - LDAP Server portnumber
#--------------------------------------------------------------------
import java

#-------------------------------------------------------
# get the line separator and use to do the parsing
```

```
# since the line separator on different platform are different
lineSeparator = java.lang.System.getProperty('line.separator')

#-------------------------------------------------------------------------------
# add LDAP host
#-------------------------------------------------------------------------------
def LDAPAdd (ldapServer, ldapPort):
    global AdminConfig, lineSeparator, ldapUserRegistryId
    try:
        ldapObject = AdminConfig.list("LDAPUserRegistry")
        if len(ldapObject) == 0:
            print "LDAPUserRegistry ConfigId was not found\n"
            return

        ldapUserRegistryId = ldapObject.split(lineSeparator)[0]
        print "Got LDAPUserRegistry ConfigId is " + ldapUserRegistryId + "\n"
    except:
        print "AdminConfig.list('LDAPUserRegistry') caught an exception\n"

    try:
        secMbeans = AdminControl.queryNames('WebSphere:type=SecurityAdmin,*')
        if len(secMbeans) == 0:
            print "Security Mbean was not found\n"
            return

        secMbean = secMbeans.split(lineSeparator)[0]
        print "Got Security Mbean is " + secMbean + "\n"
    except:
        print "AdminControl.queryNames('WebSphere:type=SecurityAdmin,*') caught an exception\n"

    attrs2 = [["hosts", [[["host", ldapServer], ["port", ldapPort]]]]]
    try:
        AdminConfig.modify(ldapUserRegistryId, attrs2)
        try:
            AdminConfig.save()
            print "Done setting up attributes values for LDAP User Registry"
            print "Updated was saved successfully\n"
        except:
            print "AdminConfig.save() caught an exception\n"
    except:
        print "AdminConfig.modify(" + ldapUserRegistryId + ", " + attrs2 + ") caught an exception\n"
    return

#-------------------------------------------------------------------------------
# Main entry point
#-------------------------------------------------------------------------------
if len(sys.argv) < 2 or len(sys.argv) > 3:
        print("LDAPAdd: this script requires 2 parameters: LDAP server hostname and LDAP server port number\n")
        print("e.g.: LDAPAdd ldaphost 389\n")
        sys.exit(1)
else:
        ldapServer = sys.argv[0]
        ldapPort = sys.argv[1]
        LDAPAdd(ldapServer, ldapPort)
        sys.exit(0)
```

Selecting an authentication mechanism

An *authentication mechanism* defines rules about security information, such as whether a credential is forwardable to another Java process, and the format of how security information is stored in both credentials and tokens. You can select and configure an authentication mechanism by using the administrative console.

About this task

Authentication is the process of establishing whether a client is who or what it claims to be in a particular context. A client can be either an end user, a machine, or an application. An authentication mechanism in WebSphere Application Server typically collaborates closely with a *user registry*. The user registry is the user and groups account repository that the authentication mechanism consults with when performing authentication. The authentication mechanism is responsible for creating a *credential*, which is an internal product representation of a successfully authenticated client user. Not all credentials are created equally. The abilities of the credential are determined by the configured authentication mechanism.

WebSphere Application Server provides three authentication mechanisms: Lightweight Third Party Authentication (LTPA), Kerberos, and RSA token authentication mechanism.

Security support for Kerberos as the authentication mechanism has been added for this release of WebSphere Application Server. Kerberos (KRB5) is a mature, flexible, open, and very secure network authentication protocol. Kerberos includes authentication, mutual authentication, message integrity and confidentiality and delegation features. KRB5 is used for Kerberos in the administrative console and in the **sas.client.props**, **soap.client.props** and **ipc.client.props** files.

The RSA token authentication mechanism is new to this release of WebSphere Application Server. It aids the flexible management objective to preserve the base profiles configurations and isolate them from a security perspective. This mechanism permits the base profiles managed by an administrative agent to have different Lightweight Third-Party Authentication (LTPA) keys, different user registries, and different administrative users.

Note: Simple WebSphere Authentication Mechanism (SWAM) is deprecated in this release. SWAM does not provide authenticated communication between different servers.

Authentication is required for enterprise bean clients and web clients when they access protected resources. Enterprise bean clients, like a servlet or other enterprise beans or a pure client, send the authentication information to a web application server using one of the following protocols:

- Common Secure Interoperability Version 2 (CSIv2)
- Secure Authentication Service (SAS)

Note: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

Web clients use the HTTP or HTTPS protocol to send the authentication information.

The authentication information can be basic authentication (user ID and password), a credential token, or a client certificate. The web authentication is performed by the web authentication module.

You can configure web authentication for a web client by using the administrative console. Click **Security > Global security**. Under Authentication, expand **Web and SIP security** and click **General settings**. The following options exist for Web authentication:

Authenticate only when the URI is protected
Specifies that the web client can retrieve an authenticated identity only when it accesses a protected Uniform Resource Identifier (URI). WebSphere Application Server challenges the web client to provide authentication data when the web client accesses a URI that is protected by a J2EE role. This default option is also available in previous versions of WebSphere Application Server.

Use available authentication data when an unprotected URI is accessed
Specifies that the web client is authorized to call the `getRemoteUser`, `isUserInRole`, and `getUserPrincipal` methods; retrieves an authenticated identity from either a protected or an unprotected URI. Although the authentication data is not used when you access an unprotected URI, the authentication data is retained for future use. This option is available when you select the **Authentication only when the URI is protected** check box.

Authenticate when any URI is accessed
Specifies that the web client must provide authentication data regardless of whether the URI is protected.

Default to basic authentication when certificate authentication for the HTTPS client fails.
Specifies that WebSphere Application Server challenges the web client for a user ID and password when the required HTTPS client certificate authentication fails.

The enterprise bean authentication is performed by the Enterprise JavaBeans (EJB) authentication module.

The EJB authentication module resides in the CSIv2 and SAS layer.

The authentication module is implemented using the Java Authentication and Authorization Service (JAAS) login module. The web authenticator and the EJB authenticator pass the authentication data to the login module, which can use the following mechanisms to authenticate the data:

- Kerberos
- LTPA
- RSA token
- Simple WebSphere Authentication Mechanism (SWAM)

  Note: SWAM was deprecated in WebSphere Application Server Version 8.0 and will be removed in a future release.

The authentication module uses the registry that is configured on the system to perform the authentication. Four types of registries are supported:

- Federated repositories
- Local operating system
- Standalone Lightweight Directory Access Protocol (LDAP) registry
- Stand-alone custom registry

External registry implementation following the registry interface that is specified by IBM can replace either the local operating system or the LDAP registry.

The login module creates a JAAS subject after authentication and stores the credential that is derived from the authentication data in the public credentials list of the subject. The credential is returned to the web authenticator or to the enterprise beans authenticator.

The web authenticator and the enterprise beans authenticator store the received credentials in the Object Request Broker (ORB) current for the authorization service to use in performing further access control checks. If the credentials are forwardable, they are sent to other application servers.

You can configure authentication mechanisms in the administrative console by doing the following:

Procedure

1. **Click Security > Global security.**
2. Under Authentication mechanisms and expiration, select an authentication mechanism to configure.

Lightweight Third Party Authentication

Lightweight Third Party Authentication (LTPA) is intended for distributed, multiple application server and machine environments. LTPA supports forwardable credentials and single sign-on (SSO). LTPA can support security in a distributed environment through cryptography. This support permits LTPA to encrypt, digitally sign, and securely transmit authentication-related data, and later decrypt and verify the signature.

Application servers can securely communicate using the LTPA protocol. It also provides the single sign-on (SSO) feature wherein a user is required to authenticate only once in a domain name system (DNS) domain and can access resources in other WebSphere Application Server cells without getting prompted. The realm names on each system in the DNS domain are case sensitive and must match identically.

For local OS, the realm name is the same as the host name.

For the Lightweight Directory Access Protocol (LDAP), the realm name is the `host:port` value of the LDAP server.

The LTPA protocol uses cryptographic keys to encrypt and decrypt user data that passes between the servers. These keys must be shared between the different cells for the resources in one cell to access resources in other cells, assuming that all the cells involved use the same LDAP or custom registry.

When using LTPA, a token is created with the user information and an expiration time and is signed by the keys. The LTPA token is time sensitive. All product servers that participate in a protection domain must have their time and date synchronized. If not, LTPA tokens appear prematurely expired and cause authentication or validation failures. Coordinated Universal Time (UTC) is used by default, and all other machines must have the same UTC time. Consult your operating system documentation for information regarding how to ensure this.

This token passes to other servers, in the same cell or in a different cell through cookies, for web resources when SSO is enabled, or through the authentication protocol layer for enterprise beans.

If the receiving servers share the same keys as the originating server, the token can be decrypted to obtain the user information, which then is validated to make sure that it has not expired and that the user information in the token is valid in its registry. On successful validation, the resources in the receiving servers are accessible after the authorization check.

Each server must have valid credentials. When the credentials expire, the server is required to communicate to the user registry to authenticate. User registry outages can cause server processes to hang, requiring them to be restarted to recover. Extending the time the LTPA token remains cached reduces this risk, but does present a slightly increased security risk to be considered when defining your security policies.

All of the WebSphere Application Server processes in a cell (deployment manager, nodes, application servers) share the same set of keys. If key sharing is required between different cells, export them from one cell and import them to the other. For security purposes, the exported keys are encrypted with a random generated key and a user-defined password is used to protect the keys. This same password is needed when importing the keys into another cell. The password is only used to protect the keys and is not used to generate the keys.

WebSphere Application Server supports the LTPA, Kerberos and the Simple WebSphere Authentication Mechanism (SWAM) protocols.

Note: SWAM is deprecated in WebSphere Application Server Version 8.0 and will be removed in a future release.

When security is enabled during profile creation time, LTPA is configured by default.

LTPA requires that the configured user registry be a centrally shared repository such as LDAP or a Windows domain-type registry so that users and groups are the same, regardless of the machine.

The use of LTPA with the local OS user registry is only applicable to configurations where all of the servers reside on the same system.

Lightweight Third Party Authentication key sets and key set groups:

Key set groups contain lists of key sets and Lightweight Third Party Authentication (LTPA) key generation schedules. Each key set contains key references to keys in key stores.

Note: It is not recommended that you choose to generate new keys automatically . Keys should only be generated during off hours. Once keys are generated, you might need to export the keys and to import the keys to other WebSphere cells or IBM products in which the keys are required to be sync to communicate with each other.

The keys for some key configurations must be generated together. The LTPA key pair is referenced in one key set while the secret or private key is in a separate key set. When the key set group is created, the two key sets are added as members of the key set group. Key set group settings determine whether the keys for both key sets are generated together automatically or manually.

The key set group contains the following attributes:

- Member key sets
- Choice of either manual or automatic key generation in the member key sets
- Schedule for automatically generating keys

Configuring LTPA and working with keys

You must configure Lightweight Third Party Authentication (LTPA) when you set up security for the first time. LTPA is the default authentication mechanism for WebSphere Application Server. After you have configured LTPA you can generate LTPA keys manually or automatically.

Procedure

1. Configure LTPA and generate the first LTPA keys. Use the administrative console to configure LTPA or Kerberos when you set up security for the first time. The LTPA keys are generated automatically the first time. Read the Configuring the Lightweight Third Party Authentication mechanism article for more information.

   Application servers distributed in multiple nodes and cells can securely communicate using the LTPA protocol. Key set groups contain lists of key sets and LTPA authentication key generation schedules. Each key set contains key references to keys in key stores. To generate keys automatically, each key set must be a member of a key set group.

   Read the Lightweight Third Party Authentication key sets and key set groups article for more information.

   The keys for some key configurations must be generated together. The LTPA key pair is referenced in one key set while the secret or private key is in a separate key set. When the key set group is created, the two key sets are added as members of the key set group. Key set group settings determine whether the keys for both key sets are generated together automatically or manually.

   The key set group contains the following attributes:

   - Member key sets
   - Choice of either manual or automatic key generation in the member key sets
   - Schedule for automatically generating keys

2. Generate keys manually or automatically, and control the number of active keys. WebSphere Application Server generates Lightweight Third Party Authentication (LTPA) keys automatically during the first server startup. You can generate additional keys as you need them in the Authentication mechanisms and expiration panel.

   You can disable the automatic generation of new LTPA keys for key sets that are members of a key set group. Automatic generation creates new keys on a schedule that you specify when you configure a key set group, which manages one or more key sets. WebSphere Application Server uses key set groups to automatically generate cryptographic keys or multiple synchronized key sets.

   Generating keys manually or enabling or disabling the generation of keys are tasks that require you to recycle the node agents and application servers to accept the new keys. If any of the node agents are down, run a manual file synchronization utility from the node agent machine to synchronize the security configuration from the deployment manager.

   Key sets manage LTPA keys in a key store that is based on a key alias prefix. A key alias prefix is automatically generated when you generate a new key and store it in a key store. Key stores can contain multiple versions of keys for any given key alias prefix. You can specify a maximum number of active keys in the key set configuration.

   Read the Generating Lightweight Third Party Authentication keys article for more information.

3. Import and export keys. To support single sign-on (SSO) in WebSphere® Application Server across multiple WebSphere Application Server domains or cells, you must share the LTPA keys and the password among the domains. You can import LTPA keys from other domains and export keys to other domains.

   Note: You should disable automatic key generation if you import or export keys to or from another cell. This disabling causes the imported keys to get lost and the exported keys to no longer interoperate with this cell over time

   You must recycle the node agents and application servers to accept the new keys. If any of the node agents are down, run a manual file synchronization utility from the node agent machine to synchronize the security configuration from the deployment manager.

   Read the Importing Lightweight Third Party Authentication keys and Exporting Lightweight Third Party Authentication keys articles for more information.
4. Manage keys from multiple cells. You can specify the shared keys and configure the authentication mechanism that is used to exchange information between servers to import and export LTPA keys across multiple WebSphere® Application Server cells.

   You must start the server again for any changes you make to become active.

   Read the Managing LTPA keys from multiple WebSphere Application Server cells article for more information.

Kerberos (KRB5) authentication mechanism support for security

The Kerberos authentication mechanism enables interoperability with other applications (such as .NET, DB2 and others) that support Kerberos authentication. It provides single sign on (SSO) end-to-end interoperable solutions and preserves the original requester identity.

Note: Security support for Kerberos as the authentication mechanism was added for WebSphere Application Server Version 7.0. Kerberos is a mature, flexible, open, and very secure network authentication protocol. Kerberos includes authentication, mutual authentication, message integrity and confidentiality and delegation features. You can enable Kerberos on the server side. Support is provided to enable the rich Java client to use the Kerberos token for authentication to the WebSphere Application Server.

The following sections describe Kerberos authentication in more detail:

- “What is Kerberos?”
- “The benefits of having Kerberos as an authentication mechanism” on page 1417
- “Kerberos authentication in a single Kerberos realm environment” on page 1417
- “Kerberos authentication in a cross or trusted Kerberos realm environment” on page 1418
- “Things to consider before setting up Kerberos as the authentication mechanism for WebSphere Application Server” on page 1422
- “Support information for Kerberos authentication” on page 1423
- “Setting up Kerberos as the authentication mechanism for WebSphere Application Server” on page 1424
- “Setting up Kerberos as the authentication mechanism for the pure Java client” on page 1424

What is Kerberos?

Kerberos has withstood the test of time and is now at version 5.0. Kerberos enjoys wide spread platform support (for example, for Windows, Linux, Solaris, AIX, and z/OS) partly because the Kerberos source code is freely downloadable from the Massachusetts Institute of Technology (MIT) where it was originally created.

Kerberos is composed of three parts: a client, a server, and a trusted third party known as the Kerberos Key Distribution Center (KDC). The KDC provides authentication and ticket granting services.

The KDC maintains a database or repository of user accounts for all of the security principals in its realm. Many Kerberos distributions use file-based repositories for the Kerberos principal and policy DB and others use Lightweight Directory Access Protocol (LDAP) as the repository.

Kerberos does not support any notion of groups (that is, iKeys groups or groups of users or principals). The KDC maintains a long-term key for each principal in its accounts database. This long-term key is derived from the password of the principal. Only the KDC and the user that the principal represents should know what the long-term key or password is.

The benefits of having Kerberos as an authentication mechanism

The benefits of having Kerberos as the authentication mechanism for WebSphere Application Server include the following:

- The Kerberos protocol is a standard. This enables interoperability with other applications (such as .NET, DB2 and others) that support Kerberos authentication. It provides single sign on (SSO) end-to-end interoperable solutions and preserves the original requester identity.
- When using Kerberos authentication, the user clear text password never leaves the user machine. The user authenticates and obtains a Kerberos ticket granting ticket (TGT) from a KDC by using a one-way hash value of the user password. The user also obtains a Kerberos service ticket from the KDC by using the TGT. The Kerberos service ticket that represents the client identity is sent to WebSphere Application Server for authentication.
- A Java client can participate in Kerberos SSO using the Kerberos credential cache to authenticate to WebSphere Application Server.
- J2EE, web service, .NET and web browser clients that use the HTTP protocol can use the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) token to authenticate to the WebSphere Application Server and participate in SSO by using SPNEGO web authentication. Support for SPNEGO as the web authentication service is new to this release of WebSphere Application Server.

  Read about “Single sign-on for HTTP requests using SPNEGO web authentication” on page 1444 for more information.
- WebSphere Application Server can support both Kerberos and Lightweight Third-Party Authentication (LTPA) authentication mechanisms at the same time.
- Server-to-server communication using Kerberos authentication is provided.

Kerberos authentication in a single Kerberos realm environment

WebSphere Application Server supports Kerberos authentication in a single Kerberos realm environment as shown in the following figure:

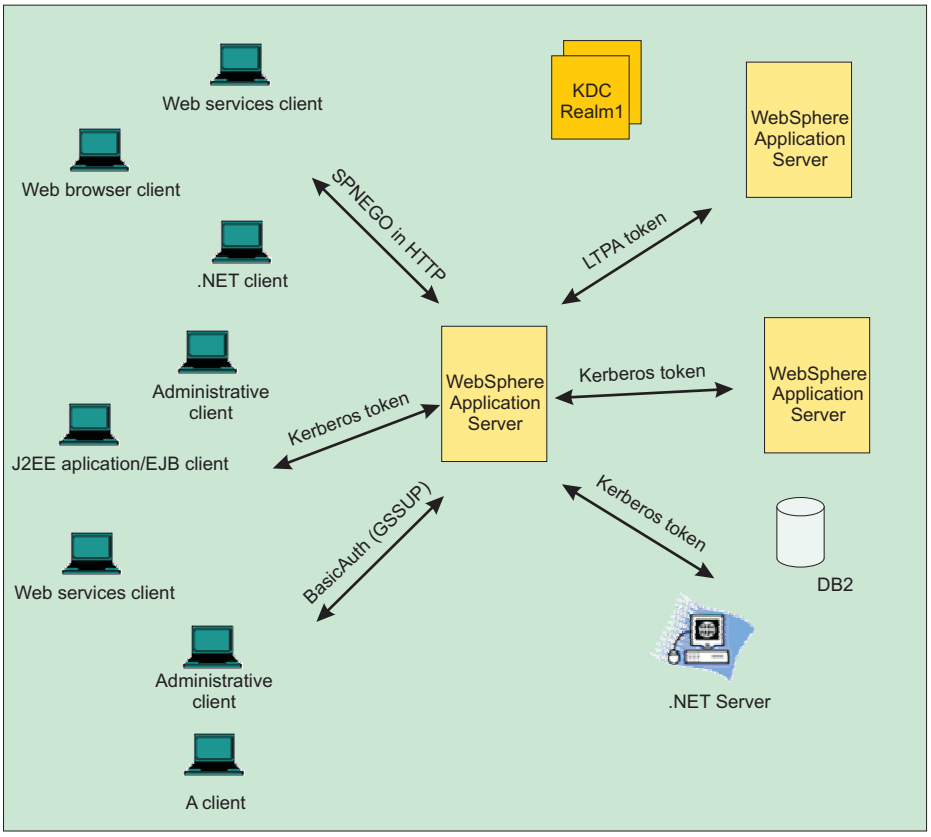

Figure 10. Kerberos authentication in a single Kerberos realm environment

When the WebSphere Application Server receives a Kerberos or SPNEGO token for authentication, it uses the Kerberos service principal (SPN) to establish a security context with a requestor. If a security context is established, the WebSphere Kerberos login module extracts a client GSS delegation credential, creates a Kerberos authentication token base on the Kerberos credential, and places them in the client subject with other tokens.

If the server must use a downstream server or back-end resources, it uses the client GSS delegation credential. If a downstream server does not support Kerberos authentication, the server uses the LTPA token instead of the Kerberos token. If a client does not include a GSS delegation credential in the request, the server uses the LTPA token for the downstream server . The Kerberos authentication token and principal are propagated to the downstream server as part of the security attributes propagation feature.

If the WebSphere Application Server and the KDC do not use the same user registry, then a JAAS custom login module might be required to map the Kerberos principal name to the WebSphere user name.

Kerberos authentication in a cross or trusted Kerberos realm environment

WebSphere Application Server also supports Kerberos authentication in a cross or trusted Kerberos realm environment as shown in the following figure:

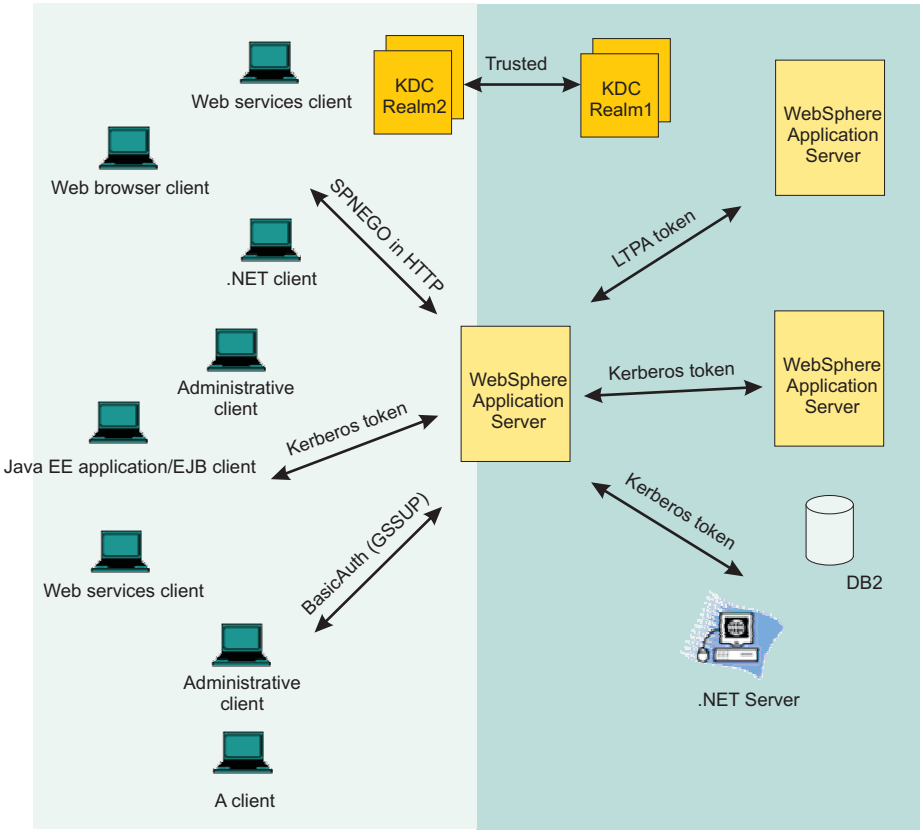

Figure 11. Kerberos authentication in a cross or trusted Kerberos realm environment

When the WebSphere Application Server receives a Kerberos or SPNEGO token for authentication, it uses the Kerberos service principal (SPN) to establish a security context with a requestor. If a security context is established, the WebSphere Kerberos login module always extracts a client GSS delegation credential and Kerberos ticket and places them in the client subject with other tokens.

If the server must use a downstream server or backend resources, it uses the client GSS delegation credential. If a downstream server does not support Kerberos authentication, the server uses the LTPA token instead of the Kerberos token. If a client does not include a GSS delegation credential in the request, the server uses the LTPA token for the downstream server . The Kerberos authentication token and principal are propagated to the downstream server as part of the security attributes propagation feature.

If the WebSphere Application Server and the KDC do not use the same user registry, then a JAAS custom login module might be required to map the Kerberos principal name to the WebSphere user name.

In this release of WebSphere Application Server, the new security multiple domains only support Kerberos at the cell level. All WebSphere Application Servers must be used by the same Kerberos realm. However, the clients and or backend resources (such as DB2, .NET server, and others) that support Kerberos authentication can have their own Kerberos realm. Only peer-to-peer and transitive trust cross-realm authentication are supported. The following steps must be performed for trusted Kerberos realms:

- The Kerberos trusted realm setup must be done on each of the Kerberos KDCs. See your Kerberos Administrator and User's guide for more information about how to set up a Kerberos trusted realm.
- The Kerberos configuration file might need to list the trusted realm.
- Add Kerberos trusted realms in the administrative console by clicking **Global security > CSIv2 outbound communications > Trusted authentication realms - outbound**.

The following figure shows a Java and administrative client that uses a Kerberos credential cache to authenticate to WebSphere Application Server with a Kerberos token in a trusted Kerberos realm:

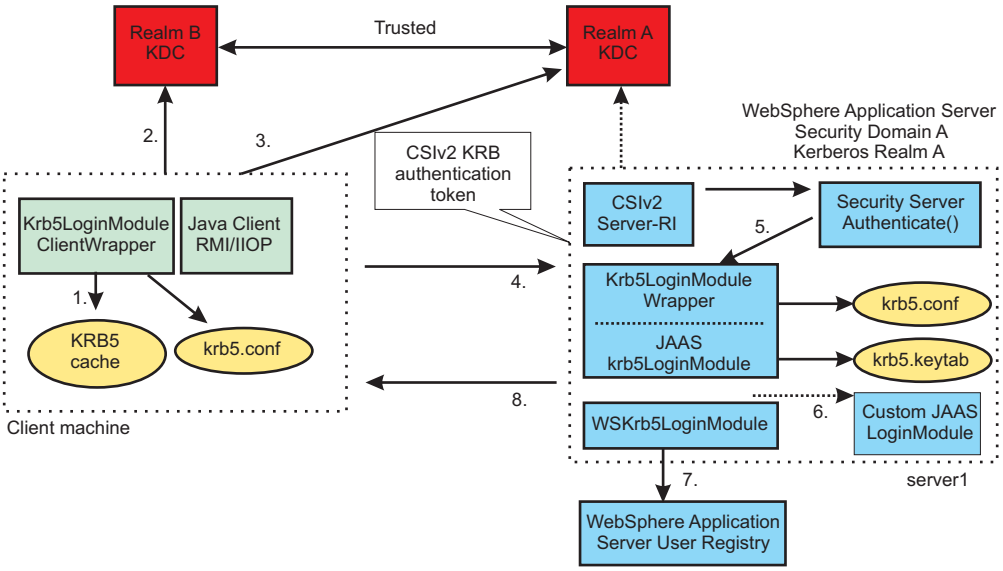

Figure 12. Using a Kerberos credential cache to authenticate to WebSphere Application Server with a Kerberos token in a trusted Kerberos realm

In the figure above, the following events occur:

1. The client uses the Kerberos credential cache if it exists.
2. The client requests a cross realm ticket (TGS_REQ) for `Realm A` from the `Realm B` KDC using the Kerberos credential cache.
3. The client uses a cross realm ticket to request Kerberos service ticket for `server1` (TGS_REQ) from the `Realm A` KDC.
4. The Kerberos token returned from the KDC (TGS_REP) is added to the CSIv2 message authentication token and sent to `server1` for authentication.
5. The server calls Krb5LoginModuleWrapper to establish security context with the client using the server Kerberos Service Principal Name (SPN) and keys from the **krb5.keytab** file. If the server successfully establishes a security context with the client, it always extracts the client GSS delegation credential and tickets and places them in the client subject.
6. Optionally, a custom JAAS Login Module might be needed if the KDC and WebSphere Application Server do not use the same user registry.
7. The user is validated with the user registry for WebSphere Application Server.
8. The results (success or failure) are returned to the client.

The following figure shows a Java and administrative client that uses a Kerberos principal name and password to authenticate to WebSphere Application Server with a Kerberos token:

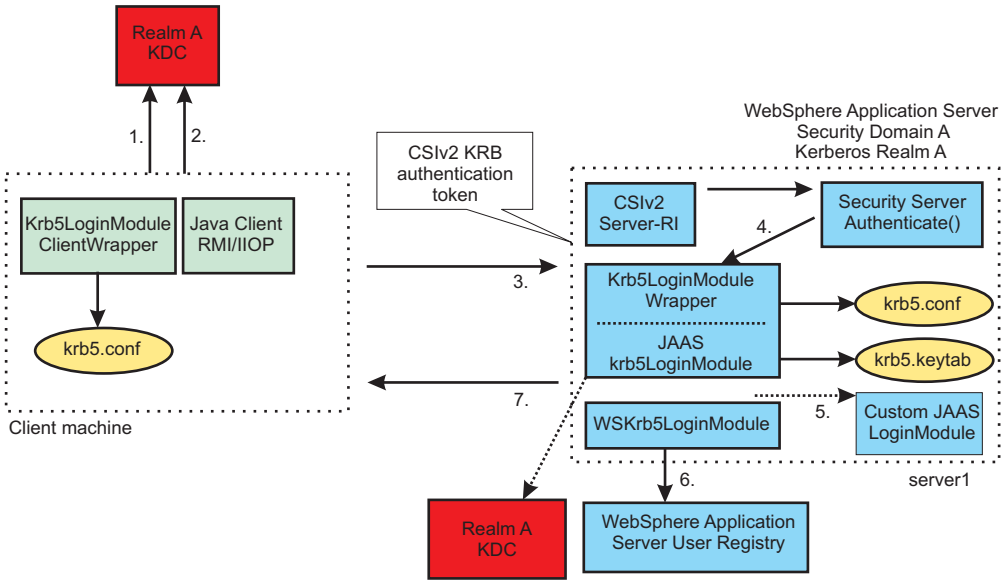

Figure 13. Using a Kerberos principal name and password to authenticate to WebSphere Application Server with a Kerberos token

In the figure above, the following events occur:

1. The client obtains the Kerberos granting ticket (TGT) from the KDC.
2. The client obtains a Kerberos service ticket for `server1` (TGS_REQ) using the TGT.
3. The Kerberos token returned from the KDC (TGS_REP) is added to the CSIv2 message authentication token and sent to `server1` for authentication.
4. The server calls Krb5LoginModuleWrapper to establish security context with the client using the server Kerberos Service Principal Name (SPN) and keys from the **krb5.keytab** file. If the server successfully establishes a security context with the client, it always extracts the client GSS delegation credential and tickets and places them in the client subject.
5. Optionally, a custom JAAS Login Module might be needed if the KDC and WebSphere Application Server do not use the same user registry.
6. The user is validated with the user registry for WebSphere Application Server.
7. The results are returned to the client.

The following figure shows server-to-server communications:

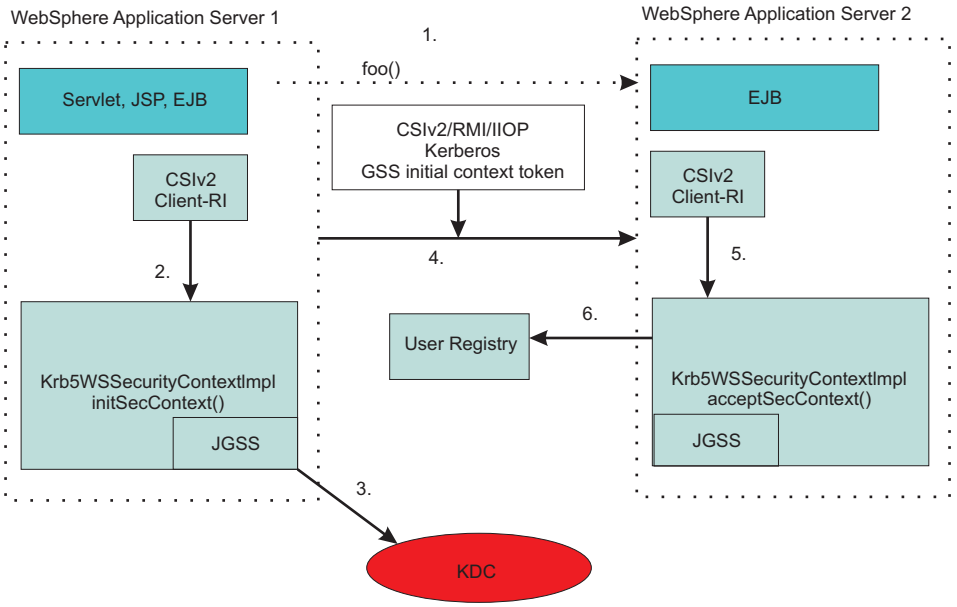

Figure 14. Server to server communications

When a WebSphere Application Server starts up, it uses the server ID and password to login to the KDC and then obtains the TGT. It then uses the TGT to request a service ticket to communicate with another server. If a WebSphere Application Server uses the internal server ID instead of the server ID and password, server-to-server communication is done using an LTPA token. In the figure above, the following events occur:

1. WebSphere Application Server 1 invokes a method, foo(), on an Enterprise JavaBeans (EJB) running in WebSphere Application Server 2.
2. `Server1` obtains a Kerberos service ticket for `Server2` (TGS_REQ) using the `Server1` TGT.
3. Same as step 2.
4. The Kerberos token returned from a KDC (TGS_REP) is added to the CSIv2 message authentication token and sent to `Server2` for authentication.
5. `Server2` calls the acceptSecContext() method to establish security context with `server1` using the `server2` Kerberos Service Principal Name (SPN) and keys from the **krb5.keytab** file. If `server2` successfully establishes a security context with `server1`, it always extracts the `server1` GSS delegation credential and tickets and places them in the subject.
6. The server id is validated with the WebSphere user registry.

Note: If a Java client application and the application server exist on the same machine and they use different Kerberos realm names, the run time uses the default realm name from the Kerberos configuration file. Alternatively, you can specify the realm name during the login process.

Things to consider before setting up Kerberos as the authentication mechanism for WebSphere Application Server

WebSphere Application Server now supports SPNEGO tokens in the HTTP header, Kerberos tokens, LTPA tokens and BasicAuth (GSSUP) for authentication.

To provide end-to-end Kerberos and end-to-end SPNEGO to Kerberos solutions, be aware of the following:

- The **Enabled delegation of Kerberos credentials** option must be selected. Read about Configuring Kerberos as the authentication mechanism using the administrative console for more information about this option.

- A client must obtain a ticket-granting ticket (TGT) with forwardable, address-less and renewable flags so that a target server can extract a client delegation Kerberos credential and use it for going to the downstream server.
- A client TGT that has an address can not be used for a downstream server, Data replication service (DRS) cache and cluster environments.
- See your Kerberos KDC platforms to make sure that it allows for client delegation Kerberos.
- For a long running application, a client should request a TGT with a renewable flag so that a target server can renew the delegation Kerberos.
- For a long-running application, ensure that the Kerberos ticket is valid for a period of time that is at least as long as the application runs. For example, if the application processes a transaction that takes 5 minutes, the Kerberos ticket must be valid for at least 5 minutes.
- Kerberos authentication and SPNEGO web authentication are both supported for Active Directory cross domain trusts within the same forest.
- In order for an administrative agent to use the Kerberos authentication mechanism, it must exchange an LTPA key with an administrative subsystem profile.
- If you plan to use the client delegation Kerberos credential for downstream authentication, make sure the client can request a service ticket that is greater than 10 minutes. If the client delegation Kerberos credential lifetime is less than 10 minutes, then the server attempts to renew it.

Note: The client, WebSphere Application Server and KDC machines must keep the clock synchronized. The best practice is to use a time server to keep all of the systems synchronized.

For this release of WebSphere Application Server, be aware of the following:

- Complete end-to-end Kerberos support with Tivoli Access Manager is available using the following KDCs:
  - z/OS
  - Microsoft (single or multi-realm)
  - AIX
  - Linux
- You can now configure and enable Kerberos cross realms for WebSphere Application Server and the thin client.
- WebSphere Application Server administrative function with Kerberos is limited by the following:
  - The preferred authentication mechanism for flexible management activities is the Rivest Shamir Adleman (RSA) authentication mechanism (by default).
  - Job Manager configured with Kerberos as the administrative authentication does not support Cross-Kerberos realms. They must be in the same Kerberos realm as registered nodes, or have the administrative authentication set to RSA
  - While Kerberos authentication is supported for administrative clients (wsadmin or Java clients) you should use the same KDC realm as the WebSphere Application Server it administers. Otherwise, a user id and password are recommended.
  - Mixed cell Kerberos and LTPA configuration is not supported when some of the nodes are WebSphere Application Server Release 6.x nodes or earlier.

Support information for Kerberos authentication

The following scenarios are supported:

- External domain trusts that are not on the same forests
- Domain trust within the same forest
- Kerberos realm trust

The following scenarios are not supported:

- Cross-forest trust
- Forest external trusts

Setting up Kerberos as the authentication mechanism for WebSphere Application Server

You must perform the steps in order as listed in “Setting up Kerberos as the authentication mechanism for WebSphere Application Server” to set up Kerberos as the authentication mechanism for WebSphere Application Server.

Note: Kerberos authentication mechanism on the server side must be done by the system administrator and on the Java client side by end users. The Kerberos keytab file must to be protected.

Setting up Kerberos as the authentication mechanism for the pure Java client

End users can optionally set up Kerberos authentication mechanism for the pure Java client. Read about Configuring a Java client for Kerberos authentication for more information.

Setting up Kerberos as the authentication mechanism for WebSphere Application Server

You must perform steps in this article in order to set up Kerberos as the authentication mechanism for WebSphere Application Server.

About this task

Note: Kerberos authentication mechanism on the server side must be done by the system administrator and on the Java client side by end users. The Kerberos keytab file must to be protected.

You must first ensure that the KDC is configured. See your Kerberos Administrator and User's guide for more information.

gotcha: When configuring the envar file for a z/OS KDC, order the encryption types from most secure to least secure for the SKDC_TKT_ENCTYPES environment variable. The z/OS KDC prefers to use the encryption types that are first in the list, from left to right.

You must perform the following steps in order to set up Kerberos as the authentication mechanism for WebSphere Application Server.

Procedure

1. Create a Kerberos service principal name and keytab file You can create a Kerberos service principal name and keytab file using Microsoft Windows, iSeries, Linux, Solaris, Massachusetts Institute of Technology (MIT) and z/OS operating systems key distribution centers (KDCs).

   Kerberos prefers servers and services to have a host-based service ID. The format of this ID is `<service name>/<fully qualified hostname>`. The default service name is `WAS`. For Kerberos authentication, the service name can be any strings that are allowed by the KDC. However, for SPNEGO web authentication, the service name must be HTTP. An example of a WebSphere Application Sever server ID is `WAS/myhost.austin.ibm.com`.

   Each host must have a server ID unique to the hostname. All processes on the same node share the same host-based service ID.

   A Kerberos administrator creates a Kerberos service principal name (SPN) for each node in the WebSphere cell. For example, for a cell with 3 nodes (such as `server1.austin.ibm.com`, `server2.austin.ibm.com` and `server3.austin.ibm.com`), the Kerberos administrator must create the following Kerberos service principals: `WAS/server1.austin.ibm.com`, `WAS/server2.austin.ibm.com` and `WAS/server3.austin.ibm.com`.

   The Kerberos keytab file (**krb5.keytab**) contains all of the SPNs for the node and must be protected. This file can be placed in the `config/cells/<cell_name>` directory

Read the Creating a Kerberos principal and keytab article for more information.

2. Create a Kerberos configuration file The IBM implementation of the Java Generic Security Service (JGSS) and KRB5 require a Kerberos configuration file (**krb5.conf** or **krb5.ini**) on each node or Java virtual machine (JVM). In this release of WebSphere Application Server, this configuration file should be placed in the `config/cells/<cell_name>` directory so that all application servers can access this file. If you do not have a Kerberos configuration file, use a **wsadmin** command to create one.

   Read the Creating a Kerberos configuration article for more information.

3. Configure Kerberos as the authentication mechanism for WebSphere Application Sever using the administrative console Use the administrative console to configure Kerberos as the authentication mechanism for the application server. When you have entered and applied the required information to the configuration, the Kerberos service principal name is formed as *<service name>/<fully qualified hostname>*`@KerberosRealm`, and is used to verify incoming Kerberos token requests.

   Read the Configuring Kerberos as the authentication mechanism using the administrative console article for more information.

4. Map a client Kerberos principal name to the WebSphere user registry ID You can map the Kerberos client principal name to the WebSphere user registry ID for both Simple and Protected GSS-API Negotiation (SPNEGO) web authentication and Kerberos authentication.

   Read the Mapping of a client Kerberos principal name to the WebSphere user registry ID article for more information.

5. Set up Kerberos as the authentication mechanism for the pure Java client (optional) A Java client can authenticate with WebSphere Application server with a Kerberos principal name and password or with the Kerberos credential cache (krb5Ccache).

   Read the Configuring a Java client for Kerberos authentication article for more information.

RSA token authentication mechanism

The Rivest Shamir Adleman (RSA) Authentication Mechanism is used to simplify the security environment for the Flexible Management Topology. It supports the ability to securely and easily register new servers to the Flexible Management topology. With the Flexible Management topology, you can submit and manage administrative jobs, locally or remotely, by using a job manager that manages applications, performs product maintenance, modifies configurations, and controls the application server runtime. The RSA authentication mechanism is only used for server-to-server administrative authentication, such as admin connector and file transfer requests. The RSA authentication mechanism does not replace LTPA or Kerboros for use by applications.

Note: The RSA token authentication mechanism aids the flexible management objective to preserve the base profiles configurations and isolate them from a security perspective. This mechanism permits the base profiles managed by an administrative agent to have different Lightweight Third-Party Authentication (LTPA) keys, different user registries, and different administrative users.

Important: The RSA token is not related to the RSA SecureId token. Please note that the application server does not provide support for SecureId.

Authentication is the process of establishing whether a client is who or what it claims to be in a particular context. A client can be either an end user, a machine, or an application. An authentication mechanism in WebSphere Application Server typically collaborates closely with a *user registry*. The user registry is the user and groups account repository that the authentication mechanism consults with when performing authentication. The authentication mechanism is responsible for creating a *credential*, which is an internal product representation of a successfully authenticated client user. Not all credentials are created equally. The abilities of the credential are determined by the configured authentication mechanism.

Authentication process

The RSA token authentication mechanism ensures that after the RSA root signer certificate (15 year lifetime) is exchanged between two administrative processes, there is no need to synchronize security

information among disparate profiles for administrative requests. The RSA personal certificate (1 year lifetime) is used to perform the cryptographic operations on the RSA tokens and can be verified by the long-lived RSA root. RSA token authentication is different from LTPA where keys are shared and if one side changes, all sides need to change. Since RSA token authentication is based on a PKI infrastructure, it benefits from the scalability and manageability of this technology in a large topology.

An RSA token has more advanced security features than LTPA; this includes a nonce value that makes it a one-time use token, a short expiration period (since it's a one-time use token), and trust, which is established based on certificates in the target RSA trust store.

RSA token authentication does not use the same certificates as used by Secure Sockets Layer (SSL). This is the reason RSA has it's own keystores. In order to isolate the trust established for RSA, the trust store, keystore, and root keystore, need to be different from the SSL configuration.

Note: SSL personal certificates given to pure clients are often signed by the same SSL root certificate used by servers, and this allows a pure client to send an RSA token to a server and act as an administrator. This should be avoided for the RSA token authentication mechanism. The RSA token authentication mechanism has its own root certificate which signs personal certificates that are used to encrypt and sign parts of the token.

The data stored in an RSA token is based on the identity of the client subject. The client subject can be based on LTPA or Kerberos, but the RSA token does not use this protection for administrative requests. The RSA token is easier to use while still maintaining a secure transportation of the identity. The data in an RSA token includes:

- Version
- Nonce
- Expiration
- Realm
- Principal
- Access ID
- Roles (not currently used)
- Groups
- Custom data

Custom data can be added to the WSCredential on the sending side (prior to going outbound) by creating a properties object, adding custom attributes, and adding this to the WSCredential in the following way.

```
import com.ibm.websphere.security.cred.WSCredential;

java.util.Properties props = new java.util.Properties();
props.setProperty("myAttribute", "myValue");
WSCredential.put ("customRSAProperties", props);
```

Once the Subject is created at the target process, you can get access to these attributes in the following way.

```
java.util.Properties props = (java.util.Properties) WSCredential.get("customRSAProperties");
```

This data is placed into a hash table at the target side and the hash table is used in a Java™ Authentication and Authorization Service (JAAS) login to obtain a subject at the target that contains the same attributes from the RSA token. With the target containing the same attributes from the RSA token, you can have a subject at the target side that is not from the same realm used by the target. For this authorization to succeed, a cross-realm mapping is required within the administrative authorization table unless the identity is a trusted server ID.

The figure (below) is an overview of the RSA token authentication mechanism and describes the process that takes place when a request is sent from a server-as-client to a target server. The server-as-client has an administrative subject on the thread that is used as input to create the RSA token. The other information needed is RSA public certificate of the target server. This certificate must be retrieved by making a “bootstrap” MBean request to the target process prior to sending any real requests. The target bootstrap request retrieves the public certificate from the target process. When creating an RSA token, the primary purpose of obtaining the target's public certificate is to encrypt the secret key. Only the target can decrypt the secret key, which is used to encrypt the user data.

The client's private key is used to sign both the secret key and the user data. The client's public key is embedded in the RSA token and validated at the target. If the client's public key is not trusted when calling the CertPath APIs at the target, the RSA token validation cannot continue. If the client's public key is trusted, it can be used to verify the secret key and user data signatures.

The basic goal is to convert the client subject into a subject at the target by securely propagating the required information. After the subject is generated at the target, the RSA authentication mechanism process is complete.

Configuring the RSA token authentication mechanism

You use the WebSphere Application Server administrative console to configure the Rivest Shamir Adleman (RSA) token authentication mechanism. The RSA token authentication mechanism can only be used for administrative requests. As such, the authentication mechanism choices for administrative authentication are part of the Global Security panel of the administrative console.

Before you begin

RSA token authentication mechanism is the default selection for the application server, administrative agent, and job manager profiles. LTPA is still the default for the deployment manager profile to preserve the same behavior for the existing topology.

About this task

You configure Lightweight Third-Party Authentication (LTPA) and Kerberos on the main authentication mechanism panels of the administrative console as well as configure RSA token authentication. During registration of a base profile with the administrative agent, the trusted certificates on both sides are updated with the root signer for the other. The same process occurs during registration of an administrative agent or deployment manager with a job manager. When removing the registration, the trusted signers are removed from both sides so that trust is no longer established.

By default, the RSA mechanism is set up correctly during the registration tasks, such as **registerNode** or **registerWithJobManager**. No further actions are necessary to establish trust within these environments. However, if you need to establish trust between two base servers or between two admin agents, for example, you can use the following steps to further configure the RSA token authentication mechanism:

Procedure

1. Click **Security > Global security** . Under Administrative security click the link to **Administrative authentication**.
2. Select the RSA token radio button. Select a data encryption keystore from the drop-down list. The option is recommend for flexible systems administration.
3. Optional: To exchange the root signers between two base servers:
   a. Select the root keystore from the Data encryption keystore drop-down list (such as NodeRSATokenRootStore).

b. Click **Extract Signer**.
c. Enter a fully-qualified name in the Certificate file name field.
d. Click **OK**.

4. Optional: Transfer the extracted root signer to the other server, and add it to that server's trusted signers keystore:
   a. Select the trusted keystore from the drop-down list (such as NodeRSATokenTrustedStore).
   b. Click **Add Signer**.
   c. Enter a unique name for the Alias.
   d. Enter a fully-qualified name for the signer key file.
   e. Click **OK**.
5. Enter the nonce cache timeout value.
6. Enter token timeout value.
7. Click **Apply** and **Save**.

Results

You have configured the RSA token authentication mechanism.

RSA token authentication settings:

Use this panel to configure RSA token authentication.

To view this administrative console page, click **Security > Global security**. Under Administrative security click **Administrative authentication**.

The administrative authentication method is used when an administrative process on this profile connects to another profile. If the primary authentication method is set to RSA token and that primary method fails, the system attempts to use the current application authentication method (which could be SWAM, Kerberos, or LTPA for example).

Note: SWAM is deprecated and will be removed in a future release.

RSA token (recommended for flexible systems administration):

RSA token is an authentication mechanism using certificates for signing and encryption portions of the security information being propagated.

Default: Enabled

Data encryption keystore:

This is the keystore that contains the personal certificate used to encrypt and sign RSA tokens.

Data type: text

Personal certificate for encryption:

This is the alias found in the Data encryption keystore that is used to encrypt and sign RSA tokens.

Data type: text

Trusted signers keystore:

This is the keystore used to contain signer certificates that can validate RSA tokens sent by other servers. The RSA token contains a sending certificate that needs to be validated by this trust store using a CertPath validation.

Data type: text

Nonce cache timeout:

Specifies the amount of time, in minutes, that the issued token is valid.

This field displays the maximum timeout, in minutes, for a token to be considered valid.

Data type: Integer
Default: 20
Minimum: 10
Maximum: Integer.MAX_VALUE

Token timeout:

Specifies the amount of time, in minutes, that the issued token is valid.

This field displays the maximum timeout, in minutes, for a token to be considered valid.

Data type: Integer
Default: 10
Minimum: 10
Maximum: Integer.MAX_VALUE

Only use the active application authentication mechanism (currently LTPA):

Select to encrypt authentication information so that the application server can send the data from one server to another in a secure manner.

The encryption of authentication information that is exchanged between servers involves the Lightweight Third-Party Authentication (LTPA) mechanism.

Kerberos:

Select to encrypt authentication information so that the application server can send the data from one server to another in a secure manner.

The encryption of authentication information that is exchanged between servers involves the Kerberos mechanism.

Note: Kerberos must be configured before this option can be selected.

RSA token certificate use:

The Rivest Shamir Adleman (RSA) token uses certificates in a similar way that Secure Sockets Layer (SSL) uses them. However, the trust established for SSL and RSA are different, and RSA certificates should not use SSL certificates and vice versa. The SSL certificates can be used by pure clients, and when used for the RSA mechanism would allow the client to send an RSA token to the server. The RSA token authentication mechanism is purely for server-to-server requests and should not be used by pure clients. The way to prevent this is to control the certificates used by RSA in such as a way so they are

never distributed to any clients. There is a different root certificate for RSA that prevents trust being established with clients who only need SSL certificates.

RSA root certificate

For each profile there is a root certificate stored in the **rsatoken-root-key.p12** keystore. The sole purpose of this RSA root certificate is to sign the RSA personal certificate which is stored in the **rsatoken-key.p12** keystore. The RSA root certificate has a default lifetime of 15 years. The signer from the RSA root certificate is shared with other processes to establish trust.

The keytool utility is available using the QShell Interpreter. Using the keytool utility, you can list the contents of these keystores and display the keyEntry (personal certificate). The example below illustrated how this is accomplished for the **rsatoken-root-key.p12** (RSA root certificate) and **rsatoken-key.p12** (RSA personal certificate).

```
${profile_root}\config\cells\${cellname}\nodes\${nodename}> keytool -list -v -keystore rsatoken-root-key.p12
–storepass WebAS -storetype PKCS12

```

The purpose of the RSA personal certificate is to sign and encrypt information in the RSA token. The RSA personal certificate has a default lifetime of one year because it is used to sign and encrypt data that is transmitted over the wire. Refreshing the certificate is performed by the certificate expiration monitor, which is used for any other certificate in the system including SSL certificates.

RSA token trust is established when the **rsatoken-trust.p12** of the target process contains the signer of the root certificate of the client process that sends a token. Inside the RSA token is the public certificate of the client, which must be validated at the target before being used to decrypt data. The validation of the client's public certificate is performed using the CertPath APIs, which use the **rsatoken-trust.p12** as the source of certificates used during the validation.

The following example shows the use of the keytool utility to list the **rsatoken-trust.p12** keystore.

Note: This trust store contains three trustedCertEntry (public certificate) entries. The root public certificate from the administrative agent, a root public certificate from a job manager to which it is registered, and a root public certificate from a base profile to which it is registered.

```
${profile_root}\config\cells\${cellname}\nodes\${nodename}> keytool -list -v -keystore rsatoken-trust.p12

You can use the WebSphere Application Server certificate management tools to create a new personal certificate, and then replace the RSA personal certificate in the rsa-key.p12 and the public key in the rsa-trust.p12 with this newly created personal certificate. If you replace the RSA personal certificate prior to federation to an administrative agent or job manager, the exchange of certificates is done for you. If you change the certificate after federation, you need to make sure the rsa-trust.p12 on the administrative agent or job manager is updated with the signer for your new certificate to establish trust.

Simple WebSphere authentication mechanism (deprecated)

The Simple WebSphere authentication mechanism (SWAM) defines rules about security information and the format of how security information is stored in both credentials and tokens. SWAM is intended for simple, non-distributed, single application server runtime environments.

Note: SWAM was deprecated in WebSphere Application Server Version 8.0 and will be removed in a future release.

The single application server restriction is due to the fact that SWAM does not support *forwardable* credentials. If a servlet or enterprise bean in application server process 1, invokes a remote method on an enterprise bean living in another application server process 2, the identity of the caller identity in process 1

is not transmitted to server process 2. What is transmitted is an unauthenticated credential, which, depending on the security permissions configured on the EJB methods, can cause authorization failures.

Because SWAM is intended for a single application server process, single sign-on (SSO) is not supported.

The SWAM authentication mechanism is suitable for simple environments, software development environments, or other environments that do not require a distributed security solution.

Message layer authentication

Defines the credential information and sends that information across the network so that a receiving server can interpret it.

When you send authentication information across the network using a token the transmission is considered message layer authentication because the data is sent with the message inside a service context.

A pure Java client uses Kerberos (KRB5) or basic authentication, or Generic Security Services Username Password (GSSUP), as the authentication mechanism to establish client identity.

However, a servlet can use either basic authentication (GSSUP) or the authentication mechanism of the server, Kerberos (KRB5) or Lightweight Third Party Authentication (LTPA), to send security information in the message layer. Use KRB5 or LTPA by authenticating or by mapping the basic authentication credentials to the security mechanism of the server.

The security token that is contained in a token-based credential is authentication mechanism-specific. The way that the token is interpreted is only known by the authentication mechanism. Therefore, each authentication mechanism has an object ID (OID) representing it. The OID and the client token are sent to the server, so that the server knows which mechanism to use when reading and validating the token. The following list contains the OIDs for each mechanism:

BasicAuth (GSSUP): oid:2.23.130.1.1.1
KRB5: OID: 1.2.840.113554.1.2.2
LTPA: oid:1.3.18.0.2.30.2
SWAM: No OID because it is not forwardable

Note: SWAM is deprecated in WebSphere Application Server Version 8.0 and will be removed in a future release.

On the server, the authentication mechanisms can interpret the token and create a credential, or they can authenticate basic authentication data from the client, and create a credential. Either way, the created credential is the *received* credential that the authorization check uses to determine if the user has access to invoke the method. You can specify the authentication mechanism by using the following property on the client side:

- com.ibm.CORBA.authenticationTarget

Basic authentication (BasicAuth) and KRB5 are currently the only valid values. You can configure the server through the administrative console.

Note: When **perform basic authentication** is enabled, if the client is not similarly configured (and does not pass a credential such as a user ID and password).

Configuring authentication retries

Situations occur where you want a prompt to display again if you entered your user ID and password incorrectly or you want a method to retry when a particular error occurs back at the client. If you can

correct the error by information at the client side, the system automatically performs a retry without the client seeing the failure, if the system is configured appropriately.

Some of these errors include:
- Entering a user ID and password that are not valid
- Having an expired credential on the server
- Failing to find the stateful session on the server

By default, authentication retries are enabled and perform three retries before returning the error to the client. Use the com.ibm.CORBA.authenticationRetryEnabled property (`True` or `False`) to enable or disable authentication retries. Use the com.ibm.CORBA.authenticationRetryCount property to specify the number of retry attempts.

Integrating third-party HTTP reverse proxy servers

These steps are required to use a trust association interceptor with a reverse proxy security server.

About this task

WebSphere Application Server enables you to use multiple trust association interceptors. The application server uses the first interceptor that can handle the request.

Procedure

1. Access the administrative console.

   Type `http://`*`server_name`*`:`*`port_number`*`/ibm/console` in a web browser.

   Port 9060 is the default port number for accessing the administrative console. During installation, however, you might have specified a different port number. Use the appropriate port number.
2. Click **Security > Global security**.
3. Under Web and SIP security, click **Trust association**.
4. Select the **Enable trust association** option.
5. Under Additional properties, click **Interceptors**. The default value appears.
6. Verify that the appropriate trust association interceptors are listed.

Results

Trust association is enabled.

What to do next

1. If you are enabling security, make sure that you complete the remaining steps for enabling security.
2. Save, stop and restart all of the product servers (deployment managers, nodes and application servers) for the changes to take effect.

Trust associations

Trust association enables the integration of IBM WebSphere Application Server security and third-party security servers. More specifically, a reverse proxy server can act as a front-end authentication server while the product applies its own authorization policy onto the resulting credentials that are passed by the proxy server.

Demand for such an integrated configuration has become more compelling, especially when a single product cannot meet all of the customer needs or when migration is not a viable solution. This article provides a conceptual background behind the approach.

In this setup, WebSphere Application Server is used as a back-end server to further exploit its fine-grained access control. The reverse proxy server passes the HTTP request to WebSphere Application Server that includes the credentials of the authenticated user. WebSphere Application Server then uses these credentials to authorize the request.

Trust association model

The idea that WebSphere Application Server can support trust association implies that the product application security recognizes and processes HTTP requests that are received from a reverse proxy server. WebSphere Application Server and the proxy server engage in a contract in which the product gives its full trust to the proxy server and the proxy server applies its authentication policies on every web request that is dispatched to WebSphere Application Server. This trust is validated by the interceptors that reside in the product environment for every request received. The method of validation is agreed upon by the proxy server and the interceptor.

Running in trust association mode does not prohibit WebSphere Application Server from accepting requests that did not pass through the proxy server. In this case, no interceptor is needed for validating trust.

WebSphere Application Server supports the following trust association interceptor (TAI) interfaces:

com.ibm.ws.security.web.TAMTrustAssociationInterceptorPlus
: This TAI interceptor implementation that implements the new WebSphere Application Server interface supports WebSphere Application Server Version 5.1.1 and later. The interface supports WebSEAL Version 5.1, but does not support WebSEAL Version 4.1. For an explanation of security attribute propagation, see “Security attribute propagation” on page 1544.

com.ibm.ws.security.spnego.TrustAssociationInterceptorImpl
: This interceptor is new to this release. SPNEGO has replaced SPNEGO TAI as the web authenticator for WebSphere Application Server.

IBM WebSphere Application Server: WebSEAL Integration

The integration of WebSEAL and WebSphere Application Server security is achieved by placing the WebSEAL server at the front-end as a reverse proxy server. From a WebSEAL management perspective, a junction is created with WebSEAL on one end, and the product web server on the other end. A junction is a logical connection that is created to establish a path from the WebSEAL server to another server.

In this setup, a request for web resources that are stored in a protected domain of the product is submitted to the WebSEAL server where it is authenticated against the WebSEAL security realm. If the requesting user has access to the junction, the request is transmitted to the WebSphere Application Server HTTP server through the junction, and then to the application server.

Meanwhile, WebSphere Application Server validates every request that comes through the junction to ensure that the source is a trusted party. This process is referenced as *validating the trust* and it is performed by a WebSEAL product-designated interceptor. If the validation is successful, WebSphere Application Server authorizes the request by checking whether the client user has the required permissions to access the web resource. If so, the web resource is delivered to the WebSEAL server through the web server, which then gives the resource to the client user.

WebSEAL server

The policy director delegates all of the web requests to its web component, the WebSEAL server. One of the major functions of the server is to perform authentication of the requesting user. The WebSEAL server

consults a Lightweight Directory Access Protocol (LDAP) directory. It can also map the original user ID to another user ID, such as when global single sign-on (GSO) is used.

For successful authentication, the server plays the role of a client to WebSphere Application Server when channeling the request. The server needs its own user ID and password to identify itself to WebSphere Application Server. This identity must be valid in the security realm of WebSphere Application Server. The WebSEAL server replaces the basic authentication information in the HTTP request with its own user ID and password. In addition, WebSphere Application Server must determine the credentials of the requesting client so that the application server has an identity to use as a basis for its authorization decisions. This information is transmitted through the HTTP request by creating a header called `iv-creds`, with the Tivoli Access Manager user credentials as its value.

HTTP server

The junction that is created in the WebSEAL server must get to the HTTP server that serves as the product front end. However, the HTTP server is shielded from knowing that trust association is used. As far as it is concerned, the WebSEAL product is just another HTTP client, and as part of its normal routines, it sends the HTTP request to the product. The only requirement on the HTTP server is a Secure Sockets Layer (SSL) configuration using server authentication only. This requirement protects the requests that flow within the junction.

Web collaborator

When trust association is enabled, the web collaborator manages the interceptors that are configured in the system. The web collaborator loads and initializes these interceptors when you restart your servers. When a request is passed to WebSphere Application Server by the Web server, the web collaborator eventually receives the request for a security check. Two actions must take place:

1. The request must be authenticated.
2. The request must be authorized.

The web authenticator is called to authenticate the request by passing the HTTP request. If successful, a good credential record is returned by the authenticator, which the web collaborator uses to base its authorization for the requested resource. If the authorization succeeds, the web collaborator indicates to WebSphere Application Server that the security check has succeeded and that the requested resource can be served.

Web authenticator

The web authenticator is asked by the web collaborator to authenticate a given HTTP request. Knowing that trust association is enabled, the task of the web authenticator is to find the appropriate trust association interceptor to direct the request for processing. The web authenticator queries every available interceptor. If no target interceptor is found, the web authenticator processes the request as though trust association is not enabled.

Note:

> WebSphere Application Server Version 4 through WebSphere Application Server Version 6.*x* support the com.ibm.websphere.security.TrustAssociationInterceptor.java interface. WebSphere Application Server Version 7.0.*x* and later supports the com.ibm.ws.security.spnego.TrustAssociationInterceptorImpl interface.

Trust association interceptor interface

The intent of the trust association interceptor interface is to have reverse proxy security servers (RPSS) exist as the exposed entry points to perform authentication and coarse-grained authorization, while WebSphere Application Server enforces further fine-grained access control. Trust associations improve security by reducing the scope and risk of exposure.

In a typical e-business infrastructure, the distributed environment of a company consists of web application servers, web servers, existing systems, and one or more RPSS, such as the Tivoli WebSEAL product. Such reverse proxy servers, front-end security servers, or security plug-ins registered within web servers, guard the HTTP access requests to the web servers and the web application servers. While protecting access to the Uniform Resource Identifiers (URIs), these RPSS perform authentication, coarse-grained authorization, and request routing to the target application server.

When a web server, such as an IBM HTTP Server, uses a TAI to communicate with WebSphere Application Server, sometimes it is essential for the TAI to know whether a request came through a web server or came directly to WebSphere Application Sever. Therefore the WebSphere Application Server Web container uses three HttpServletRequest attributes to provide the TAI with the certificate information for a request:

- The com.ibm.websphere.ssl.direct_connection_peer_certificates attribute contains a X509Certificate[] object of the certificate for a direct peer.
- The com.ibm.websphere.ssl.direct_connection_cipher_suite attribute contains a string object of a direct cipher suite.
- The com.ibm.websphere.webcontainer.is_direct_connection attribute contains a boolean object that indicates whether the connection was made through a web server, or was made directly to WebSphere Application Server.

See the topic *Web container request attributes* for more information about these attributes.

Trust association settings

Use this page to enable trust association, which integrates application server security and third-party security servers. More specifically, a reverse proxy server can act as a front-end authentication server while the product applies its own authorization policy onto the resulting credentials passed by the proxy server.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. Under Authentication, expand Web security and click **Trust association**.

When security is enabled and any of these properties change, go to the Global security panel and click **Apply** to validate the changes.

Enable trust association:

Specifies whether trust association is enabled.

Data type:	Boolean
Default:	Disable
Range:	Enable or Disable

Trust association interceptor collection

Use this page to specify trust information for reverse security proxy servers.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. Under Authentication, expand Web and SIP security and click **Trust association**.
3. Under Additional Properties, click **Interceptors**.

When security is enabled and any of these properties are changed, go to the Global security panel and click **Apply** to validate the changes.

Interceptor class name:

Specifies the trust association interceptor class name.

Data type
String

Trust association interceptor settings

Use this page to specify trust information for reverse security proxy servers.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. Under Authentication, click **Web and SIP security**.
3. Click **Trust association**.
4. Under Additional Properties, click **Interceptors > New**.

Interceptor class name:

Specifies the trust association interceptor class name.

Data type
String

Single sign-on for authentication

With single sign-on (SSO) support, web users can authenticate once when accessing both WebSphere Application Server resources, such as HTML, JavaServer Pages (JSP) files, servlets, enterprise beans, and Lotus Domino resources, such as documents in a Domino database, or accessing resources in multiple WebSphere Application Server domains.

There are various ways to accomplish SSO, with the most common in WebSphere using LTPA cookies. LTPA cookies do not require any particular client and allow SSO across different cells provide the registry and LTPA keys are the same.

There are other flavors of SSO, including Simple and Protected GSS-API Negotiation (SPNEGO), which is a way to use the token from a Kerberos login (typically Windows) to authenticate to WebSphere Application Server. This prevents the user from having to type in their userid and passwords again.

Note: In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. This function was deprecated In WebSphere Application Server 7.0. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

TAIs are also a form of single sign-on when used in combination with a Proxy server that does the front-end authentication. The TAI allows the credentials to flow to WebSphere from the Proxy server and to be used to login without the need to re-authenticate the user.

Single sign-on for authentication using LTPA cookies

With single sign-on (SSO) support, web users can authenticate once when accessing both WebSphere Application Server resources, such as HTML, JavaServer Pages (JSP) files, servlets, enterprise beans, and Lotus Domino resources, such as documents in a Domino database, or accessing resources in multiple WebSphere Application Server domains.

Application servers distributed in multiple nodes and cells can securely communicate using the Lightweight Third Party Authentication (LTPA) protocol. LTPA is intended for distributed, multiple application server and machine environments. LTPA can support security in a distributed environment through cryptography. This support permits LTPA to encrypt, digitally sign, and securely transmit authentication-related data, and later decrypt and verify the signature.

LTPA also provides the SSO feature wherein a user is required to authenticate only once in a domain name system (DNS) domain and can access resources in other WebSphere Application Server cells without getting prompted. Web users can authenticate once to a WebSphere Application Server or to a Domino server. This authentication is accomplished by configuring WebSphere Application Servers and the Domino servers to share authentication information.

Without logging in again, web users can access other WebSphere Application Servers or Domino servers in the same DNS domain that are enabled for SSO. You can enable SSO among WebSphere Application Servers by configuring SSO for WebSphere Application Server. To enable SSO between WebSphere Application Servers and Domino servers, you must configure SSO for both WebSphere Application Server and for Domino.

Prerequisites and conditions

To take advantage of support for SSO between WebSphere Application Servers or between WebSphere Application Server and a Domino server, applications must meet the following prerequisites and conditions:

- Verify that all servers are configured as part of the same DNS domain. The realm names on each system in the DNS domain are case sensitive and must match identically. For example, if the DNS domain is specified as `mycompany.com`, then SSO is effective with any Domino server or WebSphere Application Server on a host that is part of the `mycompany.com` domain, for example, `a.mycompany.com` and `b.mycompany.com`.
- Verify that all servers share the same registry.

  This registry can be either a supported Lightweight Directory Access Protocol (LDAP) directory server or, if SSO is configured between two WebSphere Application Servers, a stand-alone custom registry.Domino servers do not support stand-alone custom registries, but you can use a Domino-supported registry as a stand-alone custom registry within WebSphere Application Server.

  You can use a Domino directory that is configured for LDAP access or other LDAP directories for the registry. The LDAP directory product must have WebSphere Application Server support. Supported products include both Domino and LDAP servers, such as IBM Tivoli Directory Server. Regardless of the choice to use an LDAP or a stand-alone custom registry, the SSO configuration is the same. The difference is in the configuration of the registry.
- Define all users in a single LDAP directory. Using multiple Domino directory assistance documents to access multiple directories also is not supported.
- Enable HTTP cookies in browsers because the authentication information that is generated by the server is transported to the browser in a cookie. The cookie is used to propagate the authentication information for the user to other servers, exempting the user from entering the authentication information for every request to a different server.
- For a Domino server:
  - Domino Release 6.5.4 for iSeries and other platforms are supported.
  - A Lotus Notes® client Release 5.0.5 or later is required for configuring the Domino server for SSO.
  - You can share authentication information across multiple Domino domains.
- For WebSphere Application Server:
  - WebSphere Application Server Version 3.5 or later for all platforms are supported.

- You can use any HTTP web server that is supported by WebSphere Application Server.
- You can share authentication information across multiple product administrative domains.
- Basic authentication (user ID and password) using the basic and form-login mechanisms is supported.

  Note: Form-login mechanisms for web applications require that SSO is enabled.
- By default, WebSphere Application Server does a case-sensitive comparison for authorization. This comparison implies that a user who is authenticated by Domino matches the entry exactly (including the base distinguished name) in the WebSphere Application Server authorization table. If case sensitivity is not considered for the authorization, enable the **Ignore Case** property in the LDAP user registry settings.

Using a WebSphere Application Server API to achieve downstream web single sign-on with an LtpaToken2 cookie

You can programmatically perform downstream Single Sign On (SSO) web propagation of a Lightweight Third Party Authentication (LTPA) cookie without the need for an application to store and send user credentials.

WebSphere Application Server provides API support to propagate an LtpaToken2 cookie to downstream web single sign-on applications.

Note:

Web applications running in mid-tier WebSphere servers might need to propagate LtpaToken2 cookies on downstream web invocations. In this release of WebSphere Application Server, a new Application Programming Interface (API) is provided for application developers to programmatically perform downstream SSO without the need for an application to store and send user credentials.

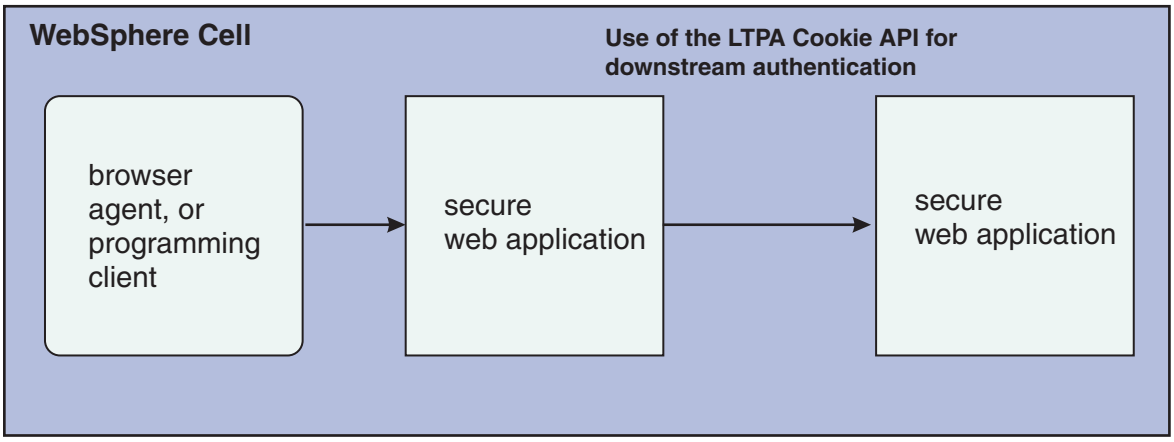

Figure 15. Use of the LTPA Cookie API for downstream authentication

This function is a public API in package com.ibm.websphere.security.WSSecurityHelper, and is defined as follows:

```
/**
   * Extracts an LTPA sso token from the subject of current
   * thread and builds a ltpa cookie out of it for use on
   * downstream web invocations.
   * When the returned value is not null use Cookie methods
   * getName() and getValue() to set the Cookie header
   * on an http request with header value of
   * Cookie.getName()=Cookie.getValue()
```

```
   *
   * @return an object of type javax.servlet.http.Cookie.
   *
   */
```

The following is an example of how you can use the new WSSecurityHelper API:

```
import javax.servlet.http.Cookie;
import com.ibm.websphere.security.WSSecurityHelper;

Cookie ltpaCookie = WSSecurityHelper.getLTPACookieFromSSOToken()
```

Subsequently, the LTPA cookie can be set on an HTTP request header. In this case, the value of the cookie header is the string:

```
ltpaCookie.getName()=ltpaCookie.getValue()
```

For example, if you use org.apache.commons.httpclient.HttpMethod to build your HTTP request, the LTPA cookie can be set as follows:

```
HttpMethod method = .;  // new your HttpMethod based on the
                        // target URL for the web application
if (ltpaCookie != null)
     method.setRequestHeader("Cookie", ltpaCookie.getName()+"="+ltpaCookie.getValue());
```

Note: You should only send LTPA cookies over SSL connections.

Note: You must check whether the LTPA cookie that is returned from calling WSSecurityHelper.getLTPACookieFromSSOToken() in the example above is not `null` before you issue any `getter` methods. Also, to successfully retrieve a LTPA cookie object, and to ensure an SSO token on the thread of execution, make sure that the user has established a successful authentication with the mid-tier server.

Note: WebSphere Application Server does not ship supporting jars for HTTP programming, such as the Apache httpclient. You must provide your own supporting functions for HTTP programming.

Enterprise Identity Mapping

Enterprise Identity Mapping (EIM) for iSeries is the OS/400 implementation of an IBM infrastructure that allows administrators and application developers to solve the problem of managing multiple user registries across their enterprise.

Most network enterprises face the problem of multiple user registries, which require each person or entity within the enterprise to have a user identity in each registry. The need for multiple user registries quickly grows into a large administrative problem that affects users, administrators, and application developers. EIM enables inexpensive solutions for easier management of multiple user registries and user identities in your enterprise.

EIM is a mechanism for mapping and associating a person or entity to the appropriate user identities in various registries throughout the enterprise. EIM provides application programming interfaces (API) for creating and managing these identity mapping relationships and provides APIs that applications use to query this information. In addition, OS/400 uses EIM and Kerberos capabilities to provide a single sign-on environment.

iSeries Navigator, the iSeries graphical user interface, provides wizards to configure and manage EIM. In addition, administrators can manage EIM relationships for user profiles through iSeries Navigator.

For more information on Enterprise Identity Mapping, see Enterprise Identity Mapping concepts.

Global single sign-on principal mapping for authentication

You can use the Java Authorization Contract for Containers (JACC) provider for Tivoli Access Manager to manage authentication to enterprise information systems (EIS) such as databases, transaction processing systems, and message queue systems that are located within the WebSphere Application Server security domain. Such authentication is achieved using the global single sign-on (GSO) principal mapper Java Authentication and Authorization Service (JAAS) login module for Java Platform, Enterprise Edition (Java EE) Connector Architecture resources.

With GSO principal mapping, a special-purpose JAAS login module inserts a credential into the subject header. This credential is used by the resource adapter to authenticate to the EIS. The JAAS login module used is configured on a per-connection factory basis. The default principal mapping module retrieves the user name and password information from XML configuration files. The JACC provider for Tivoli Access Manager bypasses the credential that is stored in the Extensible Markup Language (XML) configuration files and uses the Tivoli Access Manager global sign-on (GSO) database instead to provide the authentication information for the EIS security domain.

WebSphere Application Server provides a default principal mapping module that associates user credential information with EIS resources. The default mapping module is defined in the WebSphere Application Server administrative console on the Application login panel. To access the panel, click **Security > Global security**. Under Java Authentication and Authorization Service, click **Application logins**. The mapping module name is DefaultPrincipalMapping.

The EIS security domain user ID and password are defined under each connection factory by an authDataAlias attribute. The authDataAlias attribute does not contain the user name and password; this attribute contains an alias that refers to a user name and password pair that is defined elsewhere.

The Tivoli Access Manager principal mapping module uses the authDataAlias attribute to determine the GSO resource name and the user name that is required to perform the lookup on the Tivoli Access Manager GSO database. The Tivoli Access Manager Policy Server retrieves the GSO data from the user registry.

Tivoli Access Manager stores authentication information on the Tivoli Access Manager GSO database against a resource and user name pair.

GSO principal mapping architecture

Implementing single sign-on to minimize web user authentications

With single sign-on (SSO) support, web users can authenticate once when accessing web resources across multiple WebSphere Application Servers. Form login mechanisms for web applications require that SSO is enabled. Use this topic to configure single sign-on for the first time.

Before you begin

SSO is supported only when Lightweight Third Party Authentication (LTPA) is the authentication mechanism.

When SSO is enabled, a cookie is created containing the LTPA token and inserted into the HTTP response. When the user accesses other web resources in any other WebSphere Application Server process in the same domain name service (DNS) domain, the cookie is sent in the request. The LTPA token is then extracted from the cookie and validated. If the request is between different cells of WebSphere Application Servers, you must share the LTPA keys and the user registry between the cells for SSO to work. The realm names on each system in the SSO domain are case sensitive and must match identically.

The realm name is the same as the host name.

For the Lightweight Directory Access Protocol (LDAP) the realm name is the host:port realm name of the LDAP server. The LTPA authentication mechanism requires that you enable SSO if any of the web applications have form login as the authentication method.

Because single sign-on is a subset of LTPA, it is recommended that you read “Lightweight Third Party Authentication” on page 1413 for more information.

When you enable security attribute propagation, the following cookie is always added to the response:

LtpaToken2
LtpaToken2 contains stronger encryption and enables you to add multiple attributes to the token. This token contains the authentication identity and additional information such as the attributes that are used for contacting the original login server and the unique cache key for looking up the Subject when considering more than just the identity in determining uniqueness.

Note: The following cookie is optionally added to the response when the **Interoperability mode** flag is enabled:

LtpaToken
LtpaToken is used for inter-operating with previous releases of WebSphere Application Server. This token contains the authentication identity attribute only.

Note: LtpaToken is generated for releases prior to WebSphere Application Server Version 5.1.1. LtpaToken2 is generated for WebSphere Application Server Version 5.1.1 and beyond.

Table 87. LTPA token types. This table describes the LTPA token types.

Token type	Purpose	How to specify
LtpaToken2 only	This is the default token type. It uses the AES-CBC-PKCS5 padding encryption strength (128-bit key size). This token is stronger than the older LtpaToken used prior to WebSphere Application Server Version 6.02. This is the recommended option when interoperability with older releases is not necessary.	Disable the **Interoperability mode** option in the SSO configuration panel within the administrative console. To access this panel, complete the following steps: 1. Click **Security > Global security**. 2. Under Web security, click **Single sign-on (SSO)**.
LtpaToken and LtpaToken2	Use to interoperate with releases prior to WebSphere Application Server Version 5.1.1. The older LtpaToken cookie is present along with the new LtpaToken2 cookie. Provided the LTPA keys are correctly shared, you should be able to interoperate with any version of WebSphere using this option.	Enable the **Interoperability mode** option in the SSO configuration panel within the administrative console. To access this panel, complete the following steps: 1. Click **Security > Global security**. 2. Under Web security, click **Single sign-on (SSO)**.

About this task

The following steps are required to configure SSO for the first time.

Procedure

1. Open the administrative console.

   Type `http://server_name:port_number/ibm/console` to access the administrative console in a web browser.

   Port 9060 is the default port number for accessing the administrative console. During installation, however, you might have specified a different port number. Use the appropriate port number.
2. Click **Security > Global security**.
3. Under Web security, click **Single sign-on (SSO)**.

4. Click the **Enabled** option if SSO is disabled. After you click the **Enabled** option, make sure that you complete the remaining steps to enable security.
5. Click **Requires SSL** if all of the requests are expected to use HTTPS.
6. Enter the fully qualified domain names in the **Domain name** field where SSO is effective. If you specify domain names, they must be fully qualified. If the domain name is not fully qualified, WebSphere Application Server does not set a domain name value for the LtpaToken cookie and SSO is valid only for the server that created the cookie.

   When you specify multiple domains, you can use the following delimiters: a semicolon (**;**), a space ( ), a comma (**,**), or a pipe (**|**). WebSphere Application Server searches the specified domains in order from left to right. Each domain is compared with the host name of the HTTP request until the first match is located. For example, if you specify `ibm.com®; austin.ibm.com` and a match is found in the ibm.com domain first, WebSphere Application Server does not continue to search for a match in the austin.ibm.com domain. However, if a match is not found in either the ibm.com or austin.ibm.com domains, then WebSphere Application Server does not set a domain for the LtpaToken cookie.

Table 88. Values to configure the Domain name field.

This table describes the values to configure the Domain name field.

Domain name value type	Example	Purpose
Blank		The domain is not set. This causes the browser to set the domain to the request host name. The sign-on is valid on that single host only.
Single domain name	austin.ibm.com	If the request is to a host within the configured domain, the sign-on is valid for all hosts within that domain. Otherwise, it is valid on the request host name only.
UseDomainFromURL	UseDomainFromURL	If the request is to a host within the configured domain, the sign-on is valid for all hosts within that domain. Otherwise, it is valid on the request host name only.
Multiple domain names	austin.ibm.com;raleigh.ibm.com	The sign-on is valid for all hosts within the domain of the request host name.
Multiple domain names and UseDomainFromURL	• austin.ibm.com;raleigh.ibm.com; UseDomainFromURL	The sign-on is valid for all hosts within the domain of the request host name.

   If you specify the UseDomainFromURL, WebSphere Application Server sets the SSO domain name value to the domain of the host that makes the request. For example, if an HTTP request comes from server1.raleigh.ibm.com, WebSphere Application Server sets the SSO domain name value to `raleigh.ibm.com` .

   Tip: The value, `UseDomainFromURL`, is case insensitive. You can type `usedomainfromurl` to use this value.

   For more information, see “Single sign-on settings” on page 1501.
7. Optional: Enable the **Interoperability mode** option if you want to support SSO connections in WebSphere Application Server version 5.1.1 or later to interoperate with previous versions of the application server.

   This option sets the old-style LtpaToken token into the response so it can be sent to other servers that work only with this token type. Otherwise, only the LtpaToken2 token is added to the response.

   If performance is a consideration, and you are only connecting to Version 6.1 or later servers that and are not running products that depend on the LtpaToken, do not enable Interoperability mode. When Interoperability mode is not enabled, an LtpaToken is not returned in a response.
8. Optional: Enable the **Web inbound security attribute propagation** option if you want information added during the login at a specific front-end server to propagate to other front-end servers. The SSO token does not contain any sensitive attributes, but does understand where the original login server exists in cases where it needs to contact that server to retrieve serialized information. For more information, see “Security attribute propagation” on page 1544.

Important: If the following statements are true, it is recommended that you disable the **Web inbound security attribute propagation** option for performance reasons:

- You do not have any specific information added to the Subject during a login that cannot be obtained at a different front-end server.
- You did not add custom attributes to the PropagationToken token using WSSecurityHelper application programming interfaces (APIs).

If you find that you are missing custom information in the Subject, re-enable the **Web inbound security attribute propagation** option to see if the information is propagated successfully to other front-end application servers.

The following two custom properties might help to improve performance when security attribute propagation is enabled:

- **com.ibm.CSI.propagateFirstCallerOnly**

  The default value of this property is `true`. When this custom property is set to `true` the first caller in the propagation token that stays on the thread is logged when security attribute propagation is enabled. When this property is set to `false`, all of the caller switches are logged, which can affect performance.
- **com.ibm.CSI.disablePropagationCallerList**

  When this custom property is set to `true` the ability to add a caller or host list in the propagation token is completely disabled. This function is beneficial when the caller or host list in the propagation token is not needed in the environment.

9. Click **OK**.

What to do next

For the changes to take effect, save, stop, and restart all the product servers.

Single sign-on for HTTP requests using SPNEGO web authentication

You can securely negotiate and authenticate HTTP requests for secured resources in WebSphere Application Server by using the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) as the web authentication service for WebSphere Application Server.

Note: In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. This function was deprecated in WebSphere Application Server Version 7.0. SPNEGO web authentication has taken its place to provide the following enhancements:

- You can configure and enable SPNEGO web authentication and filters on WebSphere Application Server by using the administrative console.
- Dynamic reload of SPNEGO is provided without the need to stop and restart WebSphere Application Server.
- Fallback to an application login method is provided if the SPNEGO web authentication fails.
- SPNEGO can be customized at the WebSphere security domain level. Read about “Multiple security domains” on page 1222 for more information.

You can enable either SPNEGO TAI or SPNEGO Web Authentication but not both.

The following sections describe SPNEGO web authentication in more detail:

- “What is SPNEGO?” on page 1445
- “The benefits of SPNEGO web authentication” on page 1446
- “SPNEGO web authentication in a single Kerberos realm” on page 1446
- “SPNEGO web authentication in a trusted Kerberos realm” on page 1447

- “Support information for SPNEGO web authentication with a Java client using the HTTP protocol” on page 1448
- “Support information for SPNEGO web authentication with a browser client” on page 1448
- “Setting up SPNEGO as the web authentication mechanism for WebSphere Application Server” on page 1448

What is SPNEGO?

SPNEGO is a standard specification defined in The Simple and Protected GSS-API Negotiation Mechanism (IETF RFC 2478).

When WebSphere Application Server global and application security are enabled, and SPNEGO web authentication is enabled, SPNEGO is initialized when processing a first inbound HTTP request. The web authenticator component then interacts with SPNEGO, which is defined and enabled in the security configuration repository. When the filter criteria is met, SPNEGO is responsible for authenticating access to the secured resource that is identified in the HTTP request.

In addition to WebSphere Application Server security runtime services, some external components are required to enable the operation of SPNEGO. These external components include:
- A client application, for example, Microsoft .NET, or web service and J2EE client that supports the SPNEGO web authentication mechanism, as defined in IETF RFC 2478. Microsoft Internet Explorer Version 5.5 or later and Mozilla Firefox Version 1.0 are browser examples. Any browser must be configured to use the SPNEGO web authentication mechanism. For more information on performing this configuration, see Configuring the client browser to use SPNEGO.

The authentication of HTTP requests is triggered by the requestor (the client-side), which generates a SPNEGO token. WebSphere Application Server receives this token. Specifically, the SPNEGO web authentication decodes and retrieves the requester's identity from the SPNEGO token. The identity is used to establish a secure context between the requester and the application server.

SPNEGO web authentication is a server-side solution in WebSphere Application Server. Client-side applications are responsible for generating the SPNEGO token for use by SPNEGO web authentication. The requester's identity in the WebSphere Application Server security registry must be identical to the identity that the SPNEGO web authentication retrieves. An identical match does occur when Microsoft Windows Active Directory server is the Lightweight Directory Access Protocol (LDAP) server that is used in WebSphere Application Server. A custom login module is available as a plug-in to support custom mapping of the identity from the Active Directory to the WebSphere Application Server security registry.

Read about Mapping of a client Kerberos principal name to the WebSphere user registry ID for more information about using this custom login module.

WebSphere Application Server validates the identity against its security registry. If the validation is successful, the client Kerberos ticket and GSS delegation credential are retrieved and placed in the client subject, which then produces a Lightweight Third Party Authentication (LTPA) security token. It then places and returns a cookie to the requester in the HTTP response. Subsequent HTTP requests from this same requester to access additional secured resources in WebSphere Application Server use the LTPA security token previously created to avoid repeated login challenges.

The web administrator has access to the following SPNEGO security components and associated configuration data, as shown in the following figure:

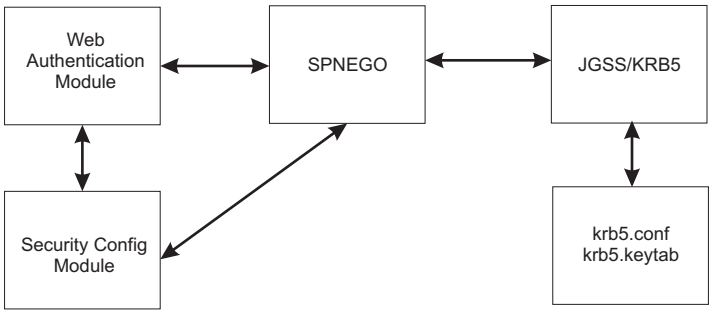

Figure 16. SPNEGO web authentication and security configuration elements

The benefits of SPNEGO web authentication

The benefits of having WebSphere Application Server use SPNEGO as the web authentication service for WebSphere Application Server include the following:

- The cost of administering a large number of ids and passwords is reduced.
- A secure and mutually authenticated transmission of security credentials from the web browser or Microsoft .NET clients is established.
- Interoperability with web services and Microsoft .NET, or web service applications that use SPNEGO authentication at the transport level is achieved.
- With Kerberos authentication support, SPNEGO web authentication can provide an end-to-end SPNEGO to Kerberos solution and preserve the Kerberos credential from the client.

SPNEGO web authentication in a single Kerberos realm

SPNEGO web authentication is supported in a single Kerberos realm. The challenge-response handshake process is shown in the following figure:

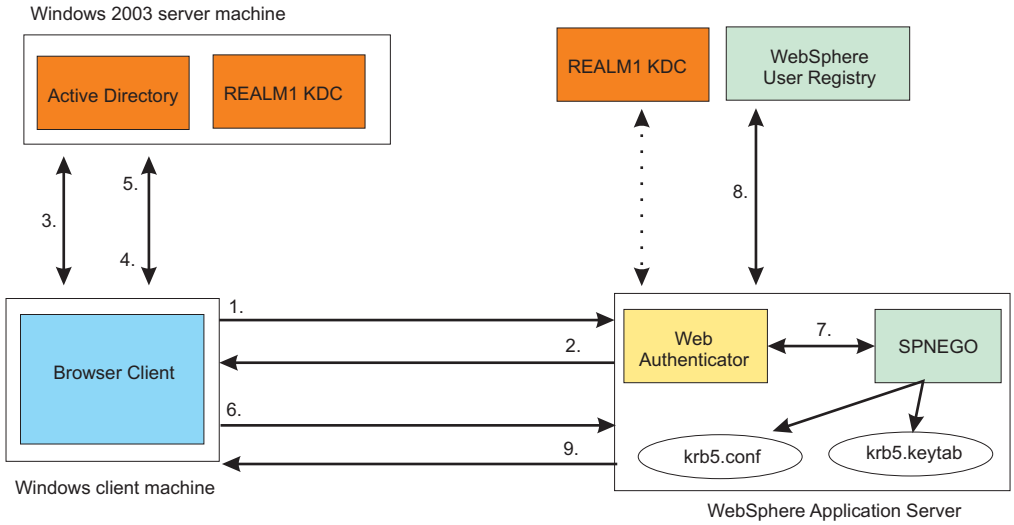

Figure 17. SPNEGO web authentication in a single Kerberos realm

In the figure above, the following events occur:

1. The client sends an HTTP/Post/Get/Web-Service request to WebSphere Application Server.
2. WebSphere Application Server returns `HTTP 401` Authenticate/Negotiate.
3. The client obtains a Ticket Granting Ticket (TGT).

4. The client requests a Service Ticket (TGS_REQ).
5. The client obtains a Service Ticket (TGS_REP).
6. The client sends HTTP/Post/Get/Web-Service and an authorization SPNEGO token to WebSphere Application Server.
7. WebSphere Application Server validates the SPNEGO token. If the validation is successful, it retrieves the user ID and the GSS delegation credential from the SPNEGO token. Create a KRBAuthnToken with a client Kerberos credential.
8. WebSphere Application Server validates the user ID with the WebSphere user registry and creates an LTPA token.
9. WebSphere Application Server returns `HTTP 200`, content and the LTPA token to the client.

Note: Other clients (for example, web services, .NET and J2EE) that support SPNEGO do not have to follow the challenge-response handshake process as shown above. Those clients can obtain a ticket-granting ticket (TGT) and a Kerberos service ticket for the target server, create a SPNEGO token, insert it in the HTTP header, and then follow the normal process for creating an HTTP request.

SPNEGO web authentication in a trusted Kerberos realm

SPNEGO web authentication is also supported in a trusted Kerberos realm. The challenge-response handshake process is shown in the following figure:

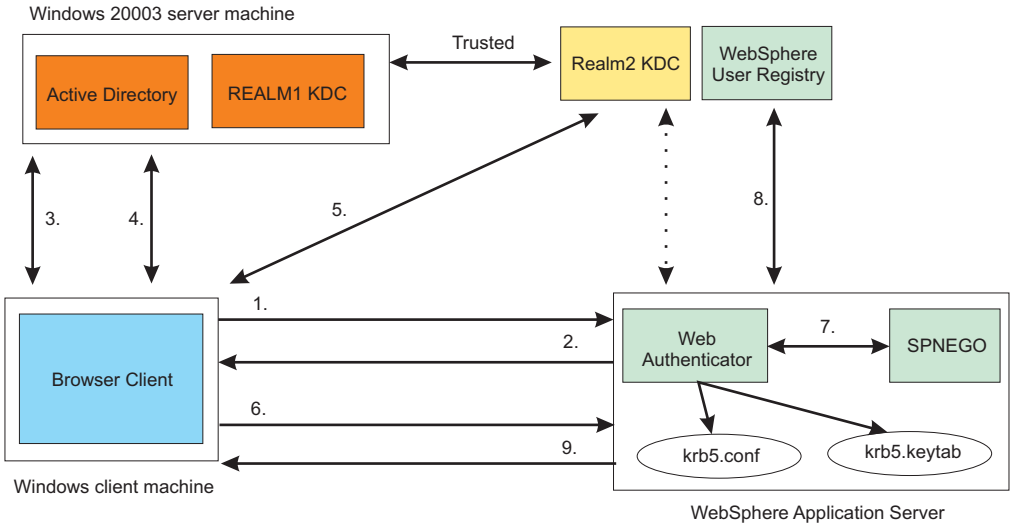

Figure 18. SPNEGO web authentication in a trusted Kerberos realm

In the figure above, the following events occur:

1. The client sends an HTTP/Post/Get/Web-Service request to WebSphere Application Server.
2. WebSphere Application Server returns `HTTP 401` Authenticate/Negotiate
3. The client obtains a Ticket Granting Ticket (TGT).
4. The client requests a cross realm ticket (TGS_REQ) for `REALM2` from the `REALM1` KDC.
5. The client uses the cross-realm ticket from step 4 to request a Service Ticket from the `REALM2` KDC.
6. The client sends HTTP/Post/Get/Web-Service and an authorization SPNEGO token to WebSphere Application Server.

7. WebSphere Application Server validates the SPNEGO token. If the validation is successful, it retrieves the user ID and the GSS delegation credential from the SPNEGO token. Create a KRBAuthnToken with a client Kerberos credential.
8. WebSphere Application Server validates the user ID with the WebSphere user registry and creates an LTPA token.
9. WebSphere Application Server returns `HTTP 200`, content and the LTPA token to the client.

In the trusted Kerberos realms environment, be aware of the following:

- The Kerberos trusted realm setup must be done on each of the Kerberos KDCs. See your Kerberos Administrator and User's guide for more information about how to set up Kerberos trusted realms.
- The Kerberos client principal name from the SPNEGO token might not exist in the WebSphere user registry; the Kerberos principal mapping to the WebSphere user registry might require it.

  Read about Mapping of a client Kerberos principal name to the WebSphere user registry ID for more information.

Support information for SPNEGO web authentication with a Java client using the HTTP protocol

The following scenarios are supported:

- Domain trust within the same forest
- External domain trust directly between domains within different forests.
- Kerberos realm trust

The following scenarios are not supported:

- Cross-forest trust
- Forest external trust

Support information for SPNEGO web authentication with a browser client

The following scenarios are supported:

- Cross-forest trusts
- Domain trust within the same forest
- Kerberos realm trust

The following scenarios are not supported:

- Forest external trusts
- Domain external trusts

Setting up SPNEGO as the web authentication mechanism for WebSphere Application Server

Before you set up SPNEGO web authentication in the administrative console or by using **wsadmin** commands, you must perform the steps as listed in “Creating a single sign-on for HTTP requests using SPNEGO Web authentication” to set up SPNEGO web authentication for WebSphere Application Server.

Note: SPNEGO web authentication on the server side must be done by the system administrator. The Kerberos keytab file must be protected.

Creating a single sign-on for HTTP requests using SPNEGO Web authentication

Creating single sign-ons for HTTP requests using the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) web authentication for WebSphere Application Server requires the performance of

several distinct, yet related functions that when completed, allow HTTP users to log in and authenticate to the Microsoft domain controller only once at their desktop and to receive automatic authentication from the WebSphere Application Server.

Before you begin

Note:

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. This function was deprecated in WebSphere Application Server Version 7.0. SPNEGO web authentication has taken its place to provide the following enhancements:

- You can configure and enable SPNEGO web authentication and filters on the WebSphere Application Server server side by using the administrative console.
- Dynamic reload of SPNEGO is provided without the need to stop and restart the WebSphere Application Server server.
- Fallback to an application login method is provided if the SPNEGO web authentication fails.

You can enable either SPNEGO TAI or SPNEGO Web Authentication but not both.

Read about “Single sign-on for HTTP requests using SPNEGO web authentication” on page 1444 for a better understanding of what SPNEGO Web Authentication is and how it is supported in this version of WebSphere Application Server.

Before starting this task, complete the following checklist:

- The domain member has users who can log on to the domain. Specifically, you need to have a functioning Microsoft Windows active directory domain that includes:
  - Domain controller
  - Client workstation
  - Users who can login to the client workstation
- A server platform with WebSphere Application Server running and application security enabled.
- Users on the active directory must be able to access WebSphere Application Server protected resources using a native WebSphere Application Server authentication mechanism.
- The domain controller and the host of WebSphere Application Server should have the same local time.
- Ensure the clock on clients, Microsoft Active Directory and WebSphere Application Server are synchronized to within five minutes.
- Be aware that client browsers must be SPNEGO enabled, which you perform on the client application machine (with details explained in procedure 4, "Configure the client application on the client application machine").

About this task

The objective of this machine arrangement is to permit users to successfully access WebSphere Application Server resources without having to authenticate again and thus achieve Microsoft Windows desktop single sign-on capability.

Configuring the members of this environment to establish Microsoft Windows single sign-on involves specific activities that are performed on three distinct machines:

- A Microsoft Windows server running the Active Directory Domain Controller and associated Kerberos Key Distribution Center (KDC).
- A Microsoft Windows domain member (client application), such as a browser or Microsoft .NET client.
- A server platform with WebSphere Application Server running.

Continue with the following steps to create a single sign-on for HTTP requests using SPNEGO Web authentication:

Procedure

1. Create a Kerberos service principal (SPN) and keytab file on your Microsoft domain controller machine You must configure your domain controller machine to create single sign-ons for HTTP requests using the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) web authentication for WebSphere® Application Server. Configure the Microsoft Windows Server running the Active Directory Domain Controller and associated Kerberos Key Distribution Center (KDC).

   Read the Configuring your domain controller machine to create single sign-ons for HTTP requests using SPNEGO article for more information.
2. Create a Kerberos configuration file The IBM implementation of the Java Generic Security Service (JGSS) and KRB5 require a Kerberos configuration file (**krb5.conf** or **krb5.ini**) on each node or Java virtual machine (JVM). In this release of WebSphere Application Server, this configuration file should be placed in the `config/cells/<cell_name>` directory so that all application servers can access this file. If you do not have a Kerberos configuration file, use a **wsadmin** command to create one.

   Read the Creating a Kerberos configuration article for more information.
3. Configure and enable SPNEGO web authentication using the administrative console on your WebSphere Application Server machine You can enable and configure the Simple and Protected GSS-API Negotiation (SPNEGO) as the web authenticator for the application server by using the administrative console on the WebSphere Application Server machine.

   Read the Enabling and configuring SPNEGO web authentication using the administrative console article for more information.
4. Configure the client application on the client application machine Client-side applications are responsible for generating the SPNEGO token. You begin this configuration process by configuring your web browser to use SPNEGO authentication.

   Read the Configuring the client browser to use SPNEGO article for more information.
5. Create SPNEGO tokens for J2EE, .NET, Java, web service clients for HTTP requests (optional) You can create a Simple and Protected GSS-API Negotiation (SPNEGO) token for your applications and insert this token into the HTTP headers to authenticate to the WebSphere Application Server.

   Read the Creating SPNEGO tokens for J2EE, .NET, Java, web service clients for HTTP requests article for more information.

Creating a single sign-on for HTTP requests using the SPNEGO TAI (deprecated)

Creating single sign-ons for HTTP requests using the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server requires the performance of several distinct, yet related functions that when completed, allow HTTP users to log in and authenticate only once at their desktop and receive automatic authentication from the WebSphere Application Server.

Before you begin

Note:

> In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

Before starting this task, complete the following checklist:

- The domain member has users who can log on to the domain. Specifically, you need to have a functioning Microsoft Windows active directory domain that includes:

  - Domain controller
  - Client workstation
  - Users who can login to the client workstation
- A server platform with WebSphere Application Server running and application security enabled.
- Users on the active directory must be able to access WebSphere Application Server protected resources using a native WebSphere Application Server authentication mechanism.
- The domain controller and the host of WebSphere Application Server should have the same local time.
- Ensure the clock on clients, Microsoft Active Directory and WebSphere Application Server are synchronized to within five minutes.
- Be aware that client browsers have to be SPNEGO enabled, which you perform on the client application machine (with details explained in step 2 of this task).

About this task

The objective of this machine arrangement is to permit users to successfully access WebSphere Application Server resources without having to reauthenticate and thus achieve Microsoft Windows desktop single sign-on capability.

Configuring the members of this environment to establish Microsoft Windows single sign-on involves specific activities that are performed on three distinct machines:

- Microsoft Windows Server running the Active Directory Domain Controller and associated Kerberos Key Distribution Center (KDC)
- A Microsoft Windows domain member (client application), such as a browser or Microsoft .NET client.
- A server platform with WebSphere Application Server running.

Perform the following steps on the indicated machines to create single sign-on for HTTP requests using SPNEGO

Procedure

1. **Domain Controller Machine** - Configure the Microsoft Windows Server running the Active Directory Domain Controller and associated Kerberos Key Distribution Center (KDC) This configuration activity has the following steps:
   - Create a user account for the WebSphere Application Server in a Microsoft Active Directory. This account will be eventually mapped to the Kerberos service principal name (SPN).
   - On the Microsoft Active Directory machine where the Kerberos key distribution center (KDC) is active, map the user account to the Kerberos service principal name (SPN). This user account represents the WebSphere Application Server as being a Kerberize'd service with the KDC. Use the **setspn** command to map the Kerberos service principal name to a Microsoft user account. The topic, “Creating a Kerberos service principal and keytab file that is used by the WebSphere Application Server SPNEGO TAI (deprecated)” on page 1455 has more details about using the **setspn** command.
   - Create the Kerberos keytab file and make it available to WebSphere Application Server. Use the **ktpass** tool to create the Kerberos keytab file (`krb5.keytab`). The topic, “Creating a Kerberos service principal and keytab file that is used by the WebSphere Application Server SPNEGO TAI (deprecated)” on page 1455 has more details about using the **ktpass** command. to create the keytab file.

     Note: You make the keytab file available to WebSphere Application Server by copying the `krb5.keytab` file from the Domain Controller (LDAP machine) to the WebSphere Application Server machine. See “Using the ktab command to manage the Kerberos keytab file” on page 1459 for more details.

   Important: Your domain controller operations must lead to the following results:

- A user account is created in the Microsoft Active Directory and mapped to a Kerberos service principal name.
- A Kerberos keytab file (`krb5.keytab`) is created and made available to the WebSphere Application Server. The Kerberos keytab file contains the Kerberos service principal keys WebSphere Application Server uses to authenticate the user in the Microsoft Active Directory and the Kerberos account.

2. **Client Application Machine** - Configure the client application. Client-side applications are responsible for generating the SPNEGO token for use by the SPNEGO TAI. You begin this configuration process by configuring your web browser to use SPNEGO authentication. See “Configuring the client browser to use SPNEGO TAI (deprecated)” on page 1473 for the detailed steps required for your browser.
3. **WebSphere Application Server Machine** - Configure and enable the Application Server and the associated SPNEGO TAI by performing the following tasks:
   - Ensure that LTPA is enabled. See Configuring the Lightweight Third Party Authentication mechanism for more details.
   - Enable the SPNEGO TAI. See “Configuring WebSphere Application Server and enabling the SPNEGO TAI (deprecated)” on page 1460 for more details.
   - Create SPNEGO TAI properties using either the wsadmin command task or the administrative console.
     – For using the wsadmin command task, see
       - SpnegoTAICommands group for the AdminTask object (deprecated)
     – For using the administrative console, see “Configuring WebSphere Application Server and enabling the SPNEGO TAI (deprecated)” on page 1460 for more details.
   - Configure JVM properties and enable the SPNEGO TAI in Application Server in which it is defined. See “Configuring JVM custom properties, filtering HTTP requests, and enabling SPNEGO TAI in WebSphere Application Server (deprecated)” on page 1475 or “Enabling the SPNEGO TAI as JVM custom property using scripting (deprecated)” on page 1476 for more details.
   - Install the Kerberos keytab file (created in step 1) on the WebSphere Application Server machine. “Creating a Kerberos service principal and keytab file that is used by the WebSphere Application Server SPNEGO TAI (deprecated)” on page 1455 provides the details.
   - Create a basic Kerberos configuration file (krb5.ini or krb5.conf). See The Kerberos configuration file for details.
   - Map the client Kerberos principal name to the WebSphere user registry ID, but only if the WebSphere Application Server does not use Micorsoft Active Directory. See “Mapping Kerberos client principal name to WebSphere user registry ID for SPNEGO TAI (deprecated)” on page 1480 for more details.
4. Optional: **Using a remote HTTP server** - To use a remote server, you must complete the following steps, which assume that you have already configured the JVM properties and enabled the SPNEGO TAI in the Application Server in which it is defined (as described in the previous three steps).
   a. Complete the steps in “Creating a Kerberos service principal and keytab file that is used by the WebSphere Application Server SPNEGO TAI (deprecated)” on page 1455 for the remote proxy server.
   b. Merge the previous keytab file created in step 1 with the keytab file created in step 4a. See “Using the ktab command to manage the Kerberos keytab file” on page 1459 for more information.
   c. Create the SPN for the remote proxy server using the `addSpnegoTAIProperties wsadmin` command task. For more information, see SpnegoTAICommands group for the AdminTask object (deprecated).
   d. Restart the WebSphere Application Server.

Single sign-on for HTTP requests using SPNEGO TAI (deprecated):

WebSphere Application Server provides a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources in WebSphere Application Server.

Note:

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

Read about “Creating a single sign-on for HTTP requests using SPNEGO Web authentication” on page 1448 for more information.

SPNEGO is a standard specification defined in The Simple and Protected GSS-API Negotiation Mechanism (IETF RFC 2478).

When WebSphere Application Server administrative security is enabled, the SPNEGO TAI is initialized. While processing inbound HTTP requests, the web authenticator component interacts with the SPNEGO TAI, which is defined and enabled in the security configuration repository. One interceptor is selected and is responsible for authenticating access to the secured resource that is identified in the HTTP request.

Important: The use of TAIs is an optional feature. If no TAI is selected, the authentication process continues normally.

HTTP users log in and authenticate only once at their desktop and are subsequently authenticated (internally) with WebSphere Application Server. The SPNEGO TAI is invisible to the end-user of WebSphere applications. The SPNEGO TAI is only visible to the web administrator who is responsible for ensuring a proper configuration, capacity, and maintenance of the web environment.

In addition to WebSphere Application Server security runtime services, some external components are required to completely enable operation of the SPNEGO TAI. The external components include:

- A client application, for example, a browser or Microsoft .NET client, that supports the SPNEGO authentication mechanism, as defined in IETF RFC 2478. Microsoft Internet Explorer Version 5.5 or later and Mozilla Firefox Version 1.0 are browser examples. Any browser needs to be configured to use the SPNEGO mechanism. For more information on performing this configuration, see “Configuring the client browser to use SPNEGO TAI (deprecated)” on page 1473.

The authentication of HTTP requests is triggered by the requestor (the client-side), which generates a SPNEGO token. WebSphere Application Server receives this token and validates trust between the requester and WebSphere Application Server. Specifically, the SPNEGO TAI decodes and retrieves the requester's identity from the SPNEGO token. The identity is used to establish a secure context between the requester and the application server.

Remember: The SPNEGO TAI is a server-side solution in WebSphere Application Server. Client-side applications are responsible for generating the SPNEGO token for use by the SPNEGO TAI. The requester's identity in WebSphere Application Server security registry must be identical to that identity the SPNEGO TAI retrieves. An identical match does occur when Microsoft Windows Active Directory server is the Lightweight Directory Access Protocol (LDAP) server that is used in WebSphere Application Server. A custom login module is available as a plug-in to support custom mapping of the identity from the Active Directory to the WebSphere Application Server security registry. See “Mapping Kerberos client principal name to WebSphere user registry ID for SPNEGO TAI (deprecated)” on page 1480 for details on using this custom login module.

WebSphere Application Server validates the identity against its security registry and, if the validation is successful, produces a Lightweight Third Party Authentication (LTPA) security token and places and returns a cookie to the requester in the HTTP response. Subsequent HTTP requests from this same requester to access additional secured resources in WebSphere Application Server use the LTPA security token previously created, to avoid repeated login challenges.

The challenge-response handshake process is illustrated in the following graphic:

Figure 19. HTTP request processing, WebSphere Application Server - SPNEGO TAI

The SPNEGO TAI can be enabled for all or for selected WebSphere Application Servers in a WebSphere Application Server cell configuration. Also, the behavior of each SPNEGO TAI instance is controlled by custom configuration properties that are used to identify, for example, the criteria used to filter HTTP requests, such as the host name and security realm name used to construct the Kerberos Service Principal Name (SPN). For more information regarding establishing and setting the SPNEGO TAI custom configuration properties, see the following topics:

- Setting up the Kerberos configuration properties. See The Kerberos configuration file.
- Setting or adjusting the SPNEGO TAI custom properties. See “SPNEGO TAI custom properties configuration (deprecated)” on page 1469.
- Adjusting the SPNEGO TAI filter settings. See “Configuring JVM custom properties, filtering HTTP requests, and enabling SPNEGO TAI in WebSphere Application Server (deprecated)” on page 1475
- Using the custom login module to map the identity from the Active Directory to the WebSphere Application Server registry. See Mapping user Ids from client to server for SPNEGO.
- Setting the major and additional Java virtual machine (JVM) custom properties. See “SPNEGO TAI JVM configuration custom properties (deprecated)” on page 1477

The web administrator has access to the following SPNEGO TAI security components and associated configuration data, as illustrated in the following graphic.

Figure 20. SPNEGO TAI security and configuration elements

- The web authentication module and the Lightweight Third Party Authentication (LTPA) mechanism provide the plug-in runtime framework for trust association interceptors. See Configuring the Lightweight Third Party Authentication mechanism for more detail is configuring the LTPA mechanism for use with the SPNEGO TAI.
- The Java Generic Security Service (JGSS) provider is included in the Java SDK (*app_server_root*/java/endorsed/ibmjgssprovider.jar) and used to obtain the Kerberos security context and credentials that are used for authentication. IBM JGSS 1.0 is a Java Generic Security Service Application Programming Interface (GSSAPI) framework with Kerberos V5 as the underlying default security mechanism. GSSAPI is a standardized abstract interface under which can be plugged different security mechanisms based on private-key, public-key and other security technologies. GSSAPI shields secure applications from the complexities and peculiarities of the different underlying security mechanisms. GSSAPI provides identity and message origin authentication, message integrity, and message confidentiality. For more information, see JGSS.
- The Kerberos configuration properties (krb5.conf or krb5.ini) and Kerberos encryption keys (stored in a Kerberos keytab file) are used to establish secure mutual authentication.

  The Kerberos key table manager (Ktab), which is part of JGSS, allows you to manage the principal names and service keys stored in a local Kerberos keytab file. Principal name and key pairs listed in the

Kerberos keytab file allow services running on a host to authenticate themselves to the Kerberos Key Distribution Center (KDC). Before a server can use Kerberos, a Kerberos keytab file must be initialized on the host that runs the server.

"Using the ktab command to manage the Kerberos keytab file" on page 1459 highlights the Kerberos configuration requirements for the SPNEGO TAI as well as the use of Ktab.

- The SPNEGO provider supplies the implementation of the SPNEGO authentication mechanism, located at *app_server_root*/java/ext/ibmspnego.jar.
- The custom configuration properties control the runtime behavior of the SPNEGO TAI. Configuration operations are performed with the administrative console or scripting facilities. Refer to "SPNEGO TAI custom properties configuration (deprecated)" on page 1469 for more information about these custom configuration properties.
- Java virtual machine (JVM) custom properties control diagnostic trace information for problem determination of the JGSS security provider and use of the property reload feature."SPNEGO TAI JVM configuration custom properties (deprecated)" on page 1477 describes these JVM custom properties

The benefits of having WebSphere Application Server use the SPNEGO TAI include:

- The cost of administering a large number of ids and passwords is reduced.
- A secure and mutually authenticated transmission of security credentials from the web browser or Microsoft .NET clients is established.
- Interoperability with web services and Microsoft .NET applications that use SPNEGO authentication at the transport level is achieved.

Using the SPNEGO TAI in your WebSphere Application Server environment requires planning then implementation. See "Single sign-on capability with SPNEGO TAI - checklist (deprecated)" on page 1484 in planning for SPNEGO TAI. Implementing the use of the SPNEGO TAI is divided into the following areas of responsibility:

End browser user
The end user must configure the web browser or Microsoft .NET application to issue HTTP requests that are processed by the SPNEGO TAI.

Web administrator
The web administrator is responsible for configuring the SPNEGO TAI of WebSphere Application Server to respond to HTTP requests of the client.

WebSphere Application Server administrator
The WebSphere Application Server administrator is responsible for configuring WebSphere Application Server and the SPNEGO TAI for optimum installation performance.

See "Creating a single sign-on for HTTP requests using the SPNEGO TAI (deprecated)" on page 1450 for an explanation of the tasks required to use the SPNEGO TAI and how the responsible party performs these tasks.

Creating a Kerberos service principal and keytab file that is used by the WebSphere Application Server SPNEGO TAI (deprecated):

You perform this configuration task on the Microsoft Active Directory domain controller machine. This task is a necessary part of preparing to process single sign on browser requests to WebSphere Application Server and thee SPNEGO trust association interceptor (TAI).

Before you begin

You need to have a running domain controller and at least one client machine in that domain.

Note:

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

About this task

This task is performed on the active directory domain controller machine. Complete the following steps to ensure that the Microsoft Windows Server that is running the active directory domain controller is configured properly to the associated key distribution center (KDC). For information on the supported Microsoft Windows Servers, see the System Requirements for WebSphere Application Server Version 8.0 on Windows.

Procedure

1. Create a user account in the Microsoft Active Directory for the WebSphere Application Server.

   Click **Start->Programs->Administrative Tools->Active Directory Users and Computers**

   Use the name for the WebSphere Application Server. For example, if the Application Server you are running on the WebSphere Application Server machine is called `myappserver.austin.ibm.com`, create a new user in Active Directory called `myappserver`.

   Important: Do not select "User must change password at next logon."

   Important: Make sure that you do not have the computer name `myappserver` under Computers and Domain Controllers (You check for this condition as illustrated below.). If you already have a computer name `myappserver`, then you need to create a different user account name.
   - Goto **Start -> Programs -> Administrative Tools -> Active Directory Users and Computers->Computers**
   - Goto **Start -> Programs -> Administrative Tools -> Active Directory Users and Computers->Domain Controllers**

2. Use the **setspn** command to map the Kerberos service principal name, `HTTP/<host name>`, to a Microsoft user account. An example of **setspn** usage is as follows:

   ```
   C:\Program Files\Support Tools>
   setspn -A HTTP/myappserver.austin.ibm.com myappserver
   ```

   Note: There may already be some SPNs related to the Microsoft Windows hosts that have been added to the domain. You can display those that exist by using the `setspn -L` command, but you still have to add an HTTP SPN for WebSphere Application Server. For example, `setspn -L myappserver` would list the SPNs.

   Important: Make sure that you do not have the same SPNs mapping to more than one Microsoft user account. If you map the same SPN to more than one user account, the web browser client can send a NTLM instead of SPNEGO token to WebSphere Application Server.

   More information about the **setspn** command can be found here, Windows 2003 Technical Reference (setspn command)

3. Create the Kerberos keytab file and make it available to WebSphere Application Server. Use the ktpass command to create the Kerberos keytab file (krb5.keytab).

   Use the **ktpass** tool from the Windows Server toolkit to create the Kerberos keytab file for the service principal name (SPN). Use the latest version of the **ktpass** tool that matches the Windows server level that you are using. For example, use the Windows 2003 version of the tool for a Windows 2003 server.

   To determine the appropriate parameter values for the **ktpass** tool, run the `ktpass -?` command from the command line. This command lists whether the **ktpass** tool, which corresponds to the particular

operating system, uses the `-crypto RC4-HMAC` or `-crypto RC4-HMAC-NT` parameter value. To avoid warning messages from the toolkit, you must specify the `-ptype KRB5_NT_PRINCIPAL` parameter value.

The Windows 2003 server version of the **ktpass** tool supports the encryption type, RC4-HMAC, and Single data encryption standard (DES). For more information about the **ktpass** tool, see Windows 2003 Technical Reference (Kerberos keytab file and ktpass command).

The following code shows the functions that are available when you enter `ktpass -?` command on the command line. This information might be different depending on the version of the toolkit that you are using.

```
C:\Program Files\Support Tools>ktpass -?
Command line options:

---------------------most useful args
[- /]          out : Keytab to produce
[- /]        princ : Principal name (user@REALM)
[- /]         pass : password to use
                     use "*" to prompt for password.
[- +]      rndPass : ... or use +rndPass to generate a random password
[- /]      minPass : minimum length for random password (def:15)
[- /]      maxPass : maximum length for random password (def:256)
---------------------less useful stuff
[- /]      mapuser : map princ (above) to this user account (default:
don't)
[- /]        mapOp : how to set the mapping attribute (default: add it)
[- /]        mapOp :  is one of:
[- /]        mapOp :        add : add value (default)
[- /]        mapOp :        set : set value
[- +]      DesOnly : Set account for des-only encryption (default:don't)
[- /]           in : Keytab to read/digest
---------------------options for key generation
[- /]       crypto : Cryptosystem to use
[- /]       crypto :  is one of:
[- /]       crypto : DES-CBC-CRC : for compatibility
[- /]       crypto : DES-CBC-MD5 : for compatibliity
[- /]       crypto : RC4-HMAC-NT : default 128-bit encryption
[- /]        ptype : principal type in question
[- /]        ptype :  is one of:
[- /]        ptype : KRB5_NT_PRINCIPAL : The general ptype-- recommended
[- /]        ptype : KRB5_NT_SRV_INST : user service instance
[- /]        ptype : KRB5_NT_SRV_HST : host service instance
[- /]         kvno : Override Key Version Number
                     Default: query DC for kvno.  Use /kvno 1 for Win2K
compat.
[- +]       Answer : +Answer answers YES to prompts.  -Answer answers
NO.
[- /]       Target : Which DC to use.  Default:detect
---------------------options for trust attributes (Windows Server 2003
Sp1 Only
[- /] MitRealmName : MIT Realm which we want to enable RC4 trust on.
[- /]  TrustEncryp : Trust Encryption to use; DES is default
[- /]  TrustEncryp :  is one of:
[- /]  TrustEncryp :        RC4 : RC4 Realm Trusts (default)
[- /]  TrustEncryp :        DES : go back to DES
```

Important: Do not use the `-pass` switch on the **ktpass** command to reset a password for a Microsoft Windows server account.

See Windows 2003 Technical Reference (Kerberos keytab file and ktpass command) for more information. You must use the -mapUser option with ktpass command to enable the KDC to create an encryption key. Otherwise, when the SPENGO token is received, it fails the validation process and the application server challenges the user for a user name and password.

Depending on the encryption type, you use the **ktpass** tool in one of the following ways to create the Kerberos keytab file. The following section shows the different types of encryption that are used by the ktpass tool. It is important that you run the ktpass -? command to determine which -crypto parameter value is expected by the particular toolkit in your Microsoft Windows environment.

- For a single DES encryption type

  From a command prompt, run the **ktpass** command:

```
ktpass -out c:\temp\myappserver.keytab
-princ HTTP/myappserver.austin.ibm.com@WSSEC.AUSTIN.IBM.COM
-mapUser myappserv
-mapOp set
-pass was1edu
-crypto DES-CBC-MD5
-pType KRB5_NT_PRINCIPAL
+DesOnly
```

Table 89. Using ktpass for a single DES encryption type.

This table describes how to use ktpass for a single DES encryption type.

Option	Explanation
`-out c:\temp\myappserver.keytab`	The key is written to this output file.
`-princ HTTP/ myappserver.austin.ibm.com@WSSEC.AUSTIN.IBM.COM`	The concatenation of the user logon name, and the realm must be in uppercase.
`-mapUser`	The key is mapped to the user, `myappserver`.
`-mapOp`	This option sets the mapping.
`-pass was1edu`	This option is the password for the user ID.
`-crypto DES-CBC-MD5`	This option uses the single DES encryption type.
`-pType KRB5_NT_PRINCIPAL`	This option specifies the `KRB5_NT_PRINCIPAL` principal value. Specify this option to avoid toolkit warning messages.
`+DesOnly`	This option generates only DES encryptions.

- For the RC4-HMAC encryption type

  Important: RC4-HMAC encryption is only supported when using a Windows 2003 Server as KDC. From a command prompt, run the **ktpass** command.

```
ktpass -out c:\temp\myappserver.keytab
-princ HTTP/myappserver.austin.ibm.com@WSSEC.AUSTIN.IBM.COM
-mapUser myappserver
-mapOp set
–pass was1edu
-crypto RC4-HMAC
-pType KRB5_NT_PRINCIPAL
```

Table 90. Using ktpass for the RC4-HMAC encryption type.

This table identifies and describes the ktpass options for RC4-HMAC encryption

Option	Explanation
`-out c:\temp\myappserver.keytab`	The key is written to this output file.
`-princ HTTP/ myappserver.austin.ibm.com@WSSEC.AUSTIN.IBM.COM`	The concatenation of the user logon name, and the realm must be in uppercase.
`-mapUser`	The key is mapped to the user, `myappserver`.
`-mapOp`	This option sets the mapping.
`-pass was1edu`	This option is the password for the user ID.
`-crypto RC4-HMAC`	This option chooses the RC4-HMAC encryption type.
`-pType KRB5_NT_PRINCIPAL`	This option specifies the `KRB5_NT_PRINCIPAL` principal value. Specify this option to avoid toolkit warning messages.

- For the RC4-HMAC-NT encryption type

  From a command prompt, run the **ktpass** command.

```
ktpass -out c:\temp\myappserver.keytab
-princ HTTP/myappserver.austin.ibm.com@WSSEC.AUSTIN.IBM.COM
-mapUser myappserver
-mapOp set
-pass was1edu
-crypto RC4-HMAC-NT
-pType KRB5_NT_PRINCIPAL
```

Table 91. Using ktpass for the RC4-HMAC encryption type. This table describes the use of ktpass for RC4-HMAC encryption types.

Option	Explanation
`-out c:\temp\myappserver.keytab`	The key is written to this output file.
`-princ HTTP/ myappserver.austin.ibm.com@WSSEC.AUSTIN.IBM.COM`	The concatenation of the user logon name, and the realm must be in uppercase.
`-mapUser`	The key is mapped to the user, `myappserver`.
`-mapOp`	This option sets the mapping.
`-pass was1edu`	This option is the password for the user ID.
`-crypto RC4-HMAC-NT`	This option chooses the RC4-HMAC-NT encryption type.
`-pType KRB5_NT_PRINCIPAL`	This option specifies the `KRB5_NT_PRINCIPAL` principal value. Specify this option to avoid toolkit warning messages.

The Kerberos keytab file is created for use with the SPNEGO TAI.

Note: A Kerberos keytab configuration file contains a list of keys that are analogous to user passwords. It is important for hosts to protect their Kerberos keytab files by storing them on the local disk, which makes them readable only be authorized users.

You make the keytab file available to WebSphere Application Server by copying the `krb5.keytab` file from the Domain Controller (LDAP machine) to the WebSphere Application Server machine.

```
ftp> bin
ftp> put c:\temp\KRB5_NT_SEV_HST\krb5.keytab
```

Results

Your active directory domain controller is properly configured to process single sign on requests to WebSphere Application Server and the SPNEGO TAI

Using the ktab command to manage the Kerberos keytab file:

The Kerberos key table manager command (Ktab) allows the product administrator to manage the Kerberos service principal names and keys stored in a local Kerberos keytab file. With the IBM Software Development Kit (SDK) or Sun Java Development Kit (JDK) 1.6 or later, you can use the ktab command to merge two Kerberos keytab files.

Kerberos service principal (SPN) name and keys listed in the Kerberos keytab file allow services running on the host to validate the incoming Kerberos or SPNEGO token request. Before configuring Kerberos or SPNEGO web authentication, the WebSphere Application Server administrator must setup a Kerberos keytab file on the host that is running WebSphere Application Server.

Note:

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server Version 7.0, this function is now deprecated.

SPNEGO web authentication has taken its place to provide the following enhancements:

- Configure and enable SPNEGO Web Authentication and filters on the WebSphere Application Server side by using the administrative console.
- Provide dynamic reload of SPNEGO without having to stop and restart the WebSphere Application Server.
- Provide fallback to an application login method if the SPNEGO web authentication fails.

Important:

- It is important to protect the keytab files and make them readable only by authorized product users.
- Any updates to the Kerberos keytab file using Ktab do not affect the Kerberos database. If you change the keys in the Kerberos keytab file, you must also make the corresponding changes to the Kerberos database.

The syntax of Ktab is illustrated below by using Ktab with the `-help` operand.

```
$ ktab -help

Usage: java com.ibm.security.krb5.internal.tools.Ktab [options]
Available options:
-l                              list the keytab name and entries
-a <principal_name> [password]  add an entry to the keytab
-d <principal_name>             delete an entry from the keytab
-k <keytab_name>                specify keytab name and path with FILE: prefix
-m <source_keytab_name> <destination_keytab_name>      specify merging source keytab file name and destination keytab file name
```

Below is an example of how Ktab is used to merge the krb5Host1.keytab file to the krb5.keytab file:

```
[root@wssecjibe bin]# ./ktab -m /etc/krb5Host1.keytab /etc/krb5.keytab
Merging keytab files:   source=krb5Host1.keytab   destination=krb5.keytab
Done!
[root@wssecjibe bin]# ls /etc/krb5.*
/etc/krb5Host1.keytab/etc/krb5.keytab
/etc/krb5.keytab
```

Below is an example of how Ktab is used on a LINUX platform to add new principal names to the Kerberos keytab file, where ot56prod is the password for the Kerberos principal name:

```
[root@wssecjibe bin]# ./ktab -a
HTTP/wssecjibe.austin.ibm.com@WSSEC.AUSTIN.IBM.COM ot56prod -k /etc/krb5.keytab
Done!
Service key for principal HTTP/wssecjibe.austin.ibm.com@WSSEC.AUSTIN.IBM.COM saved
```

Below is an example of how Ktab is used on a Linux platform to list Kerberos keytab file content.

```
[root@wssecjibe bin]# ./ktab

        KVNO    Principal
        ----    ---------

        1       HTTP/wssecjibe.austin.ibm.com@WSSEC.AUSTIN.IBM.COM

[root@wssecjibe bin]# ls /etc/krb5.*
/etc/krb5.conf
/etc/krb5.keytab
```

Configuring WebSphere Application Server and enabling the SPNEGO TAI (deprecated):

Performing this task helps you, as web administrator, to ensure that WebSphere Application Server is properly configured to enable the operation of the Simple and Protected GSS-API Negotiation (SPNEGO) trust association interceptor (TAI).

Before you begin

You need to know how to use the WebSphere Application Server administrative console to manage the security configuration and have the proper authority to modify the security configuration of the application server.

Note:

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application

Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

About this task

Complete the following steps to enable the operation of the SPNEGO TAI.

Procedure

1. Log on to the WebSphere Application Server administrative console.
2. Click **Security > Global security**.
3. Expand **Web security** and click **Trust association**.
4. Under the General Properties heading, select the **Enable trust association** check box, then click **Interceptors**.
5. Select the SPNEGO TAI in the list of interceptors.
6. Then click **Custom properties**.
7. Click **New** and then fill in the **Name** and **Value** fields. Click **OK**. Repeat this step for each custom property that you want to apply to the SPNEGO TAI. See “SPNEGO TAI custom properties configuration (deprecated)” on page 1469 for a complete list of SPNEGO TAI custom properties.

   Note: It is recommended that you use the **wsadmin** utility to manage the SPNEGO TAI properties. You can add, modify, and delete SPNEGO TAI properties as well as display them using wsadmin. See “Adding SPNEGO TAI properties using the wsadmin utility (deprecated)” on page 1463 to add, “Modifying SPNEGO TAI properties using the wsadmin utility (deprecated)” on page 1465 to modify, and “Deleting SPNEGO TAI properties using the wsadmin utility (deprecated)” on page 1467 to delete SPNEGO TAI properties.
8. After you finish defining your custom properties, click **Save** to store the updated SPNEGO TAI configuration.
9. Optional: If an alias for a connecting host name is added dynamically after the application server is started, you need to configure the alias. Refer to the “Using an alias host name for SPNEGO TAI or SPENGO web authentication using the administrative console (deprecated)” topic.

Results

Your SPNEGO TAI configuration is now configured for WebSphere Application Server.

Using an alias host name for SPNEGO TAI or SPENGO web authentication using the administrative console (deprecated):

When you use the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for authentication, and you would like to use alias host name as the host name for the application server, you must configure a custom property to resolve the alias host name to the actual hostname for SPNEGO single sign-on. Then, you can dynamically add or modify an alias name in the DNS without changing the application server's configuration. If you enable this custom property you will no longer need to set alias host names through the SPNEGO configuration.

Before you begin

You must have completed the steps as described in “Creating a single sign-on for HTTP requests using the SPNEGO TAI (deprecated)” on page 1450 and “Configuring WebSphere Application Server and enabling the SPNEGO TAI (deprecated)” on page 1460 before these settings will have an effect. This configuration requires a working SPNEGO-TAI single sign-on environment.

About this task

The application server will perform a DNS lookup as an HTTP request comes in, and if the alias host name is resolved as a host name that is already configured for SPNEGO single sign-on, the application server will continue to process it. It is usually not required to add alias hostname to a SPNEGO account.

Procedure

1. Define the actual host name for the com.ibm.ws.security.spnego.SPNx.hostName variable.
   a. From administration console, click **Global security** > **Web and SIP security** > **Trust association** > **Interceptors** > **com.ibm.ws.security.spnego.TrustAssociationInterceptorImpl** > **Custom Properties**
   b. Add or modify the com.ibm.ws.security.spnego.SPNx.hostName variable. For example:

      Name com.ibm.ws.security.spnego.SPNx.hostName

      Value *real_host_name*

      This custom property specifies the actual host name to which the application server can resolve an alias host name for SPNEGO single sign-on. You can then dynamically add or modify an alias name in the DNS without changing the configuration for the application server.

      You can optionally define the alias host name, but you are only required to define the real host name. The application server resolves the alias host name to real host name as the HTTP request is received.
2. Turn on the Canonical support flag.
   a. From administration console, click **Global security** > **Custom properties**
   b. Add or modify the com.ibm.websphere.security.krb.canonical_host variable and set it to "true".

      Name com.ibm.websphere.security.krb.canonical_host

      Value true

      This custom property specifies whether the application server uses the canonical form of the URL/HTTP host name in authenticating a client. If you set this custom property to `false`, a Kerberos ticket can contain a host name that differs from the HTTP host name header and the application server might issue the following message:

```
CWSPN0011E: An invalid SPNEGO token has been encountered while authenticating a HttpServletRequest
```

      If you set this custom property to `true`, you can avoid this error message and allow the application server to authenticate using the canonical form of the URL/HTTP host name.
3. Configure the browser. On the browser for the client machine, the alias host name needs to be configured as a trusted host.
   - For Internet Explorer:
     a. Select **Tools** > **Internet options**.
     b. Select the Security tab.
     c. Click **Local intranet** > **Sites** > **Advanced**
     d. Add the alias host name in this panel.
   - For Mozilla Firefox:
     a. Type **About:config** in the address bar and press ENTER to access configuration options.
     b. Locate the **network.negotiate-auth.trusted-uris** preference name, right-click on the preference, and select **Modify**. If you do not have this preference, right-click within the panel, and select **New** > **string**.
     c. Add alias host names in the text box, separating host names with a comma.
4. Ensure that the real host name is added to the keytab file.

   config: You can configure the keytab file in two ways:

- If com.ibm.websphere.security.krb.canonical_host is set to "true", the application server expects the real host name to be in the keytab files. Aliases are not necessary.
- If com.ibm.websphere.security.krb.canonical_host is set to false and aliases are defined, aliases need to be present in the keytab file.

Adding SPNEGO TAI properties using the wsadmin utility (deprecated):

You use the wsadmin utility to add properties for the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) in the security configuration for WebSphere Application Server.

About this task

Note:

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

Use the wsadmin utility to configure the SPNEGO TAI for WebSphere Application Server:

Procedure

1. Start WebSphere Application Server.
2. Start the command-line utility by running the **wsadmin** command from the *app_server_root*/bin directory from the Qshell command line.
3. At the **wsadmin** prompt, enter the following command:

   ```
   $AdminTask addSpnegoTAIProperties
   ```

   You can use the following parameters with this command:

Option	Description
<spnId>	This parameter is optional. It is the SPN identifier for the group of custom properties that are to be defined with this command. If you do not specify this parameter, an unused SPN identifier is assigned.
<host>	This parameter is required. It specifies the host name portion in the SPN used by the SPNEGO TAI to establish a Kerberos secure context.
<filter>	This parameter is optional. It defines the filtering criteria used by the class specified with the above attribute. If you do not specify this parameter, all HTTP requests are subject to SPNEGO authentication.
<filterClass>	This parameter is optional. It specifies the name of the Java class used by the SPNEGO TAI to select which HTTP requests will be subject to SPNEGO authentication. If you do not specify this paramter, the default filter class, com.ibm.ws.security.spnego.HTTPHeaderFilter, is used.

Option	Description
<noSpnegoPage>	This parameter is optional. It specifies the URL of a resource that contains the content the SPNEGO TAI will include in the HTTP response to be displayed by the (browser) client application if it does not support SPNEGO authentication. If you do not specify the noSpnegoPage paramter then the default is used: `"<html><head><title>SPNEGO authentication is not supported. </title></head>" + "<body>SPNEGO authentication is not supported on this client. </body></html>";`
<ntlmTokenPage>	This parameter is optional. It specifies the URL of a resource that contains the content the SPNEGO TAI will include in the HTTP response that is to be displayed by the (browser) client application when the SPNEGO token received by the interceptor (after the challenge-response handshake) contains a NT LAN manager (NTLM) token instead of the expected SPNEGO token. If you do not specify the ntlmTokenPage parameter then the default is used: `"<html><head><title>An NTLM Token was received.</title></head>" + "<body>Your browser configuration is correct, but you have not logged into a supported Windows Domain." + "<p>Please login to the application using the normal login page.</html>";`
<trimUserName>	This parameter is optional. It specifies whetheror not the SPNEGO TAI is to remove the suffix of the principal user name, starting from the "@" that precedes the Kerberos realm name. If this parameter is set to `true`, the suffix of the principal user name is removed. If this paramter is set to `false`, the suffix of the principal name is retained. The default value used is `true`.

Results

SPNEGO TAI properties have been added for this WebSphere Application Server.

Example

Example 1

The following example configures the SPNEGO TAI to intercept HTTP requests that contain `IE 6` in the user agent request header. The SPNEGO TAI uses the SPN of HTTP/ myhost.ibm.com@<default_realm> to authenticate the request originator.

```
$AdminTask addSpnegoTAIProperties -host myhost.ibm.com -filter user-agent%=IE 6
```

Example 2

The following is an example of adding SPNEGOTAIProperties for SPN1 to use the default filterClass and to intercept all requests for the host, central01.austin.ibm.com.

```
wsadmin>$AdminTask addSpnegoTAIProperties -interactive
Add SPNEGO TAI properties

Add SPNEGO TAI configuration properties.

*Host name in Service Principal Name (host): central01.austin.ibm.com
Service Principal Name identifier (spnId): 1
HTTP header filter rule (filter):
Name of class used to filter HTTP requests (filterClass):
SPNEGO not supported browser response (noSpnegoPage):
NTLM Token received browser response (ntlmTokenPage):
Trim User Name browser response (trimUserName):

Add SPNEGO TAI properties

F (Finish)
C (Cancel)

Select [F, C]: [F] f
WASX7278I: Generated command line: $AdminTask addSpnegoTAIProperties {-host central01.austin.ibm.com}
com.ibm.ws.security.spnego.SPN1.hostName=central01.austin.ibm.com
wsadmin>
```

Modifying SPNEGO TAI properties using the wsadmin utility (deprecated):

You use the wsadmin utility to modify the properties in the configuration of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server.

About this task

Note:

> In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

You use the wsadmin utility to configure the SPNEGO TAI for WebSphere Application Server:

Procedure

1. Start WebSphere Application Server.
2. Start the command-line utility by running the **wsadmin** command from the *app_server_root*/bin directory from the Qshell command line.
3. At the **wsadmin** prompt, enter the following command:

   ```
   $AdminTask modifySpnegoTAIProperties
   ```

   You can use the following parameters with this command:

Option	Description
<spnId>	This parameter is required. It is the SPN identifier for the group of custom properties that are to be defined with this command.
<host>	This parameter is optional. It specifies the host name portion in the SPN used by the SPNEGO TAI to establish a Kerberos secure context.

Option	Description
<filter>	This parameter is optional. It defines the filtering criteria used by the class specified with the above attribute.
<filterClass>	This parameter is optional. It specifies the name of the Java class used by the SPNEGO TAI to select which HTTP requests will be subject to SPNEGO authentication. If no class is specified, all HTTP requests will be subject to SPNEGO authentication.
<noSpnegoPage>	This parameter is optional. It specifies the URL of a resource that contains the content the SPNEGO TAI will include in the HTTP response to be displayed by the (browser) client application if it does not support SPNEGO authentication. If you do not specify the noSpnegoPage attribute then the default is used: `"<html><head><title>SPNEGO authentication is not supported. </title></head>" + "<body>SPNEGO authentication is not supported on this client. </body></html>";`
<ntlmTokenPage>	This parameter is optional. The ntlmTokenPage parameter specifies the URL of a resource that contains the content the SPNEGO TAI will include in the HTTP response, which will be displayed by the (browser) client application. The (browser) client application displays this HTTP response when the browser client sends a NT LAN manager (NTLM) token instead of the expected SPNEGO token during the challange-response handshake. If you do not specify the ntlmTokenPage attribute then the default is used: `"<html><head><title>An NTLM Token was received.</title></head>" + "<body>Your browser configuration is correct, but you have not logged into a supported Windows Domain." + "<p>Please login to the application using the normal login page.</html>";`
<trimUserName>	This parameter is optional. It specifies whether (`true`) or not (`false`) the SPNEGO TAI is to remove the suffix of the principal user name, starting from the "@" that precedes the Kerberos realm name. If this attribute is set to `true`, the suffix of the principal user name is removed. If this attribute is set to `false`, the suffix of the principal name is retained. The default value used is `true`.

Results

SPNEGO TAI properties are modified for this WebSphere Application Server.

Example

Example 1

The following example configures the SPNEGO TAI to intercept HTTP requests that contain `IE 6` in

the user agent request header. The SPNEGO TAI uses the SPN of HTTP/ myhost.ibm.com@<default_realm> to authenticate the request originator. Then the example modifies the value of the filter custom property that was defined and changes it from `user-agent%=IE 6` to `host==myhost.company.com`.

```
$AdminTask addSpnegoTAIProperties -host myhost.ibm.com -filter user-agent%=IE 6
$AdminTask modifySpnegoTAIProperties -spnId 1 -filter host==myhost.company.com
```

Example 2

This is an example of modifying the SPNEGO TAI for SPN1 properties to add a filter for host central01.austin.ibm.com.

```
wsadmin>$AdminTask modifySpnegoTAIProperties -interactive
Modify SPNEGO TAI properties

Modify SPNEGO TAI configuration properties

*Service Principal Name identifier (spnId): 1
Host name in Service Principal Name (host): central01.austin.ibm.com
HTTP header filter rule (filter): request-url!=noSPNEGO;request-url%=snoop
Name of class used to filter HTTP requests (filterClass):
SPNEGO not supported browser response (noSpnegoPage):
NTLM Token received browser response (ntlmTokenPage):
Trim User Name browser response (trimUserName):

Modify SPNEGO TAI properties

F (Finish)
C (Cancel)

Select [F, C]: [F] f
WASX7278I: Generated command line: $AdminTask modifySpnegoTAIProperties {-spnId
1 -host w2003secdev.austin.ibm.com -filter request-url!=noSPNEGO;request-url%=sn
oop}
com.ibm.ws.security.spnego.SPN1.filter=request-url!=noSPNEGO;request-url%=snoop
com.ibm.ws.security.spnego.SPN1.hostName=central01.austin.ibm.com
wsadmin>
```

Deleting SPNEGO TAI properties using the wsadmin utility (deprecated):

You use the wsadmin utility to delete properties in the configuration of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server.

About this task

Note:

> In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

You use the wsadmin utility to configure the SPNEGO TAI for WebSphere Application Server:

Procedure

1. Start WebSphere Application Server.
2. Start the command-line utility by running the **wsadmin** command from the *app_server_root*/bin directory from the Qshell command line.

3. At the **wsadmin** prompt, enter the following command:
   ```
   $AdminTask deleteSpnegoTAIProperties
   ```

   You can use the following parameters with this command:

Option	Description
<spnId>	This is an optional parameter. It is the SPN identifier for the group of custom properties that are to be deleted with this command. If you do not specify this parameter, all SPNEGO TAI custom properties are deleted.

Results

SPNEGO TAI properties are deleted for this WebSphere Application Server.

Example

Example 1

The following example deletes all the SPNEGO TAI properties for SPN2

```
wsadmin>$AdminTask deleteSpnegoTAIProperties {-spnId 2}
```

Example 2

The following example deletes all SPNEGO TAI properties

```
wsadmin>$AdminTask deleteSpnegoTAIProperties
com.ibm.ws.security.spnego.SPN1.filter=request-url!=noSPNEGO;request-url%=snoop
com.ibm.ws.security.spnego.SPN1.hostName=central01.austin.ibm.com
com.ibm.ws.security.spnego.SPN2.hostName=wssecpd.austin.ibm.com
wsadmin>
```

Displaying SPNEGO TAI properties using the wsadmin utility (deprecated):

You use the wsadmin utility to display the properties in the configuration of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server.

About this task

Note:

> In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

You use the wsadmin utility to configure the SPNEGO TAI for WebSphere Application Server:

Procedure

1. Start WebSphere Application Server.
2. Start the command-line utility by running the **wsadmin** command from the *app_server_root*/bin directory from the Qshell command line.
3. At the **wsadmin** prompt, enter the following command:
   ```
   $AdminTask showSpnegoTAIProperties
   ```

   You can use the following parameters with this command:

Option	Description
<spnId>	This is an optional parameter. It is the service principal name (SPN) identifier for the group of custom properties that are to be displayed with this command. If you do not specify this parameter, all SPNEGO TAI custom properties are displayed.

Results

SPNEGO TAI properties are displayed for this WebSphere Application Server.

Example

Example 1

The following example displays all SPNEGO TAI properties.

```
wsadmin>$AdminTask showSpnegoTAIProperties
com.ibm.ws.security.spnego.SPN1.filter=request-url!=noSPNEGO;request-url%=snoop
com.ibm.ws.security.spnego.SPN1.hostName=central01.austin.ibm.com
com.ibm.ws.security.spnego.SPN2.hostName=wssecpd.austin.ibm.com
wsadmin>
```

Example 2

The following example displays SPNEGO TAI properties for SPN1 and host, central01.austin.ibm.com.

```
wsadmin>$AdminTask showSpnegoTAIProperties -interactive
Show SPNEGO TAI configuration properties.

Display SPNEGO TAI configuration properties.

Service Principal Name identifier (spnId): 1

Show SPNEGO TAI configuration properties.

F (Finish)
C (Cancel)

Select [F, C]: [F]
WASX7278I: Generated command line: $AdminTask showSpnegoTAIProperties {-spnId 1}

com.ibm.ws.security.spnego.SPN1.filter=request-url!=noSPNEGO;request-url%=snoop
com.ibm.ws.security.spnego.SPN1.hostName=central01.austin.ibm.com
com.ibm.ws.security.spnego.SPN1.trimUserName=true
wsadmin>
```

SPNEGO TAI custom properties configuration (deprecated):

The Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) custom configuration properties control different operational aspects of the SPNEGO TAI. You can specify different property values for each application server.

Note:

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

Each of the properties defined in the following table is specified in the Custom Properties panel for the SPNEGO TAI using the administrative console facility. For convenience, you can optionally place these properties in a properties file. In this case, the SPNEGO TAI loads the configuration properties from the file instead of the Custom Properties panel definition. Refer to com.ibm.ws.security.spnego.propertyReloadFile property as defined in “SPNEGO TAI JVM configuration custom properties (deprecated)” on page 1477.

To assign unique property names that identify each possible SPN, an SPN<id> is embedded in the property name and used to group the properties that are associated with each SPN. The SPN<id>s are numbered sequentially for each property group.

Table 92. SPNEGO TAI custom properties.

This table lists the SPNEGO TAI custom properties.

Property Name	Required	Default Value
“com.ibm.ws.security.spnego.SPN<id>.enableCredDelegate”	No	false
“com.ibm.ws.security.spnego.SPN<id>.filter”	No	See the description that follows.
“com.ibm.ws.security.spnego.SPN<id>.filterClass” on page 1472	No	See the description that follows.
“com.ibm.ws.security.spnego.SPN<id>.hostName” on page 1472	Yes	None
“com.ibm.ws.security.spnego.SPN<id>.NTLMTokenReceivedPage” on page 1472	No	See the description that follows.
“com.ibm.ws.security.spnego.SPN<id>.spnegoNotSupportedPage” on page 1472	No	See the description that follows.
“com.ibm.ws.security.spnego.SPN<id>.trimUserName” on page 1472	No	true

Note: The following commands tasks can be used to operate on these SPNEGO TAI properties:

- “Adding SPNEGO TAI properties using the wsadmin utility (deprecated)” on page 1463
- “Deleting SPNEGO TAI properties using the wsadmin utility (deprecated)” on page 1467
- “Modifying SPNEGO TAI properties using the wsadmin utility (deprecated)” on page 1465
- “Displaying SPNEGO TAI properties using the wsadmin utility (deprecated)” on page 1468

com.ibm.ws.security.spnego.SPN<id>.enableCredDelegate:

This property is optional. It indicates whether or not the Kerberos delegated credentials are stored by the SPNEGO TAI. This property enables the capability for an application to retrieve the stored credentials and propagate them to other applications downstream for additional SPNEGO authentication.

This property requires use of the advanced Kerberos credential delegation feature and requires development of custom logic by the application developer. The developer must interact directly with the Kerberos Ticket Granting Service (TGS) to obtain a Ticket Granting Ticket (TGT) using the delegated Kerberos credentials on behalf of the end-user who originated the request. The developer must also construct the appropriate Kerberos SPNEGO token and include it in the HTTP request to continue the downstream SPNEGO authentication process, including handling additional SPNEGO challenge-response exchange, if necessary.

com.ibm.ws.security.spnego.SPN<id>.filter:

This property is optional. It defines the filtering criteria that is used by the specified class with the com.ibm.ws.security.spnego.SPN<id>.filterClass property. It defines arbitrary criteria that is meaningful to the implementation class used.

The com.ibm.ws.security.spnego.HTTPHeaderFilter default implementation class uses this property to define a list of selection rules that represent conditions that are matched against the HTTP request headers to determine whether or not the HTTP request is selected for SPNEGO authentication.

Each condition is specified with a key-value pair, separated from each other by a semicolon. The conditions are evaluated from left to right, as they display in the specified property. If all conditions are met, the HTTP request is selected for SPNEGO authentication.

The key and value in the key-value pair are separated by an operator that defines which condition is checked. The key identifies an HTTP request header to extract from the request and its value is compared with the value that is specified in the key-value pair according to the operator specification. If the header that is identified by the key is not present in the HTTP request, the condition is treated as not being met.

Any of the standard HTTP request headers can be used as the key in the key-value pairs. Refer to the HTTP specification for the list of valid headers. In addition, two keys are defined to extract information from the request, also useful as a selection criterion, which is not available through standard HTTP request headers. The remote-address key is used as a pseudo header to retrieve the remote TCP/IP address of the client application that sent the HTTP request. The request-URL key is used as a pseudo header to retrieve the URL that is used by the client application to make the request. The interceptor uses the result of the getRequestURL operation in the javax.servlet.http.HttpServletRequest interface to construct the web address. If a query string is present, the result of the getQueryString operation in the same interface is also used. In this case, the complete URL is constructed as follows:

```
String url = request.getRequestURL() + '?' + request.getQueryString();
```

The following operators and conditions are defined:

Table 93. Filter conditions and operations.

This table defines the conditions and operators used in filtering and gives examples.

Condition	Operator	Example
Match exactly	= = Arguments are compared as equal.	host=host.my.company.com
Match partially (includes)	%= Arguments are compared with a partial match being valid.	user-agent%=IE 6
Match partially (includes one of many)	^= Arguments are compared with a partial match being valid for one of many arguments specified.	request-url^=webApp1|webApp2|webApp3
Does not match	!= Arguments are compared as not equal.	request-url!=noSPNEGO
Greater than	> Arguments are compared lexogaphically as greater than.	remote-address>192.168.255.130
Less than	< Arguments are compared lexographically as less than.	remote-address<192.168.255.135

com.ibm.ws.security.spnego.SPN<id>.filterClass:

This property is optional. It specifies the name of the Java class that is used by the SPNEGO TAI to select which HTTP requests are subject to SPNEGO authentication.

If no class is specified, the default com.ibm.ws.security.spnego.HTTPHeaderFilter implementation class is used. The Java class that is specified must implement the `com.ibm.wsspi.security.spnego.SpnegoFilter` interface. A default implementation of this interface is provided. Specify the `com.ibm.ws.security.spnego.HTTPHeaderFilter` class to use the default implementation. This class uses the selection rules specified with the `com.ibm.ws.security.spnego.SPN<id>.filter` property.

com.ibm.ws.security.spnego.SPN<id>.hostName:

This property is required. It specifies the hostname in the SPN used by the SPNEGO TAI to establish a Kerberos secure context. It has no default value.

Note: The hostname is the long form of hostname. For example, `myHostName.austin.ibm.com`.
The Kerberos SPN is a string of the form `HTTP/hostname@realm`. The complete SPN is used with the Java Generic Security Service (JGSS) by the SPNEGO provider to obtain the security credential and security context that are used in the authentication process.

com.ibm.ws.security.spnego.SPN<id>.NTLMTokenReceivedPage:

This property is optional. It specifies the web address of a resource that contains the content that the SPNEGO TAI includes in the HTTP response that the (browser) client application displays when the SPNEGO token is received by the interceptor when the challenge-response handshake contains a NT LAN Manager (NTLM) token instead of the expected SPNEGO token.

It can specify a web (http://) or a file (file://) resource. If this property is not specified or the interceptor cannot find the specified resource, the following content is used:

```
<html><head><title>An NTLM Token was received.</title></head>
<body>Your browser configuration is correct, but you have not logged into a supported
Microsoft(R) Windows(R) Domain.
<p>Please login to the application using the normal login page.</html>
```

com.ibm.ws.security.spnego.SPN<id>.spnegoNotSupportedPage:

This property is optional. It specifies the web address of a resource that contains the content that the SPNEGO TAI includes in the HTTP response that the (browser) client application displays if it does not support SPNEGO authentication. It can specify a Web (http://) or a file (file://) resource.

If this property is not specified or the interceptor cannot find the specified resource, the following content is used:

```
<html><head><title>SPNEGO authentication is not supported</title></head>
<body>SPNEGO authentication is not supported on this client</body></html>;
```

com.ibm.ws.security.spnego.SPN<id>.trimUserName:

This property is optional. It specifies whether (`true`) or not (`false`) the SPNEGO TAI is to remove the suffix of the principal user name, starting from the "@" that precedes the Kerberos realm name.

If this property is set to `true`, the suffix of the principal user name is removed. If this property is set to `false`, the suffix of the principal name is retained. The default value used is `true`. For example,

When com.ibm.ws.security.spnego.SPN<id>.trimUserName = true

```
bobsmith@myKerberosRealm  becomes  bobsmith
```

When com.ibm.ws.security.spnego.SPN<id>.trimUserName = false

```
bobsmith@myKerberosRealm  remains  bobsmith@myKerberosRealm
```

SPNEGO TAI configuration requirements (deprecated):

The configuration that is used by the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) on each selected application server is governed by various system requirements.

Note:

> In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, the SPNEGO TAI was deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

The following list of configuration requirements highlights those attributes, properties, qualities, restrictions, exclusions, inclusions, and dependencies that you need to be aware of when planning a WebSphere Application Server configuration that incorporates the use of the SPNEGO TAI.

Table 94. SPNEGO TAI requirements.

This table lists the SPNEGO TAI configuration requirements.

Function item	Description
SPNEGO TAI	The SPNEGO TAI is a server side solution in WebSphere Application Server. Client-side applications are responsible for generating the SPNEGO token for use by the SPNEGO TAI.
Microsoft Windows	Microsoft Windows Servers with Active Directory domain and its associated Kerberos key distribution center (KDC) is required. For information on the supported Microsoft Windows Servers, see the System Requirements for WebSphere Application Server Version 8.0 on Windows.
Client application (browser or .NET client)	A browser (client application) or .NET client that supports the SPNEGO authentication mechanism, as defined in IETF RFC 2478 is required.
Simple and Protected GSS-API Negotiation Mechanism (SPNEGO)	SPNEGO authentication, as defined in IETF RFC 2478 is used.
Internet browsers	• Use Microsoft Internet Explorer version 5.5 or higher • Use Mozilla Firefox version 1.0
Kerberos Level	Kerberos version 5 is required.
WebSphere Application Server	Version 7.0 is required.
Java SDK level	Java 6.0 SDK is required.
Encryption Types	RC4-HMAC encryption is only supported when using a Windows 2003 Server as Kerberos key distribution center (KDC).
J2EE client	Client application (browser or .NET client) A browser (client application) or .NET client that supports the SPNEGO authentication mechanism, as defined in IETF RFC 2478 is required.

Configuring the client browser to use SPNEGO TAI (deprecated):

You can configure your browser to utilize the Simple and Protected GSS-API Negotiation (SPNEGO) mechanism. Authentication of your browser requests are processed by the SPNEGO trust association interceptor (TAI) in the WebSphere Application Server.

Before you begin

You need to know how to display and set options in the Microsoft Internet Explorer browser or any other browser (such as Firefox). You must have a browser installed that supports SPNEGO authentication.

Note:

> In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

About this task

Complete the following steps to ensure that your Microsoft Internet Explorer browser is enabled to perform SPNEGO authentication.

Procedure

1. At the desktop, log in to the windows active directory domain.
2. Activate Internet Explorer.
3. In the Internet Explorer window, click **Tools > Internet Options > Security** tab.
4. Select the **Local intranet** icon and click **Sites**.
5. In the Local intranet window, ensure that the "check box" to include all local (intranet) not listed in other zones is selected, then click **Advanced**.
6. In the **Local intranet** window, fill in the Add this web site to the zone field with the web address of the host name so that the single sign-on (SSO) can be enabled for the list of websites shown in the websites field. Your site information technology staff provides this information. Click **OK** to complete this step and close the Local intranet window.
7. On the **Internet Options** window, click the **Advanced** tab and scroll to **Security settings**. Ensure that the **Enable Integrated Windows Authentication (requires restart)** box is selected.
8. Click **OK**. Restart your Microsoft Internet Explorer to activate this configuration.

Results

Complete the following steps to ensure that your Firefox browser is enabled to perform SPNEGO authentication.

1. At the desktop, log in to the windows active directory domain.
2. Activate Firefox.
3. At the address field, type **about:config**.
4. In the Filter, type **network.n**
5. Double click on **network.negotiate-auth.trusted-uris**. This preference lists the sites that are permitted to engage in SPNEGO Authentication with the browser. Enter a comma-delimited list of trusted domains or URLs.

   Note: You must set the value for **network.negotiate-auth.trusted-uris**.

6. If the deployed SPNEGO solution is using the advanced Kerberos feature of Credential Delegation double click on **network.negotiate-auth.delegation-uris**. This preference lists the sites for which the browser may delegate user authorization to the server. Enter a comma-delimited list of trusted domains or URLs.
7. Click **OK**. The configuration appears as updated.
8. Restart your Firefox browser to activate this configuration.

Your Internet browser is properly configured for SPNEGO authentication. You can use applications that are deployed in WebSphere Application Server that use secured resources without being repeatedly requested for an ID and password.

Configuring JVM custom properties, filtering HTTP requests, and enabling SPNEGO TAI in WebSphere Application Server (deprecated):

Performing this task helps you, as web administrator, to ensure that WebSphere Application Server is configured to enable the operation of the Simple and Protected GSS-API Negotiation mechanism (SPNEGO) trust association interceptor (TAI) with the required Java virtual machine (JVM) property and with the appropriate filtering of HTTP requests.

Before you begin

You need to know how to use the WebSphere Application Server administrative console to manage the security configuration and have the proper authority to modify the security configuration of the application server.

Note:

> In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

About this task

Verify the configuration of your SPNEGO TAI. The deployment of the SPNEGO TAI can vary from a single WebSphere Application Server system on which a single application is running to a large multinode WebSphere Application Server, Network Deployment (ND) cell, with dozens of application servers, hosting many applications. Every SPNEGO TAI is installed at the cell level. You must be aware of your particular SPNEGO TAI configuration.

The default behavior of the SPNEGO TAI is to not intercept HTTP requests. This default behavior ensures that the SPNEGO TAI can be installed into an existing cell, configured for a single application server and not change any other application servers in the cell. Other WebSphere Application Servers can run exactly as before within a given configuration.

Decide whether or not to use the sample SPN<id>.filterClass and determine the exact filter properties to use.

Note: The default behavior of the SPNEGO TAI is to use the `com.ibm.ws.security.spnego.SPN<id>.filterClass` and intercept all requests.
If the default behavior is not appropriate, you can use a customer provided class, or extend or modify the sample class as required. The system programmer interface, `com.ibm.ws.security.spnego.SpnegoFilter`

allows you to implement a custom filter to determine whether or not to intercept a particular HTTP request. With the default implementation, you can set filter rules for coarse as well as fine-grained criteria in selecting which HTTP requests to intercept.

Note: For an alternative to the steps below for enabling the SPNEGO TAI, you can use scripting to perform the operation. See "Enabling the SPNEGO TAI as JVM custom property using scripting (deprecated)" for the details.

Complete the following steps to enable the operation of the SPNEGO TAI with your selected filtering and with the JVM required property.

Procedure

1. Log on to WebSphere Application Server administrative console.
2. Click **Servers > Application servers**.
3. Select the appropriate server. Under Server Infrastructure, expand **Java and process management > Process Definition**.
4. Click **Java virtual machine**. Under Additional Properties, click **Custom Properties**. Create a new custom property, if required, by clicking **New**, then code `com.ibm.ws.security.spnego.isEnabled` in the name field and `true` in the value field.
5. Click **Apply > OK** to save the configuration
6. Identify when the SPNEGO TAI intercepts a given request. A set of filter properties is provided, but you must determine what is appropriate and modify the `com.ibm.ws.security.spnego.SPN<id>.filterClass` accordingly.

Results

The application server is configured and ready to provide a single sign-on environment for end users who have successfully authenticated in a Microsoft Active Directory domain. You must restart each application server that is configured for SPNEGO web authentication. Then your SPNEGO TAI is set to filter HTTP request when it is operating.

Enabling the SPNEGO TAI as JVM custom property using scripting (deprecated):

You use the wsadmin utility to enable the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) for WebSphere Application Server.

Before you begin

Before starting this task, the wsadmin tool must be running. See the information about starting the wsadmin scripting client using wsadmin scripting.

Note:

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

About this task

Perform the following steps to enable the SPNEGO TAI:

Procedure

1. Identify the server and assign it to the `server1` variable:
   - Using Jacl:

     ```
     set server1 [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
     ```

   - Using Jython:

     ```
     server1 = AdminConfig.getid("/Cell:mycell/Node:mynode/Server:server1/")
     print server1
     ```

   Example output:

   ```
   server1(cells/mycell/nodes/mynode|servers/seerver1|server.xml#Server_1)
   ```

2. Identify the Java virtual machine (JVM) belonging to this server and assign it to the `jvm` variable:
   - Using Jacl:

     ```
     set jvm [$AdminConfig list JavaVirtualMachine $server1]
     ```

   - Using Jython:

     ```
     jvm = AdminConfig.list('JavaVirtualMachine',server1)
     ```

   Example output:

   ```
   (cells/mycell/nodes/mynode/servers/server1:server.xml#JavaVirtualMachine_1)
   (cells/mycell/nodes/mynode/servers/server1:server.xml#JavaVirtualMachine_2)
   ```

3. Identify the controller JVM of the server:
   - Using Jacl:

     ```
     set cjvm [lindex $jvm 0]
     ```

   - Using Jython:

     ```
     # get line separator
     import java
     lineSeparator = java.lang.System.getProperty('line.separator')
     arrayJVMs = jvm.split(lineSeparator)
     cjvm = arrayJVMs[0]
     ```

4. Modify the generic JVM arguments to enable SPNEGO TAI:
   - Using Jacl:

     ```
     set attr_name           [list name com.ibm.ws.security.spnego.isEnabled]
     set attr_value          [list value true]
     set attr_required       [list required false]
     set attr_description    [list description "Enabled SPNEGO TAI"]

     set attrs [list $attr_name $attr_value $attr_required $attr_description]

     $AdminConfig create Property $cjvm $attrs
     ```

   - Using Jython:

     ```
     attr_name  = ['name', "com.ibm.ws.security.spnego.isEnabled"]
     attr_value = ['value', "true"]
     attr_required = ['required', "false"]
     attr_description = ['description', "Enabled SPNEGO TAI"]
     attr_list = [attr_name, attr_value, attr_required, attr_description]
     property=['systemProperties',[attr_list]]
     AdminConfig.modify(cjvm, [property])
     ```

5. Save the configuration changes.

SPNEGO TAI JVM configuration custom properties (deprecated):

Java virtual machine (JVM) custom properties control the operation of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI).

Note:

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

The following JVM custom properties control operation of the SPNEGO TAI. Different custom property values can be specified for each application server.

Table 95. JVM configuration custom properties.

This table lists the SPNEGO JVM configuration custom properties.

Custom Property Name	Required	Value Type	Default Value	Recommended Value
com.ibm.ws.security.spnego.isEnabled	No	Boolean	False	True

com.ibm.ws.security.spnego.propertyReloadFile	No	String	None	For Windows
				`C:\temp\TAI.props`
				
				For UNIX
				`/tmp/TestTAI.Properties`

com.ibm.ws.security.spnego.propertyReloadTimeout	No	Integer	None	120

com.ibm.ws.security.spnego.isEnabled
Use this custom property to enable or disable operation of the SPNEGO TAI in a given application server. When set to `false`, the SPNEGO TAI is disabled and not used by the web authentication module for authenticating any web requests. When set to `true`, the SPNEGO TAI is enabled and used by the web authentication module for authenticating any web requests.

com.ibm.ws.security.spnego.propertyReloadFile
Use this custom property to identify the file that contains configuration properties for the SPNEGO TAI, when it is not convenient to stop and restart the application server. The properties contained in this file can be reloaded to configure the SPNEGO TAI.

Important: The properties that are defined in the specified file override any properties defined using the administrative console.

A sample of this reload file follows:

```
#########################################################
# Template properties files for SPNEGO TAI
#
# Where possible defaults have been provided.
#
#########################################################

#---------------------------------------------------------
# Hostname
#---------------------------------------------------------
#com.ibm.ws.spnego.SPN1.HostName=wsecurity.austin.ibm.com

#---------------------------------------------------------
# (Optional) SpnegoNotSupportedPage
#---------------------------------------------------------
#com.ibm.ws.spnego.SPN1.SpnegoNotSupportedPage=

#---------------------------------------------------------
# (Optional) NTLMTokenReceivedPage
#---------------------------------------------------------
#com.ibm.ws.spnego.SPN1.NTLMTokenReceivedPage=
```

```
#-----------------------------------------------------------
# (Optional) FilterClass
#-----------------------------------------------------------
#com.ibm.ws.spnego.SPN1.FilterClass=com.ibm.ws.spnego.HTTPHeaderFilter

#-----------------------------------------------------------
# (Optional) Filter
#-----------------------------------------------------------
#com.ibm.ws.spnego.SPN1.Filter=
```

Important: If com.ibm.ws.security.spnego.propertyReloadFile custom property is set, but the com.ibm.ws.security.spnego.propertyReloadTimeout custom property is not, then the SPNEGO TAI is not initialized.

com.ibm.ws.security.spnego.propertyReloadTimeout
Use this custom property to specify a time interval in seconds that elapses after which the SPNEGO TAI reloads the configuration properties. Also, the SPNEGO TAI reloads the configuration properties if the file that is identified by the com.ibm.ws.security.spnego.propertyReloadFile custom property changed since the last time the configuration custom properties were retrieved. This time interval in seconds must be specified as a positive integer.

Important:

- If the com.ibm.ws.security.spnego.propertyReloadFile custom property and the com.ibm.ws.security.spnego.propertyReloadTimeout custom property are not set, then the SPNEGO TAI properties are only loaded once from the SPNEGO TAI custom properties defined in the WebSphere Application Server configuration data. This one time loading occurs when the JVM is initialized.
- If com.ibm.ws.security.spnego.propertyReloadTimeout custom property is set, but the com.ibm.ws.security.spnego.propertyReloadFile custom property is not, then the SPNEGO TAI is not initialized. “Configuring JVM custom properties, filtering HTTP requests, and enabling SPNEGO TAI in WebSphere Application Server (deprecated)” on page 1475 or how to configure the JVM custom properties for SPNEGO TAI.

Remember: You can also use the wsadmin command for the AdminConfig scripting object to interactively set the com.ibm.ws.security.spnego.isEnabled custom property. See “Enabling the SPNEGO TAI as JVM custom property using scripting (deprecated)” on page 1476 for more information.

The following custom properties are not used directly by the SPNEGO TAI; however, they affect the operation of the core security runtime and can also be used for problem determination.

Table 96. JVM configuration custom properties.

This table describes the JVM configuration custom properties

Custom Property Name	Required	Value Type	Default Value	Recommended Value
com.ibm.security.jgss.debug	No	String	None	"off" or "all"
com.ibm.security.krb5.Krb5Debug	No	String	None	"off" or "all"
java.security.properties	No	String	None	
javax.security.auth.useSubjectCredsOnly	Yes	Boolean	True	False

com.ibm.security.jgss.debug
This custom property is optional. It can be used to collect diagnostic trace information for problem determination in the Java Generic Security Service (JGSS) application programmer interface (API) implementation. The value can be set to `all` or `off` to enable or disable tracing, respectively. See Java Generic Security Service User's Guide for specific JGSS API information.

com.ibm.security.krb5.Krb5Debug
This custom property is optional. It can be used to collect additional diagnostic trace information for problem determination in the JGSS implementation. The value can be set to `all` or `off` to enable or disable tracing, respectively.

java.security.properties
This property is optional. It can be used when different application servers in a cell have different security requirements and it is not convenient to modify the global `java.security` file for the entire cell. In such situations, the java.security.properties custom property is used to specify the location of the `java.security` file used by the JVM for each application server.

javax.security.auth.useSubjectCredsOnly
JGSS includes an optional Java Authentication and Authorization Service (JAAS) login facility that saves `Principal` credentials and secret keys in the `Subject` of the application's JAAS login context. JGSS retrieves credentials and secret keys from the `Subject` by default. This feature can be disabled by setting the Java property javax.security.auth.useSubjectCredsOnly to `false`.

Attention: The SPNEGO TAI does not use the optional JAAS login module. The javax.security.auth.useSubjectCredsOnly property must be set to `false`.

Mapping Kerberos client principal name to WebSphere user registry ID for SPNEGO TAI (deprecated):

You can use a system programming interface to customize the behavior of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) by implementing arbitrary mappings of the end-user's identity, which is retrieved from Microsoft Active Directory to the identity that is used in the WebSphere Application Server security registry.

Before you begin

You need to perform some administrative tasks in the WebSphere Application Server environment to use SPNEGO TAI and to ensure that the requester's identity matches the identity in the WebSphere Application Server user registry.

Note:

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

Note: Make sure the following tasks have been performed successfully:

1. Configuring the web browser to use SPNEGO. See “Configuring the client browser to use SPNEGO TAI (deprecated)” on page 1473
2. Configuring Java virtual machine (JVM) properties, custom SPNEGO TAI properties, and enabling the SPNEGO TAI. See “Configuring JVM custom properties, filtering HTTP requests, and enabling SPNEGO TAI in WebSphere Application Server (deprecated)” on page 1475

About this task

In the simplest deployment of the SPNEGO TAI, it is assumed that the requester's identity in the WebSphere Application Server user registry is identical to the identity retrieved. This is the case when Microsoft Windows Active Directory server is the lightweight directory access protocol (LDAP) server used in WebSphere Application Server. This is default behavior of the SPNEGO TAI.

You do not need to use this simple deployment of the SPNEGO TAI. WebSphere Application Server can use a different registry, such as a local OS, LDAP, or custom registry instead of the Microsoft Active Directory. If WebSphere Application Server uses a different registry than the Microsoft Active Directory, then a mapping from the Microsoft Windows user Id to a WebSphere Application Server user Id is necessary.

Procedure

Use the JAAS custom login module to perform any custom mapping of a client Kerberos principal name from the Microsoft Active Directory to the WebSphere user registry identity. The JAAS custom login module is a plug-in mechanism that is defined for authenticating incoming and outgoing requests in WebSphere Application Server and is inserted before the `ltpaLoginModule`. The JAAS custom login module retrieves a client Kerberos principal name in the `javax.security.auth.Subject` using `subject.getPrincipals(KerberosPrincipal.class)` method, maps the client Kerberos principal name to the WebSphere user registry identity, and inserts the mapping identity in the hash table property `com.ibm.wsspi.security.cred.userId`. The `ltpaLoginModule` then uses the mapped identity to create a `WSCredential`.

Note: The custom login module can also supply the full set of security properties in the `javax.security.auth.Subject` in the `com.ibm.wsspi.security.tai.TAIResult` to fully assert the mapped identity. When the identity is fully asserted, the `wsMapDefaultInboundLoginModule` maps those security properties to a `WSCredential`.

A sample of the custom login module follows:

```
package com.ibm.ws.security.server.lm;

import java.util.Map;
import java.lang.reflect.Array;
import javax.security.auth.Subject;
import javax.security.auth.callback.*;
import javax.security.auth.login.LoginException;
import javax.security.auth.spi.LoginModule;
import javax.security.auth.kerberos.*;
import com.ibm.websphere.security.auth.WSLoginFailedException;
import com.ibm.wsspi.security.token.AttributeNameConstants;

/**
 *
 * @author IBM Corporation
 * @version 1.0
 * @since 1.0
 *
 */

public class sampleSpnegoMappingLoginModule implements LoginModule {
    /*
     *
     * Constant that represents the name of this mapping module.  Whenever this sample
     * code is used to create a class with a different name, this value should be changed.
     *
     */
    private final static String MAPPING_MODULE_NAME = "com.ibm.websphere.security.sampleSpnegoMappingLoginModule";

    private String mapUid = null;

```

Results

Using the custom login module, Microsoft Active Directory identities are mapped to the WebSphere Application Server's security registry and the behavior of the SPNEGO TAI is customized.

Single sign-on capability with SPNEGO TAI - checklist (deprecated):

WebSphere Application Server provides a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources in WebSphere Application Server. To deploy and use the SPNEGO TAI you need to examine your installation and decide on how best to configure the SPNEGO TAI.

Note:

In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

Lightweight Third Party Authentication (LTPA) is the default authentication mechanism for WebSphere Application Server. However, you may need to configure LTPA prior to configuring the SPNEGO TAI. LTPA is the required authentication mechanism for all trust association interceptors. You can configure LTPA by clicking **Security > Global security > Authentication mechanisms and expiration**.

Note: Enabling web security single sign-on (SSO) is optional when you configure the SPNEGO TAI. For more information, see “Implementing single sign-on to minimize web user authentications” on page 1441.

Answer the following questions to establish how the SPNEGO TAI is deployed.

1. What is your criteria for intercepting HTTP requests?

   You must decide if the SPNEGO TAI deployment will use the HTTPHeaderFilter class as the default. If you do use this class, then you must specify the exact filter properties for this class. The default behavior of the SPNEGO TAI is to use the com.ibm.ws.spnego.HTTPHeaderFilter class to intercept all requests.

   If you do not use the sample com.ibm.ws.spnego.HTTPHeaderFilter class, then you must define a new class that implements the com.ibm.wsspi.security.spnego.SpnegoTAIFilter interface.

   You can decide to further control what HTTP requests are intercepted using the Service Provider Programming Interface (SPI), “Filtering HTTP requests for SPNEGO TAI (deprecated)” on page 1486

   See “SPNEGO TAI custom properties configuration (deprecated)” on page 1469 for descriptions of

   - com.ibm.ws.security.spnego.SPN<id>.filterClass
   - com.ibm.ws.security.spnego.SPN<id>.filter

2. Is user Id mapping to be used? If not, why not?

   WebSphere Application Server enables you to define or develop a custom login module to map user IDs. See “Mapping Kerberos client principal name to WebSphere user registry ID for SPNEGO TAI (deprecated)” on page 1480 for more detail about performing this mapping.

   You must decide, before deploying the TAI, whether or not to use this custom login module to perform the SPNEGO TAI identity mapping

3. What type of encryption is to be used to process the SPNEGO tokens?

   Microsoft Windows Active Directory supports two different Kerberos encryption types: RC4-HMAC and DES-CBC-MD5. The IBM Java Generic Security Service (JGSS) library (and SPNEGO library) support both of these encryption types.

   Restriction: RC4-HMAC encryption is only supported with a Windows 2003 Server key distribution center (KDC).

4. How will you handle credential delegation?

   Kerberos supports the delegation of credentials. A server that receives Kerberos credentials from a client can impersonate that client to other servers by using delegated credentials. Since SPNEGO TAI

tokens are a wrapping of a Kerberos credential, a server that receives Kerberos credentials within an SPNEGO token can use those Kerberos credentials to impersonate the original user. That server can interact using SPNEGO over HTTP as a SPNEGO client to other SPNEGO servers by composing an appropriate HTTP Authorization header.

5. Will the SPNEGO TAI be deployed in a single or multiple domain name service (DNS) domain environment?

   Web browsers running on Windows are sensitive to DNS domains. They only send a SPNEGO token when the target host name identifies a host name defined in the DNS domain of the client machine. You can use HTTP redirection to support this configuration with the creation of a pseudo Kerberos service principal name (SPN) in each DNS domain. All SPNs that WebSphere Application Server supports must have their secret keys available in Kerberos `keytab` files. To enable single sign-on across multiple DNS domains, a separate Kerberos keytab file is generated for each SPN per domain. These individual Kerberos keytab files must be merged before they can be used by WebSphere Application Server.

6. How frequently will application servers reload the SPNEGO TAI properties?

   The SPNEGO TAI has an optional property reload feature that allows the reloading of the TAI properties without restarting the Java virtual machine (JVM). This reload feature is controlled by the system properties `com.ibm.ws.security.spnego.propertyReloadFile` and `com.ibm.ws.security.spnego.propertyReloadTimeout`. These properties taken together enable the SPNEGO TAI internal properties to be reloaded from a file on the file system after a certain time period. If the com.ibm.ws.security.spnego.propertyReloadTimeout attribute is set to a valid integer value, and the com.ibm.ws.security.spnego.propertyReloadFile attribute points to a file on the file system, then each JVM reloads the SPNEGO TAI properties from the file after the timeout period expires. Also, the SPNEGO TAI properties are reloaded only if the date on the file has changed. If these reload properties are not set, then the SPNEGO TAI properties are only loaded once, at JVM initialization, from the SPNEGO TAI custom properties that are defined in WebSphere Application Server configuration data. See “SPNEGO TAI JVM configuration custom properties (deprecated)” on page 1477 for more information about these reload properties.

The Windows Active Directory (Web) administrator, the WebSphere Application Server administrator, and the application team review and answer these questions to determine the best deployment and configuration settings for the SPNEGO TAI.

Filtering HTTP requests for SPNEGO TAI (deprecated):

You can use a system programming interface to customize the behavior of the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) trust association interceptor (TAI) by specifying whether or not a particular HTTP request should be intercepted.

Before you begin

Before you begin, you need to understand the deployment of the SPNEGO TAI in your installation.

Note:

> In WebSphere Application Server Version 6.1, a trust association interceptor (TAI) that uses the Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) to securely negotiate and authenticate HTTP requests for secured resources was introduced. In WebSphere Application Server 7.0, this function is now deprecated. SPNEGO web authentication has taken its place to provide dynamic reload of the SPNEGO filters and to enable fallback to the application login method.

About this task

Verify the configuration of your SPNEGO TAI. The deployment of the SPNEGO TAI can vary from a single WebSphere Application Server system on which a single application is running to a large multinode WebSphere Application Server, Network Deployment (ND) cell, with dozens of application servers, hosting many applications. Every SPNEGO TAI is installed at the cell level. You must be aware of your particular SPNEGO TAI configuration.

The default behavior of the SPNEGO TAI is to not intercept HTTP requests. This default behavior ensures that the SPNEGO TAI can be installed into an existing cell, configured for a single application server and not change any other application servers in the cell. Other WebSphere Application Servers can run exactly as before within a given configuration.

Then decide whether or not to use the sample SPN<id>.filter class and determine the exact filter properties to use.

Note: The default behavior of the SPNEGO TAI is to use the com.ibm.ws.security.spnego.SPN<id>.filter class and intercept all requests.

If the default behavior is not appropriate, you can use a customer provided class, or extend or modify the sample class as required. The system programmer interface, com.ibm.ws.security.spnego.SpnegoFilter allows you to implement a custom filter to determine whether or not to intercept a particular HTTP request. With the default implementation, you can set filter rules for coarse as well as fine-grained criteria in selecting which HTTP requests to intercept.

Procedure

1. Set the `com.ibm.ws.security.spnego.isEnabled` Java virtual machine (JVM) custom property to `true` to enable the SPNEGO TAI on any JVM.
2. Identify when the SPNEGO TAI intercepts a given request. A set of filter properties is provided, but you must determine what is appropriate and modify the `com.ibm.ws.security.spnego.SPN<id>.filter class` accordingly.

Results

Your SPNEGO TAI is set to filter HTTP requests when it is operating.

Configuring single sign-on capability with Enterprise Identity Mapping

The Enterprise Identity Mapping (EIM) identity token connection factory is a type of Java 2 Connector (J2C) connection factory. Using EIM identity token connection factories along with EIM identity token-enabled products, such as IBM Toolbox for Java, provides a single sign-on capability for WebSphere Application Server applications that need to access server data and resources through your user ID.

Before you begin

The EIM identity token connection factory is supported on the following WebSphere Application Server products.

Attention: Either Lightweight Third Party Authentication (LTPA) or Simple WebSphere Authentication Mechanism (SWAM) may be used with the EIM identity token connection factory. Enabling web security single sign-on (SSO) is optional when LTPA is used with the EIM identity token connection factory. See the information about implementing single sign-on to minimize web user authentications.

Table 97. Supported editions per product.

This table lists the supported edition names per product.

Edition name	Supported products
Version 8.0	WebSphere Application Server, Express for IBM iWebSphere Application Server (base)
Version 6.1	WebSphere Application Server, Express for IBM iWebSphere Application Server (base)
Version 6.0.x	WebSphere Application Server, Express for OS/400WebSphere Application Server (base)

This topic describes how to configure EIM identity token connection factories for Version 8.0 only and provides information about a sample application that might be helpful to you when you develop your own applications.

Attention: Configuration tasks can vary slightly for other WebSphere Application Server products and editions.

About this task

The sample application uses an EIM identity token connection factory to provide EIM identity tokens for use with IBM Toolbox for Java com.ibm.as400.access.AS400 objects. For example, if the sample application is deployed on SERVER A, you can log in once to WebSphere Application Server and use the sample application to perform IBM i server commands under your IBM i user profiles on SERVER B, SERVER C, or SERVER D.

When you make a request to the sample application, you must log in with your WebSphere Application Server user ID and password. Each request contains the server command and the target server name where the command runs. When the request is received, the application calls the connection factory to generate an identity token. The connection factory extracts your user ID from a Java Authentication and Authorization Service (JAAS) subject object provided by WebSphere Application Server security, and it collaborates with the EIM domain controller to create the identity token that is returned to the application. The application then creates a com.ibm.as400.access.AS400 object for SERVER B and provides it with the identity token (instead of your IBM i user profile) before it passes the server command to run.

Attention: A new identity token and com.ibm.as400.access.AS400 object are created each time you send a request that contains a new target server. All com.ibm.as400.access.AS400 objects are stored in an HTTP Session for use with subsequent requests.

Procedure

1. Verify that you have all of the necessary prerequisites installed to use the EIM token connection factory. You must verify that you have installed the necessary program temporary fixes (PTF) to your server and applications. For more information, see “Verifying Enterprise Identity Mapping identity token connection factory prerequisite applications” on page 1489.
2. Configure EIM work with the identity token connection factory. These instructions explain how to complete the following tasks:
   a. Create a domain in EIM.
   b. Add the domain to domain management.
   c. Create a source user registry definition.
   d. Create a user identifier.
   e. Create a target association.
   f. Create a source association.
   g. Test the connection to the EIM domain controller

   For more information, see “Configuring Enterprise Identity Mapping” on page 1489.

3. Configure the EIM identity token connection factory. This step involves configuring two Java Archive (JAR) files and a shared library. For more information, see “Configuring the Enterprise Identity Mapping identity token connection factory” on page 1492.
4. Configure the connection factory. For more information, see “Automatically configuring the connection factory” on page 1497.

Results

After completing the previous steps, you have configured single sign-on for Enterprise Identity Mapping.

Verifying Enterprise Identity Mapping identity token connection factory prerequisite applications:

Use the following procedure to verify that the necessary prerequisites have been installed before using the Enterprise Identity Mapping (EIM) identity token connection factory.

Before you begin

Before you can use the EIM identity token connection factory, you must have the required cumulative program temporary fix (PTF) applied to your server. You might also need to apply PTFs to run the sample application.

About this task

Perform the following steps to verify that you have the necessary prerequisites installed to use the EIM identity token connection factory:

Procedure

1. Verify that OS/400 - Extended Base Directory Support (5761–SS1 or 5770-SS1 option 3) is installed on the IBM i system that hosts WebSphere Application Server. This product is a requirement for the EIM Identity Token Connection Factory.
2. Verify that the latest operating system PTFs are applied to your IBM i system for the EIM Identity Token Connection Factory. For information about the latest operating system PTFs, search the Technotes for "EIM Identity Token Connection Factory" on the WebSphere Application Server support page at: http://www.ibm.com/software/webservers/appserv/support.html.
3. Install the required PTFs for the sample application.

   To run the sample application, verify that the latest IBM Toolbox for Java service packs and the required operating system PTFs are installed on all of your iSeries servers. For information on obtaining the latest service packs and required operating system PTFs, see Toolbox for Java and JTOpen Service Packs.

Results

After verifying that you have the necessary prerequisite applications installed, you can configure EIM for use with the identity token connection factory.

What to do next

Configure EIM. See “Configuring Enterprise Identity Mapping.”

Configuring Enterprise Identity Mapping:

Use the iSeries Navigator to configure Enterprise Identity Mapping (EIM) for use with the identity token connection factory.

Before you begin

For these steps, assume that your EIM controller, which is your Lightweight Directory Access Protocol (LDAP) directory server, is your local directory server and that it resides on the iSeries server that is being configured for EIM. For detailed information about EIM, see “Enterprise Identity Mapping” on page 1440.

You need the LDAP server administrator distinguished name (DN) and password to perform this task.

Tip: A server can participate only in one EIM domain at a time. If your server is already joined to an EIM domain and the domain is added to domain management, use that domain, and skip to Create a source user registry definition in EIM.

Procedure

1. The identity token connection factory requires you to configure an EIM domain.
   Create a domain in EIM:

   Note: Depending on the setup of the machine, these steps might appear in a slightly different order. This assumes that LDAP is already configured and the network authentication service has not been configured.

   a. Make sure that the LDAP server started. You can verify the LDAP server administrator distinguished name (DN) and password. However, be aware that the LDAP server is stopped by the wizard later on.
   b. In iSeries Navigator, expand ***server_name*** **> Network > Enterprise Identity Mapping**, where *server_name* is the name of your iSeries server.
   c. Click **Enterprise Identity Mapping**.
   d. Right-click **Configuration** and select **Configure** to start the EIM Configuration wizard.

      Note: This option is labeled **Reconfigure** if EIM has been previously configured on the system.

   e. On the Welcome page of the wizard, select **Create and join a new domain**.
   f. Click **Next**.
   g. On the Specify EIM Domain Location page, select **On the local Directory server** and then click **Next**.
   h. If the network authentication service has not been configured on the system to set up a single sign-on environment, the Configure Network Authentication Service page is displayed. Network Authentication Service is not required for the EIM identity token connection factory. Select **No** and then click **Next**.
   i. On the Specify User for Connection page, specify the distinguished name and password for the LDAP administrator to ensure that the wizard has enough authority to administer the EIM domain and the objects in it. Click **Next**.

      Note: If you have not configured the local directory server before you use the EIM Configuration wizard, the Configure Directory Server page displays instead. Use this page to specify the distinguished name and password for the LDAP administrator and continue with the next step in this procedure. The LDAP distinguished name (DN) identifies the LDAP administrator for the directory server. The EIM Configuration wizard creates this LDAP administrator DN and uses it to configure the directory server as the domain controller for the new domain that you are creating.

   j. On the Specify Domain page, provide the name of the EIM domain, and click **Next**.
   k. On the Specify Parent DN for Domain page, select **Yes** to specify a parent DN for the domain that you are creating, or specify **No** to have EIM data stored in a directory location with a suffix whose name is derived from the EIM domain name. Click **Next**.
   l. A message is displayed that indicates that you must stop the LDAP server. Click **Yes** to continue.

m. On the Registry Information page, select **Local OS/400** and then click **Next**.

n. On the Specify EIM System User page, select **Distinguished name and password** as the user type, provide the DN and password for the directory server administrator, and optionally, verify the DN and password. Click **Next**.

o. In the Summary panel, review the configuration information that you have provided. If all information is correct, click **Finish**.

2. Add the domain to domain management:

   a. In the iSeries Navigator, expand ***system_name*> Network > Enterprise Identity Mapping > Domain Management**.

   b. Right-click **Domain Management** and then select **Add Domain**.

   c. In the Add Domain dialog, specify the domain you created earlier and click **OK**.

3. Create a source user registry definition in EIM.

   The identity token connection factory requires a source user registry definition entry in EIM. The source user registry definition represents the registry that WebSphere Application Server uses for authentication. This registry can be a local OS registry or an LDAP registry.

   a. In iSeries Navigator, expand ***system_name* > Network > Enterprise Identity Mapping > Domain Management > *domain_name*> User Registries**.

   b. If you are prompted for the LDAP server password, provide the password and click **OK**.

   c. Right-click **User Registries** and select **Add Registry** > **System** to start the configuration wizard that adds the registry to your domain.

      Provide the registry name and type. If your application server is hosted on an iSeries server and configured to use the local OS user registry, select **OS/400** as the EIM user registry type. If your application server is configured to use the LDAP user registry, enter `LDAP - short name` as the EIM registry type.

      Note: Prior to IBM i V5R4, instead of `LDAP - short name` use `1.3.18.02.33.14-caseIgnore`. The value `1.3.18.02.33.14-caseIgnore` is the ObjectIdentifier-normalization form of the user registry type and principals are identified by the LDAP short name attribute. The wizard does not handle the descriptive name for this registry type.

   d. Click **OK**.

4. Create user identifier in EIM

   The identity token connection factory requires a user identifier entry, which is equivalent to an EIM identifier; in EIM, the user identifier entry represents the user of the application.

   a. In iSeries Navigator, expand ***system* > Network > Enterprise Identity Mapping > Domain Management > *domain* > Identifiers.**

   b. Right-click **Identifiers**, and select **New Identifier**.

   c. Enter an identifier name, such as your full name, and click **OK**.

5. Create a target association in EIM for the user identifier.

   A target association represents the user profile on the target iSeries server for the identifier created earlier.

   a. In iSeries Navigator, expand ***system* > Network > Enterprise Identity Mapping > Domain Management > *domain* > Identifiers**.

   b. Double-click the **Application Identifier** for the user created previously.

   c. Click the **Associations** tab.

   d. Click **Add**.

   e. Provide the IBM i user profile for the EIM identifier in the User field and click **OK**.

   f. Click **OK** to save the association.

6. Create a source association in EIM for the user identifier.

   A source association is used to authenticate to WebSphere Application Server.

a. In iSeries Navigator, expand ***system*** > **Network** > **Enterprise Identity Mapping** > **Domain Management** > ***domain*** > **Identifiers**.
b. Double-click the **Application Identifier** for the user created previously.
c. Click the **Associations** tab.
d. Click **Add**.
e. Click **Browse** and select the WebSphere Application Server user registry.
f. Specify your WebSphere Application Server user ID, such as `my_id`.
g. Select **Source**.
h. Click **OK** to add the new association.
i. Click **OK** to save the association.

7. Optional: Test the connection to the EIM domain controller.

   Use the **idsldapsearch** command to test the connection to the EIM domain controller. For example, if the LDAP server is located on the `my_server` host, the EIM domain name is `My_EIM_Domain`, and the source user registry is `WAS Registry`, the steps to test the connection are as follows:

   a. Log on to the iSeries server that hosts your WebSphere Application Server profile.
   b. From a CL command line, specify `QSH` and press Enter.
   c. Specify the following command and press Enter:
