```
idsldapsearch -h my_server -p 389 -D cn=administrator
-w secret -b "ibm-eimDomainName=My_EIM_Domain"
"ibm-eimRegistryName=WAS_Registry"
```

   where:

   - *my_server* is the name of the host server of the LDAP server.
   - `389` is the port that is used by the LDAP server.
   - `cn=administrator` is the LDAP DN of the LDAP administrator.
   - `secret` is the LDAP administrator password.
   - `ibm-eimDomainName=My_EIM_Domain` is the LDAP DN of the EIM domain name entry.

   The previous lines display as multiple lines for illustrative purposes only. Specify the command as one continuous line.

   In this example, no EIM domain parent name exists. If an EIM domain parent name did exist, such as dc=myserver,dc=ibm,dc=com, the LDAP DN is `ibm-eimDomainName=My_EIM_Domain,dc=myserver,dc=ibm,dc=com`.

Results

The expected output looks similar to the following example:

```
ibm-eimRegistryName=WAS Registry,cn=Registries,ibm-eimdomainname=My_EIM_Domain
   objectclass=top
   objectclass=ibm-eimRegistry
   objectclass=ibm-eimSystemRegistry
   ibm-eimRegistryName=WAS_Registry
   ibm-eimRegistryType=1.3.18.0.2.33.9-caseIgnore
   description=Example Registry for WebSphere Application Server
```

What to do next

Configure the EIM identity token connection factory. See “Configuring the Enterprise Identity Mapping identity token connection factory.”

Configuring the Enterprise Identity Mapping identity token connection factory:

The Enterprise Identity Mapping (EIM) identity token connection factory requires the `eim.jar` file to be located in the class path for the connection factory. The `jt400.jar` file must be in the class path for the sample application.

About this task

Perform the following steps to configure the `eim.jar` and `jt400.jar` files:

Procedure

1. “Configuring the eim.jar and jt400.jar files” on page 1494
2. “Configuring a shared library for the jt400.jar file” on page 1495

Enterprise Identity Mapping identity token connection factory parameters:

The following table is a summary of the parameters or custom properties that are referenced by the Enterprise Identity Mapping (EIM) identity token connection factory. These parameters are necessary when you configure the EIM identity token connection factory.

Table 98. Parameters and custom properties referenced by EIMidentity token connection factory.

This table lists the parameters and custom properties referenced by EIMidentity token connection factory.

Parameter description	Parameter example	Required	Initially set by	Referenced by
LDAP administrator ID and password	`cn=administrator`	Yes	LDAP administrator using the iSeries Navigator when configuring LDAP	J2C Authentication Data entry
LDAP host name and port	`mysystem.com and 389`	Yes	LDAP administrator using the iSeries Navigator	LdapHostName and LdapHostPort identity token resource adaptor properties
EIM domain name and parent domain	`EIM` and `dc=mysystem,dc=com`	Yes	EIM administrator using the iSeries Navigator when configuring EIM	EimDomainName and ParentDomain identity token resource adaptor properties
sourceRegistryName	`LDAP`	Yes	EIM administrator using the iSeries Navigator when configuring EIM user registries that are used by applications	sourceRegistryName identity token resource adaptor property
Key time out and size	`1200` and `512`	No	WebSphere Application Server administrator using the administrative console	KeyTimeoutSeconds and KeySize identity token resource adaptor properties
UseSSL	`false`	No	WebSphere Application Server administrator using the administrative console	UseSSL identity token resource adaptor property
TrustStoreName	`profile_root/etc/idtokTrustFile.jks`	No	WebSphere Application Server administrator using the administrative console	TrustStoreName identity token resource adaptor property

Table 98. Parameters and custom properties referenced by EIMidentity token connection factory (continued).

This table lists the parameters and custom properties referenced by EIMidentity token connection factory.

Parameter description	Parameter example	Required	Initially set by	Referenced by
TrustStorePassword	`tspwd`	No	WebSphere Application Server administrator using the administrative console	TrustStorePassword identity token resource adaptor property
KeyStoreName	`profile_root/etc/idtokKeyFile.jks`	No	WebSphere Application Server administrator using the administrative console	KeyStoreName identity token resource adaptor property
KeyStorePassword	`kspwd`	No	WebSphere Application Server administrator using the administrative console	KeyStorePassword identity token resource adaptor property

Identity token files

After applying the required PTFs, all of the files in the table below can be found on the server where you have WebSphere Application Server installed.

Table 99. Files found after required PTFs are applied.. This table lists the files found after required PTFs are applied.

File Name	Directory
`idTokenRA.rar`	`/QIBM/ProdData/OS400/security/eim`
`testIdentityToken.ear`	`/QIBM/ProdData/OS400/security/eim`
`cfgIdToken.jacl`	`/QIBM/ProdData/OS400/security/eim`
`eim.jar`	`/QIBM/ProdData/OS400/security/eim`
`jt400.jar`	`/QIBM/ProdData/HTTP/public/jt400/lib`
`idTokenRA.JCA15.rar`	`/QIBM/ProdData/OS400/security/eim`

Configuring the eim.jar and jt400.jar files:

You can configure the EIM identity token factory by using the following procedure.

About this task

Completing the steps in this topic is the first part of configuring the EIM identity token connection factory.

Procedure

The `eim.jar` file is already configured on your iSeries server and no additional action is required.

Results

The `eim.jar` and the `jt400.jar` files are configured.

What to do next

If you copy the jt400.jar file to a different directory, you must configure a shared library for the file. For OS/400 or IBM i, JTOpen Version 4.3 or later of the jt400.jar file is already on your server. However, you still must configure a shared library for the jt400.jar file. See the “Configuring a shared library for the jt400.jar file” topic for more information.

Configuring a shared library for the jt400.jar file:

Use the WebSphere Application Server administrative console to create a shared library for the jt400.jar file.

About this task

If you copied the jt400.jar file to a different directory, completing the steps in this topic is part of configuring the Enterprise Identity Mapping (EIM) token connection factory.

Procedure

1. Create a shared library:
   a. In the WebSphere Application Server administrative console, expand **Environment**.
   b. Click **Shared Libraries**.
   c. Click to expand the **Scope** field.
   d. Select the node where you want to create the shared library.
   e. Click **Apply**.
   f. Click **New**.
   g. Specify the name of the shared library in the **Name** field.
   h. Specify the full path name of the jt400.jar file in the **Classpath** field. The default path name is /QIBM/ProdData/HTTP/public/jt400/lib/jt400.jar.
   i. Click **OK**.
2. Create an application class loader for the shared library. This step makes the jt400.jar file available to all applications that are deployed on the application server.
   a. In the WebSphere Application Server administrative console, click **Servers > Application servers > *server_name***.
   b. Under the Server Infrastructure heading, click **Java and Process Management > Class loader > New**.
   c. Keep the Class loader order default as **Classes loaded with parent class loader first** and click **OK**.
   d. Click the Class loader ID for the class loader that was created.
   e. Under Additional properties, click **Shared library references**.
   f. Click **Add**.
   g. Select the name of the shared library you created earlier.
   h. Click **OK**.
3. Grant the java.security.AllPermission permission to the jt400.jar file in the server.policy file.

   To grant the required permission to the jt400.jar file, edit the server.policy file for your WebSphere Application Server profile and add the following statement. The server.policy file is in the *profile_root*/properties directory.

   ```
   grant codeBase "file:path_name/jt400.jar" {
     permission java.security.AllPermission;
   };
   ```

   where *path_name* is the fully qualified path name of the directory that contains the jt400.jar file. The default path name is /QIBM/ProdData/HTTP/public/jt400/lib/jt400.jar.

4. Save your configuration changes.
   a. Expand **System administration** and click **Save Changes to Master Repository**.
   b. Click **Save**.

Results

The shared library for the `jt400.jar` file is configured.

What to do next

After completing these steps, continue with configuring the connection factory. See “Manually configuring the connection factory” to configure the connection factory manually, or see “Automatically configuring the connection factory” on page 1497 to use a Jacl script to automatically configure the connection factory.

Manually configuring the connection factory:

The following steps help you manually configure the connection factory.

Before you begin

Configure the `eim.jar` and `jt400.jar` files.

About this task

After you configure the `eim.jar` and `jt400.jar` files, you can choose to manually or automatically configure the connection factory. If you choose to automatically configure the connection factory, see “Automatically configuring the connection factory” on page 1497 for more information. Perform the following steps to manually configure the Java 2 Connector (J2C) authentication data, the resource adapter, and the connection factory.

Procedure

1. Configure the Java 2 Connector (J2C) authentication data.
   a. In the WebSphere Application Server administrative console, click **Security >Global security**.
   b. Under Java Authentication and Authorization Service, click **J2C Authentication data > New**
   c. Specify the values for each of the required fields. The User ID (cn=administrator for example) and Password values are those that are used by the connection factory to bind to the Lightweight Directory Access Protocol (LDAP) server that contains your Enterprise Identity Mapping (EIM) data.
   d. Click **OK**.
2. Configure the resource adapter.
   a. In the WebSphere Application Server administrative console, click **Resources > Resource adapters > Resource adapters**.
   b. Select the node where you want to install the resource adapter.
   c. Click **Apply**.
   d. Click **Install RAR**.
   e. Select **Local path** if you have a drive that is mapped to your iSeries server. Otherwise, select **Server path**.
   f. Specify the path name or browse to the path name for the `idTokenRA.JCA15.rar` RAR file.
   g. Click **Next**.
   h. Specify the name of your adapter in the Name field. For example, specify `identitytoken`.
   i. Click **OK**.
3. Configure the connection factory.

a. On the Resource Adapters panel, click the name of your newly created resource adapter.
b. Under Additional Properties, click **J2C connection factories > New**.
c. Specify the name of your connection factory in the Name field. For example, specify `idtokenconnection`.
d. Specify `eis/IdentityToken` in the Java Naming and Directory Interface (JNDI) name field. This name must match the JNDI name used during the deployment of the sample application. The name is used for reference binding.
e. In the Component-managed authentication alias and Container-managed authentication alias fields, select the authentication data alias that you created earlier.
f. In the Mapping-configuration alias field, select **DefaultPrincipalMapping**.
g. Click **Apply**.
h. Under Additional Properties, click **Custom properties**. The custom properties are used by the connection factory to communicate with the EIM controller. View the custom property descriptions, and determine whether the properties are required or optional. For more information, see "Enterprise Identity Mapping identity token connection factory parameters" on page 1493.

   To set a property value, complete the following steps:

   1) Click the name of the custom property.
   2) Type the value of the property in the Value field.
   3) Click **OK**.

4. Save your configuration changes.
   a. Expand **System administration** and click **Save Changes to Master Repository**.
   b. Click **Save**.

Results

You have manually configured the connection factory.

What to do next

After saving your configuration changes, you can deploy the EIM sample application into the WebSphere Application Server environment. The source code files that are used in the sample application can be used as a model for creating your own applications. See "Deploying the Enterprise Identity Mapping sample application" on page 1498 for more information.

Automatically configuring the connection factory:

You can use the `cfgIdToken.jacl` script to automatically configure the Java 2 Connector (J2C) authentication data, the resource adapter, and the connection factory.

Before you begin

Configure the `eim.jar` and `jt400.jar` files.

About this task

After you configure the `eim.jar` and the `jt400.jar` files, you can choose to manually or automatically configure the connection factory. If you choose to manually configure the connection factory, see "Manually configuring the connection factory" on page 1496 for more information.

Perform the following steps to create a connection factory named CF1 in the `my_profile` WebSphere Application Server profile:

Procedure

1. Verify that your application server is started.
2. On the CL command line, enter `QSH`. This command starts the Qshell environment.
3. Change to the *app_server_root*`/bin` directory and specify the following command:

```
wsadmin -profileName my_profile -f /QIBM/ProdData/OS400/security/eim/cfgIdToken.jacl
  CF1 sys1.ibm.com 389 "Eim Domain 1"  "Registry For my_profile"
  -rarFile /QIBM/ProdData/OS400/security/eim/idTokenRA.JCA15.rar  -authAlias myAlias1
  -authUserName cn=administrator -authPassword pwd1
```

   Note: The `/QIBM/ProdData/OS400/security/eim` directory contains two resource adapter archive files, `idTokenRA.rar` and `idTokenRA.JCA15.rar`. The resource adapter contained in `idTokenRA.rar` is implemented to the Java EE Connector Architecture (JCA) 1.0 specification, while the adapter in `idTokenRA.JCA15.rar` is implemented to the JCA 1.5 specification. The JCA 1.5 specification is included in the Java EE 1.4 specification.

   where:

   - *my_profile* is the name of the WebSphere Application Server profile.
   - `/QIBM/ProdData/OS400/security/eim/cfgIdToken.jacl` is the path name to the `cfgIdToken.jacl` script.
   - `CF1` is the name of the connection factory.
   - *sys1.ibm.com* is the Lightweight Directory Access Protocol (LDAP) server host name for the Enterprise Identity Mapping (EIM) domain controller.
   - `389` is the LDAP server port.
   - *Eim Domain 1* is the EIM domain name.
   - *Registry For my_profile* is the EIM source user registry.
   - `/QIBM/ProdData/OS400/security/eim/idTokenRA.JCA15.rar` is the path name to the `idTokenRA.JCA15.rar` file.
   - *myAlias1* is the authentication alias name that is referenced by the connection factory when it authenticates to the EIM domain controller (LDAP server).
   - `cn=administrator` is the distinguished name that is associated with the authentication alias.
   - `pwd1` is the password that is associated with the authentication alias.

   Notes®:

   - The previous sample displays on multiple lines for illustrative purposes only. Type the command on one continuous line.
   - Quote all argument values that contain embedded blanks.

Results

You have automatically configured the connection factory.

What to do next

After performing the previous steps, you can deploy the EIM sample application into the WebSphere Application Server environment. The source code files that are used in the sample application can be used as a model for creating your own applications. See “Deploying the Enterprise Identity Mapping sample application” for more information.

Deploying the Enterprise Identity Mapping sample application:

You can deploy the sample application into the WebSphere Application Server environment.

Before you begin

Using Enterprise Identity Mapping (EIM) identity token connection factories requires that WebSphere Application Server administrative security be enabled. However, no restrictions or limitations exist on how you choose to configure administrative security.

Before you deploy the sample application, you must enable WebSphere Application Server administrative security. This step is not required if you already have administrative security enabled for your WebSphere Application Server profile. For more information on how to configure security, see “Enabling security” on page 1172.

About this task

The source code files that are used to implement the sample application are contained in the `testIdentityToken.ear` file and can be used as a model for creating your own applications.

The com.ibm.identitytoken.IdentityTokenTest class is a servlet in the sample application. After the application is deployed, the source code file for the IdentityTokenTest servlet is in this directory:

profile_root/installedApps/testIdentityToken.ear/testIdentityTokenWeb.war
/WEB-INF/source/com/ibm/identityToken/IdentityTokenTest.java

Note the IdentityTokenTest servlet design features when you implement your own application.

- A profile variable with a String type and the name, sourceApplicationID, is set in the init method of the IdentityTokenTest servlet. This variable is later used with the setSourceApplicationID method of a ConnectionSpecImpl object to uniquely identify the application to Enterprise Identity Mapping (EIM). When you implement your own applications, use a similar convention to assign a unique SourceApplicationID ID.
- After an identity token is generated, it is used to create a com.ibm.as400.access.AS400 object, which is stored in an HTTPSession object immediately after the AS400 object is used to run the OS/400 server command on the selected host server. Only the AS400 object persists across requests to the server (not the IdentityToken object), which provides improved performance for subsequent requests, and the identity token does not expire.

The following steps help you deploy the sample application into the WebSphere Application Server environment.

Procedure

1. Restart your application server.
2. Deploy the sample application.
   a. In the WebSphere Application Server administrative console, click **Applications > Install applications**.
   b. Select **Local path** if you have a drive mapped to your iSeries server. Otherwise, select **Server path**.
   c. Specify the path name or browse to the path name for the `testidentitytoken.ear` enterprise archive (EAR) file. This file is found in the `/QIBM/ProdData/OS400/security/eim/` directory on your server.
   d. Click **Next**.
   e. Optional: Change the virtual host values.
   f. Click **Next**.
   g. Select your installation options, and click **Next**.
   h. Decide whether to map modules to servers and click **Next**.
   i. Select your module in the Map resource references to resources panel and click **Next**.

j. Optional: Change the Java Naming and Directory Interface (JNDI) name for the `eis/IdentityToken_Shared_Reference` reference binding . Do this step if you configured your connection factory with a JNDI name other than `eis/IdentityToken`.

k. Accept the default values for the remainder of the panels and click **Next**.

l. On the Summary panel, click **Finish**.

m. Expand **System administration** and click **Save Changes to Master Repository**.

n. Click **Save**.

3. Run the sample application.

a. In the WebSphere Application Server administrative console, click **Applications > Enterprise applications**.

b. Select the **testIdentityToken** application.

c. Click **Start**.

d. Open a new session of your web browser.

e. If you mapped the sample application web module to an external web server, refresh your WebSphere Application Server web server plug-in.

To refresh the web server plug-in, perform the following steps:

1) Click **Servers > Web servers > *Web_server_name***.

2) Click **Generate Plug-in**.

f. Specify the application welcome page from your web browser. Use the following web address:

```
http://your.server.name:port/testIdentityTokenWeb/IDTknTest.jsp
```

The *your.server.name* and *port* variables are the values for your external web server or internal HTTP transport (WebSphere Application Server container).

g. Specify a value for OS/400 host system name and for OS/400 command. For example, if you have EIM configured for the my_server server, specify `my_server` in the **OS/400 host system name** field. Specify `crtlib my_library` in the **OS/400 command** field.

h. Click **Submit**.

i. Specify a user ID and password at the login prompt.

After you click **Submit**, the request is sent to the IdentityTokenTest servlet, which is protected by the allUsers role. The allUsers role is bound to the AllAuthenticated special subject so any user in the WebSphere Application Server user registry is authorized to access the IdentityTokenTest servlet.

j. Click **OK**. If you specified `my_library`, the response is similar to the following example:

```
Library my_library created.
```

k. Verify that the library is created under the user profile that is mapped by EIM:

1) From a CL command line, enter `wrklnk '/QSYS.LIB/my_library.lib'`.

2) On the Work with Object Links screen, enter `8` in the option field to the left of `my_library.lib`.

3) Verify that the value of the Owner attribute for the `my_library` library is the user profile that is mapped by EIM.

Configuring single sign-on capability with Tivoli Access Manager or WebSEAL

Use the following information to enable single sign-on to WebSphere Application Server using either WebSEAL or the plug-in for web servers.

About this task

Either Tivoli Access Manager WebSEAL or Tivoli Access Manager plug-in for web servers can be used as reverse proxy servers to provide access management and single sign-on (SSO) capability to WebSphere Application Server resources. With such an architecture, either WebSEAL or the plug-in authenticates users and forwards the collected credentials to WebSphere Application Server in the form of an IV Header. Two types of single sign-on are available, the TAI interface and the TAI++ interface, so named as both use

WebSphere Application Server trust association interceptors (TAI). With the TAI, the end-user name is extracted from the HTTP header and forwarded to embedded Tivoli Access Manager where the end-user name is used to construct the client credential information and authorize the user. With the TAI++, all of the user credential information is available in the HTTP header and not just the user name. The TAI++ is the more efficient of the two solutions because a Lightweight Directory Access Protocol (LDAP) call is not required. TAI functionality is retained for backwards compatibility.

Complete the following tasks to enable single sign-on to WebSphere Application Server using either WebSEAL or the plug-in for web servers. These tasks assume that embedded Tivoli Access Manager is configured for use.

Procedure

1. Create a trusted user account for Tivoli Access Manager in the shared Lightweight Directory Access Protocol (LDAP) user registry. For more information, see “Creating a trusted user account in Tivoli Access Manager” on page 1507.
2. Configure either WebSEAL or the Tivoli Access Manager plug-in for Web servers to work with WebSphere Application Server. For more information, see either of the following articles:
   - “Configuring WebSEAL for use with WebSphere Application Server” on page 1507
   - “Configuring Tivoli Access Manager plug-in for web servers for use with WebSphere Application Server” on page 1508
3. Configure single sign-on using either the TAI or TAI++ interface. For more information, see either of the following articles:
   - “Configuring single sign-on using trust association” on page 1509
   - “Configuring single sign-on using trust association interceptor ++” on page 1510

Single sign-on settings:

Use this page to set the configuration values for single sign-on (SSO).

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. Under Authentication, click **Web and SIP security > Single sign-on (SSO)**.

Note: The Set security cookies as HTTPOnly to resist cross-site scripting attacks check box has been added to the Single sign-on settings page for this release. The HttpOnly attribute is a browser attribute created to prevent client side applications (such as Java scripts) from accessing cookies to prevent some cross-site scripting vulnerabilities. The attribute specifies that LTPA and WASReqURL cookies include the HTTPOnly field.

Enabled:

Specifies that the single sign-on function is enabled.

Web applications that use J2EE FormLogin style login pages, such as the administrative console, require single sign-on (SSO) enablement. Only disable SSO for certain advanced configurations where LTPA SSO-type cookies are not required.

Data type:	Boolean
Default:	Enabled
Range:	Enabled or Disabled

Requires SSL:

Specifies that the single sign-on function is enabled only when requests are made over HTTPS Secure Sockets Layer (SSL) connections.

Data type: Boolean
Default: Disable
Range: Enable or Disable

Domain name:

Specifies the domain name (.ibm.com, for example) for all single sign-on hosts.

The application server uses all the information after the first period, from left to right, for the domain names. If this field is not defined, the web browser defaults the domain name to the host name where the web application is running. Also, single sign-on is then restricted to the application server host name and does not work with other application server host names in the domain.

You can specify multiple domains separated by a semicolon (;), a space ( ), a comma (,), or a pipe (|). Each domain is compared with the host name of the HTTP request until the first match is located. For example, if you specify ibm.com;austin.ibm.com and a match is found in the ibm.com domain first, the application server does not match the austin.ibm.com domain. However, if a match is not found in either ibm.com or austin.ibm.com, then the application server does not set a domain for the LtpaToken cookie.

If you specify the `UseDomainFromURL` value, the application server sets the SSO domain name value to the domain of the host that is used in the web address. For example, if an HTTP request comes from `server1.raleigh.ibm.com`, the application server sets the SSO domain name value to `raleigh.ibm.com`.

Tip: The UseDomainFromURL value is case insensitive. You can type `usedomainfromurl` to use this value.

Data type: String

Interoperability mode:

Specifies that an interoperable cookie is sent to the browser to support back-level servers.

In WebSphere Application Server, Version 6 and later, a new cookie format is needed by the security attribute propagation functionality. When the interoperability mode flag is enabled, the server can send a maximum of two single sign-on (SSO) cookies back to the browser. In some cases, the server just sends the interoperable SSO cookie.

Web inbound security attribute propagation:

When web inbound security attribute propagation is enabled, security attributes are propagated to front-end application servers. When this option is disabled, the single sign-on (SSO) token is used to log in and recreate the Subject from the user registry.

With this information, the receiving server can contact the originating server using an MBean call to get the original serialized security attributes.

Set security cookies as HTTPOnly to resist cross-site scripting attacks:

The HttpOnly attribute is a browser attribute created to prevent client side applications (such as Java scripts) from accessing cookies to prevent some cross-site scripting vulnerabilities. The attribute specifies that LTPA and WASReqURL cookies include the HTTPOnly field.

For session cookies, see the session settings for servers, applications, and web modules.

Data type:	boolean
Default:	enabled
Range:	enabled or disabled

com.tivoli.pd.jcfg.PDJrteCfg utility for Tivoli Access Manager single sign-on:

The com.tivoli.pd.jcfg.PDJrteCfg utility configures the Java Runtime Environment component for Tivoli Access Manager. This utility enables Java applications to use the Tivoli Access Manager policy and authorization servers.

Purpose

Steps

To run the pdjrtecfg script, perform the following steps:

1. Log into your system with a user profile and the all object (*ALLOBJ) authority.
2. On the command line, enter the Start Qshell (STRQSH) command.
3. Change to the `/bin` subdirectory of WebSphere Application Server. For example:

   `cd` *`app_server_root`*`Base/bin`
4. Run the script. For example:

```
 pdjrtecfg -action config -profileName myprofile
-host mypolicy.mycompany.com -config_type full
```

   The previous example was split onto multiple lines for illustrative purposes only.

Syntax

The following syntax diagram shows the usage of the pdjrtecfg script:

```
pdjrtecfg
    -action config
          -profileName profile_name
          -host policy_server_name
          -config_type { full | standalone }
          -cfgfiles_path configuration_file_path
    -action unconfig
          -profileName profile_name
```

Parameters

`-action {config|unconfig}`
Specifies the action to be performed. Actions include:

config Use to configure the Access Manager Java Runtime Environment component.

unconfig
Use to reconfigure the Access Manager Java Runtime Environment component.

`-cfgfiles_path`
Specifies where the generated configuration files will be placed.

Note: This parameter is required.

`-config_type {full|standalone}`
Specifies the configuration type of Java Runtime Environment for Tivoli Access Manager. Specify `full` or `standalone` with this argument. This option is required.

`-host` *`policy_server_host`*
Specifies the policy server host name.

Valid values for *policy_server_host* include any valid IP host name.

Examples include:

```
host = libra
host = libra.dallas.ibm.com
```

Notifies Tivoli Access Manager Runtime for Java that the WebSphere Application Server version is being configured so it is not necessary to perform certain steps such as copying the Java security jar files and PD.jar file since they were already placed in the appropriate directory by the WebSphere Application Server installer.

-profileName
Specifies the name of the WebSphere Application Server profile. If not specified, the default profile is used.

Specifies the fully qualified path to the Java runtime (such as the directory ending in jre). If this parameter is not specified, the home directory for the jre in the PATH statement is used. If the home directory for the jre is not in the PATH statement, this utility can create an incorrect parameter in the output files.

Comments

This command copies Tivoli Access Manager Java libraries to a library extensions directory that exists for a Java runtime that has already been installed on the system.

You can install more than one Java Runtime Environment (JRE) on a given machine. The `pdjrtecfg` command can be used to configure the Tivoli Access Manager Java Runtime Environment component independently for each of the JRE configurations.

com.tivoli.pd.jcfg.SvrSslCfg utility for Tivoli Access Manager single sign-on:

The utility is used to configure and remove the configuration information associated with WebSphere Application Server and the Tivoli Access Manager server.

Purpose

The svrsslcfg script creates a user account and server entries that represent your WebSphere Application Server profile in the Tivoli Access Manager user registry. In addition, a configuration file and a Java keystore file, which securely stores a client certificate, are created in the application server profile. This client certificate permits callers to use Tivoli Access Manager authentication services. You can also choose to remove the user and server entries from the user registry and clean up the local configuration and keystore files.

The svrsslcfg script wraps the SvrSslCfg class and provides support for multiple WebSphere Application Server profiles. The use of multiple profiles allows you to create multiple WebSphere Application Server environments that are completely isolated from one another.

Steps

To run the svrsslcfg script, perform the following steps:

1. Log on with a user profile and all object (*ALLOBJ) authority.
2. On the CL command line, enter the `Start Qshell (STRQSH)` command.
3. Change directories to the *app_server_root*`/bin` directory.
4. Enter the svrsslcfg command with the options that you want.

   For example:

```
svrsslcfg -profileName myprofile -action config -admin_id sec_master
  -admin_pwd pwd123 -appsvr_id ibm9 -appsvr_pwd ibm9pwd -mode remote
  -port 8888 -policysvr ourserv.rochester.ibm.com:7135:1
  -authzsvr ourserv.rochester.ibm.com:7136:1
  -key_file profile_root/myprofile/etc/ibm9.kdb
  -cfg_action create
```

The previous example displays on multiple lines for illustrative purposes only.

Syntax

The configuration syntax is:

```
svrsslcfg -action config
          [ -profileName profile_name ]
            -admin_id admin_user_id
            -admin_pwd admin_password
            -appsvr_id application_server_name
            -port port_number
            -mode { local | remote }
            -policysvr policy_server_name
            -authzsvr authorization_server_name
            -key_file fully_qualified_name_of_key_file
            -appsvr_pwd application_server_password
            -cfg_action { create | replace }
          [ -domain Tivoli_Access_Manager_domain ]
```

The unconfigure syntax is:

```
svrsslcfg -action unconfig
          [ -profileName profile_name ]
            -admin_id admin_user_id
            -admin_pwd admin_password
            -appsvr_id application_server_name
            -policysvr policy_server_name
          [ -domain Tivoli_Access_Manager_domain ]
```

You can enter the previous syntax as one continuous line.

Parameters

-action {config | unconfig}
Specifies the configuration action that is performed by the script. The following options apply:

-action config
Configuring a server creates user and server information in the user registry and creates local configuration and key store files on the application server. Use the `-action unconfig` option to reverse this operation.

If this action is specified, the following options are required: `-admin_id`, `-admin_pwd`, `-appsvr_id`, `-port`, `-mode`, `-policysvr`, `-authzsvr`, and `-key_file`.

-action unconfig
Reconfigures an application server to complete the following actions:

- Remove the user and server information from the user registry
- Delete the local key store file
- Remove information for this application from the configuration file without deleting the file

The reconfiguration operation fails only if the caller is unauthorized or the policy server cannot be contacted.

This action can succeed when a configuration file does not exist. When the configuration file does not exist, it is created and used as a temporary file to hold configuration information during the operation, and then the file is deleted completely.

If this action is specified, the following options are required: `-admin_id`, `-admin_pwd`, `-appsvr_id`, and `-policysvr`.

-admin_id *admin_user_ID*
Specifies the Tivoli Access Manager administrator name. If this option is not specified, `sec_master` is the default.

A valid administrative ID is an alphanumeric, case-sensitive string. String values are expected to be characters that are part of the local code set. You cannot use a space in the administrative ID.

For example, for U.S. English the valid characters are the letters a-Z, the numbers 0-9, a period (.), an underscore (_), a plus sign (+), a hyphen (-), an at sign (@), an ampersand (&), and an asterisk (*). The minimum and maximum lengths of the administrative ID, if there are limits, are imposed by the underlying registry.

-admin_password *admin_password*

Specifies the password of the Tivoli Access Manager administrator user that is associated with the **-admin_id** parameter. The password restrictions depend upon the password policy for your Tivoli Access Manager configuration.

-appsvr_id *application_server_name*
Specifies the name of the application server. The name is combined with the host name to create unique names for Tivoli Access Manager objects created for your application. The following names are reserved for Tivoli Access Manager applications: ivacld, secmgrd, ivnet, and ivweb.

-appsvr_pwd *application_server_password*
Specifies the password of the application server. This option is required. A password is created by the system and the configuration file is updated with the password created by the system.

If this option is not specified, the server password will be read from standard input.

-authzsvr *authorization_server_name*
Specifies the name of the Tivoli Access Manager authorization server with which the application server communicates. The server is specified by fully qualified host name, the SSL port number, and the rank. The default SSL port number is 7136. For example: myauth.mycompany.com:7136:1. You can specify multiple servers if the entries are separated by a comma (,).

-cfg_action {create | replace}
Specifies the action to take when creating the configuration and key files. Valid values are **create** or **replace**. Use the **create** option to initially create the configuration and keystore files. Use the **replace** option if these files already exist. If you use the **create** option and the configuration or keystore files already exist, an exception is created.

Options are as follows:

create Specifies to create the configuration and key store files during server configuration. Configuration fails if either of these files already exists.

replace
Specifies to replace the configuration and key store files during server configuration. Configuration deletes any existing files and replaces them with new ones.

-domain *Tivoli_Access_Manager_domain*
Specifies the Tivoli Access Manager domain name to which the administrator is authenticated. This domain must exist and an the administrator ID and password must be valid for this domain. The application server is specified in this domain.

If not specified, the local domain that was specified during Tivoli Access Manager runtime configuration will be used. The local domain value will be retrieved from the configuration file.

A valid domain name is an alphanumeric, case-sensitive string. String values are expected to be characters that are part of the local code set. You cannot use a space in the domain name.

For example, for U.S. English the valid characters for domain names are the letters a-Z, the numbers 0-9, a period (.), an underscore (_), a plus sign (+), a hyphen (-), an at sign (@), an ampersand (&), and an asterisk (*). The minimum and maximum lengths of the domain name, if there are limits, are imposed by the underlying registry.

-key_file *fully_qualified_name_of_keystore_file*
Specifies the directory that is to contain the key files for the server. A valid directory name is determined by the operating system. Use a fully qualified file name that contains the application server certificate and key file.

Make sure that server user (for example, `ivmgr`) or all users have permission to access the `.kdb` file and the folder that contains the `.kdb` file.

This option is required.

-mode *server_mode*
Specifies the mode in which the application server processes requests. Only the `remote` mode is supported.

-policysvr *policy_server_name*
Specifies the names of servers that run the Tivoli Access Manager policy server (ivmgrd) with which the application server communicates. A server is specified by a fully qualified host name, the SSL port number, and the rank. The default SSL port number is 7135. For example: `mypolicy.mycompany.com:7135:1`. You can specify multiple servers if the entries are separated by a comma (,).

-port *port_number*
Specifies the TCP/IP communications port on which the application server listens for communications from the policy servers.

-profileName *profile_name*
Specifies the name of your WebSphere Application Server profile. If this option is not specified, the default `server1` profile is used.

Creating a trusted user account in Tivoli Access Manager:

Tivoli Access Manager trust association interceptors require the creation of a trusted user account in the shared LDAP user registry.

About this task

This account includes the ID and password that WebSEAL uses to identify itself to WebSphere Application Server. To prevent potential vulnerabilities, do not use the sec_master ID as the trusted user account and ensure that the password you use is unique and generated randomly. Use the trusted user account for the TAI or TAI++ only.

Procedure

1. Use either the Tivoli Access Manager pdadmin command-line utility or Web Portal Manager to create the trusted user. For example, from the **pdadmin** command line.
2. Reference the code listed below as an example for creating a trusted user account.
3. Reference the following additional resources for more information:
   a. “Configuring WebSEAL for use with WebSphere Application Server”
   b. “Configuring Tivoli Access Manager plug-in for web servers for use with WebSphere Application Server” on page 1508

Example

```
pdadmin> user create webseal_userid webseal_userid_DN firstname
         surname password

pdadmin> user modify webseal_userid account-valid yes
```

Configuring WebSEAL for use with WebSphere Application Server:

Use this topic to set the SSO password in WebSEAL for single sign-on to WebSphere Application Server.

About this task

A junction must be created between WebSEAL and WebSphere Application Server. This junction carries the iv-credentials (for TAI++) or iv-user (for TAI) and the HTTP basic authentication headers with the request. You can configure WebSEAL to pass the end user identity in other ways, the iv-credentials header is the only one supported by the TAI++ and the iv-user is the only one supported by TAI.

Communications over the junction should use Secure Sockets Layer (SSL) for increased security. Setting up SSL across this junction requires that you configure the HTTP Server used by WebSphere Application Server, and WebSphere Application Server itself, to accept inbound SSL traffic and route it correctly to WebSphere Application Server. This activity requires importing the necessary signing certificates into the WebSEAL certificate keystore, and possibly also the HTTP Server certificate keystore.

Create the junction between WebSEAL and WebSphere Application Server using the **-c iv_creds** option for TAI++ and **-c iv_user** for TAI. Enter either of the following commands as one line using the variables that are appropriate for your environment:

TAI++

```
server task webseald-server create -t ssl -b supply -c iv_creds
 -h host_name -p websphere_app_port_number junction_name
```

TAI

```
server task webseald-server create -t ssl -b supply -c iv_user
 -h host_name -p websphere_app_port_number junction_name
```

Notes:

1. If warning messages are displayed about the incorrect setup of certificates and key databases, delete the junction, correct problems with the key databases, and recreate the junction.
2. The junction can be created as `-t tcp` or `-t ssl`, depending on your requirements.

For single sign-on (SSO) to WebSphere Application Server the SS) password must be set in WebSEAL. To set the password, complete the following steps:

Procedure

1. Edit the WebSEAL configuration file *webseal_install_directory*`/etc/webseald-default.conf` Set the following parameter: `basicauth-dummy-passwd=`*webseal_userid_passwd*

   where *webseal_userid_passwd* is the SSO password for the trusted user account set in “Creating a trusted user account in Tivoli Access Manager” on page 1507.
2. Restart WebSEAL.

What to do next

For more details and options about how to configure junctions between WebSEAL and WebSphere Application Server, including other options for specifying the WebSEAL server identity, refer to the *Tivoli Access Manager WebSEAL Administration Guide* as well as to the documentation for the HTTP Server you are using with your WebSphere Application Server. Tivoli Access Manager documentation is available at http://publib.boulder.ibm.com/tividd/td/tdprodlist.html.

Configuring Tivoli Access Manager plug-in for web servers for use with WebSphere Application Server:

Tivoli Access Manager plug-in for web servers can be used as a security gateway for your protected WebSphere Application Server resources.

About this task

With such an arrangement the plug-in authorizes all user requests before passing the credentials of the authorized user to WebSphere Application Server in the form of an iv-creds header. Trust between the plug-in and WebSphere Application Server is established through use of basic authentication headers containing the single sign-on (SSO) user password.

Procedure

1. The Tivoli Access Manager plug-in for web servers configuration shows IV headers configured for post-authorization processing, and basic authentication that is configured as the authentication mechanism and for post-authorization processing, as shown in the example below.
2. After a request is authorized, the basic authentication header is removed from the request (`strip-hdr=always`) and a new one is added (`add-hdr=supply`).
3. Included in this new header is the password that is set when the SSO user is created in "Creating a trusted user account in Tivoli Access Manager" on page 1507.
4. Specify this password in the **supply-password** parameter and it is passed in the newly created header. This basic authentication header enables trust between WebSphere Application Server and the plug-in.
5. An iv-creds header is also added (`generate=iv-creds`), which contains the credential information of the user passed onto WebSphere Application Server. Session cookies are used to maintain session state.

Example

```
[common-modules]
authentication = BA
session = session-cookie
post-authzn = BA
post-authzn = iv-headers

[iv-headers]
accept = all
generate = iv-creds

[BA]
strip-hdr = always
add-hdr = supply
supply-password = sso_user_password
```

What to do next

"Configuring single sign-on using trust association" or "Configuring single sign-on using trust association interceptor ++" on page 1510

Configuring single sign-on using trust association:

This task is performed to enable single sign-on using trust association. Trust association is used to connect reversed proxy servers to the application server.

Before you begin

Note: Use of TAIs for Simple and Protected GSS-API Negotiation Mechanism (SPNEGO) authentication is deprecated in this release. The SPNEGO web authentication panels provide a much easier and less error-prone way to configure SPNEGO.

To establish the trust association for the single sign-on, perform the following steps:

Procedure

1. From the administrative console for WebSphere Application Server, click **Security > Global security**.
2. From Authentication mechanisms, click **Web and SIP security > Trust association**.
3. Select the **Enable trust association** option.

4. Under Additional properties, click the **Interceptors** link.
5. Click **com.ibm.ws.security.web.TAMTrustAssociationInterceptorPlus** to use a WebSEAL interceptor, or **com.ibm.ws.security.spnego.TrustAssociationInterceptorImpl** to use a SPNEGO interceptor.
6. Under Custom properties, select a custom property to edit or click **New** to create a new one. Enter the property name and value pairs.
7. Click **OK**.
8. Save the configuration and log out.
9. Restart WebSphere Application Server.

Configuring single sign-on using trust association interceptor ++:

Perform this task to enable single sign-on using trust association interceptor ++. The steps involve setting up trust association and creating the interceptor properties.

Before you begin

Lightweight Third Party Authentication (LTPA) is the default authentication mechanism for WebSphere Application Server. However, you may need to configure LTPA prior to configuring the TAMTrustAssociationInterceptorPlus. LTPA is the required authentication mechanism for all trust association interceptors. You can configure LTPA by clicking **Security > Global security > Authentication mechanisms and expiration**.

Note: Enabling web security single sign-on (SSO) is optional when you configure the TAMTrustAssociationInterceptorPlus. For more information, see “Implementing single sign-on to minimize web user authentications” on page 1441.

Although you can use Simple WebSphere Authentication Mechanism (SWAM) by selecting the **Use SWAM-no authenticated communication between servers** option on the Authentication mechanisms and expiration panel, single sign-on (SSO) requires LTPA as the configured authentication mechanism.

To establish the trust association for the single sign-on, perform the following steps:

Procedure

1. From the administrative console for WebSphere Application Server, click **Security > Global security**.
2. Under Web security, click **Trust association**.
3. Click **Enable Trust Association**.
4. Click **Interceptors**.
5. Click **com.ibm.ws.security.web.TAMTrustAssociationInterceptorPlus** to use a WebSEAL interceptor. This interceptor is one of two WebSEAL interceptors that are supplied for your use. You choose to use this interceptor by supplying properties as described in the next step.

   Attention: WebSphere Application Server attempts to initialize both of these interceptors even if you only supplied properties for the **com.ibm.ws.security.web.TAMTrustAssociationInterceptorPlus** interceptor. As a result, messages AWXRB0008E and SECJ0384E can appear during initialization to indicate that the interceptor you did not choose has failed to initialize. This is normal processing and does not affect the initialization of the interceptor you did select. To inhibit the display of messages AWXRB0008E and SECJ0384E, you can delete the interceptor you do not want to use prior to beginning the initialization. You can add that interceptor back later if your environment changes.
6. Click **Custom Properties**.
7. Click **New** to enter the property name and value pairs. Ensure that the following parameters are set:

Table 100. Custom properties.

This table describes the TAI custom properties.

Option	Description
com.ibm.websphere.security.webseal.checkViaHeader	You can configure TAI so that the via header can be ignored when validating trust for a request. Set this property to *false* if none of the hosts in the via header need to be trusted. When set to *false* you do not need to set the trusted host names and host ports properties. The only mandatory property to check when via header is *false* is com.ibm.websphere.security.webseal.loginId. The default value of the check via header property is *false*. When using Tivoli Access Manager plug-in for web servers, set this property to *false*. **Note:** The via header is part of the standard HTTP header that records the server names the request that passed through.
com.ibm.websphere.security.webseal.loginId	The WebSEAL trusted user as created in "Creating a trusted user account in Tivoli Access Manager" on page 1507 The format of the username is the short name representation. This property is mandatory. If it is not set in WebSphere Application Server, the TAI initialization fails.
com.ibm.websphere.security.webseal.id	A comma-separated list of headers that exists in the request. If all of the configured headers do not exist in the request, trust cannot be established. The default value for the ID property is *iv-creds*. Any other values set in WebSphere Application Server are added to the list along with iv-creds, separated by commas.
com.ibm.websphere.security.webseal.hostnames	Do not set this property if using Tivoli Access Manager Plug-in for Web Servers. The property specifies the host names (case sensitive) that are trusted and expected in the request header. Requests arriving from un-listed hosts might not be trusted. If the checkViaHeader property is not set or is set to false then the trusted host names property has no influence. If the checkViaHeader property is set to `true`, and the trusted host names property is not set, TAI initialization fails.
com.ibm.websphere.security.webseal.ports	Do not set this property if using Tivoli Access Manager plug-in for web servers. This property is a comma-separated list of trusted host ports. Requests that arrive from unlisted ports might not be trusted. If the checkViaHeader property is not set, or is set to `false` this property has no influence. If the checkViaHeader property is set to `true`, and the trusted host ports property is not set in WebSphere Application Server, the TAI initialization fails.

com.ibm.websphere.security.webseal.viaDepth	A positive integer that specifies the number of source hosts in the via header to check for trust. By default, every host in the via header is checked, and if any host is not trusted, trust cannot be established. The via depth property is used when only some of the hosts in the via header have to be trusted. The setting indicates the number of hosts that are required to be trusted.
	
	As an example, consider the following header:
	`Via: HTTP/1.1 webseal1:7002, 1.1 webseal2:7001`
	
	If the viaDepth property is not set, is set to 2 or is set to 0, and a request with the previous via header is received then both `webseal1:7002` and `webseal2:7001` need to be trusted. The following configuration applies:
	`com.ibm.websphere.security.webseal.hostnames = webseal1,webseal2`
	`com.ibm.websphere.security.webseal.ports = 7002,7001`
	
	If the via depth property is set to 1, and the previous request is received, then only the last host in the via header needs to be trusted. The following configuration applies:
	`com.ibm.websphere.security.webseal.hostnames = webseal2`
	`com.ibm.websphere.security.webseal.ports = 7001`
	
	The viaDepth property is set to `0` by default, which means all of the hosts in the via header are checked for trust.

com.ibm.websphere.security.webseal.ssoPwdExpiry	After trust is established for a request, the single sign-on user password is cached, eliminating the need to have the TAI re-authenticate the single sign-on user with Tivoli Access Manager for every request. You can modify the cache timeout period by setting the single sign-on password expiry property to the required time in seconds. If the password expiry property is set to `0`, the cached password never expires. The default value for the password expiry property is `600`.
com.ibm.websphere.security.webseal.ignoreProxy	This property can be used to tell the TAI to ignore proxies as trusted hosts. If set to `true` the comments field of the hosts entry in the via header is checked to determine if a host is a proxy. Remember that not all proxies insert comments in the via header indicating that they are proxies. The default value of the ignoreProxy property is `false`. If the checkViaHeader property is set to `false` then the ignoreProxy property has no influence in establishing trust.
com.ibm.websphere.security.webseal.configURL	Set this property to *profile_root*`/etc/pd/PolicyDirector/PDPerm.properties`. For the TAI to establish trust for a request, it requires that a PDPerm.properties file exists in each node within the cell. Also, the correct URL of the properties file must be set in the config URL property. If this property is not set or the `PDPerm.properties` file is not in the specified location, the TAI initialization fails. The `PDPerm.properties` file is part of the Tivoli Access Manager configuration for a node. To create the Tivoli Access Manager configuration, run the **pdjrtecfg** script and then the **svrsslcfg** script for each node in the cell. The `PDPerm.properties` file is created in the*profile_root*`/etc/pd/PolicyDirector/` directory.

8. Click **OK**.

9. Save the configuration and log out.
10. Restart WebSphere Application Server.

Configuring global sign-on principal mapping:

You can create a new application login that uses the Tivoli Access Manager GSO database to store the login credentials.

Procedure

1. Click **Security > Global security**.
2. Under Authentication, click **Java Authentication and Authorization Service > Application logins**.
3. Click **New** to create a new Java Authentication and Authorization Service (JAAS) login configuration.
4. Enter the alias name of the new application login. Click **Apply**.
5. Under Additional properties, click **JAAS login modules** to define the JAAS Login Modules.
6. Click **New** and enter the following information:

   Module class name: com.tivoli.pdwas.gso.AMPrincipalMapper
   Use Login Module Proxy: enable
   Authentication strategy: REQUIRED
7. Click **Apply**
8. Under Additional Properties section, click **Custom Properties** to define login module-specific values that are passed directly to the underlying login modules.
9. Click **New**.

   The Tivoli Access Manager principal mapping module uses the `authDataAlias` configuration string to retrieve the correct user name and password from the security configuration.

   The authDataAlias attribute that is passed to the module is configured for the J2C connection factory. Because the authDataAlias attribute is an arbitrary string that is entered at configuration time, the following scenarios are possible:

   - The authDataAlias attribute contains both the global sign-on (GSO) resource name and the user name. The format of this string is `"Resource/User"`.
   - The authDataAlias attribute contains the GSO Resource name only. The user name is determined by using the Subject of the current session.

   The scenario to use is determined by a JAAS configuration option, as shown here:

   Name: com.tivoli.pd.as.gso.AliasContainsUserName

   Value: True, if the alias contains the user name; false, if the user name must be retrieved from the security context

   When entering `authDataAlias` attributes through the WebSphere Application Server administrative console, the node name is automatically pre-pended to the alias. The JAAS configuration entry determines whether this node name is removed or included as part of the resource name, as shown here:

   Name: com.tivoli.pd.as.gso.AliasContainsNodeName

   Value: True, if the alias contains the node name

   Note: If the `PdPerm.properties` configuration file is not located in the `JAVA_HOME/PdPerm.properties` default location, then you also need to add the following property:

   Name: com.tivoli.pd.as.gso.AMCfgURL

   Value: file:///*path to PdPerm.properties*

   Enter each new parameter using the following scenario information as a guide, then click **Apply**.

Scenario 1
Auth Data Alias - BackendEIS/eisUser
Resource - BackEndEIS
User - eisUser
Principal Mapping Parameters

Table 101. Principal Mapping Parameters.

This table lists the principal mapping parameters.

Name	Value
delegate	com.tivoli.pdwas.gso.AMPrincipalMapper
com.tivoli.pd.as.gso.AliasContainsUserName	true
com.tivoli.pd.as.gso.AliasContainsNodeName	false
com.tivoli.pd.as.gso.AMLoggingURL	file:///*jlog_props_path*
debug	false

Scenario 2
Auth Data Alias - BackendEIS
Resource - BackEndEIS
User - Currently authenticated WebSphere Application Server user
Principal Mapping Parameters

Table 102. Principal Mapping Parameters.

This table lists the principal mapping parameters.

Name	Value
delegate	com.tivoli.pdwas.gso.AMPrincipalMapper
com.tivoli.pd.as.gso.AliasContainsUserName	false
com.tivoli.pd.as.gso.AliasContainsNodeName	false
com.tivoli.pd.as.gso.AMLoggingURL	file:///*jlog_props_path*
debug	false

Scenario 3
Auth Data Alias - nodename/BackendEIS/eisUser
Resource - BackEndEIS
User - eisUser
Principal Mapping Parameters

Table 103. Principal Mapping Parameters.

This table lists the principal mapping parameters.

Name	Value
delegate	com.tivoli.pdwas.gso.AMPrincipalMapper
com.tivoli.pd.as.gso.AliasContainsUserName	true
com.tivoli.pd.as.gso.AliasContainsNodeName	true
com.tivoli.pd.as.gso.AMLoggingURL	file:///*jlog_props_path*
debug	false

Scenario 4
Auth Data Alias - nodename/BackendEIS/eisUser
Resource - nodename/BackEndEIS (notice that node name is not removed)
User - eisUser
Principal Mapping Parameters

Table 104. Principal Mapping Parameters.

This table lists the principal mapping parameters.

Name	Value
delegate	com.tivoli.pdwas.gso.AMPrincipalMapper
com.tivoli.pd.as.gso.AliasContainsUserName	true
com.tivoli.pd.as.gso.AliasContainsNodeName	false
com.tivoli.pd.as.gso.AMLoggingURL	file:///*jlog_props_path*
debug	false

Scenario 5
Auth Data Alias - BackendEIS/eisUser
Resource - BackEndEIS
User - eisUser
Principal Mapping Parameters

Table 105. Principal Mapping Parameters.

This table lists the principal mapping parameters.

Name	Value
delegate	com.tivoli.pdwas.gso.AMPrincipalMapper
com.tivoli.pd.as.gso.AliasContainsUserName	false
com.tivoli.pd.as.gso.AliasContainsNodeName	true
com.tivoli.pd.as.gso.AMLoggingURL	file:///*jlog_props_path*
debug	false

Scenario 6
Auth Data Alias - nodename/BackendEIS/eisUser
Resource - nodename/BackendEIS/eisUser
(notice that the resource is the same as Auth Data Alias).
User - Currently authenticated WebSphere Application Server user
Principal Mapping Parameters

Table 106. Principal Mapping Parameters.

This table lists the principal mapping parameters.

Name	Value
delegate	com.tivoli.pdwas.gso.AMPrincipalMapper
com.tivoli.pd.as.gso.AliasContainsUserName	false
com.tivoli.pd.as.gso.AliasContainsNodeName	false
com.tivoli.pd.as.gso.AMLoggingURL	file:///*jlog_props_path*
debug	false

10. Create the Java 2 Connector (J2C) authentication aliases. The user name and password that are assigned to these alias entries are irrelevant because Tivoli Access Manager is responsible for providing user names and passwords. However, the user name and password that are assigned to the J2C authentication aliases need to exist so that they can be selected for the J2C connection factory in the administrative console.

    To create the J2C authentication aliases, from the WebSphere Application Server administrative console, click **Security** >**Global security**. Under Authentication, click **Java Authentication and Authorization Service** > **J2C authentication data**, and then click **New** for each new entry. Refer to the previous table for scenario inputs.

    The connection factories for each resource adapter that need to use the GSO database must be configured to use the Tivoli Access Manager Principal mapping module:

a. From the WebSphere Application Server administrative console, click **Applications > Enterprise Applications** > *application_name* **> Resourcer references**. Note that J2C connection factories must be already configured for the selected application. To configure a new J2C connection factory, see the Configuring Java EE Connector connection factories in the administrative console article.

b. Under Additional properties, click **Resource Adapter**.

   The resource adapter can be stand-alone and does not need to be packaged with the application. The resource adapter is configured from **Resources** > **Resource Adapters** for stand-alone scenarios.

c. Under Additional properties, click **J2C Connection Factories**.

d. Click **New** and enter the connection factory properties.

e. When finished, click **Apply > Save**.

Attention:
Custom mapping configuration for the connection factory is deprecated in WebSphere Application Server Version 6. To configure the GSO credential mapping, use the Map Resource References to Resources panel on the administrative console. For more information, see the J2EE connector security article.

Configuring administrative authentication

An authentication mechanism defines rules about security information, such as whether a credential is forwardable to another Java process, and the format of how security information is stored in both credentials and tokens. The Rivest Shamir Adleman (RSA) token authentication mechanism simplifies the security environment for flexible management topology, that is, the topology where you can locally or remotely submit and manage administrative jobs through a job manager that manages applications, perform product maintenance, modify configurations, and control the application server runtime. You use the administrative console to configure administrative authentication, which involves the configuring of the Rivest Shamir Adleman (RSA) token authentication mechanism.

Before you begin

The following keystore, truststore, and rootstore descriptions give you an idea of where certificates are stored and how trust is configured between processes.

The **NodeRSATokenKeyStore** contains the Rivest Shamir Adleman (RSA) token personal certificate used for this process. Not only is the public/private key from this certificate used to create RSA tokens, but the public key is used by other processes to create tokens. The RSA personal certificate is signed by an RSA root certificate.

The **NodeRSATokenTrustStore** contains all RSA signer certificates from other processes that are trusted to send RSA tokens to this process. The signers in this trust store are placed there automatically during the registration process. However, this task allows an administrator to configure trust between to processes not normally involved in the same administrative domain. There may be requirements where two base servers are communicating administratively. When using the RSA token authentication mechanism, the base servers need to share RSA signers if administrative communications is operating in both directions.

The NodeRSATokenRootStore contains the root personal certificate that is used to create new RSA personal certificates. Do not use the root certificate to create RSA tokens because this usage compromises the long-lived keys. Only use the root certificate to sign other certificates.

No manual steps are required with these keystores, and this allows uncommon trust establishment among processes not in the same administrative domain. You can also replace the RSA personal certificate with a personal certificate obtained from a certificate authority (CA) if desired. In this case, make sure the CA root

certificate is placed in all RSA trust stores in the same administrative domain.

Procedure

1. Click **Security** > **SSL certificate and key management**.
2. Under **Related Items**, click **Key stores and certificates**.
3. Under **Keystore usages**, select **RSA token keystores**.
4. Select the RSA token key store you want to administer.
5. Modify the description if required.
6. Modify the path if required.
7. Select **read only**, **initialize at setup**, or both if required.
8. Enter the correct password to make these modifications
9. Click **Apply** and **Save**.

Results

You configured administrative authentication.

What to do next

In cases where the process is back-level or a target RSA certificate cannot be obtained, the fallback mechanism is Lightweight Third-Party Authentication (LTPA) which is supported in all previous releases for administrative communications. The fallback occurs automatically. If the LTPA keys are not shared and a fallback occurs, LTPA will fail as well. However, this situation is typically an error case in the RSA mechanism and should occur infrequently.

Java Authentication and Authorization Service

The standard Java 2 security application programming interface (API) helps enforce access control based on the location of the code source or the author or packager of the code that signed the jar file. The current principal of the running thread is not considered in the Java 2 security authorization. Instances where authorization is based on the principal, as opposed to the code base, and the user exist. The Java Authentication and Authorization Service is a standard Java API that supports the Java 2 security authorization to extend the code base on the principal as well as the code base and users.

The Java Authentication and Authorization Service (JAAS) Version 1.0 extends the Java 2 security architecture of the Java 2 platform with additional support to authenticate and enforce access control with principals and users. JAAS implements a Java version of the standard Pluggable Authentication Module (PAM) framework, and extends the access control architecture of the Java 2 platform in a compatible fashion to support user-based authorization or principal-based authorization. WebSphere Application Server fully supports the JAAS architecture. JAAS extends the access control architecture to support role-based authorization for Java Platform, Enterprise Edition (Java EE) resources including servlets, JavaServer Pages (JSP) files, and Enterprise JavaBeans (EJB) components.

Refer to “Java 2 security” on page 1176 for more information.

The following sections cover the JAAS implementation and programming model:
- Login configuration for Java Authentication and Authorization Service
- Programmatic login for JAAS
- “Java Authentication and Authorization Service authorization” on page 1517

The JAAS documentation can be found at http://www.ibm.com/developerworks/java/jdk/security. Scroll down to find the JAAS documentation for your platform.

Java Authentication and Authorization Service authorization

Java 2 security architecture uses a security policy to specify which access rights are granted to running code. This architecture is *code-centric*. The permissions are granted based on code characteristics including where the code is coming from, whether it is digitally signed, and by whom. Authorization of the Java Authentication and Authorization Service (JAAS) augments the existing code-centric access controls with new user-centric access controls. Permissions are granted based on what code is running and who is running it.

When using JAAS authentication to authenticate a user, a *subject* is created to represent the authenticated user. A subject is comprised of a set of principals, where each principal represents an identity for that user. You can grant permissions in the policy to specific principals. After the user is authenticated, the application can associate the subject with the current access control context. For each subsequent security-checked operation, the Java runtime automatically determines whether the policy grants the required permission to a specific principal only. If so, the operation is supported if the subject that is associated with the access control context contains the designated principal only.

Associate a subject with the current access control context by calling the static doAs method from the subject class, passing it an authenticated subject and the java.security.PrivilegedAction or java.security.PrivilegedExceptionAction method. The doAs method associates the provided subject with the current access control context and then invokes the run method from the action. The run method implementation contains all the code that ran as the specified subject. The action runs as the specified subject.

In the Java 2 Platform, Enterprise Edition (J2EE) programming model, when invoking the Enterprise JavaBeans (EJB) method from an enterprise bean or servlet, the method runs under the user identity that is determined by the run-as setting. The J2EE Version 1.4 Specification does not indicate which user identity to use when invoking an enterprise bean from a Subject.doAs action block within either the EJB code or the servlet code. A logical extension is to use the proper identity that is specified in the subject when invoking the EJB method within the Subject doAs action block.

Letting the Subject.doAs action overwrite the run-as identity setting is an ideal way to integrate the JAAS programming model with the J2EE run-time environment. However, JAAS introduced an issue into the Software Development Kit (SDK), Java Technology Edition Versions 1.3 or later when integrating the JAAS Version 1.0 or later implementation with the Java 2 security architecture. A subject, which is associated with the access control context is cut off by a doPrivileged call when a doPrivileged call occurs within the Subject.doAs action block. Until this problem is corrected, no reliable and run-time efficient way is available to guarantee the correct behavior of Subject.doAs action in a J2EE run-time environment.

The problem can be explained better with the following example:

```
Subject.doAs(subject, new java.security.PrivilegedAction() {
   Public Object run() {
       // Subject is associated with the current thread context
       java.security.AccessController.doPrivileged( new
           java.security.PrivilegedAction() {
                        public Object run() {
                        // Subject was cut off from the current
                        // thread context
   return null;
                }
        });
        // Subject is associated with the current thread context
        return null;
   }
});
```

In the previous code example, the Subject object is associated with the context of the current thread. Within the run method of a doPrivileged action block, the Subject object is removed from the thread context. After leaving the doPrivileged block, the Subject object is restored to the current thread context. Because doPrivileged blocks can be placed anywhere along the running path and instrumented quite often in a server environment, the run-time behavior of a doAs action block becomes difficult to manage.

To resolve this difficulty, WebSphere Application Server provides a WSSubject helper class to extend the JAAS authorization to a J2EE EJB method invocation, as described previously. The WSSubject class provides static doAs and doAsPrivileged methods that have identical signatures to the subject class. The WSSubject.doAs method associates the Subject to the currently running thread. The WSSubject.doAs and WSSubject.doAsPrivileged methods then invoke the corresponding Subject.doAs and Subject.doAsPrivileged methods. The original credential is restored and associated with the running thread upon leaving the WSSubject.doAs and WSSubject.doAsPrivileged methods.

The WSSubject class is not a replacement of the subject object, but rather a helper class to ensure consistent run-time behavior as long as an EJB method invocation is a concern.

The following example illustrates the run-time behavior of the WSSubject.doAs method:

```
WSSubject.doAs(subject, new java.security.PrivilegedAction() {
   Public Object run() {
       // Subject is associated with the current thread context
       java.security.AccessController.doPrivileged( new
           java.security.PrivilegedAction() {
                      public Object run() {
                         // Subject was cut off from the current thread
                         // context.
   return null;
              }
        });
        // Subject is associated with the current thread context
   return null;
   }
});
```

The Subject.doAs and Subject.doAsPrivileged methods are not integrated with the J2EE run-time environment. EJB methods that are invoked within the Subject.doAs and Subject.doAsPrivileged action blocks run under the identity that is specified by the run-as setting and not by the subject identity.

- The Subject object that is generated by the WSLoginModuleImpl instance and the WSClientLoginModuleImpl instance contains a principal that implements the WSPrincipal interface. Using the getCredential method for a WSPrincipal object returns an object that implements the WSCredential interface. You can also find the WSCredential object instance in the PublicCredentials list of the subject instance. Retrieve the WSCredential object from the PublicCredentials list instead of using the getCredential method.
- The getCallerPrincipal method for the WSSubject class returns a string that represents the caller security identity. The return type differs from the getCallerPrincipal method of the java.security.Principal EJBContext interface.
- The Subject object that is generated by the Java 2 Connector (J2C) DefaultPrincipalMapping module contains a resource principal and a PasswordCredentials list. The resource principal represents the RunAs identity.

For more information, see J2EE connector security.

Using the Java Authentication and Authorization Service programming model for web authentication

WebSphere Application Server supports the Java Platform, Enterprise Edition (Java EE) declarative security model. You can define the authentication and access control policy using the Java EE deployment descriptor. You can further stack custom login modules to customize the WebSphere Application Server authentication mechanism.

Before you begin

A custom login module can perform principal and credential mapping, custom security token and custom credential-processing, and error-handling among other possibilities. Typically, you do not need to use application code to perform authentication function. Use the programming techniques that are described in this section if you have to perform authentication function in application code. For example, if you have applications that programmed to the SSOAuthenticator helper function, you can use the following programming interface. The SSOAuthenticator helper function was deprecated starting with WebSphere Application Server Version 4.0. Use declarative security as a rule; use the techniques that are described in this section as a last resort.

About this task

When the Lightweight Third-Party Authentication (LTPA) mechanism single sign-on (SSO) option is enabled, the web client login session is tracked by an LTPA SSO token cookie after successful login. At logout, this token is deleted to terminate the login session, but the server-side subject is not deleted. When you use the declarative security model, the WebSphere Application Server web container performs client authentication and login session management automatically. You can perform authentication in application code by setting a login page without a Java EE security constraint and by directing client requests to your login page first. Your login page can use the Java Authentication and Authorization Service (JAAS) programming model to perform authentication. To enable WebSphere Application Server web login modules to generate SSO cookies, use the following steps.

Procedure

1. Create a new system login JAAS configuration. To access the panel, click **Security > Global security**. Under Java Authentication and Authorization Service, click **System logins**.
2. Manually clone the WEB_INBOUND login configuration, and give it a new alias. To clone the login configuration, click **New**, enter a name for the configuration, click **Apply**, then click **JAAS login modules** under Additional properties. Click **New** and configure the JAAS login module. For more information, see Login module settings for Java Authentication and Authorization Service. WebSphere Application Server web container uses the WEB_INBOUND login configuration to authenticate web clients. Changing the WEB_INBOUND login configuration affects all web applications in the cell. You should create your own login configuration by cloning the contents of the WEB_INBOUND login configuration.
3. Select the `wsMapDefaultInboundLoginModule` login module and click **Custom properties**. There are two login modules defined in your login configuration: `ltpaLoginModule` and `wsMapDefaultInboundLoginModule`.
4. Add a login property name *cookie* with a value of **true**. The two login modules are enabled to generate LTPA SSO cookies. Do not add the cookie login option to the original WEB_INBOUND login configuration.
5. Stack your custom LoginModule(s) in the new login configuration (optional).
6. Use your login page for programmatic login by perform a JAAS LoginContext.login using your newly defined login configuration. After a successful login, either the `ltpaLoginModule` or the `wsMapDefaultInboundLoginModule` generates an LTPA SSO cookie upon a successful authentication. Exactly which LoginModule generates the SSO cookie depends on many factors, including system authentication configuration and runtime condition (which is beyond the scope of this section).

7. Call the modified `WSSubject.setRunAsSubject` method to add the subject to the authentication cache. The subject must be a WebSphere Application Server JAAS subject created by `LoginModule`. Adding the subject to the authentication cache recreates a subject from SSO token.
8. Use your programmatic logout page to revoke SSO cookies by invoking the `revokeSSOCookies` method from the WSSecurityHelper class. The term cookies is used because WebSphere Application Server Release 5.1.1 (and later) release supports a new LTPA SSO token with a different encryption algorithm, but can be configured to generate the original LTPA SSO token for backward compatibility. Note that the subject is still in the authentication cache and only the SSO cookies are revoked.

Example

Use the following code sample to perform authentication.

gotcha: If you set the password for the WSCallbackHandlerFactoryset factory class for getting handlers to `null`, as is done in the following example, you allow identity assertion without a password.

```
Suppose you wrote a LoginServlet.java:

 Import com.ibm.wsspi.security.auth.callback.WSCallbackHandlerFactory;
 Import com.ibm.websphere.security.auth.WSSubject;

 public Object login(HttpServletRequest req, HttpServletResponse res)
 throws ServletException {

 PrintWriter out = null;
 try {
  out =  res.getWriter();
      res.setContentType("text/html");
 } catch (java.io.IOException e){
  // Error handling
 }

 Subject subject = null;
 try {
 LoginContext lc = new LoginContext("system.Your_login_configuration",
WSCallbackHandlerFactory.getInstance().getCallbackHandler(
userid, null, password, req, res, null));
  lc.login();
  subject = lc.getSubject();
      WSSubject.setRunAsSubject(subject);
 } catch(Exception e) {
  // catch all possible exceptions if you want or handle them separately
  out.println("Exception in LoginContext login + Exception = " +
 e.getMessage());
  throw new ServletException(e.getMessage());
 }

The following is sample code to revoke the SSO cookies upon a programming logout:

The LogoutServlet.java:

 public void logout(HttpServletRequest req, HttpServletResponse res,
 Object retCreds)  throws ServletException {
   PrintWriter out =null;
   try {
    out =  res.getWriter();
        res.setContentType("text/html");
   } catch (java.io.IOException e){
   // Error Handling
   }
   try {
     WSSecurityHelper.revokeSSOCookies(req, res);
   } catch(Exception e) {
    // catch all possible exceptions if you want or handle them separately
    out.println("JAASLogoutServlet: logout Exception = " + e.getMessage());
    throw new ServletException(e);
   }
  }
```

What to do next

For more information on JAAS authentication, refer to Developing programmatic logins with the Java Authentication and Authorization Service. For more information on the AuthenLoginModule login module, refer to Example: Customizing a server-side Java Authentication and Authorization Service authentication and login configuration.

Developing custom login modules for a system login configuration for JAAS

For WebSphere Application Server, multiple Java Authentication and Authorization Service (JAAS) plug-in points exist for configuring system logins. WebSphere Application Server uses system login configurations to authenticate incoming requests, outgoing requests, and internal server logins.

About this task

Application login configurations are called by Java Platform, Enterprise Edition (Java EE) applications for obtaining a Subject that is based on specific authentication information. This login configuration enables the application to associate the Subject with a specific protected remote action. The Subject is picked up on the outbound request processing. The following list identifies the main system plug-in points. If you write a login module that adds information to the Subject of a system login, these are the main login configurations to plug in:

- WEB_INBOUND
- RMI_OUTBOUND
- RMI_INBOUND
- DEFAULT

Procedure

- Authenticate web requests with the WEB_INBOUND login configuration.

  The WEB_INBOUND login configuration authenticates web requests.

  For more detailed information on the WEB_INBOUND configuration including its associated callbacks, see "RMI_INBOUND, WEB_INBOUND, DEFAULT" in System login configuration entry settings for Java Authentication and Authorization Service. Figure 1 shows an example of a configuration using a trust association interceptor (TAI) that creates a Subject with the initial information that is passed into the WEB_INBOUND login configuration. If the trust association interceptor is not configured, the authentication process goes directly to the WEB_INBOUND system login configuration, which consists of all the login modules combined in Figure 1. Figure 1 shows where you can plug in custom login modules and where the ltpaLoginModule and the wsMapDefaultInboundLoginModule login modules are required.

  Figure 1

- Handle outbound requests with the RMI_OUTBOUND login configuration.

  The RMI_OUTBOUND login configuration is a plug point for handling outbound requests. WebSphere Application Server uses this plug point to create the serialized information that is sent downstream based on the invocation Subject passed in and other security context information such as propagation tokens. A custom login module can use this plug point to change the identity. For more information, see “Configuring outbound identity mapping to a different target realm” on page 1540. Figure 2 shows where you can plug in custom login modules and shows where the wsMapCSIv2OutboundLoginModule login module is required.

  Figure 2

  For more information on the RMI_OUTBOUND login configuration, including its associated callbacks, see "RMI_OUTBOUND" in System login configuration entry settings for Java Authentication and Authorization Service.

- Handle inbound authentication for enterprise bean requests with the RMI_INBOUND login configuration.

  The RMI_INBOUND login configuration is a plug point that handles inbound authentication for enterprise bean requests. WebSphere Application Server uses this plug point for either an initial login or a propagation login. For more information about these two login types, see “Security attribute propagation” on page 1544. During a propagation login, this plug point is used to deserialize the information that is received from an upstream server. A custom login module can use this plug point to change the identity, handle custom tokens, add custom objects into the Subject, and so on. For more information on

changing the identity using a Hashtable object, which is referenced in figure 3, see “Configuring inbound identity mapping” on page 1533. Figure 3 shows where you can plug in custom login modules and shows that the ltpaLoginModule and the wsMapDefaultInboundLoginModule login modules are required.

Figure 3

For more information on the RMI_INBOUND login configuration, including its associated callbacks, see "RMI_INBOUND, WEB_INBOUND, DEFAULT" in System login configuration entry settings for Java Authentication and Authorization Service.

- Handle all other types of authentication requests with the DEFAULT login configuration. **DEFAULT login configuration**

  The DEFAULT login configuration is a plug point that handles all of the other types of authentication requests, including administrative SOAP requests and internal authentication of the server ID. Propagation logins typically do not occur at this plug point.

  For more information on the DEFAULT login configuration including its associated callbacks, see "RMI_INBOUND, WEB_INBOUND, DEFAULT" in System login configuration entry settings for Java Authentication and Authorization Service.

- Develop login configuration logic to know when specific information is present and how to use the information. **Writing a login module**

  When you write a login module that plugs into a WebSphere Application Server application login or system login configuration, read the JAAS programming model, which is located at: http://java.sun.com/products/jaas. The JAAS programming model provides basic information about JAAS. However, before writing a login module for the WebSphere Application Server environment, read the following sections in this article:

  – Useable callbacks
  – Shared state variables
  – Initial versus propagation logins
  – Sample custom login module

  Useable Callbacks

  Each login configuration must document the callbacks that are recognized by the login configuration. However, the callbacks are not always passed data. The login configuration must contain logic to know when specific information is present and how to use the information. For example, if you write a custom login module that can plug into all four of the pre-configured system login configurations mentioned previously, three sets of callbacks might be presented to authenticate a request. Other callbacks might be present for other reasons, including propagation and making other information available to the login configuration.

  Login information can be presented in the following combinations:

  User name (NameCallback) and password (PasswordCallback)
  This information is a typical authentication combination.

  User name only (NameCallback)
  This information is used for identity assertion, trust association interceptor (TAI) logins, and certificate logins.

  Token (WSCredTokenCallbackImpl)
  This information is for Lightweight Third Party Authentication (LTPA) token validation.

  Propagation token list (WSTokenHolderCallback)
  This information is used for a propagation login.

  The first three combinations are used for typical authentication. However, when the WSTokenHolderCallback callback is present in addition to one of the first three information combinations, the login is called a *propagation login*. A propagation login means that some security attributes are propagated to this server from another server. The servers can reuse these security attributes if the authentication information validates successfully. In some cases, a

WSTokenHolderCallback callback might not have sufficient attributes for a full login. Check the requiresLogin method on the WSTokenHolderCallback callback to determine if a new login is required. You can always ignore the information returned by the requiresLogin method, but, as a result, you might duplicate information. The following list contains the callbacks that might be present in the system login configurations. The list includes the callback name and a description of their responsibility.

callbacks[0] = new javax.security.auth.callback.NameCallback("Username: ");
This callback handler collects the user name for the login. The result can be the user name for a basic authentication login (user name and password) or a user name for an identity assertion login.

callbacks[1] = new javax.security.auth.callback.PasswordCallback("Password: ", false);
This callback handler collects the password for the login.

callbacks[2] = new com.ibm.websphere.security.auth.callback.WSCredTokenCallbackImpl("Credential Token: ");
This callback handler collects the Lightweight Third Party Authentication (LTPA) token or other token type for the login. This callback handler is typically present when a user name and password are not present.

callbacks[3] = new com.ibm.wsspi.security.auth.callback.WSTokenHolderCallback("Authz Token List: ");
This callback handler collects the ArrayList of TokenHolder objects that are returned from a call to the WSOpaqueTokenHelper.createTokenHolderListFromOpaqueToken API using the Common Secure Interoperability Version 2 (CSIv2) authorization token as input.

callbacks[4] = new com.ibm.websphere.security.auth.callback.WSServletRequestCallback("HttpServletRequest: ");
This callback handler collects the HTTP servlet request object, if present. This callback handler enables login modules to get information from the HTTP request for use in the login, and is presented from the WEB_INBOUND login configuration only.

callbacks[5] = new com.ibm.websphere.security.auth.callback.WSServletResponseCallback("HttpServletResponse: ");
This callback handler collects the HTTP servlet response object, if present. This callback handler enables login modules to put information into the HTTP response as a result of the login. An example of this situation might be adding the SingleSignonCookie cookie to the response.This callback handler is presented from the WEB_INBOUND login configuration only.

callbacks[6] = new com.ibm.websphere.security.auth.callback.WSAppContextCallback("ApplicationContextCallback: ");
This callback handler collects the web application context that is used during the login. This callback handler consists of a HashMap object, which contains the application name and the redirect web address, if present. The callback handler is presented from the WEB_INBOUND login configuration only.

callbacks[7] = new WSRealmNameCallbackImpl("Realm Name: ", *default_realm***);**
This callback handler collects the realm name for the login information. The realm information might not always be provided. If the realm information is not provided, assume that it is the current realm.

callbacks[8] = new WSX509CertificateChainCallback("X509Certificate[]: ");
This callback handler contains the certificate that was validated by Secure Sockets Layer (SSL) if the login source is an X509Certificate from SSL client authentication. The ltpaLoginModule calls the same mapping functions as WebSphere Application Server releases prior to version 6.1. However, having it passed into the login gives a custom login module the opportunity to map the certificate in a custom way. Then, it performs a Hashtable login. See “Configuring inbound identity mapping” on page 1533 for more information on a Hashtable login.

- Use shared state variables to share information between login modules during the login phase.

If you want to access the objects that WebSphere Application Server creates during a login, refer to the following shared state variables. The variables are set in the following login modules: ltpaLoginModule, swamLoginModule, and wsMapDefaultInboundLoginModule.

Shared state variable
com.ibm.wsspi.security.auth.callback.Constants.WSPRINCIPAL_KEY

Purpose
Specifies the com.ibm.websphere.security.auth.WSPrincipal object. See the WebSphere Application Server API documentation for application programming interface (API) usage. This shared state variable is for read-only purposes. Do not set this variable in the shared state for custom login modules.

The login module in which variables are set
ltpaLoginModule, swamLoginModule, and wsMapDefaultInboundLoginModule

Shared state variable
com.ibm.wsspi.security.auth.callback.Constants.WSCREDENTIAL_KEY

Purpose
Specifies the com.ibm.websphere.security.cred.WSCredential object. See the WebSphere Application Server API documentation for API usage. This shared state variable is for read-only purposes. Do not set this variable in the shared state for custom login modules.

Login module in which variables are set
wsMapDefaultInboundLoginModule

Shared state variable
com.ibm.wsspi.security.auth.callback.Constants.WSAUTHZTOKEN_KEY

Purpose
Specifies the default com.ibm.wsspi.security.token.AuthorizationToken object. Login modules can use this object to set custom attributes plugged in after the wsMapDefaultInboundLoginModule login module. The information set here is propagated downstream and is available to the application. See the WebSphere Application Server API documentation for API usage.

Initial versus propagation logins

As mentioned previously, some logins are considered initial logins because of the following reasons:

– It is the first time authentication information is presented to WebSphere Application Server.

– The login information is received from a server that does not propagate security attributes so this information must be gathered from a user registry.

Other logins are considered propagation logins when a WSTokenHolderCallback callback is present and contains sufficient information from a sending server to recreate all the required objects needed by WebSphere Application Server runtime. In cases where there is sufficient information for the WebSphere Application Server runtime, the information you might add to the Subject is likely to exist from the previous login. To verify if your object is present, you can get access to the ArrayList object that is present in the WSTokenHolderCallback callback, and search through this list looking at each TokenHolder getName method. This search is used to determine if WebSphere Application Server is deserializing your custom object during this login. Check the class name returned from the getName method using the String startsWith method because the runtime might add additional information at the end of the name to know which Subject is set to add the custom object after deserialization.

- Code your login() method to determine when sufficient information is present.

  The following code snippet can be used in your login() method to determine when sufficient information is present. For another example, see “Configuring inbound identity mapping” on page 1533.

```
// This is a hint provided by WebSphere Application Server that
// sufficient propagation information does not exist and, therefore,
// a login is required to provide the sufficient information. In this
// situation, a Hashtable login might be used.
boolean requiresLogin = ((com.ibm.wsspi.security.auth.callback.
WSTokenHolderCallback) callbacks[1]).requiresLogin();
```

```
if (requiresLogin)
{
// Check to see if your object exists in the TokenHolder list,
if not, add it.
java.util.ArrayList authzTokenList = ((WSTokenHolderCallback) callbacks[6]).
getTokenHolderList();boolean found = false;

if (authzTokenList != null)
{
Iterator tokenListIterator = authzTokenList.iterator();

while (tokenListIterator.hasNext())
{
com.ibm.wsspi.security.token.TokenHolder th = (com.ibm.wsspi.security.token.
TokenHolder) tokenListIterator.next();

if (th != null && th.getName().startsWith("com.acme.myCustomClass"))
{
found=true;
break;
}
}
if (!found)
{
// go ahead and add your custom object.
}
}
}
else
{
// This code indicates that sufficient propagation information is present.
// User registry calls are not needed by WebSphere Application Server to
// create a valid Subject. This code might be a no-op in your login module.
}
```

Sample custom login module

You can use the following sample to get ideas on how to use some of the callbacks and shared state variables.

```
{
 // Defines your login module variables
 com.ibm.wsspi.security.token.AuthenticationToken customAuthzToken = null;
 com.ibm.wsspi.security.token.AuthenticationToken defaultAuthzToken = null;
 com.ibm.websphere.security.cred.WSCredential credential = null;
 com.ibm.websphere.security.auth.WSPrincipal principal = null;
 private javax.security.auth.Subject _subject;
 private javax.security.auth.callback.CallbackHandler _callbackHandler;
 private java.util.Map _sharedState;
 private java.util.Map _options;

 public void initialize(Subject subject, CallbackHandler callbackHandler,
     Map sharedState, Map options)
 {
  _subject = subject;
  _callbackHandler = callbackHandler;
  _sharedState = sharedState;
  _options = options;
 }

 public boolean login() throws LoginException
 {
  boolean succeeded = true;

  // Gets the CALLBACK information
  javax.security.auth.callback.Callback callbacks[] = new javax.security.
        auth.callback.Callback[7];
  callbacks[0] = new javax.security.auth.callback.NameCallback(

- Configure the system login for your custom login module.

  After developing your custom login module for a system login configuration, you can configure the system login using either the administrative console or using the wsadmin utility. To configure the system login using the administrative console, click **Security > Global security**. Under Java Authentication and Authorization Service, click **System logins**. For more information on using the wsadmin utility for system login configuration, see Customizing a server-side Java Authentication and Authorization Service authentication and login configuration. Also refer to that article for information on system login modules and to determine whether to add additional login modules.

Customizing application login with Java Authentication and Authorization Service:

Using Java Authentication and Authorization Service (JAAS), you can customize your application login.

About this task

Java Authentication and Authorization Service (JAAS) is an API that enables applications to access authentication and access control services without being tied to those services. The following topics explaining customizing your application with JAAS are covered in this section:

Procedure

1. Develop programmatic logins with JAAS.

   You can develop programmatic logins with JAAS, which represents the strategic application programming interfaces (API) for authentication.
2. Configure programmatic logins with JAAS.

   A new JAAS login configuration can be added and modified using the administrative console. The changes are saved in the cell-level security document and are available to all managed application servers.

3. Customize an application login to perform an identity assertion using JAAS.

   Using the JAAS login framework, you can create a JAAS login configuration that can be used to perform login to an identity assertion.
4. Configure a server-side JAAS authentication and login configuration.

   WebSphere Application Server supports plugging in a custom JAAS login module before or after the WebSphere Application Server system login module. However, WebSphere Application Server does not support the replacement of the WebSphere Application Server system login modules, which are used to create the WSCredential credential and WSPrincipal principal in the Subject. By using a custom login module, you can either make additional authentication decisions or add information to the Subject to make additional, potentially finer-grained, authorization decisions inside a Java Platform, Enterprise Edition (Java EE) application.

Enabling identity assertion with trust validation using JAAS:

By enabling identity assertion with trust validation, an application can use the JAAS login configuration to perform a programmatic identity assertion.

About this task

To enable an identity assertion with trust validation, follow these steps:

Procedure

1. Create a custom login module to perform a trust validation. The login module must set trust and identity information in the shared state, which is then passed on to the IdentityAssertionLoginModule. The trust and identity information is stored in a map in the shared state under the key, com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.state. If this key is missing from the shared state, a WSLoginFailedException error is thrown by the IdentityAssertionLoginModule module. The custom login module should include the following:
   - A trust key named com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.trust. If the trust key is set to `true`, trust is established. If the trust key is set to `false`, the IdentityAssertionLoginModule module creates a WSLoginFailedException error.
   - The identity of the java.security.Principal type set in the com.ibm.wsspi.security.common.auth.module.IdenityAssertionLoginModule.principal key.
   - The identity in the form of a java,security.cert.X509Certificate[] certificate set in the com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.certificates key.

   Note: If both a principal and a certificate are supplied, the principal is used, and a warning is issued.
2. Create a new Java Authentication and Authorization Service (JAAS) configuration for application logins. It contains the user-implemented trust validation custom login module and the IdentityAssertionLoginModule module. To configure an application login configuration from the administrative console, complete the following steps:
   a. Click **Security > Global security**.
   b. Under Java Authentication and Authorization Service, click **Application logins > New**.
   c. Supply the JAAS configuration with an alias, and then click **Apply**.
   d. Under Additional properties, click **JAAS Login Modules > New**.
   e. Enter the module class name of the user-implemented trust validation custom login module, and then click **Apply**.
   f. Enter the com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule module class name.
   g. Make sure that the module class name classes are in the correct order. The user-implemented trust validation login module must be the first class in the list, and the IdentityAssertionLoginModule module must be the second class.

h. Click **Save**. The new JAAS configuration is used by the application to perform an identity assertion.

What to do next

An application can now use the JAAS login configuration to perform a programmatic identity assertion. The application can create a login context for the JAAS configuration created in step 2, then login to that login context with the identity it asserts to. If the login is successful, that identity can be set in the current running process, as in the following example:

```
MyCallbackHandler handler = new MyCallbackHandler(new MyPrincipal("Joe"));
LoginContext lc = new LoginContext("MyAppLoginConfig", handler);
lc.login();  //assume successful
Subject s = lc.getSubject();
WSSubject.setRunAsSubject(s);
// From here on, the runas identity is "Joe"
```

Performing identity mapping for authorization across servers in different realms

Identity mapping is a one-to-one mapping of a user identity between two servers so that the proper authorization decisions are made by downstream servers. Identity mapping is necessary when the integration of servers is needed, but the user registries are different and not shared between the systems.

About this task

In most cases, requests flow downstream between two servers that are part of the same security domain. In WebSphere Application Server, two servers that are members of the same cell are also members of the same security domain. In the same cell, the two servers have the same user registry and the same Lightweight Third Party Authentication (LTPA) keys for token encryption. These two commonalities ensure that the LTPA token, among other user attributes, which flows between the two servers, not only can be decrypted and validated, but also the user identity in the token can be mapped to attributes that are recognized by the authorization engine.

The most reliable and recommended configuration involves two servers within the same cell. However, sometimes you need to integrate multiple systems that cannot use the same user registry. When the user registries are different between two servers, the security domain or realm of the target server does not match the security domain of the sending server.

WebSphere Application Server enables mapping to occur either before sending the request outbound or before enabling the existing security credentials to flow to the target server. The credentials are mapped inbound with the specification that the target realm is trusted.

An alternative to mapping is to send the user identity without the token or the password to a target server without actually mapping the identity. The use of the user identity is based on trust between the two servers. Use Common Secure Interoperability Version 2 (CSIv2) identity assertion. When enabled, the server sends just the X.509 certificate, principal name, or distinguished name (DN) based upon what was used by the original client to perform the initial authentication. During CSIv2 identity assertion, trust is established between WebSphere Application Servers.

The user identity must exist in the target user registry for identity assertion to work. This process can also enable interoperability between other Java 2 Platform, Enterprise Edition (J2EE) Version 1.4 and higher compliant application servers. If both the sending server and target servers have identity assertion configured, WebSphere Application Server always uses this method of authentication, even when both servers are in the same security domain. For more information on CSIv2 identity assertion, see “Identity assertion to the downstream server” on page 1597.

When the user identity is not present in the user registry of the target server, identity mapping must occur either before the request is sent outbound or when the request comes inbound. This decision depends upon your environment and requirements. However, it is typically easier to map the user identity before the request is sent outbound for the following reasons:

- You know the user identity of the existing credential as it comes from the user registry of the sending server.
- You do not have to worry about sharing Lightweight Third Party Authentication (LTPA) keys with the other target realm because you are not mapping the identity to LTPA credentials. Typically, you are mapping the identity to a user ID and password that are present in the user registry of the target realm.

When you do perform outbound mapping, in most cases, it is recommended that you use Secure Sockets Layer (SSL) to protect the integrity and confidentiality of the security information sent across the network. If LTPA keys are not shared between servers, an LTPA token cannot be validated at the inbound server. In this case, outbound mapping is necessary because the user identity cannot be determined at the inbound server to do inbound mapping. For more information, see “Configuring outbound identity mapping to a different target realm” on page 1540.

When you need inbound mapping, potentially due to the mapping capabilities of the inbound server, you must ensure that both servers have the same LTPA keys so that you can get access to the user identity. Typically, in secure communications between servers, an LTPA token is passed into the WSCredTokenCallback callback of the inbound JAAS login configuration for the purposes of client authentication. A method is available that enables you to open the LTPA token, if valid, and get access to the user unique ID so that mapping can be performed. For more information, see “Configuring inbound identity mapping.” In other cases, such as identity assertion, you might receive a user name in the NameCallback callback of the inbound login configuration that enables you to map the identity.

The following topics are covered in this section:

Procedure

- Configuring inbound identity mapping For inbound identity mapping, you can write a custom login module and configure WebSphere Application Server to run the login module first within the system login configurations. Consider the following steps when you write your custom login module: “Configuring inbound identity mapping.”
- Configuring outbound identity mapping to a different target realm By default, when WebSphere Application Server makes an outbound request from one server to another server in a different security realm, the request is rejected. This topic details alternatives for enabling one server to send outbound requests to a target server in a different realm. For more information, see “Configuring outbound identity mapping to a different target realm” on page 1540

Configuring inbound identity mapping

For inbound identity mapping, write a custom login module and configure WebSphere Application Server to run the login module first within the system login configurations. Consider the following steps when you write your custom login module.

Procedure

1. Get the inbound user identity from the callbacks and map the identity, if necessary This step occurs in the login method of the login module. A valid authentication has either or both NameCallback and the WSCredTokenCallback callbacks present. The following code sample shows you how to determine the user identity:

```
javax.security.auth.callback.Callback callbacks[] =
   new javax.security.auth.callback.Callback[3];
 callbacks[0] = new javax.security.auth.callback.NameCallback("");
 callbacks[1] = new javax.security.auth.callback.PasswordCallback
     ("Password: ", false);
 callbacks[2] = new com.ibm.websphere.security.auth.callback.
     WSCredTokenCallbackImpl("");
```

```
callbacks[3] = new com.ibm.wsspi.security.auth.callback.
    WSTokenHolderCallback("");

try
{
 callbackHandler.handle(callbacks);
}
catch (Exception e)
{
 // Handles exceptions
 throw new WSLoginFailedException (e.getMessage(), e);
}

// Shows which callbacks contain information
boolean identitySwitched = false;
String uid = ((NameCallback) callbacks[0]).getName();
char password[] = ((PasswordCallback) callbacks[1]).getPassword();
byte[] credToken = ((WSCredTokenCallbackImpl) callbacks[2]).getCredToken();
java.util.List authzTokenList = ((WSTokenHolderCallback)
    callbacks[3]).getTokenHolderList();

if (credToken != null)
{
 try
 {
  String uniqueID = WSSecurityPropagationHelper.validateLTPAToken(credToken);
  String realm = WSSecurityPropagationHelper.getRealmFromUniqueID (uniqueID);
      // Now set the string to the UID so that you can use the result for either
      // mapping or logging in.
  uid = WSSecurityPropagationHelper.getUserFromUniqueID (uniqueID);
 }
 catch (Exception e)
 {
  // Handles the exception
 }
}
else if (uid == null)
{
    // Throws an exception if authentication data is not valid.
    // You must have either UID or CredToken
 throw new WSLoginFailedException("invalid authentication data.");
}
else if (uid != null && password != null)
{
    // This is a typical authentication. You can choose to map this ID to
    // another ID or you can skip it and allow WebSphere Application Server
    // to log in for you. When passwords are presented, be very careful to not
    // validate the password because this is the initial authentication.

 return true;
}

   // If desired, map this uid to something else and set the identitySwitched
   // boolean. If the identity was changed, clear the propagated attributes
   // below so they are not used incorrectly.
uid = myCustomMappingRoutine (uid);

   // Clear the propagated attributes because they are no longer applicable
   // to the new identity
if (identitySwitched)
{
 ((WSTokenHolderCallback) callbacks[3]).setTokenHolderList(null);
}
```

2. Check to see if attribute propagation occurred and if the attributes for the user are already present when the identity remains the same. Check to see if the user attributes are already present from the sending server to avoid duplicate calls to the user registry lookup. To check for the user attributes, use

a method on the WSTokenHolderCallback callback that analyzes the information present in the callback to determine if the information is sufficient for WebSphere Application Server to create a Subject. The following code sample checks for the user attributes:

```
boolean requiresLogin =
((com.ibm.wsspi.security.auth.callback.WSTokenHolderCallback)
callbacks[2]).getrequiresLogin();
```

If sufficient attributes are not present to form the WSCredential and the WSPrincipal objects that are needed to perform authorization, the previous code sample returns a `true` result. When the result is `false`, you can choose to discontinue processing as the necessary information exists to create the Subject without performing additional remote user registry calls.

3. Optional: Look up the required attributes from the user registry, put the attributes in a hashtable, and add the hashtable to the shared state. If the identity is switched in this login module, you must complete the following steps:
   a. Create the hashtable of attributes, as shown in the following example.
   b. Add the hashtable to the shared state.

   If the identity is not switched, but the value of the requiresLogin code sample shown previously is `true`, you can create the hashtable of attributes. However, you are not required to create a hashtable in this situation as WebSphere Application Server handles the login for you. However, you might consider creating a hashtable to gather attributes in special cases where you are using your own special user registry. Creating a UserRegistry implementation, using a hashtable, and letting WebSphere Application Server gather the user attributes for you might be the easiest solution. The following table shows how to create a hashtable of user attributes:

```
if (requiresLogin || identitySwitched)
 {
  // Retrieves the default InitialContext for this server.
  javax.naming.InitialContext ctx = new javax.naming.InitialContext();

  // Retrieves the local UserRegistry implementation.
  com.ibm.websphere.security.UserRegistry reg = (com.ibm.websphere.
        security.UserRegistry)
  ctx.lookup("UserRegistry");

     // Retrieves the user registry uniqueID based on the uid specified
     // in the NameCallback.
  String uniqueid = reg.getUniqueUserId(uid);
   uid = WSSecurityPropagationHelper.getUserFromUniqueID (uniqueid);

     // Retrieves the display name from the user registry based on the uniqueID.
  String securityName = reg.getUserSecurityName(uid);

     // Retrieves the groups associated with the uniqueID.
  java.util.List groupList = reg.getUniqueGroupIds(uid);

     // Creates the java.util.Hashtable with the information that you gathered
     // from the UserRegistry implementation.
  java.util.Hashtable hashtable = new java.util.Hashtable();
  hashtable.put(com.ibm.wsspi.security.token.AttributeNameConstants.
       WSCREDENTIAL_UNIQUEID, uniqueid);
     hashtable.put(com.ibm.wsspi.security.token.AttributeNameConstants.
       WSCREDENTIAL_SECURITYNAME, securityName);
  hashtable.put(com.ibm.wsspi.security.token.AttributeNameConstants.
       WSCREDENTIAL_GROUPS, groupList);

     // Adds a cache key that is used as part of the lookup mechanism for
     // the created Subject. The cache key can be an object, but should have
     // an implemented toString method. Make sure that the cacheKey contains
     // enough information to scope it to the user and any additional attributes
     // that you are using. If you do not specify this property the Subject is
     // scoped to the returned WSCREDENTIAL_UNIQUEID, by default.
  hashtable.put(com.ibm.wsspi.security.token.AttributeNameConstants.
```

```
        WSCREDENTIAL_CACHE_KEY, "myCustomAttribute" + uniqueid);
  // Adds the hashtable to the sharedState of the Subject.
  _sharedState.put(com.ibm.wsspi.security.token.AttributeNameConstants.
        WSCREDENTIAL_PROPERTIES_KEY, hashtable);
 }
```

The following rules define in more detail how a hashtable login is performed. You must use a java.util.Hashtable object in either the Subject (public or private credential set) or the shared-state HashMap. The com.ibm.wsspi.security.token.AttributeNameConstants class defines the keys that contain the user information. If the Hashtable object is put into the shared state of the login context using a custom login module that is listed prior to the Lightweight Third Party Authentication (LTPA) login module, the value of the java.util.Hashtable object is searched using the following key within the shared-state hashMap:

Property
com.ibm.wsspi.security.cred.propertiesObject

Reference to the property
AttributeNameConstants.WSCREDENTIAL_PROPERTIES_KEY

Explanation
This key searches for the Hashtable object that contains the required properties in the shared state of the login context.

Expected result
A java.util.Hashtable object.

If a java.util.Hashtable object is found either inside the Subject or within the shared state area, verify that the following properties are present in the hashtable:

Property
com.ibm.wsspi.security.cred.uniqueId

Reference to the property
AttributeNameConstants.WSCREDENTIAL_UNIQUEID

Returns
java.util.String

Explanation
The value of the property must be a unique representation of the user. For the WebSphere Application Server default implementation, this property represents the information that is stored in the application authorization table. The information is located in the application deployment descriptor after it is deployed and user-to-role mapping is performed. See the expected format examples if the user to role mapping is performed using a lookup to a WebSphere Application Server user registry implementation.

If a third-party authorization provider overrides the user-to-role mapping, then the third-party authorization provider defines the format. To ensure compatibility with the WebSphere Application Server default implementation for the unique ID value, call the WebSphere Application Server public String getUniqueUserId(String userSecurityName) UserRegistry method.

Expected format examples

Table 107. Format examples.

This table gives some format examples when configuring inbound identity mapping.

Realm	Format (uniqueUserId)
Lightweight Directory Access Protocol (LDAP)	`ldaphost.austin.ibm.com:389/cn=user,o=ibm,c=us`
Windows	`MYWINHOST/S-1-5-21-963918322-163748893-4247568029-500`
UNIX	`MYUNIXHOST/32`

The com.ibm.wsspi.security.cred.uniqueId property is required.

Property
com.ibm.wsspi.security.cred.securityName

Reference to the property
AttributeNameConstants. WSCREDENTIAL_ SECURITYNAME

Returns
java.util.String

Explanation
This property searches for the securityName of the authentication user. This name is commonly called the *display name* or *short name*. WebSphere Application Server uses the securityName attribute for the getRemoteUser, getUserPrincipal and getCallerPrincipal application programming interfaces (APIs). To ensure compatibility with the WebSphere Application Server default implementation for the securityName value, call the WebSphere Application Server public String getUserSecurityName(String uniqueUserId) UserRegistry method.

Expected format examples

Table 108. Format examples. This table gives expected format examples.

Realm	Format (uniqueUserId)
LDAP	user (*LDAP UID*)
Windows	user (*Windows username*)
UNIX	user (*UNIX username*)

The com.ibm.wsspi.security.cred.securityName property is required.

Property
com.ibm.wsspi.security.cred.groups

Reference to the property
AttributeNameConstants. WSCREDENTIAL_GROUPS

Returns
java.util.ArrayList

Explanation
This key searches for the array list of groups to which the user belongs. The groups are specified in the *realm_name*/*user_name* format. The format of these groups is important as the groups are used by the WebSphere Application Server authorization engine for group-to-role mappings in the deployment descriptor. The format that is provided must match the format expected by the WebSphere Application Server default implementation. When you use a third-party authorization provider, you must use the format that is expected by the third-party provider. To ensure compatibility with the WebSphere Application Server default implementation for the unique group IDs value, call the WebSphere Application Server public List getUniqueGroupIds(String uniqueUserId) UserRegistry method.

Expected format examples for each group in the array list

Table 109. Format examples. This table gives expected format examples for each group in the array list.

Realm	Format
LDAP	`ldap1.austin.ibm.com:389/cn=group1,o=ibm,c=us`
Windows	`MYWINREALM/S-1-5-32-544`
UNIX	`MY/S-1-5-32-544`

The com.ibm.wsspi.security.cred.groups property is not required. A user is not required to have associated groups.

Property
com.ibm.wsspi.security.cred.cacheKey

Reference to the property
AttributeNameConstants. WSCREDENTIAL_CACHE_KEY

Returns
java.lang.Object

Explanation
This key property can specify an object that represents the unique properties of the login, including the user-specific information and the user dynamic attributes that might affect uniqueness. For example, when the user logs in from location A, which might affect their access control, the cache key needs to include location A so that the Subject that is received is the correct Subject for the current location.

This com.ibm.wsspi.security.cred.cacheKey property is not required. When this property is not specified, the cache lookup is the value that is specified for WSCREDENTIAL_UNIQUEID. When this information is found in the java.util.Hashtable object, WebSphere Application Server creates a Subject similar to the Subject that goes through the normal login process at least for LTPA. The new Subject contains a WSCredential object and a WSPrincipal object that is fully populated with the information found in the Hashtable object.

4. Add your custom login module into the RMI_INBOUND, WEB_INBOUND, and DEFAULT Java Authentication and Authorization Service (JAAS) system login configurations. Configure the RMI_INBOUND login configuration so that WebSphere Application Server loads your new custom login module first.
   a. Click **Security > Global security > Java Authentication and Authorization Service > System logins > RMI_INBOUND**
   b. Under Additional Properties, click **JAAS login modules > New** to add your login module to the RMI_INBOUND configuration.
   c. Return to the JAAS login modules panel for RMI_INBOUND.
   d. Click **Set order** to change the order that the login modules are loaded so that WebSphere Application Server loads your custom login module first. Use the **Move Up** or **Move Down** buttons to arrange the order of the login modules.
   e. Repeat the previous three steps for the WEB_INBOUND and DEFAULT login configurations.

Results

This process configures identity mapping for an inbound request.

Example

The “Example: Custom login module for inbound mapping” topic shows a custom login module that creates a java.util.Hashtable hashtable that is based on the specified NameCallback callback. The java.util.Hashtable hashtable is added to the sharedState java.util.Map map so that the WebSphere Application Server login modules can locate the information in the hashtable.

Example: Custom login module for inbound mapping:

This sample shows a custom login module that creates a java.util.Hashtable hashtable that is based on the specified NameCallback callback. The java.util.Hashtable hashtable is added to the sharedState java.util.Map map so that the WebSphere Application Server login modules can locate the information in the Hashtable.

```
public customLoginModule()
{

public void initialize(Subject subject, CallbackHandler callbackHandler,
   Map sharedState, Map options)
{
```

```
 // (For more information on initialization, see
 //  "Developing custom login modules for a system login configuration for JAAS" on page 1521.)
 _sharedState = sharedState;
}

public boolean login() throws LoginException
{
 // (For more information on what to do during login, see
 //  "Developing custom login modules for a system login configuration for JAAS" on page 1521.)

Configuring outbound identity mapping to a different target realm

By default, when WebSphere Application Server makes an outbound request from one server to another server in a different security realm, the request is rejected. This topic details alternatives for enabling one server to send outbound requests to a target server in a different realm.

About this task

This outbound request is rejected to protect against a rogue server reading potentially sensitive information if successfully impersonating the home of the object. Select one of the following alternative procedures so that one server can send outbound requests to a target server in a different realm. When you are finished with a procedure on the administrative console, click **Apply**.

Procedure

- Do not perform mapping. Instead, allow the existing security information to flow to a trusted target server, even if the target server resides in a different realm. Complete the following steps in the administrative console:
  1. Click **Security > Global security**.
  2. Under RMI/IIOP security, click **CSIv2 outbound authentication**.
  3. Specify the target realms in the **Trusted target realms** field. You can specify each trusted target realm that is separated by a pipe (|) character. For example, specify *server_name*.*domain*:*port_number* for a Lightweight Directory Access Protocol (LDAP) server or the machine name for local operating system. If you want to propagate security attributes to a different target realm, you must specify that target realm in the **Trusted target realms** field.
- Use the Java Authentication and Authorization Service (JAAS) WSLogin application login configuration to create a basic authentication Subject that contains the credentials of the new target realm. This configuration enables you to log in with a realm, user ID, and password that are specific to the user registry of the target realm. You can provide the login information from within the Java Platform, Enterprise Edition (Java EE) application that is making the outbound request or from within the RMI_OUTBOUND system login configuration. These two login options are described in the following information:
  1. Use the WSLogin application login configuration from within the Java EE application to log in and get a Subject that contains the user ID and the password of the target realm. The application can wrap the remote call with a WSSubject.doAs call. For an example, see “Example: Using the WSLogin configuration to create a basic authentication subject” on page 1542.
  2. Use the code sample in “Example: Using the WSLogin configuration to create a basic authentication subject” on page 1542 from this plug point within the RMI_OUTBOUND login configuration. Every outbound Remote Method Invocation (RMI) request passes through this login configuration when it is enabled. Complete the following steps to enable and plug in this login configuration:
     a. Click **Security > Global security**.
     b. Under RMI/IIOP security, click **CSIv2 outbound authentication**.
     c. Select the **Custom outbound mapping** option. If the **Security Attribute Propagation** option is selected, then WebSphere Application Server is already using this login configuration and you do not need to enable custom outbound mapping.
     d. Write a custom login module. For more information, see “Developing custom login modules for a system login configuration for JAAS” on page 1521.

        The “Example: Sample login configuration for RMI_OUTBOUND” on page 1543 shows a custom login module that determines whether the realm names match. In this example, the realm names do not match so the WSLoginmodule is used to create a basic authentication Subject based on custom mapping rules. The custom mapping rules are specific to the customer environment and must be implemented using a realm to user ID and password mapping utility.
     e. Configure the RMI_OUTBOUND login configuration so that your new custom login module is first in the list.
        1) Click **Security > Global security**.
        2) Under Java Authentication and Authorization Service, click **System logins > RMI_OUTBOUND**
        3) Under Additional Properties, click **JAAS login modules > New** to add your login module to the RMI_OUTBOUND configuration.
        4) Return to the JAAS login modules panel for RMI_OUTBOUND.
        5) Click **Set order** to change the order that the login modules are loaded so that your custom login is loaded first.
- Add the use_realm_callback and use_appcontext_callback options to the outbound mapping module for WSLogin. To add these options, complete the following steps:
  1. Click **Security > Global security**.

2. Under Java Authentication and Authorization Service, click **Application logins > WSLogin**.
3. Under Additional properties, click **JAAS login modules > com.ibm.ws.security.common.auth.module.WSLoginModuleImpl**.
4. Under Additional properties, click **Custom Properties > New**.
5. On the Custom properties panel, enter `use_realm_callback` in the **Name** field and `true` in the **Value** field.
6. Click **OK**.
7. Click **New** to enter the second custom property.
8. On the Custom properties panel, enter `use_appcontext_callback` in the **Name** field and `true` in the **Value** field.

The following changes are made to the `security.xml` file:

```
<entries xmi:id="JAASConfigurationEntry_2" alias="WSLogin">
 <loginModules xmi:id="JAASLoginModule_2"
  moduleClassName="com.ibm.ws.security.common.auth.module.proxy.WSLoginModuleProxy"
  authenticationStrategy="REQUIRED">
  <options xmi:id="Property_2" name="delegate"
   value="com.ibm.ws.security.common.auth.module.WSLoginModuleImpl"/>
  <options xmi:id="Property_3" name="use_realm_callback" value="true"/>
  <options xmi:id="Property_4" name="use_appcontext_callback" value="true"/>
 </loginModules>
</entries>
```

Example: Using the WSLogin configuration to create a basic authentication subject:

This example shows how to use the WSLogin application login configuration from within a Java 2 Platform, Enterprise Edition (J2EE) application to log in and get a Subject that contains the user ID and the password of the target realm.

```
javax.security.auth.Subject subject = null;

try
{
  // Create a login context using the WSLogin login configuration and specify a
  // user ID, target realm, and password. Note: If the target_realm_name is the
  // same as the current realm, an authenticated Subject is created. However, if
  // the target_realm_name is different from the current realm, a basic
  // authentication Subject is created that is not validated. This unvalidated
  // Subject is created so that you can send a request to the different target
  // realm with valid security credentials for that realm.
  javax.security.auth.login.LoginContext ctx = new LoginContext("WSLogin",
   new WSCallbackHandlerImpl("userid", "target_realm_name", "password"));

  // Note: The following code is an alternative that validates the user ID and
  // password specified against the target realm. The code performs a remote call
  // to the target server and will return  true if the user ID and password are
  // valid and false if the user ID and password are not valid. If false is
  // returned, a WSLoginFailedException exception is created. You can catch
  // that exception and perform a retry or stop the request from flowing by
  // allowing that exception to surface out of this login.

  // ALTERNATIVE LOGIN CONTEXT THAT VALIDATES THE USER ID AND PASSWORD TO THE
  // TARGET REALM

  /****  currently remarked out ****
  java.util.Map appContext = new java.util.HashMap();
              appContext.put(javax.naming.Context.INITIAL_CONTEXT_FACTORY,
                             "com.ibm.websphere.naming.WsnInitialContextFactory");
              appContext.put(javax.naming.Context.PROVIDER_URL,
                             "corbaloc:iiop:target_host:2809");

  javax.security.auth.login.LoginContext ctx = new LoginContext("WSLogin",
   new WSCallbackHandlerImpl("userid", "target_realm_name", "password", appContext));
  **** currently remarked out  ****/

  // Starts the login
  ctx.login();

  // Gets the Subject from the context
  subject = ctx.getSubject();
 }
 catch (javax.security.auth.login.LoginException e)
 {
  throw new com.ibm.websphere.security.auth.WSLoginFailedException (e.getMessage(), e);
 }

 if (subject != null)
 {
```

```
  // Defines a privileged action that encapsulates your remote request.
java.security.PrivilegedAction myAction = java.security.PrivilegedAction()
  {
   public Object run()
   {
    // Assumes a proxy is already defined. This example method returns a String
    return proxy.remoteRequest();
   }
  });

  // Starts this action using the basic authentication Subject needed for
     // the target realm security requirements.
  String myResult = (String) com.ibm.websphere.security.auth.WSSubject.doAs
        (subject, myAction);
 }
```

Example: Sample login configuration for RMI_OUTBOUND:

This example shows a sample login configuration for RMI_OUTBOUND that determines whether the realm names match between two servers.

```
public customLoginModule()
{
 public void initialize(Subject subject, CallbackHandler callbackHandler,
     Map sharedState, Map options)
 {
     // (For more information on what to do during initialization, see
     // "Developing custom login modules for a system login configuration for JAAS" on page 1521.)
 }

 public boolean login() throws LoginException
 {
     // (For more information on what to do during login, see
     // "Developing custom login modules for a system login configuration for JAAS" on page 1521.)

  // Gets the WSProtocolPolicyCallback object
  Callback callbacks[] = new Callback[1];
   callbacks[0] = new com.ibm.wsspi.security.auth.callback.
          WSProtocolPolicyCallback("Protocol Policy Callback: ");

  try
  {
   callbackHandler.handle(callbacks);
  }
  catch (Exception e)
  {
   // Handles the exception
  }

     // Receives the RMI (CSIv2) policy object for checking the target realm
     // based upon information from the IOR.
     // Note: This object can be used to perform additional security checks.
     // See the application programming interface (API) documentation for
     // more information.
  csiv2PerformPolicy = (CSIv2PerformPolicy) ((WSProtocolPolicyCallback)callbacks[0]).
        getProtocolPolicy();

  // Checks if the realms do not match. If they do not match, then log in to
     // perform a mapping
  if (!csiv2PerformPolicy.getTargetSecurityName().equalsIgnoreCase(csiv2PerformPolicy.
        getCurrentSecurityName()))
  {
   try
   {
    // Do some custom realm -> user ID and password mapping
    MyBasicAuthDataObject myBasicAuthData = MyMappingLogin.lookup
          (csiv2PerformPolicy.getTargetSecurityName());

          // Creates the login context with basic authentication data gathered from
          // custom mapping
    javax.security.auth.login.LoginContext ctx = new LoginContext("WSLogin",
     new WSCallbackHandlerImpl(myBasicAuthData.userid,
       csiv2PerformPolicy.getTargetSecurityName(),
                  myBasicAuthData.password));

     // Starts the login
     ctx.login();

            // Gets the Subject from the context. This subject is used to replace
            // the passed-in Subject during the commit phase.
     basic_auth_subject = ctx.getSubject();

Security attribute propagation

With *Security attribute propagation*, WebSphere Application Server can transport security attributes (authenticated Subject contents and security context information) from one server to another in your configuration. WebSphere Application Server might obtain these security attributes from either an enterprise user registry, which queries static attributes, or a custom login module, which can query static or dynamic attributes. Dynamic security attributes, which are custom in nature, might include the authentication strength that is used for the connection, the identity of the original caller, the location of the original caller, the IP address of the original caller, and so on.

Security attribute propagation provides propagation services using Java serialization for any objects that are contained in the Subject. However, Java code must be able to serialize and deserialize these objects.

The Java programming language specifies the rules for how Java code can serialize an object. Because problems can occur when dealing with different platforms and versions of software, WebSphere Application Server also offers a token framework that enables custom serialization functionality. The token framework has other benefits that include the ability to identify the uniqueness of the token. This uniqueness determines how the Subject gets cached and the purpose of the token. The token framework defines four marker token interfaces that enable the WebSphere Application Server runtime to determine how to propagate the token.

Important: Any custom tokens that are used in this framework are not used by WebSphere Application Server for authorization or authentication. The framework serves as a way to notify WebSphere Application Server that you want these tokens propagated in a particular way. WebSphere Application Server handles the propagation details, but does not handle serialization or deserialization of custom tokens. Serialization and deserialization of these custom tokens are carried out by the implementation and handled by a custom login module.

With WebSphere Application Server Version 6.0 and later, a custom Java Authorization Contract for Container (JACC) provider can be configured to enforce access control for Java Platform, Enterprise Edition (Java EE) applications. A custom JACC provider can explore the custom security attributes in the caller JAAS subject in making access control decisions.

When a request is being authenticated, a determination is made by the login modules whether this request is an *initial login* or a *propagation login*. An initial login is the process of authenticating the user information, typically a user ID and password, and then calling the application programming interfaces (APIs) for the remote user registry to look up secure attributes that represent the user access rights. A propagation login is the process of validating the user information, typically a Lightweight Third Party Authentication (LTPA) token, and then deserializing a series of tokens that constitute both custom objects and token framework objects known to WebSphere Application Server.

The following marker tokens are introduced in the framework:

Authorization token

The authorization token contains most of the authorization-related security attributes that are propagated. The default authorization token is used by the WebSphere Application Server authorization engine to make Java Platform, Enterprise Edition (Java EE) authorization decisions. Service providers can use custom authorization token implementations to isolate their data in a different token, perform custom serialization and de-serialization, and make custom authorization decisions using the information in their token at the appropriate time. For information on how to use and implement this token type, see “Using the default propagation token to propagate security attributes” on page 1554 and Implementing a custom propagation token for security attribute propagation.

Single sign-on (SSO) token

A custom SingleSignonToken token that is added to the Subject is automatically added to the response as an HTTP cookie and contains the attributes sent back to web browsers. The token interface getName method with the getVersion method defines the cookie name. WebSphere Application Server defines a default SingleSignonToken token with the LtpaToken name and Version 2. The cookie name added is LtpaToken2. Do not add sensitive information, confidential information, or unencrypted data to the response cookie.

It is also recommended that any time that you use cookies, use the Secure Sockets Layer (SSL) protocol to protect the request. Using an SSO token, web users can authenticate once when accessing web resources across multiple WebSphere Application Servers. A custom SSO token extends this functionality by adding custom processing to the single sign-on scenario. For more information on SSO tokens, see “Implementing single sign-on to minimize web user authentications” on page 1441. For information on how to use and implement this token type, see

"Using the default single sign-on token with default or custom token factory to propagate security attributes" on page 1560 and Implementing a custom single sign-on token for security attribute propagation.

Propagation token

The propagation token is not associated with the authenticated user so it is not stored in the Subject. Instead, the propagation token is stored on the thread and follows the invocation wherever it goes. When a request is sent outbound to another server, the propagation tokens on that thread are sent with the request and the tokens are run by the target server. The attributes that are stored on the thread are propagated regardless of the Java Platform, Enterprise Edition (Java EE) RunAs user switches.

The default propagation token monitors and logs all user switches and host switches. You can add additional information to the default propagation token using the WSSecurityHelper application programming interfaces (APIs). To retrieve and set custom implementations of a propagation token, you can use the WSSecurityPropagationHelper class. For information on how to use and implement this token type, see "Using the default propagation token to propagate security attributes" on page 1554 and Implementing a custom propagation token for security attribute propagation.

Authentication token

The authentication token flows to downstream servers and contains the identity of the user. This token type serves the same function as the Lightweight Third Party Authentication (LTPA) token in previous versions. Although this token type is typically reserved for internal WebSphere Application Server purposes, you can add this token to the Subject and the token is propagated using the getBytes method of the token interface.

A custom authentication token is used solely for the purpose of the service provider that adds it to the Subject. WebSphere Application Server does not use it for authentication purposes because a default authentication token exists that is used for WebSphere Application Server authentication. This token type is available for the service provider to identify how the custom data uses the token to perform custom authentication decisions. For information on how to use and implement this token type, see "Default authentication token" on page 1548 and Implementing a custom authentication token for security attribute propagation .

Kerberos authentication token

The Kerberos authentication token contains Kerberos credentials such as the Kerberos principal name, GSSCredential and Kerberos delegation credential. This token is propagated to the downstream server. Although this token type is typically reserved for internal WebSphere Application Server purposes, if it contains the GSSCredential you can use the getGSSCredential method to extract the GSSCredential. You can then place it in the subject and it can be used for your application. This token is created when you authenticate to WebSphere Application Server with either SPNEGO web or Kerberos authentication.

Horizontal propagation versus downstream propagation

In WebSphere Application Server, both horizontal propagation, which uses single sign-on for web requests, and downstream propagation, which uses Remote Method Invocation over the Internet Inter-ORB Protocol (RMI/IIOP) to access enterprise beans, are available.

Horizontal propagation

In horizontal propagation, security attributes are propagated among front-end servers. The serialized security attributes, which are the Subject contents and the propagation tokens, can contain both static and dynamic attributes. The single sign-on (SSO) token stores additional system-specific information that is needed for horizontal propagation. The information contained in the SSO token tells the receiving server where the originating server is located and how to communicate with that server. Additionally, the SSO token also contains the key to look up the serialized attributes. To enable horizontal propagation, you must

configure the single sign-on token and the web inbound security attribute propagation features. You can configure both of these features using the administrative console.

Figure 1

Performance implications for horizontal propagation

The performance implications of the JMX remote call depends upon your environment. The JMX remote call is used for obtaining the original login attributes. Horizontal propagation reduces many of the remote user registry calls in cases where these calls cause the most performance problems for an application. However, the deserialization of these objects also might cause performance degradation, but this degradation might be less than the remote user registry calls. It is recommended that you test your environment with horizontal propagation enabled and disabled. In cases where you must use horizontal propagation for preserving original login attributes, test whether JMX provides better performance in your environment.

Downstream propagation

In *downstream propagation*, a Subject is generated at the web front-end server, either by a propagation login or a user registry login. WebSphere Application Server propagates the security information downstream for enterprise bean invocations when both Remote Method Invocation (RMI) outbound and inbound propagation are enabled.

Benefits of propagating security attributes

The security attribute propagation feature of WebSphere Application Server has the following benefits:

- Enables WebSphere Application Server to use the security attribute information for authentication and authorization purposes. The propagation of security attributes can eliminate the need for user registry calls at each remote hop along an invocation. Previous versions of WebSphere Application Server propagated only the user name of the authenticated user, but ignored other security attribute information that needed to be regenerated downstream using remote user registry calls. To accentuate the benefits of this new functionality, consider the following example:

  In previous releases, you might use a reverse proxy server (RPSS), such as WebSEAL, to authenticate the user, gather group information, and gather other security attributes. As stated previously, WebSphere Application Server accepted the identity of the authenticated user, but disregarded the additional security attribute information. To create a Java Authentication and Authorization Service (JAAS) Subject containing the needed WSCredential and WSPrincipal objects, WebSphere Application Server made 5 to 6 calls to the user registry. The WSCredential object contains various security information that is required to authorize a Java EE resource. The WSPrincipal object contains the realm name and the user that represents the principal for the Subject.

  In the current release of the Application Server, information that is obtained from the reverse proxy server can be used by WebSphere Application Server and propagated downstream to other server resources without additional calls to the user registry. The retaining of the security attribute information enables you to protect server resources properly by making appropriate authorization and trust-based decisions User switches that occur because of Java EE RunAs configurations do not cause the application server to lose the original caller information. This information is stored in the PropagationToken located on the running thread.
- Enables third-party providers to plug in custom tokens. The token interface contains a getBytes method that enables the token implementation to define custom serialization, encryption methods, or both.
- Provides the ability to have multiple tokens of the same type within a Subject created by different providers. WebSphere Application Server can handle multiple tokens for the same purpose. For example, you might have multiple authorization tokens in the Subject and each token might have distinct authorization attributes that are generated by different providers.

- Provides the ability to have a unique ID for each token type that is used to formulate a more unique subject identifier than just the user name in cases where dynamic attributes might change the context of a user login. The token type has a getUniqueId() method that is used for returning a unique string for caching purposes. For example, you might need to propagate a location ID, which indicates the location from which the user logs into the system. This location ID can be generated during the original login using either an reverse proxy server or the WEB_INBOUND login configuration and added to the Subject prior to serialization. Other attributes might be added to the Subject as well and use a unique ID. All of the unique IDs must be considered for the uniqueness of the entire Subject. WebSphere Application Server has the ability to specify what is unique about the information in the Subject, which might affect how the user accesses the Subject later.

Default authentication token

Do not use the default authentication token in service provider code. This default token is used by the WebSphere Application Server run-time code only and is authentication mechanism specific.

Any modifications to this token by service provider code can potentially cause interoperability problems. If you need to create an authentication token for custom usage, see Implementing a custom authentication token for security attribute propagation for more information.

Changing the token factory that is associated with the default authentication token

When WebSphere Application Server generates a default authentication token, the application server utilizes the TokenFactory class that is specified using the com.ibm.wsspi.security.token.authenticationTokenFactory property. To modify this property using the administrative console, complete the following steps:

1. Click **Security > Global security**.
2. Under Additional properties, click **Custom properties**.

The com.ibm.ws.security.ltpa.LTPATokenFactory token factory is the default for this property. The LTPATokenFactory token factory uses the DESede/ECB/PKCS5Padding cipher. This token factory creates an interoperable Lightweight Third Party Authentication (LTPA) token.

If you associate the com.ibm.ws.security.ltpa.LTPAToken2Factory token factory with the com.ibm.wsspi.security.token.authenticationTokenFactory property, the token is Advanced Encryption Standard (AES) encrypted. However, you need to weigh the performance against your security needs. You might add additional attributes to the authentication token in the Subject during a login that are available downstream.

If you need to perform your own signing and encryption of the default authentication token, you must implement the following classes:

- com.ibm.wsspi.security.ltpa.Token
- com.ibm.wsspi.security.ltpa.TokenFactory

Your token factory implementation instantiates (createToken) and validates (validateTokenBytes) your token implementation. You can use the LTPA keys that are passed into the initialize method of the token factory or you can use your own keys. If you use your own keys, they must be the same everywhere to validate the tokens that are generated using those keys. See the API documentation, available through a link on the front page of the information center, for more information on implementing your own custom token factory. To associate your token factory with the default authentication token using the administrative console, complete the following steps:

1. Click **Security > Global security**.
2. Under Additional properties, click **Custom properties**.
3. Locate the com.ibm.wsspi.security.token.authenticationTokenFactory property and verify that the value of this property matches your custom token factory implementation.

4. Verify that your implementation classes are put into the *install_dir*/classes directory so that the WebSphere Application Server class loader can load the classes.
5. Verify that the QEJBSVR user profile has read, write, and execute (*RWX) authority to the classes directory. You can use the Work with Authority (WRKAUT) command to view the authority permissions for that directory.

Propagating security attributes among application servers

Use the security attribute propagation feature of WebSphere Application Server to send security attribute information regarding the original login to other servers using a token. This topic will help to configure WebSphere Application Server to propagate security attributes to other servers.

About this task

To fully enable security attribute propagation, you must configure the single sign-on (SSO), Common Secure Interoperability Version 2 (CSIv2) inbound, and CSIv2 outbound panels in the WebSphere Application Server administrative console. You can enable just the portions of security attribute propagation relevant to your configuration. For example, you can enable web propagation, which is propagation amongst front-end application servers, using either the push technique (DynaCache) or the pull technique (remote method to originating server).

You also can choose whether to enable Remote Method Invocation (RMI) outbound and inbound propagation, which is commonly called downstream propagation. Typically both types of propagation are enabled for any given cell. In some cases, you might want to choose a different option for a specific application server using the server security panel within the specific application server settings.

Restriction: To prevent propagating the same security attributes among application servers multiple times, WebSphere Application Server verifies that a Lightweight Third Party Authentication (LTPA) token does not exist. Two cases can occur. Absence of the LTPA token tells the Application Server that propagation can proceed. Presence of the LTPA token indicates that propagation has occurred if the LTPA token has been generated within the cluster. However, in the second case, if the LTPA token is present, but has been generated by a server outside the cluster, such as by Tivoli Access Manager, Lotus Domino or a different Application Server cluster, security attributes are not propagated.

To access the server security panel in the administrative console, click **Servers > Application Servers > *server_name***. Under Security, click **Server security**.

Complete the following steps to configure WebSphere Application Server for security attribute propagation:

Procedure

1. Access the WebSphere Application Server administrative console by typing http://*server_name*:*port_number*/ibm/console. The administrative console address might differ if you have previously changed the port number.
2. Click **Security > Global security**.
3. Under Web security, click **Single sign-on (SSO)**.
4. Optional: Select the **Interoperability Mode** option if you need to interoperate with servers that do not support security attribute propagation. Servers that do not support security attribute propagation receive the Lightweight Third Party Authentication (LTPA) token and the Propagation token, but ignore the security attribute information that they do not understand.
5. Select the **Web inbound security attribute propagation** option. The Web inbound security attribute propagation option enables horizontal propagation, which allows the receiving SSO token to retrieve the login information from the original login server. If you do not enable this option, downstream propagation can occur if you enable the Security Attribute Propagation option on both the CSIv2 Inbound authentication and CSIv2 outbound authentication panels.

Typically, you enable the web inbound security attribute propagation option if you need to gather dynamic security attributes set at the original login server that cannot be regenerated at the new front-end server. These attributes include any custom attributes that might be set in the PropagationToken token using the com.ibm.websphere.security.WSSecurityHelper application programming interfaces (APIs). You must determine whether enabling this option improves or degrades the performance of your system. While the option prevents some remote user registry calls, the deserialization and decryption of some tokens might impact performance. In some cases propagation is faster, especially if your user registry is the bottleneck of your topology. It is recommended that you measure the performance of your environment both using and not using this option. When you test the performance, it is recommended that you test in the operating environment of the typical production environment with the typical number of unique users accessing the system simultaneously.

6. Click **Security > Global security**. Under RMI/IIOP security, click **CSIv2 inbound authentication**. The Login configuration field specifies `RMI_INBOUND` as the system login configuration that is used for inbound requests. To add custom Java Authentication and Authorization Service (JAAS) login modules, complete the following steps:
   a. Click **Security > Global security**. Under Java Authentication and Authorization Service, click **System logins**. A list of the system login configurations is displayed. WebSphere Application Server provides the following pre-configured system login configurations: DEFAULT, LTPA, LTPA_WEB, RMI_INBOUND, RMI_OUTBOUND, SWAM, WEB_INBOUND, wssecurity.IDAssertion, and wssecurity.Signature. Do not delete these predefined configurations.

      Note: SWAM is deprecated in WebSphere Application Server Version 8.0 and will be removed in a future release.
   b. Click the name of the login configuration that you want to modify.
   c. Under Additional Properties, click **JAAS Login Modules**. The JAAS Login Modules panel is displayed, which lists all of the login modules that are processed in the login configuration. Do not delete the required JAAS login modules. Instead, you can add custom login modules before or after the required login modules. If you add custom login modules, do not begin their names with com.ibm.ws.security.server.

      You can specify the order in which the login modules are processed by clicking **Set Order**.
7. Select the **Security attribute propagation** option on the CSIv2 inbound authentication panel. When you select **Security Attribute Propagation**, the server advertises to other application servers that it can receive propagated security attributes from another server in the same realm over the Common Secure Interoperability version 2 (CSIv2) protocol.
8. Click **Security > Global security**. Under RMI/IIOP security, click **CSIv2 Outbound authentication**. The CSIv2 outbound authentication panel is displayed. The **Login configuration** field specifies `RMI_OUTBOUND` as the JAAS login configuration that is used for outbound configuration. You cannot change this login configuration. Instead, you can customize this login configuration by completing the substeps that are listed previously for CSIv2 Inbound authentication.
9. Optional: Verify that the **Security Attribute Propagation** option is selected if you want to enable outbound Subject and security context token propagation for the Remote Method Invocation (RMI) protocol. When you select this option, WebSphere Application Server serializes the Subject contents and the PropagationToken contents. After the contents are serialized, the server uses the CSIv2 protocol to send the Subject and PropagationToken token to the target servers that support security attribute propagation. If the receiving server does not support security attribute tokens, WebSphere Application Server sends the Lightweight Third Party Authentication (LTPA) token only.

   Important: WebSphere Application Server propagates only the objects within the Subject that it can serialize. The server propagates custom objects on a best-effort basis.

   When **Security Attribute Propagation** is enabled, WebSphere Application Server adds marker tokens to the Subject to enable the target server to add additional attributes during the inbound login. During the commit phase of the login, the marker tokens and the Subject are marked as read-only and cannot be modified thereafter.

10. Optional: Select the **Custom Outbound Mapping** option if you clear the **Security Attribute Propagation** option and you want to use the RMI_OUTBOUND login configuration. If neither the **Custom Outbound Mapping** option nor the **Security Attribute Propagation** option is selected, WebSphere Application Server does not call the RMI_OUTBOUND login configuration. If you need to plug in a credential mapping login module, you must select the **Custom Outbound Mapping** option.
11. Optional: Specify trusted target realm names in the **Trusted Target Realms** field. By specifying these realm names, information can be sent to servers that reside outside the realm of the sending server to support inbound mapping that is at these downstream servers. To perform outbound mapping to a realm different from the current realm, you must specify the realm in this field so that you can get to this point without having the request rejected because of a realm mismatch. If you need WebSphere Application Server to propagate security attributes to another realm when a request is sent, you must specify the realm name in the **Trusted Target Realms** field. Otherwise, the security attributes are not propagated to the unspecified realm. You can add multiple target realms by adding a pipe (|) delimiter between each entry.
12. Optional: Enable propagation for a pure client. For a pure client to propagate attributes added to the invocation Subject, you must add the following property to the `sas.client.props` file:

    ```
    com.ibm.CSI.rmiOutboundPropagationEnabled=true
    ```

    Note: The `sas.client.props` file is located at `<WAS-HOME>/profiles/<ProfileName>/properties>`.

Results

After completing these steps, you have configured WebSphere Application Server to propagate security attributes to other servers.

What to do next

If you need to disable security attribute propagation, determine whether you need to disable it for either the server level or the cell level.

Attention: Changes to the server-level settings override the cell settings.

To disable security attribute propagation on the server level, complete the following steps:

1. Click **Server > Application Servers > *server_name***.
2. Under Security, click **Server security**.
3. Select the **RMI/IIOP security for this server overrides cell settings** option.
4. Disable security attribute propagation for inbound requests by clicking **CSI inbound authentication** under Additional Properties and clearing the **Security attribute propagation** option.
5. Disable security attribute propagation for outbound requests by clicking **CSI outbound authentication** under Additional Properties and clearing the **Security attribute propagation** option.

To disable security attribute propagation on the cell level, undo each of the steps that you completed to enable security attribute propagation in this task.

Using the default authorization token to propagate security attributes

This topic explains how WebSphere Application Server uses the default authorization token. Consider using the default authorization token when you are looking for a place to add string attributes that get propagated downstream.

About this task

However, make sure that the attributes you add to the authorization token are specific to the user that is associated with the authenticated Subject. If they are not specific to a user, the attributes probably belong in the propagation token, which is also propagated with the request. For more information on the

propagation token, see “Using the default propagation token to propagate security attributes” on page 1554. To add attributes into the authorization token, you must plug in a custom login module into the various system login modules that are configured. Any login module configuration that has the com.ibm.ws.security.server.lm.wsMapDefaultInboundLoginModule implementation configured can receive propagated information and can generate propagation information that can be sent outbound to another server.

If propagated attributes are not presented to the login configuration during an initial login, a default authorization token is created in the wsMapDefaultInboundLoginModule login module after the login occurs in the ltpaLoginModule login module. You can obtain a reference to the default authorization token from the login method using the sharedState hashmap. You must plug in the custom login module after the wsMapDefaultInboundLoginModule implementation for WebSphere Application Server to see the default authorization token.

For more information on the Java Authentication and Authorization Service (JAAS) programming model, see the Security: Resources for learning article.

Procedure

- Obtain a reference to the default authorization token from the login method.
- Add attributes to the token.
- Read existing attributes used for authorization.
- Add your custom login module to the *profile_root*/classes directory. For more information, see Creating a classes subdirectory in your profile for custom classes.
- Modify the authorization token factory to use a token factory other than the default token factory.

  When WebSphere Application Server generates a default authorization token, the application server utilizes the TokenFactory class that is specified using the com.ibm.wsspi.security.token.authorizationTokenFactory property.

  The com.ibm.ws.security.ltpa.AuthzPropTokenFactory token factory is the default. This token factory encodes the data, but does not encrypt the data in the authorization token. Because the authorization token typically flows over Common Secure Interoperability Version 2 (CSIv2) using Secure Sockets Layer (SSL), encrypting the token is not necessary. However, if you need additional security for the authorization token, you can associate a different token factory implementation with this property to get encryption. For example, if you associate the com.ibm.ws.security.ltpa.LTPAToken2Factory token factory with this property, the token uses Advanced Encryption Standard (AES) encryption. However, you need to weigh the performance impacts against your security needs. Adding sensitive information to the authorization token is one reason to change the token factory implementation to something that encrypts rather than just encodes.

  1. Open the administrative console.
  2. Click **Security > Global security**.
  3. Under Additional properties, click **Custom properties**.
- Perform your own signing and encryption of the default authorization token.

  If you want to perform your own signing and encryption of the default authorization token, you must implement the following classes:

  – com.ibm.wsspi.security.ltpa.Token
  – com.ibm.wsspi.security.ltpa.TokenFactory

  Your token factory implementation instantiates and validates your token implementation. You can use the Lightweight Third Party Authentication (LTPA) keys that are passed into the initialize method of the token factory or you can use your own keys. If you use your own keys, they must be the same everywhere to validate the tokens that are generated using those keys. See the API documentation, that is available through a link on the front page of the information center, for more information on implementing your own custom token factory.
- Associate your token factory with the default authorization token.

To associate your token factory with the default authorization token, using the administrative console, complete the following steps:

1. Click **Security > Global security**.
2. Under Additional properties, click **Custom properties**.
3. Locate the com.ibm.wsspi.security.token.authorizationTokenFactory property and verify that the value of this property matches your custom token factory implementation.
4. Verify that your implementation classes are put into the *app_server_root*/`classes` directory so that the WebSphere Application Server class loader can load the classes.
5. Verify that the QEJBSVR user profile has read, write, and execute (*RWX) authority to the classes directory. You can use the Work with Authority (WRKAUT) command to view the authority permissions for the directory.

Example

The following example shows the complete task of obtaining a reference to the default authorization token from the login method, adding attributes to the token, and reading from the existing attributes that are used for authorization.

```
public customLoginModule()
{
 public void initialize(Subject subject, CallbackHandler callbackHandler,
         Map sharedState, Map options)
 {
     // (For more information on initialization, see
     // "Developing custom login modules for a system login configuration for JAAS" on page 1521.)

  // Get a reference to the sharedState map that is passed in during initialization.
  _sharedState = sharedState;
 }

 public boolean login() throws LoginException
 {
     // (For more information on what to do during login, see
     // "Developing custom login modules for a system login configuration for JAAS" on page 1521.)

  // Look for the default AuthorizationToken in the shared state
  defaultAuthzToken  = (com.ibm.wsspi.security.token.AuthorizationToken)
       sharedState.get
     (com.ibm.wsspi.security.auth.callback.Constants.WSAUTHZTOKEN_KEY);

  // Might not always have one of these generated. It depends on the login
     // configuration setup.
  if (defaultAuthzToken != null)
  {
   try
   {
    // Add a custom attribute
    defaultAuthzToken.addAttribute("key1", "value1");

    // Determine all of the attributes and values that exist in the token.
    java.util.Enumeration listOfAttributes = defaultAuthorizationToken.
              getAttributeNames();

    while (listOfAttributes.hasMoreElements())
    {
     String key = (String) listOfAttributes.nextElement();

     String[] values = (String[]) defaultAuthorizationToken.getAttributes (key);

     for (int i=0;  i<values.length; i++)
     {
      System.out.println ("Key: " + key + ", Value[" + i + "]: "
                 + values[i]);
     }
    }

    // Read the existing uniqueID attribute.
    String[]  uniqueID = defaultAuthzToken.getAttributes
      (com.ibm.wsspi.security.token.AttributeNameConstants.
               WSCREDENTIAL_UNIQUEID);

     // Getthe uniqueID from the String[]
     String unique_id = (uniqueID != null &&
                uniqueID[0] != null) ? uniqueID[0] : "";

    // Read the existing expiration attribute.
    String[]  expiration = defaultAuthzToken.getAttributes
      (com.ibm.wsspi.security.token.AttributeNameConstants.
```

```
            WSCREDENTIAL_EXPIRATION);

     // An example of getting a long expiration value from the string array.
     long expire_time = 0;
     if (expiration != null && expiration[0] != null)
      expire_time = Long.parseLong(expiration[0]);

    // Read the existing display name attribute.
    String[]  securityName = defaultAuthzToken.getAttributes
      (com.ibm.wsspi.security.token.AttributeNameConstants.
            WSCREDENTIAL_SECURITYNAME);

     // Get the display name from the String[]

Using the default propagation token to propagate security attributes

A default propagation token is located on the running thread for applications and the security infrastructure to use. The product propagates this default propagation token downstream and the token stays on the thread where the invocation lands at each hop.

About this task

The data is available from within the container of any resource where the propagation token lands. Remember that you must enable the propagation feature at each server where a request is sent for propagation to work. Make sure that you enable security attribute propagation for all of the cells in your environment where you want propagation

There is a WSSecurityHelper class that has application programming interfaces (APIs) for accessing the PropagationToken attributes. This topic documents the usage scenarios and includes examples. A close relationship exists between the propagation token and the work area feature. The main difference between

these features is that after you add attributes to the propagation token, you cannot change the attributes. You cannot change these attributes so that the security runtime can add auditable information and have that information remain there for the life of the invocation. Any time that you add an attribute to a specific key, an ArrayList object is stored to hold that attribute. Any new attribute that is added with the same key is added to the ArrayList object. When you call getAttributes, the ArrayList object is converted to a String array and the order is preserved. The first element in the String array is the first attribute added for that specific key.

In the default propagation token, a change flag is kept that logs any data changes to the token. These changes are tracked to enable WebSphere Application Server to know when to send the authentication information downstream again so that the downstream server has those changes. Normally, Common Secure Interoperability Version 2 (CSIv2) maintains a session between servers for an authenticated client. If the propagation token changes, a new session is generated and subsequently a new authentication occurs. Frequent changes to the propagation token during a method cause frequent downstream calls. If you change the token prior to making many downstream calls or you change the token between each downstream call, you might impact security performance.

Procedure

- Obtain the server list from the default propagation token.

  Every time the propagation token is propagated and used to create the authenticated Subject, either horizontally or downstream, the name of the receiving application server is logged into the propagation token. The format of the host is `"Cell:Node:Server"`, which provides you access to the cell name, node name, and server name of each application server that receives the invocation.

  The following code provides you with this list of names and can be called from a Java 2 Platform, Enterprise Edition (J2EE) application.

  The format of each server in the list is: *cell*:*node_name*:*server_name*. The output, for example, is: `myManager:node1:server1`

```
String[] server_list = null;

// If security is disabled on this application server, do not bother checking
if (com.ibm.websphere.security.WSSecurityHelper.isServerSecurityEnabled())
{
 try
 {
  // Gets the server_list string array
  server_list = com.ibm.websphere.security.WSSecurityHelper.getServerList();
 }
 catch (Exception e)
 {
  // Performs normal exception handling for your application
 }

 if (server_list != null)
 {
  // print out each server in the list, server_list[0] is the first server
  for (int i=0; i<server_list.length; i++)
  {
   System.out.println("Server[" + i + "] = " + server_list[i]);
  }
 }
}
```

- Obtain the list of callers, using the getCallerList API.

A default propagation token is generated any time an authenticated user is set on the running thread or anyone tries to add attributes to the propagation token. Whenever an authenticated user is set on the thread, the user is logged in the default propagation token. At times, the same user might be logged in multiple times if the RunAs user is different from the caller. The following list provides the rules that are used to determine if a user that is added to the thread gets logged into the propagation token:

– The current Subject must be authenticated. For example, an unauthenticated Subject is not logged.
– The current authenticated Subject is logged if a Subject is not previously logged.
– The current authenticated Subject is logged if the last authenticated Subject that is logged does not contain the same user.
– The current authenticated Subject is logged on each unique application server that is involved in the propagation process.

The following code sample shows how to use the getCallerList API.

The format of each caller in the list is: *cell*:*node_name*:*server_name*:*realm*:*port_number*/*securityName*. The output, for example, is: `myManager:node1:server1:ldap.austin.ibm.com:389/jsmith`.

```
String[] caller_list = null;

// If security is disabled on this application server, do not check the caller list
if (com.ibm.websphere.security.WSSecurityHelper.isServerSecurityEnabled())
{
 try
 {
  // Gets the caller_list string array
  caller_list = com.ibm.websphere.security.WSSecurityHelper.getCallerList();
 }
 catch (Exception e)
 {
  // Performs normal exception handling for your application
 }

 if (caller_list != null)
 {
  // Prints out each caller in the list, caller_list[0] is the first caller
  for (int i=0; i<caller_list.length;i++)
  {
   System.out.println("Caller[" + i + "] = " + caller_list[i]);
  }
 }
}
```

- Obtain the security name of the first authenticated user, using the getFirst Caller API.

  Whenever you want to know which authenticated caller started the request, you can call the getFirstCaller method and the caller list is parsed. However, this method returns the security name of the caller only. If you need to know more than the security name, call the getCallerList method and retrieve the first entry in the String array. This entry provides all the caller information.

  The following code sample retrieves the security name of the first authenticated caller using the getFirstCaller API.

  The output, for example, is: `jsmith`.

```
String first_caller = null;

// If security is disabled on this application server, do not bother checking
if (com.ibm.websphere.security.WSSecurityHelper.isServerSecurityEnabled())
{
```

```
 try
 {
  // Gets the first caller
  first_caller = com.ibm.websphere.security.WSSecurityHelper.getFirstCaller();

  // Prints out the caller name
  System.out.println("First caller: " + first_caller);
 }
 catch (Exception e)
 {
  // Performs normal exception handling for your application
 }
}
```

- Obtain the name of the first application server for a request, using the getFirstServer method.

  Whenever you want to know what the first application server is for this request, call the getFirstServer method directly.

  The following code sample retrieves the name of the first application server using the getFirstServer API.

  The output, for example, is: `myManager:node1:server1`.

```
String first_server = null;

// If security is disabled on this application server, do not bother checking
if (com.ibm.websphere.security.WSSecurityHelper.isServerSecurityEnabled())
{
 try
 {
  // Gets the first server
  first_server = com.ibm.websphere.security.WSSecurityHelper.getFirstServer();

  // Prints out the server name
  System.out.println("First server: " + first_server);
 }
 catch (Exception e)
 {
  // Performs normal exception handling for your application
 }
}
```

- Add custom attributes to the default propagation token, using the addPropagationAttribute API.

  You can add custom attributes to the default propagation token for application usage. This token follows the request downstream so that the attributes are available when needed. When you use the default propagation token to add attributes, you must understand the following issues:

  – Adding information to the propagation token affects CSIv2 session caching. Add information sparingly between remote requests.
  – After you add information with a specific key, the information cannot be removed.
  – You can add as many values to a specific key as you need. However, all of the values must be available from a returned String array in the order that they were added.
  – The propagation token is available only on servers where propagation and security are enabled.
  – The Java 2 Security javax.security.auth.AuthPermission wssecurity.addPropagationAttribute attribute is needed to add attributes to the default propagation token.
  – An application cannot use keys that begin with either com.ibm.websphere.security or com.ibm.wsspi.security. These prefixes are reserved for system usage.

  The following code sample shows how to use the addPropagationAttribute API.

```
// If security is disabled on this application server,
    // do not check the status of server security
if (com.ibm.websphere.security.WSSecurityHelper.isServerSecurityEnabled())
{
 try
 {
  // Specifies the key and values
  String key = "mykey";
  String value1 = "value1";
  String value2 = "value2";

  // Sets key, value1
      com.ibm.websphere.security.WSSecurityHelper.
      addPropagationAttribute (key, value1);

  // Sets key, value2
  String[] previous_values = com.ibm.websphere.security.WSSecurityHelper.
         addPropagationAttribute (key, value2);

  // Note: previous_values should contain value1
 }
 catch (Exception e)
 {
  // Performs normal exception handling for your application
 }
}
```

- Obtain your custom attributes with the get PropagationAttributes API.

  Custom attributes are added to the default propagation token using the addPropagationAttribute API. Retrieve these attributes using the getPropagationAttributes API. This token follows the request downstream so the attributes are available when needed. When you use the default propagation token to retrieve attributes, you must understand the following issues:

  – The propagation token is available only on servers where propagation and security are enabled.
  – The Java 2 Security javax.security.auth.AuthPermission "wssecurity.getPropagationAttributes" permission is needed to retrieve attributes from the default propagation token.

  See Adding custom attributes to the default PropagationToken to add attributes using the addPropagationAttributes API.

  The following code sample shows how to use the getPropagationAttributes API.

```
// If security is disabled on this application server, do not bother checking
if (com.ibm.websphere.security.WSSecurityHelper.isServerSecurityEnabled())
{
 try
 {
  String key = "mykey";
  String[] values = null;

  // Sets key, value1
      values = com.ibm.websphere.security.WSSecurityHelper.
      getPropagationAttributes (key);

  // Prints the values
  for (int i=0; i<values.length; i++)
  {
   System.out.println("Value[" + i + "] = " + values[i]);
```

```
   }
  }
  catch (Exception e)
  {
   // Performs normal exception handling for your application
  }
 }
```

The output, for example, is:

```
Value[0] = value1
Value[1] = value2
```

- Modify the propagation token factory configuration to use a token factory other than the default token factory.

  When WebSphere Application Server generates a default propagation token, the Application Server utilizes the TokenFactory class that is specified using the com.ibm.wsspi.security.token.propagationTokenFactory property.

  The default token factory that is specified for this property is called com.ibm.ws.security.ltpa.AuthzPropTokenFactory. This token factory encodes the data in the propagation token and does not encrypt the data. Because the propagation token typically flows over CSIv2 using Secure Sockets Layer (SSL), encrypting the token is not required. However, if you need additional security for the propagation token, you can associate a different token factory implementation with this property to get encryption. For example, if you choose to associate the com.ibm.ws.security.ltpa.LTPAToken2Factory token factory with this property, the token is AES encrypted. However, you need to weigh the performance impacts against your security needs. Adding sensitive information to the propagation token is a good reason to change the token factory implementation to something that encrypts rather than just encodes.

  1. Open the administrative console.
  2. Click **Security > Global security**.
  3. Click **Custom properties**.

- Perform your own signing and encryption of the default propagation token.

  If you want to perform your own signing and encryption of the default propagation token, you must implement the following classes:

  – com.ibm.wsspi.security.ltpa.Token
  – com.ibm.wsspi.security.ltpa.TokenFactory

  Your token factory implementation instantiates and validates your token implementation. You can choose to use the Lightweight Third Party Authentication (LTPA) keys and have them pass into the initialize method of the token factory, or you can use your own keys. If you use your own keys, they must be the same everywhere to validate the tokens that are generated using those keys. See the API documentation, available through a link on the front page of the information center, for more information on implementing your own custom token factory.

- Associate your token factory with the default propagation token.

  1. Open the administrative console.
  2. Click **Security > Global security**.
  3. Click **Custom properties**.
  4. Locate the com.ibm.wsspi.security.token.propagationTokenFactory property and verify that the value of this property matches your custom token factory implementation.
  5. Verify that your implementation classes are put into the *app_server_root*/`classes` directory so that the WebSphere Application Server class loader can load the classes.
  6. Verify that the QEJBSVR user profile has read, write, and execute (*RWX) authority to the classes directory. You can use the Work with Authority (WRKAUT) command to view the authority permissions for the directory.

Example

Using the default single sign-on token with default or custom token factory to propagate security attributes

Do not use the default single sign-on token in service provider code. This default token is used by the WebSphere Application Server run-time code only.

Before you begin

Size limitations exist for this token when it is added as an HTTP cookie. If you need to create an HTTP cookie using this token framework, you can implement a custom single sign-on token. To implement a custom single sign-on token see Implementing a custom single sign-on token for security attribute propagation for more information.

Procedure

- Modify the single sign-on token factory configuration to use a token factory other than the default token factory.

  When the default single sign-on token is generated, the application server utilizes the TokenFactory class that is specified using the com.ibm.wsspi.security.token.singleSignonTokenFactory property. Use the administrative console to modify the property.

  The com.ibm.ws.security.ltpa.LTPAToken2Factory token factory is the default that is specified for this property. This token factory creates a single sign-on (SSO) token called LtpaToken2, which WebSphere Application Server uses for propagation. This token factory uses the AES/CBC/PKCS5Padding cipher.

  1. Open the administrative console.
  2. Click **Security > Global security**.
  3. Under Authentication, click **Custom properties**.
- Perform your own signing and encryption of the default single sign-on token.

  If you need to perform your own signing and encryption of the default single sign-on token, you must implement the following classes:

  – com.ibm.wsspi.security.ltpa.Token

  – com.ibm.wsspi.security.ltpa.TokenFactory

  Your token factory implementation instantiates (createToken) and validates (validateTokenBytes) your token implementation. You can use the Lightweight Third-Party Authentication (LTPA) keys passed into the initialize method of the token factory or you can use your own keys. If you use your own keys, they must be the same everywhere to validate the tokens that are generated using those keys. See the API reference information for more information on implementing your own custom token factory.
- Associate your own token factory with the default single sign-on token.
  1. Open the administrative console.
  2. Click **Security > Global security**.
  3. Under Authentication, click **Custom properties**.
  4. Locate the com.ibm.wsspi.security.token.singleSignonTokenFactory property and verify that the value of this property matches your custom TokenFactory implementation.
  5. Verify that your implementation classes are put into the *app_server_root*/`classes` directory so that the WebSphere Application Server class loader can load the classes.
  6. Verify that the QEJBSVR user profile has read, write, and execute (*RWX) authority to the classes directory. You can use the Work with Authority (WRKAUT) command to view the authority permissions for the directory.

Configuring the authentication cache

The security authentication cache affects the frequency of rehashing and the distribution of the hash algorithms.

About this task

To configure the authentication cache properties, complete the following steps:

Procedure

1. Click **Servers > Application Servers > *server_name*** .
2. Under Server infrastructure, click **Java and Process Management > Process definition**.
3. Under Additional properties, click **Java Virtual Machine > Custom Properties**.
4. Click **New** to specify a new custom property.

What to do next

For information on the supported authentication cache properties, see “Authentication cache settings” on page 1252.

Configuring Common Secure Interoperability Version 2 (CSIV2) inbound and outbound communication settings

WebSphere Application Server enables you to specify Internet Inter-ORB Protocol (IIOP) authentication for both inbound and outbound authentication requests. For inbound requests, you can specify the type of accepted authentication, such as basic authentication. For outbound requests, you can specify properties such as type of authentication, identity assertion or login configurations that are used for requests to downstream servers.

About this task

Complete the following steps to configure Common Secure Interoperability Version 2 (CSIV2) and Security Authentication Service (SAS).

Important: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

Procedure

1. Determine how to configure security inbound and outbound at each point in your infrastructure.

   For example, you might have a Java client communicating with an Enterprise JavaBeans (EJB) application server, which in turn communicates to a downstream EJB application server.

   The Java client utilizes the `sas.client.props` file to configure outbound security. Pure clients must configure outbound security only.

   The upstream EJB application server configures inbound security to handle the correct type of authentication from the Java client. The upstream EJB application server utilizes the outbound security configuration when going to the downstream EJB application server.

   This type of authentication might be different than what you expect from the Java client into the upstream EJB application server. Security might be tighter between the pure client and the first EJB server, depending on your infrastructure. The downstream EJB server utilizes the inbound security configuration to accept requests from the upstream EJB server. These two servers require similar configuration options as well. If the downstream EJB application server communicates to other downstream servers, the outbound security might require a special configuration.
2. Specify the type of authentication.

   By default, authentication by a user ID and password is performed.

   Both Java client certificate authentication and identity assertion are disabled by default. If you want this type of authentication performed at every tier, use the CSIv2 authentication protocol configuration as is. However, if you have any special requirements where some servers authenticate differently from other servers, consider how to configure CSIv2 to its best advantage.

3. Configure clients and servers.

   Configuring a pure Java client is done through the `sas.client.props` file, where properties are modified.

   Configuring servers is always done from the administrative console or scripting, either from the security navigation for cell-level configurations or from the server security of the application server for server-level configurations. If you want some servers to authenticate differently from others, modify some of the server-level configurations. When you modify the server-level configurations, you are overriding the cell-level configurations.

What to do next

Use CSIV2 inbound communications settings for configuring the type of authentication information that is contained in an incoming request or transport.

Use CSIV2 outbound communications settings to specify the features that a server supports when acting as a client to another downstream server.

Configuring Common Secure Interoperability Version 2 inbound communications

Inbound communications refers to the configuration that determines the type of accepted authentication for inbound requests. This authentication is advertised in the interoperable object reference (IOR) that the client retrieves from the name server.

Procedure

1. Start the administrative console.
2. Click **Security > Global security**.
3. Under RMI/IIOP security, click **CSIv2 inbound communications**.
4. Consider the following layers of security:
   - Identity assertion (attribute layer).

     When selected, this server accepts identity tokens from upstream servers. If the server receives an identity token, the identity is taken from an originating client. For example, the identity is in the same form that the originating client presented to the first server. An upstream server sends the identity of the originating client. The format of the identity can be either a principal name, a distinguished name, or a certificate chain. In some cases, the identity is anonymous. It is important to trust the upstream server that sends the identity token because the identity authenticates on this server. Trust of the upstream server is established either using Secure Sockets Layer (SSL) client certificate authentication or basic authentication. You must select one of the two layers of authentication in both inbound and outbound authentication when you choose identity assertion.

     The server ID is sent in the client authentication token with the identity token. The server ID is checked against the trusted server ID list. If the server ID is on the trusted server list, the server ID is authenticated. If the server ID is valid, the identity token is put into a credential and used for authorization of the request.

     Note: When identity assertion is enabled, message layer or transport layer should be enabled also. For server-to-server communication, besides enabling transport layer/client authentication, identity assertion or message layer should be enabled also.

     For more information, refer to Identity assertion.
   - Message layer:

     Basic authentication (GSSUP):

     This type of authentication is the most typical. The user ID and password or authenticated token is sent from a pure client or from an upstream server. When a user ID and password are received at the server, they are authenticated with the user registry of the downstream server.

     Lightweight Third Party Authentication (LTPA):

In this case, an LTPA token is sent from the upstream server. Note that if you choose LTPA, then both servers must share the same LTPA keys

Kerberos (KRB5):

To select Kerberos, the active authentication mechanism must be Kerberos. In this case, a Kerberos token is sent from the upstream server.

For more information, read about Message layer authentication.

- Secure Sockets Layer client certificate authentication (transport layer).

  The SSL client certificate is used to authenticate instead of using user ID and Password. If a server delegates an identity to a downstream server, the identity comes from either the message layer (a client authentication token) or the attribute layer (an identity token), and not from the transport layer through the client certificate authentication.

  A client has an SSL client certificate that is stored in the keystore file of the client configuration. When SSL client authentication is enabled on this server, the server requests that the client send the SSL client certificate when the connection is established. The certificate chain is available on the socket whenever a request is sent to the server. The server request interceptor gets the certificate chain from the socket and maps this certificate chain to a user in the user registry. This type of authentication is optimal for communicating directly from a client to a server. However, when you have to go downstream, the identity typically flows over the message layer or through identity assertion.

5. Consider the following points when deciding what type of authentication to accept:
   - A server can receive multiple layers simultaneously, so an order of precedence rule decides which identity to use. The identity assertion layer has the highest priority, the message layer follows, and the transport layer has the lowest priority. The SSL client certificate authentication is used when it is the only layer provided. If the message layer and the transport layer are provided, the message layer is used to establish the identity for authorization. The identity assertion layer is used to establish precedence when provided.
   - Does this server usually receive requests from a client, from a server, or both? If the server always receives requests from a client, identity assertion is not needed. You can choose either the message layer, the transport layer, or both. You also can decide when authentication is required or just supported. To select a layer as required, the sending client must supply this layer, or the request is rejected. However, if the layer is only supported, the layer might not be supplied.
   - What kind of client identity is supplied? If the client identity is client certificates authentication and you want the certificate chain to flow downstream so that it maps to the downstream server user registries, identity assertion is the appropriate choice. Identity assertion preserves the format of the originating client. If the originating client authenticated with a user ID and password, a principal identity is sent. If authentication is done with a certificate, the certificate chain is sent.

     In some cases, if the client authenticated with a token and a Lightweight Directory Access Protocol (LDAP) server is the user registry, then a distinguished name (DN) is sent.
6. Configure a trusted server list. When identity assertion is selected for inbound requests, insert a pipe-separated (|) list of server administrator IDs to which this server can support identity token submission. For backwards compatibility, you can still use a comma-delimited list. However, if the server ID is a distinguished name (DN), then you must use a pipe-delimited (|) list because a comma delimiter does not work. If you choose to support any server sending an identity token, you can enter an asterisk (*) in this field. This action is called *presumed trust*. In this case, use SSL client certificate authentication between servers to establish the trust.
7. Configure session management. You can choose either *stateful* or *stateless* security. Performance is optimum when choosing stateful sessions. The first method request between a client and server is authenticated. All subsequent requests (or until the credential token expires) reuse the session information, including the credential. A client sends a context ID for subsequent requests. The context ID is scoped to the connection for uniqueness.

Results

When you finish configuring this panel, you have configured most of the information that a client gathers when determining what to send to this server. A client or server outbound configuration with this server inbound configuration, determines the security that is applied. When you know what clients send, the configuration is simple. However, if you have a diverse set of clients with differing security requirements, your server considers various layers of authentication.

For a J2EE application server, the authentication choice is usually either identity assertion or message layer because you want the identity of the originating client delegated downstream. You cannot easily delegate a client certificate using an SSL connection. It is acceptable to enable the transport layer because additional server security, as the additional client certificate portion of the SSL handshake, adds some overhead to the overall SSL connection establishment.

What to do next

After you determine which type of authentication data this server might receive, you can determine what to select for outbound security. For more information, see Configuring Common Secure Interoperability Version 2 outbound authentication.

Common Secure Interoperability Version 2 inbound communications settings:

Use this page to specify the features that a server supports for a client accessing its resources.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. From Authentication, click **RMI/IIOP security > CSIv2 inbound communications**.

Use common secure interoperability (CSI) inbound communications settings for configuring the type of authentication information that is contained in an incoming request or transport.

Authentication features include three layers of authentication that you can use simultaneously:

- **CSIv2 attribute layer**. The attribute layer might contain an identity token, which is an identity from an upstream server that already is authenticated. The identity layer has the highest priority, followed by the message layer, and then the transport layer. If a client sends all three, only the identity layer is used. The only way to use the SSL client certificate as the identity is if it is the only information that is presented during the request. The client picks up the interoperable object reference (IOR) from the namespace and reads the values from the tagged component to determine what the server needs for security.
- **CSIv2 transport layer**. The transport layer, which is the lowest layer, might contain a Secure Sockets Layer (SSL) client certificate as the identity.
- **CSIv2 message layer**. The message layer might contain a user ID and password or an authenticated token with an expiration.

Propagate security attributes:

Specifies support for security attribute propagation during login requests. When you select this option, the application server retains additional information about the login request, such as the authentication strength used, and retains the identity and location of the request originator.

If you do not select this option, the application server does not accept any additional login information to propagate to downstream servers.

Default: Enabled

Important: When you use the replication services, ensure that the **Propagate security attributes** option is enabled.

Use identity assertion:

Specifies that identity assertion is a way to assert identities from one server to another during a downstream Enterprise JavaBeans (EJB) invocation.

This server does not authenticate the asserted identity again because it trusts the upstream server. Identity assertion takes precedence over all other types of authentication.

Identity assertion is performed in the attribute layer and is only applicable on servers. The principal determined at the server is based on precedence rules. If identity assertion is used, the identity is always derived from the attribute layer. If basic authentication is used without identity assertion, the identity is always derived from the message layer. Finally, if SSL client certificate authentication is performed without either basic authentication, or identity assertion, then the identity is derived from the transport layer.

The identity asserted is the invocation credential that is determined by the RunAs mode for the enterprise bean. If the RunAs mode is Client, the identity is the client identity. If the RunAs mode is System, the identity is the server identity. If the RunAs mode is Specified, the identity is the one specified. The receiving server receives the identity in an identity token and also receives the sending server identity in a client authentication token. The receiving server validates the sending server identity as a trusted identity through the Trusted Server IDs entry box. Enter a list of pipe-separated (|) principal names, for example, `serverid1|serverid2|serverid3`.

All identity token types map to the user ID field of the active user registry. For an ITTPrincipal identity token, this token maps one-to-one with the user ID fields. For an ITTDistinguishedName identity token, the value from the first equal sign is mapped to the user ID field. For an ITTCertChain identity token, the value from the first equal sign of the distinguished name is mapped to the user ID field.

When authenticating to an LDAP user registry, the LDAP filters determine how an identity of type ITTCertChain and ITTDistinguishedName get mapped to the registry. If the token type is ITTPrincipal, then the principal gets mapped to the UID field in the LDAP registry.

Default: Disabled

Trusted identities:

Specifies the trusted identity that is sent from the sending server to the receiving server.

Specifies a pipe-separated (|) list of trusted server administrator user IDs, which are trusted to perform identity assertion to this server. For example, `serverid1|serverid2|serverid3`. The application server supports the comma (,) character as the list delimiter for backwards compatibility. The application server checks the comma character when the pipe character (|) fails to find a valid trusted server ID.

Use this list to decide whether a server is trusted. Even if the server is on the list, the sending server must still authenticate with the receiving server to accept the identity token of the sending server.

Data type: String

Client certificate authentication:

Specifies that authentication occurs when the initial connection is made between the client and the server during a method request.

In the transport layer, Secure Sockets Layer (SSL) client certificate authentication occurs. In the message layer, basic authentication (user ID and password) is used. Client certificate authentication typically performs better than message layer authentication, but requires some additional setup. These additional steps involve verifying that the server trusts the signer certificate of each client to which it is connected. If the client uses a certificate authority (CA) to create its personal certificate, you only need the CA root certificate in the server signer section of the SSL trust file.

When the certificate is authenticated to a Lightweight Directory Access Protocol (LDAP) user registry, the distinguished name (DN) is mapped based on the filter that is specified when configuring LDAP. When the certificate is authenticated to a local OS user registry, the first attribute of the distinguished name (DN) in the certificate, which is typically the common name, is mapped to the user ID in the registry.

The identity from client certificates is used only if no other layer of authentication is presented to the server.

Never Specifies that clients cannot attempt Secure Sockets Layer (SSL) client certificate authentication with this server.

Supported
Specifies that clients connecting to this server can authenticate using SSL client certificates. However, the server can invoke a method without this type of authentication. For example, anonymous or basic authentication can be used instead.

Required
Specifies that clients connecting to this server must authenticate using SSL client certificates before invoking the method.

Transport:

Specifies whether client processes connect to the server using one of its connected transports.

You can choose either Secure Sockets Layer (SSL), TCP/IP or both as the inbound transport that a server supports. If you specify TCP/IP, the server only supports TCP/IP and cannot accept SSL connections. If you specify SSL-supported, this server can support either TCP/IP or SSL connections. If you specify SSL-required, then any server communicating with this one must use SSL.

Note: This option is not available on the z/OS platform unless both Version 6.1 and earlier nodes exist in the cell.

TCP/IP
If you select **TCP/IP**, then the server opens a TCP/IP listener port only and all inbound requests do not have SSL protection.

SSL-required
If you select **SSL-required**, then the server opens an SSL listener port only and all inbound requests are received using SSL.

SSL-supported
If you select **SSL-supported**, then the server opens both a TCP/IP and an SSL listener port and most inbound requests are received using SSL.

Provide a fixed port number for the following ports. A zero port number indicates that a dynamic assignment is made at run time.

CSIV2_SSL_MUTUALAUTH_LISTENER_ADDRESS
CSIV2_SSL_SERVERAUTH_LISTENER_ADDRESS
SAS_SSL_SERVERAUTH_LISTENER_ADDRESS

Default: SSL-Supported

Range: TCP/IP, SSL Required, SSL-Supported

SSL settings:

Specifies a list of predefined SSL settings to choose from for inbound connection.

Data type: String
Default: DefaultSSLSettings
DefaultIIOPSSL
Range: Any SSL settings configured in the SSL Configuration Repertoire

Message layer authentication:

The following options are available for message layer authentication:

Never Specifies that this server cannot accept authentication using any of the mechanisms selected below.

Supported
Specifies that a client communicating with this server can authenticate using any of the mechanisms selected below. However, a method might be invoked without this type of authentication. For example, an anonymous or client certificate might be used instead.

Required
Specifies that clients communicating with this server must specify authentication information using of the mechanisms selected below for any method request.

Allow client to server authentication with::

Specifies client-to-server authentication using Kerberos, LTPA or Basic authentication.

The following options are available for client to server authentication:

Kerberos (KRB5)
Select to specify Kerberos as the authentication mechanism. You must first configure the Kerberos authentication mechanism. Read about Configuring Kerberos as the authentication mechanism using the administrative console for more information.

LTPA Select to specify the LTPA token authentication

Basic authentication
Basic authentication is Generic Security Services Username Password (GSSUP). This type of authentication typically involves sending a user ID and a password from the client to the server for authentication.

If you select **Basic Authentication** and **LTPA**, and the active authentication mechanism is LTPA, a user name, password, and LTPA tokens are accepted.

If you select **Basic Authentication** and **KRB5** and the active authentication mechanism is KRB5, a user name, password, Kerberos token and LTPA tokens are accepted.

If you do not select **Basic Authentication**, a user name and password are not accepted by the server.

Login configuration:

Specifies the type of system login configuration to use for inbound authentication.

You can add custom login modules by clicking **Security > Global security**. From Authentication, click **Java Authentication and Authorization Service > System logins**.

Stateful sessions:

Select this option to enable stateful sessions, which are used mostly for performance improvements.

The first contact between a client and server must fully authenticate. However, all subsequent contacts with valid sessions reuse the security information. The client passes a context ID to the server, and the ID is used to look up the session. The context ID is scoped to the connection, which guarantees uniqueness. Whenever the security session is not valid and the authentication retry is enabled, which is the default, the client-side security interceptor invalidates the client-side session and submits the request again without user awareness. This situation might occur if the session does not exist on the server; for example, the server failed and resumed operation. When this value is disabled, each method invocation must authenticate again.

Default: Enabled

Trusted authentication realms - inbound:

Select this link to establish inbound trust for realms. Inbound authentication realm settings are not specific to CSIv2; you can also configure which realms to grant inbound trust to for multiple security domains.

Inbound authentication refers to the configuration that determines the type of accepted authentication for inbound requests. This authentication is advertised in the interoperable object reference (IOR) that the client retrieves from the name server.

Configuring Common Secure Interoperability Version 2 outbound communications

The following choices are available when configuring the Common Secure Interoperability Version 2 (CSIv2) outbound communications panel.

Before you begin

Outbound communications refers to the configuration that determines the type of authentication that is performed for outbound requests to downstream servers. Several *layers* or *methods* of authentication can occur. The downstream server inbound authentication configuration must support at least one choice made in this server outbound authentication configuration. If nothing is supported, the request might go outbound as unauthenticated. This situation does not create a security problem because the authorization runtime is responsible for preventing access to protected resources. However, if you choose to prevent an unauthenticated credential from going outbound, you might want to designate one of the authentication layers as required, rather than supported. If a downstream server does not support authentication, then when authentication is required, the method request fails to go outbound.

About this task

The following choices are available in the Common Secure Interoperability Version 2 (CSIv2) outbound communications panel. Remember that you are not required to complete these steps in the displayed order. Rather, these steps are provided to help you understand your choices for configuring outbound communications.

Procedure

- Select **Identity Assertion** (attribute layer). When selected, this server sends an identity token to a downstream server if the downstream server supports identity assertion. When an originating client authenticates to this server, the authentication information supplied is preserved in the outbound identity token. If the client authenticating to this server uses client certificate authentication, then the identity

token format is a certificate chain, containing the exact client certificate chain from the inbound socket. The same scenario is true for other mechanisms of authentication. Read theIdentity Assertion topic for more information.

- Select **User ID** and **Password** (message layer). This type of authentication is the most typical. The user ID and password (if BasicAuth credential) or authenticated token (if authenticated credential) are sent outbound to the downstream server if the downstream server supports message layer authentication in the inbound authentication panel. Refer to the Message Layer Authentication article for more information.
- Select **SSL Client certificate authentication** (transport layer). The main reason to enable outbound Secure Sockets Layer (SSL) client authentication from one server to a downstream server is to create a trusted environment between those servers. For delegating client credentials, use one of the two layers mentioned previously. However, you might want to create SSL personal certificates for all the servers in your domain, and only trust those servers in your SSL truststore file. No other servers or clients can connect to the servers in your domain, except at the tiers where you want them. This process can protect your enterprise bean servers from access by anything other than your servlet servers.

Example

Typically, the outbound authentication configuration is for an upstream server to communicate with a downstream server. Most likely, the upstream server is a servlet server and the downstream server is an Enterprise JavaBeans (EJB) server. On a servlet server, the client authentication that is performed to access the servlet can be one of many different types of authentication, including client certificate and basic authentication. When receiving basic authentication data, whether through a prompt login or a form-based login, the basic authentication information is typically authenticated to from a credential of the mechanism type that is supported by the server, such as the Lightweight Third Party Authentication (LTPA). When LTPA is the mechanism, a forwardable token exists in the credential. Choose the message layer (BasicAuth) authentication to propagate the client credentials. If the credential is created using a certificate login and you want to preserve sending the certificate downstream, you might decide to go outbound with identity assertion.

Common Secure Interoperability Version 2 outbound communications settings:

Use this page to specify the features that a server supports when acting as a client to another downstream server.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. From Authentication, click **RMI/IIOP security > CSIv2 outbound communications**.

Authentication features include three layers of authentication that you can use simultaneously:

- **CSIv2 attribute layer**. The attribute layer might contain an identity token, which is an identity from an upstream server that already is authenticated. The identity layer has the highest priority, followed by the message layer, and then the transport layer. If a client sends all three, only the identity layer is used. The only way to use the SSL client certificate as the identity is if it is the only information that is presented during the request. The client picks up the interoperable object reference (IOR) from the namespace and reads the values from the tagged component to determine what the server needs for security.
- **CSIv2 transport layer**. The transport layer, which is the lowest layer, might contain a Secure Sockets Layer (SSL) client certificate as the identity.
- **CSIv2 message layer**. The message layer might contain a user ID and password or an authenticated token with an expiration.

Propagate security attributes:

Specifies to support security attribute propagation during login requests. When you select this option, the application server retains additional information about the login request, such as the authentication strength used, and retains the identity and location of the request originator.

If you do not select this option, the application server does not accept any additional login information to propagate to downstream servers.

Default: Enabled

Important: When you use the replication services, ensure that the **Propagate security attributes** option is enabled.

Use identity assertion:

Specifies that identity assertion is a way to assert identities from one server to another during a downstream Enterprise JavaBeans (EJB) invocation.

This server does not authenticate the asserted identity again because it trusts the upstream server. Identity assertion takes precedence over all other types of authentication.

Identity assertion is performed in the attribute layer and is only applicable on servers. The principal determined at the server is based on precedence rules. If identity assertion is performed, the identity is always derived from the attribute layer. If basic authentication is used without identity assertion, the identity is always derived from the message layer. Finally, if SSL client certificate authentication is performed without either basic authentication, or identity assertion, then the identity is derived from the transport layer.

The identity asserted is the invocation credential that is determined by the RunAs mode for the enterprise bean. If the RunAs mode is Client, the identity is the client identity. If the RunAs mode is System, the identity is the server identity. If the RunAs mode is Specified, the identity is the one specified. The receiving server receives the identity in an identity token and also receives the sending server identity in a client authentication token. The receiving server validates the sending server identity as a trusted identity through the Trusted Server IDs entry box. Enter a list of pipe-separated (|) principal names, for example, `serverid1|serverid2|serverid3`.

All identity token types map to the user ID field of the active user registry. For an ITTPrincipal identity token, this token maps one-to-one with the user ID fields. For an ITTDistinguishedName identity token, the value from the first equal sign is mapped to the user ID field. For an ITTCertChain identity token, the value from the first equal sign of the distinguished name is mapped to the user ID field.

When authenticating to an LDAP user registry, the LDAP filters determine how an identity of type ITTCertChain and ITTDistinguishedName get mapped to the registry. If the token type is ITTPrincipal, then the principal gets mapped to the UID field in the LDAP registry.

Default: Disabled

Use server-trusted identity:

Specifies the server identity that the application server uses to establish trust with the target server. The server identity can be sent using one of the following methods:

- A server ID and password when the server password is specified in the registry configuration.
- A server ID in a Lightweight Third Party Authentication (LTPA) token when the internal server ID is used.

For interoperability with application servers other than WebSphere Application Server, use one of the following methods:

- Configure the server ID and password in the registry.
- Select the **Server-trusted identity** option and specify the trusted identity and password so that an interoperable Generic Security Services Username Password (GSSUP) token is sent instead of an LTPA token.

Default: Disabled

Specify an alternative trusted identity:

Specifies an alternative user as the trusted identity that is sent to the target servers instead of sending the server identity.

This option is recommended for identity assertion. The identity is automatically trusted when it is sent within the same cell and does not need to be in the trusted identities list within the same cell. However, this identity must be in the registry of the target servers in an external cell, and the user ID must be on the trusted identities list or the identity is rejected during trust evaluation.

Note: You must select Basic Authentication under the Message Layer authentication section to send an alternative trusted identity. If you do not select Basic Authentication, then choose the Server Identity instead.

Default: Disabled

Trusted identity:

Specifies the trusted identity that is sent from the sending server to the receiving server.

If you specify an identity in this field, it can be selected on the panel for your configured user account repository. If you do not specify an identity, a Lightweight Third Party Authentication (LTPA) token is sent between the servers.

Specifies a pipe-separated (|) list of trusted server administrator user IDs, which are trusted to perform identity assertion to this server. For example, `serverid1|serverid2|serverid3`. The application server supports the comma (,) character as the list delimiter for backwards compatibility. The application server checks the comma character when the pipe character (|) fails to find a valid trusted server ID.

Use this list to decide whether a server is trusted. Even if the server is on the list, the sending server must still authenticate with the receiving server to accept the identity token of the sending server.

Password:

Specifies the password that is associated with the trusted identity.

Data type: Text

Confirm password:

Confirms the password that is associated with the trusted identity.

Data type: Text

Message layer authentication:

The following options are available for message layer authentication:

Never Specifies that this server cannot accept authentication using any of the mechanisms selected below.

Supported
Specifies that a client communicating with this server can authenticate using any of the mechanisms selected below. However, a method might be invoked without this type of authentication. For example, an anonymous or client certificate might be used instead.

Required
Specifies that clients communicating with this server must specify authentication information using of the mechanisms selected below for any method request.

Allow client to server authentication with::

Specifies client-to-server authentication using Kerberos, LTPA or Basic authentication.

The following options are available for client to server authentication:

Kerberos (KRB5)
Select to specify Kerberos as the authentication mechanism. You must first configure the Kerberos authentication mechanism. Read about Configuring Kerberos as the authentication mechanism using the administrative console for more information.

LTPA Select to configure and enable Lightweight Third-Party Authentication (LTPA) token authentication.

Basic authentication
Basic authentication is Generic Security Services Username Password (GSSUP). This type of authentication typically involves sending a user ID and a password from the client to the server for authentication.

If you select **Basic Authentication** and **LTPA**, and the active authentication mechanism is LTPA, the server goes with a downstream server with a user name, password or LTPA token.

If you select **Basic Authentication** and **KRB5**, and the active authentication mechanism is KRB5, the server goes with a downstream server with a user name, password, Kerberos token or LTPA token.

If you do not select **Basic Authentication**, the server does not go with a downstream server with a user name and password.

Transport:

Specifies whether client processes connect to the server using one of its connected transports.

You can choose to use either Secure Sockets Layer (SSL), TCP/IP or both as the inbound transport that a server supports. If you specify TCP/IP, the server only supports TCP/IP and cannot accept SSL connections. If you specify SSL-supported, this server can support either TCP/IP or SSL connections. If you specify SSL-required, then any server communicating with this one must use SSL.

For server-to-server communication, it is not enough to enable only the Transport layer. You must also enable either the Message layer or the Attribute layer.

TCP/IP
If you select **TCP/IP**, then the server opens a TCP/IP listener port only and all inbound requests do not have SSL protection.

SSL-required
If you select **SSL-required**, then the server opens an SSL listener port only and all inbound requests are received using SSL.

SSL-supported
If you select **SSL-supported**, then the server opens both a TCP/IP and an SSL listener port and most inbound requests are received using SSL.

Provide a fixed port number for the following ports. A zero port number indicates that a dynamic assignment is made at run time.

CSIV2_SSL_MUTUALAUTH_LISTENER_ADDRESS
CSIV2_SSL_SERVERAUTH_LISTENER_ADDRESS
SAS_SSL_SERVERAUTH_LISTENER_ADDRESS

Default: SSL-Required
Range: TCP/IP, SSL Required, SSL-Supported

SSL settings:

Specifies a list of predefined SSL settings to choose from for inbound connection.

Data type: String
Default: DefaultSSLSettings
DefaultIIOPSSL
Range: Any SSL settings configured in the SSL Configuration Repertoire

Client certificate authentication:

Specifies whether a client certificate from the configured keystore is used to authenticate to the server when the SSL connection is made between this server and a downstream server, provided that the downstream server supports client certificate authentication.

Typically, client certificate authentication has a higher performance than message layer authentication, but requires some additional setup. These additional steps include verifying that this server has a personal certificate and that the downstream server has the signer certificate of this server.

If you select client certificate authentication, the following options are available:

Never Specifies that this server does not attempt Secure Sockets Layer (SSL) client certificate authentication with downstream servers.

Supported
Specifies that this server can use SSL client certificates to authenticate to downstream servers. However, a method can be invoked without this type of authentication. For example, the server can use anonymous or basic authentication instead.

Required
Specifies that this server must use SSL client certificates to authenticate to downstream servers.

Default: Enabled

Login configuration:

Specifies the type of system login configuration to use for inbound authentication.

You can add custom login modules by clicking **Security > Global security**. From Authentication, click **Java Authentication and Authorization Service > System logins**.

Stateful sessions:

Select this option to enable stateful sessions, which are used mostly for performance improvements.

The first contact between a client and server must fully authenticate. However, all subsequent contacts with valid sessions reuse the security information. The client passes a context ID to the server, and the ID is used to look up the session. The context ID is scoped to the connection, which guarantees uniqueness. Whenever the security session is not valid and the authentication retry is enabled, which is the default, the client-side security interceptor invalidates the client-side session and submits the request again without user awareness. This situation might occur if the session does not exist on the server, for example, the server failed and resumed operation. When this value is disabled, every method invocation must authenticate again.

Enable CSIv2 session cache limit:

Specifies whether to limit the size of the CSIv2 session cache.

When you enable this option, you must set values for the **Maximum cache size** and **Idle session timeout** options. When you do not enable this option, the CSIv2 session cache is not limited.

In previous versions of the application server, you might have set this value as the com.ibm.websphere.security.util.csiv2SessionCacheLimitEnabled custom property. In this product version, it is advisable to set this value using this administrative console panel and not as a custom property.

Default: false

Maximum cache size:

Specify the maximum size of the session cache after which expired sessions are deleted from the cache.

Expired sessions are defined as sessions that are idle longer than the time that is specified in the **Idle session timeout** field. When you specify a value for the **Maximum cache size** field, consider setting its value between 100 and 1000 entries.

Consider specifying a value for this field if your environment uses Kerberos authentication and has a short clock skew for the configured key distribution center (KDC). In this scenario, a short clock skew is defined as less than 20 minutes. Consider increasing the value of this field if the small cache size causes the garbage collection to run so frequently that it impacts the performance of the application server.

In previous versions of the application server, you might have set this value as the com.ibm.websphere.security.util.csiv2SessionCacheMaxSize custom property. In this product version, it is advisable to set this value using this administrative console panel and not as a custom property.

This field only applies if you enable both the **Stateful sessions** and the **Enable CSIv2 session cache limit** options.

Default: By default, a value is not set.
Range: 100 to 1000 entries

Idle session timeout:

This property specifies the time in milliseconds that a CSIv2 session can remain idle before being deleted. The session is deleted if you select the Enable CSIv2 session cache limit option and the value of the **Maximum cache size** field is exceeded.

This timeout value only applies if you enable both the **Stateful sessions** and the **Enable CSIv2 session cache limit** options. Consider decreasing the value for this field if your environment uses Kerberos authentication and has a short clock skew for the configured key distribution center (KDC). In this scenario, a short clock skew is defined as less than 20 minutes. A small clock skew can result in a larger number of rejected CSIv2 sessions. However, with a smaller value for the **Idle session timeout** field, the application server can clean out these rejected sessions more frequently and potentially reduce the resource shortages.

In previous versions of WebSphere Application Server, you might have set this value as the com.ibm.websphere.security.util.csiv2SessionCacheIdleTime custom property. In this product version, it is advisable to set this value using this administrative console panel and not as a custom property. If you previously set it as a custom property, the value was set in milliseconds and converted on this administrative console panel to seconds. On this administrative console panel, you must specify the value in seconds.

Default: By default, a value is not set.
Range: 60 to 86,400 seconds

Custom outbound mapping:

Enables the use of custom Remote Method Invocation (RMI) outbound login modules.

The custom login module maps or completes other functions before the predefined RMI outbound call.

To declare a custom outbound mapping, complete the following steps:
1. Click **Security > Global security**.
2. From Authentication, click **Java Authentication and Authorization Service > System logins > New**.

Trusted authentication realms - outbound:

If the RMI/IIOP communication is across different realms, use this link to add outbound trusted realms.

The credential tokens are only sent to the realms that are trusted. In addition, the receiving server should trust this realm using the inbound trusted realms configuration to validate the LTPA token.

Configuring inbound transports

By using this configuration, you can configure a different transport for inbound security versus outbound security.

Before you begin

Inbound transports refer to the types of listener ports and their attributes that are opened to receive requests for this server. Both Common Secure Interoperability Specification, Version 2 (CSIv2) and Secure Authentication Service (SAS) have the ability to configure the transport.

Important: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

However, the following differences between the two protocols exist:
- CSIv2 is much more flexible than SAS, which requires Secure Sockets Layer (SSL); CSIv2 does not require SSL.
- SAS does not support SSL client certificate authentication, while CSIv2 does.
- CSIv2 can require SSL connections, while SAS only supports SSL connections.
- SAS always has two listener ports open: TCP/IP and SSL.

- CSIv2 can have as few as one listener port and as many as three listener ports. You can open one port for just TCP/IP or when SSL is required. You can open two ports when SSL is supported, and open three ports when SSL and SSL client certificate authentication is supported.

About this task

Complete the following steps to configure the Inbound transport panels in the administrative console:

Procedure

1. Click **Security > Global security**.
2. Under RMI/IIOP security, click **CSIv2 inbound communications**.
3. Under Transport, select **SSL-required**. You can choose to use either Secure Sockets Layer (SSL), TCP/IP or both as the inbound transport that a server supports. If you specify TCP/IP, the server only supports TCP/IP and cannot accept SSL connections. If you specify SSL-supported, this server can support either TCP/IP or SSL connections. If you specify SSL-required, then any server communicating with this one must use SSL.
4. Click **Apply**.
5. Consider fixing the listener ports that you configured.

   You complete this action in a different panel, but think about this action now. Most endpoints are managed at a single location, which is why they do not display in the Inbound transport panels. Managing end points at a single location helps you decrease the number of conflicts in your configuration when you assign the endpoints. The location for SSL end points is at each server. The following port names are defined in the End points panel and are used for Object Request Broker (ORB) security:
   - CSIV2_SSL_MUTUALAUTH_LISTENER_ADDRESS - CSIv2 Client Authentication SSL Port
   - CSIV2_SSL_SERVERAUTH_LISTENER_ADDRESS - CSIv2 SSL Port
   - SAS_SSL_SERVERAUTH_LISTENER_ADDRESS - SAS SSL Port
   - ORB_LISTENER_PORT - TCP/IP Port

   For an application server, click **Servers > Application servers >** *server_name*. Under Communications, click **Ports**. The Ports panel is displayed for the specified server.

   The Object Request Broker (ORB) on WebSphere Application Server uses a listener port for Remote Method Invocation over the Internet Inter-ORB Protocol (RMI/IIOP) communications, and is statically specified using configuration dialogs or during migration. If you are working with a firewall, you must specify a static port for the ORB listener and open that port on the firewall so that communication can pass through the specified port. The endPoint property for setting the ORB listener port is: ORB_LISTENER_ADDRESS.

   a. Click **Servers > Application Servers >** *server_name*. Under Communications, click **Ports > New**.
   b. Select **ORB_LISTENER_ADDRESS** from the **Port name** field in the Configuration panel.
   c. Enter the IP address, the fully qualified Domain Name System (DNS) host name, or the DNS host name by itself in the **Host** field. For example, if the host name is `myhost`, the fully qualified DNS name can be `myhost.myco.com` and the IP address can be `155.123.88.201`.
   d. Enter the port number in the **Port** field. The port number specifies the port for which the service is configured to accept client requests. The port value is used with the host name. Using the previous example, the port number might be 9000.
6. Click **Security > Global security**. Under RMI/IIOP security, click **CSIv2 inbound communications**. Select the SSL settings that are used for inbound requests from CSIv2 clients, and then click **Apply**. Remember that the CSIv2 protocol is used to inter-operate with previous releases. When configuring the keystore and truststore files in the SSL configuration, these files need the right information for inter-operating with previous releases of WebSphere Application Server.

Results

The inbound transport configuration is complete. With this configuration, you can configure a different transport for inbound security versus outbound security. For example, if the application server is the first server that is used by users, the security configuration might be more secure. When requests go to back-end enterprise bean servers, you might lessen the security for performance reasons when you go outbound. With this flexibility you can design the right transport infrastructure to meet your needs.

What to do next

When you finish configuring security, perform the following steps to save, synchronize, and restart the servers:
1. Click **Save** in the administrative console to save any modifications to the configuration.
2. Stop and restart all servers, when synchronized.

Common Secure Interoperability Version 2 transport inbound settings:

Use this page to specify which listener ports to open and which Secure Sockets Layer (SSL) settings to use. These specifications determine which transport a client or upstream server uses to communicate with this server for incoming requests.

To view this administrative console page, complete the following steps:
1. Click **Security > Global security**.
2. Under Authentication, click **RMI/IIOP security > CSIv2 inbound transport**.

Transport:

Specifies whether client processes connect to the server using one of its connected transports.

You can choose to use either Secure Sockets Layer (SSL), TCP/IP or both as the inbound transport that a server supports. If you specify TCP/IP, the server only supports TCP/IP and cannot accept SSL connections. If you specify SSL-supported, this server can support either TCP/IP or SSL connections. If you specify SSL-required, then any server communicating with this one must use SSL.

If you specify SSL-supported or SSL-required, decide which set of SSL configuration settings you want to use for the inbound configuration. This decision determines which key file and trust file are used for inbound connections to this server.

TCP/IP
If you select **TCP/IP**, then the server opens a TCP/IP listener port only and all inbound requests do not have SSL protection.

SSL-required
If you select **SSL-required**, then the server opens an SSL listener port only and all inbound requests are received using SSL.

Important: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

SSL-supported
If you select **SSL-supported**, then the server opens both a TCP/IP and an SSL listener port and most inbound requests are received using SSL.

Provide a fixed port number for the following ports. A zero port number indicates that a dynamic assignment is made at runtime.

CSIV2_SSL_MUTUALAUTH_LISTENER_ADDRESS
CSIV2_SSL_SERVERAUTH_LISTENER_ADDRESS
SAS_SSL_SERVERAUTH_LISTENER_ADDRESS

Default: SSL Required
Range: TCP/IP, SSL Required, SSL-Supported

SSL settings:

Specifies a list of predefined SSL settings to choose from for inbound connections.

These settings are configured at the SSL Repertoire panel. To access the SSL Repertoire panel, complete the following steps:

1. Clicking **Security > SSL certificate and key management**.
2. Under configuration settings, click **Manage endpoint security configurations and trust zones**.
3. Expand Inbound and click *inbound_configuration*.
4. Under Related items, click **SSL configurations**.

Data type: String
Default: DefaultSSLSettings
DefaultIIOPSSL
Range: Any SSL settings configured in the SSL Configuration Repertoire

Centrally managed:

Specifies that the selection of an SSL configuration is based upon the outbound topology view for the Java Naming and Directory Interface (JNDI) platform.

Centrally managed configurations support one location to maintain SSL configurations rather than spreading them across the configuration documents.

Default: Enabled

Use specific SSL alias:

Specifies the SSL configuration alias to use for LDAP outbound SSL communications.

This option overrides the centrally managed configuration for the JNDI platform.

z/OS SSL settings:

Specifies a list of predefined Secure Sockets Layer (SSL) settings for inbound connections. Configure these settings on the SSL panel by clicking Secure communications on the administrative console.

Secure Authentication Service inbound transport settings:

Use this page to specify transport settings for connections that are accepted by this server using the Secure Authentication Service (SAS) authentication protocol. The SAS protocol is used to communicate securely to enterprise beans with previous releases of the application server.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.

2. Under Authentication, expand RMI/IIOP security and click **SAS inbound transport**.

Attention: The panel associated with this article displays only when you have a Version 6.1 server in your environment. SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

SSL Settings:

Specifies a list of predefined SSL settings to choose from for inbound connections.

These settings are configured on the Secure Sockets Layer (SSL) configuration panel. To access the SSL configuration panel, complete the following steps:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations and trust zones**.
2. Expand Inbound > *configuration_name*.
3. Under Related Items, click **SSL configurations**.

Data type:	String
Default:	DefaultSSLSettings

Configuring outbound transports

By using this configuration, you can configure a different transport for inbound security versus outbound security.

Before you begin

Outbound transports refers to the transport that is used to connect to a downstream server. When you configure the outbound transport, consider the transports that the downstream servers support. If you are considering Secure Sockets Layer (SSL), also consider including the signers of the downstream servers in this server truststore file for the handshake to succeed.

When you select an SSL configuration, that configuration points to keystore and truststore files that contain the necessary signers.

If you configured client certificate authentication for this server by completing the following steps, then the downstream servers contain the signer certificate belonging to the server personal certificate:

1. Click **Security > Global security**.
2. Under RMI/IIOP security, click **CSIv2 outbound communications**.

About this task

Complete the following steps to configure the outbound transport panels.

Procedure

1. Select the type of transport and the SSL settings by clicking **Security > Global security**. Under RMI/IIOP security, click **CSIv2 outbound communications**. By selecting the type of transport, you choose the transport to use when connecting to downstream servers. The downstream servers support the transport that you choose. If you choose **SSL-Supported**, the transport that is used is negotiated during the connection. If both the client and server support SSL, always select the **SSL-Supported** option unless the request is considered a special request that does not require SSL, such as if an object request broker (ORB) is a request.
2. Select the **SSL required** option if you want to use Secure Sockets Layer communications with the outbound transport.

If you select the **SSL required** option or the **SSL supported** option, you can select either the **Centrally managed** or **Use specific SSL alias** option.

Centrally managed

Enables you to specify an SSL configuration for particular scope such as the cell, node, server, or cluster in one location. To use the **Centrally managed** option, you must specify the SSL configuration for the particular set of endpoints. The Manage endpoint security configurations and trust zones panel displays all of the inbound and outbound endpoints that use the SSL protocol. If you expand the Inbound or Outbound section of the panel and click the name of a node, you can specify an SSL configuration that is used for every endpoint on that node. For an outbound transport, you can override the inherited SSL configuration by specifying an SSL configuration for a particular endpoint. To specify an SSL configuration for an outbound transport, click **Security > SSL certificate and key management > Manage endpoint security configurations and trust zones** and expand **Outbound**.

Use specific SSL alias

Select the **Use specific SSL alias** option if you intend to select one of the SSL configurations in the menu below the option.

The default is *DefaultSSLSettings*. To modify or create a new SSL configuration, complete the steps described in "Creating a Secure Sockets Layer configuration" on page 1741.

3. Click **Apply**.

Results

The outbound transport configuration is complete. With this configuration, you can configure a different transport for inbound security versus outbound security. For example, if the application server is the first server used by end users, the security configuration might be more secure. When requests go to back-end enterprise beans servers, you might consider less security for performance reasons when you go outbound. With this flexibility you can design a transport infrastructure that meets your needs.

What to do next

When you finish configuring security, perform the following steps to save, synchronize, and restart the servers.

- Click **Save** in the administrative console to save any modifications to the configuration.
- Stop and restart all servers, after synchronization.

Common Secure Interoperability Version 2 outbound transport settings:

Use this page to specify which transports and Secure Sockets Layer (SSL) settings this server uses when communicating with downstream servers for outbound requests.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. Under Authentication, click **RMI/IIOP security > CSIv2 outbound transport**.

You also can view this administrative console by completing the following steps:

1. Click **Servers** > **Server Types** > **WebSphere application servers** > ***server_name***.
2. Under Security, click **Server security**.
3. Under Additional properties, click **CSIv2 outbound transport**.

Transport:

Specifies whether the client processes connect to the server using one of the server-connected transports.

You can choose to use either SSL, TCP/IP, or Both as the outbound transport that a server supports. If you specify `TCP/IP`, the server supports only TCP/IP and cannot initiate SSL connections with downstream servers. If you specify `SSL-supported`, this server can initiate either TCP/IP or SSL connections. If you specify `SSL-required`, this server must use SSL to initiate connections to downstream servers. When you do specify SSL, decide which set of SSL configuration settings you want to use for the outbound configuration.

This decision determines which keyfile and trustfile to use for outbound connections to downstream servers.

Consider the following options:

TCP/IP
If you select this option, the server opens TCP/IP connections with downstream servers only.

SSL-required
If you select this option, the server opens SSL connections with downstream servers.

SSL-supported
If you select this option, the server opens SSL connections with any downstream server that supports them and opens TCP/IP connections with any downstream servers that do not support SSL.

Default: SSL-supported
Range: TCP/IP, SSL-required, SSL-supported

SSL settings:

Specifies a list of predefined SSL settings for outbound connections. These settings are configured at the SSL Configuration Repertoires panel.

To access the panel, complete the following steps:

1. Click **Security > SSL certificate and key management**.
2. Under Configuration settings, click **Manage endpoint security configurations and trust zones**.
3. Expand Outbound > *outbound_configuration_name*.
4. Under Related items, click **SSL configurations**.

Data type: String
Range: Any SSL settings that are configured in the SSL Configuration Repertoires panel

Note: This field is available only if a Version 6.1 server exists in your environment.

SSL enabled:

Specifies whether secure socket communication is enabled to the server.

Centrally managed:

Specifies that the selection of an SSL configuration is based upon the outbound topology view for the Java Naming and Directory Interface (JNDI) platform.

Centrally managed configurations support one location to maintain SSL configurations rather than spreading them across the configuration documents.

Default: Enabled

Use specific SSL alias:

Specifies the SSL configuration alias that you want to use for outbound SSL communications.

This option overrides the centrally managed configuration for the JNDI (LDAP) protocol.

Secure Authentication Service outbound transport settings:

Use this page to specify transport settings for connections that are accepted by this server using the Secure Authentication Service (SAS) authentication protocol.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. Under Authentication, expand RMI/IIOP security and click **SAS outbound transport**.

Attention: The panel associated with this article displays only when you have a Version 6.1 server in your environment.

SSL settings:

Specifies a list of predefined Secure Sockets Layer (SSL) settings to choose from for outbound connections.

These settings are configured on the SSL configuration panel. To access the SSL configuration panel, complete the following steps:

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations and trust zones**.
2. Expand Outbound > *configuration_name*.
3. Under Related Items, click **SSL configurations**.

Data type:	String
Default:	DefaultSSLSettings

Configuring inbound messages

You can use the administrative console to configure inbound messages for CSIv2.

Procedure

1. In the administrative console, click **Security > Global security**.
2. Under Authentication, expand **RMI/HOP security**.
3. Click **CSIv2 inbound communication**.
4. Optional: Click **Propagate security attributes** or **Use identity assertion**. The **Propagate security attributes** option enables support for security attribute propagation during login requests. When you select this option, the application server retains additional information about the login request, such as the authentication strength used, and retains the identity and location of the request originator.

   The **Use identity assertion** option specifies that identity assertion is a way to assert identities from one server to another during a downstream Enterprise JavaBeans (EJB) invocation.
5. Under CSIv2 Message layer authentication, select **Supported**, **Never** or **Required**.

   Never Specifies that this server cannot accept an authentication mechanism that you select under **Allow client to server authentication with:**.

   Supported
   Specifies that clients communicating with this server can specify an authentication mechanism

that you select under **Allow client to server authentication with:**. However, a method might be invoked without this type of authentication. For example, an anonymous or client certificate might be used instead.

Required
Specifies that clients communicating with this server must specify an authentication mechanism that you select under **Allow client to server authentication with:**.

6. Under **Allow client to server authentication with:**, select **Kerberos**, **LTPA** and or **Basic authentication**. You can optionally select:

   Kerberos
   Select to enable authentication using the Kerberos token.

   LTPA Select to enable authentication using the Lightweight Third-Party Authentication (LTPA) token.

   Basic authentication
   This type of authentication typically involves sending a user ID and a password from the client to the server for authentication. This is also know as Generic Security Services Username Password (GSSUP).

   This authentication also involves delegating a credential token from an already authenticated credential, provided the credential type is forwardable; for example, LTPA.

   If you select **supported** under **CSIv2 Message layer authentication**, and check **KRB5** and **LTPA** under **Allow client to server authentication with:**, then the server does not accept the user name and password.

7. Click **OK.**

Results

You have now configured messages for CSIv2 inbound.

Configuring outbound messages

You can use the administrative console to configure outbound messages for CSIv2.

Procedure

1. In the administrative console, click **Security > Global security**.
2. Under Authentication, expand **RMI/HOP security**.
3. Click **CSIv2 outbound communication**.
4. Optional: Click **Propagate security attributes** or **Use identity assertion**. The **Propagate security attributes** option enables support for security attribute propagation during login requests. When you select this option, the application server retains additional information about the login request, such as the authentication strength used, and retains the identity and location of the request originator.

   The **Use identity assertion** option specifies that identity assertion is a way to assert identities from one server to another during a downstream Enterprise JavaBeans (EJB) invocation.

   The **Use server trusted identity** option specifies the server identity that the application server uses to establish trust with the target server.

   The **Specify an alternative trusted identity** option enables you to specify an alternative user as the trusted identity that is sent to the target servers instead of sending the server identity. If you select this option you must provide the name of the trusted identity and the password that is associated with the trusted identity.

   Note: You must select Basic Authentication under the Message Layer authentication section to send an alternative trusted identity. If you do not select Basic Authentication, then choose the Server Identity instead.

5. Under CSIv2 Message layer authentication, select **Supported**, **Never** or **Required**.

Never Specifies that this server cannot accept an authentication mechanism that you select under **Allow client to server authentication with:**.

Supported
Specifies that clients communicating with this server can specify an authentication mechanism that you select under **Allow client to server authentication with:**. However, a method might be invoked without this type of authentication. For example, an anonymous or client certificate might be used instead.

Required
Specifies that clients communicating with this server must specify an authentication mechanism that you select under **Allow client to server authentication with:**.

6. Under **Allow client to server authentication with:**, select **Kerberos**, **LTPA** and or **Basic authentication**. You can optionally select:.

   Kerberos
   Select to enable authentication using the Kerberos token.

   LTPA Select to enable authentication using the Lightweight Third-Party Authentication (LTPA) token.

   Basic authentication
   This type of authentication typically involves sending a user ID and a password from the client to the server for authentication. This is also know as Generic Security Services Username Password (GSSUP).

   This authentication also involves delegating a credential token from an already authenticated credential, provided the credential type is forwardable; for example, LTPA.

   If you select **supported** under **CSIv2 Message layer authentication**, and check **KRB5** and **LTPA** under **Allow client to server authentication with:**, then the server does not accept the user name and password.

7. Optional: Select **Custom outbound mapping**. This option enables the use of custom Remote Method Invocation (RMI) outbound login modules.

Results

You have now configured messages for CSIv2 outbound.

Common Secure Interoperability Version 2 and Security Authentication Service (SAS) client configuration

A secure Java client requires configuration properties to determine how to perform security with a server.

These configuration properties are typically put into a properties file somewhere on the client system and referenced by specifying the following system property on the command line of the Java client. For example, this property accepts any valid web address.

```
-Dcom.ibm.CORBA.ConfigURL=file:profile_root/properties/sas.client.props
```

When you use thin or thick clients, `com.ibm.CORBA.ConfigURL` is automatically set to the following file:

profile_root`/properties/sas.client.props`

When this file is processed by the Object Request Broker (ORB), security can be enabled between the Java client and the target server.

If any syntax problems exist with the ConfigURL property and the `sas.client.props` file is not found, the Java client proceeds to connect insecurely. Errors display indicating the failure to read the ConfigURL property. Typically the problem is related to having two slashes after `file`, which is not valid.

Use the following properties to configure the Secure Authentication Service (SAS) and CSIv2 authentication protocols:
• "Security Authentication Service authentication protocol client settings" on page 1588

Important: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

Authentication protocol settings for a client configuration:

You can use settings in the `sas.client.props` file to configure Security Authentication Service (SAS) and Common Secure Interoperability Version 2 (CSIv2) clients.

Use the following settings in the `sas.client.props` file to configure SAS and CSIv2 clients. By default, the `sas.client.props` file is located in the *profile_root*`/properties` directory of your WebSphere Application Server - Express installation.

Important: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

Note: The `sas.client.props` file for WebSphere Application Server Version 8.0 contains some new properties that support BasicAuth and Kerberos, such as:

```
com.ibm.IPC.authenticationTarget=BasicAuth
com.ibm.IPC.loginUserid=
com.ibm.IPC.loginPassword=
com.ibm.IPC.loginSource=prompt
com.ibm.IPC.krb5Service=WAS
com.ibm.IPC.krb5CcacheFile=
com.ibm.IPC.krb5ConfigFile=
```

com.ibm.CORBA.securityEnabled:

Use to determine if security is enabled for the client process.

Table 110. com.ibm.CORBA.securityEnabled. This table describes the com.ibm.CORBA.securityEnabled setting.

Setting	Value
Data Type	Boolean
Default	True
Valid values	True or false

com.ibm.CSI.protocol:

Use to determine which authentication protocols are active.

The client can configure protocols of `ibm`, `csiv2` or `both` as active. The only possible values for an authentication protocol are `ibm`, `csiv2` and `both`. Do not use `sas` for the value of an authentication protocol. This restriction applies to both client and server configurations. The following list provides information about using each of these protocol options:

ibm Use this authentication protocol option when you are communicating with WebSphere Application Server Version 4.x or earlier servers.

csiv2 Use this authentication protocol option when you are communicating with WebSphere Application Server Version 5 or later servers because the SAS interceptors are not loaded and running for each method request.

both Use this authentication protocol option for interoperability between WebSphere Application Server

Version 4.x or earlier servers and WebSphere Application Server Version 5 or later servers. Typically, specifying `both` provides greater interoperability with other servers.

Table 111. com.ibm.CSI.protocol. This table describes the com.ibm.CSI.protocol setting.

Setting	Value
Data type	String
Default	Both
Valid values	ibm, csiv2, both

com.ibm.CORBA.authenticationTarget:

Use to determine the type of authentication mechanism for sending security information from the client to the server.

If basic authentication is specified, the user ID and password are sent to the server. Using the Secure Sockets Layer (SSL) transport with this type of authentication is recommended; otherwise, the password is not encrypted. The target server must support the specified authentication target.

Table 112. com.ibm.CORBA.authenticationTarget. This table describes the com.ibm.CORBA.authenticationTarget setting.

Setting	Value
Data type	String
Default	BasicAuth
Valid values	BasicAuth, KRB5

com.ibm.CORBA.validateBasicAuth:

Use to determine if the user ID and password get validated immediately after the login data is entered when the authenticationTarget property is set to `BasicAuth`.

In previous releases, BasicAuth logins validated only with the initial method request. During the first request, the user ID and password are sent to the server. This request is the first time that the client can notice an error, if the user ID or password is incorrect. The validateBasicAuth method is specified and the validation of the user ID and password occurs immediately to the security server.

For performance reasons, you might want to disable this property if you do not want to verify the user ID and password immediately. If the client program can wait, it is better to have the initial method request flow to the user ID and password. However, program logic might not be this simple because of error handling considerations.

Table 113. com.ibm.CORBA.validateBasicAuth. This table describes the com.ibm.CORBA.validateBasicAuth setting.

Setting	Value
Data type	Boolean
Default	True
Valid values	True, False

com.ibm.CORBA.authenticationRetryEnabled:

Use to specify that a failed login attempt is retried. This property determines if a retry occurs for other errors, such as stateful sessions that are not found on a server or validation failures at the server because of an expiring credential.

The minor code in the exception that is returned to a client determines which errors are retried. The number of retry attempts is dependent upon the com.ibm.CORBA.authenticationRetryCount property.

Table 114. com.ibm.CORBA.authenticationRetryEnabled. This table describes the com.ibm.CORBA.authenticationRetryEnabled setting.

Setting	Value
Data type	Boolean
Default	True
Valid values	True, False

com.ibm.CORBA.authenticationRetryCount:

Use to specify the number of retries that occur until either a successful authentication occurs or the maximum retry value is reached.

When the maximum retry value is reached, the authentication exception is returned to the client.

Table 115. com.ibm.CORBA.authenticationRetryCount. This table describes the com.ibm.CORBA.authenticationRetryCount setting.

Setting	Value
Data type	Integer
Default	3
Range	1-10

com.ibm.CORBA.loginSource:

Use to specify how the request interceptor attempts to log in if it does not find an invocation credential already set.

This property is valid only if message layer authentication occurs. If only transport layer authentication occurs, this property is ignored. When specifying properties, the following two additional properties must be defined:

- com.ibm.CORBA.loginUserid
- com.ibm.CORBA.loginPassword

When performing a programmatic login, it is not necessary to specify `none` as the login source. The request fails if a credential is set as the invocation credential during a method request.

Table 116. com.ibm.CORBA.loginSource. This table describes the com.ibm.CORBA.loginSource setting.

Setting	Value
Data type	String
Default	Prompt
Valid values	Prompt, key file, stdin, none, properties

com.ibm.CORBA.loginUserid:

Use to specify the user ID when a properties login is configured and message layer authentication occurs.

This property is valid only when `com.ibm.CORBA.loginSource=properties`. Also set the com.ibm.CORBA.loginPassword property.

Table 117. com.ibm.CORBA.loginUserid. This table describes the com.ibm.CORBA.loginUserid setting.

Setting	Value
Data type	String
Range	Any string that is appropriate for a user ID in the configured user registry of the server.

com.ibm.CORBA.loginPassword:

Use to specify the password when a properties login is configured and message layer authentication occurs.

This property is valid only when `com.ibm.CORBA.loginSource=properties`. Also set the com.ibm.CORBA.loginUserid property.

Table 118. com.ibm.CORBA.loginPassword. This table describes the com.ibm.CORBA.loginPassword setting.

Setting	Value
Data type	String
Range	Any string that is appropriate for a password in the configured user registry of the server.

com.ibm.CORBA.keyFileName:

Use to specify the key file that is used to log in.

A key file is a file that contains a list of realm, user ID, and password combinations that a client uses to log into multiple realms. The realm that is used is the one found in the interoperable object reference (IOR) for the current method request. The value of this property is used when the `com.ibm.CORBA.loginSource=key file` is used.

Table 119. com.ibm.CORBA.keyFileName. This table describes the com.ibm.CORBA.keyFileName setting.

Setting	Value
Data type	String
Default	C;/WebSphere/AppServer/properties/wsserver.key
Range	Any fully qualified path and file name of a WebSphere Application Server key file.

com.ibm.CORBA.loginTimeout:

Use to specify the length of time that the login prompt stays available before it is considered a failed login.

Table 120. com.ibm.CORBA.loginTimeout. This table describes the com.ibm.CORBA.loginTimeout setting.

Setting	Value
Data type	Integer
Units	Seconds
Default	300 (5 minute intervals)
Range	0 - 600 (10 minute intervals)

com.ibm.CORBA.securityEnabled:

Use to determine if security is enabled for the client process.

Table 121. com.ibm.CORBA.securityEnabled. This table describes the com.ibm.CORBA.securityEnabled setting.

Setting	Value
Data type	Boolean
Default	True
Range	True, False

Security Authentication Service authentication protocol client settings:

In addition to those properties which are valid for both Security Authentication Service (SAS) and Common Secure Interoperability Version 2 (CSIv2), this article documents properties which are valid only for the SAS authentication protocol.

Important: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

com.ibm.CORBA.standardPerformQOPModels:

Specifies the strength of the ciphers when making a Secure Sockets Layer (SSL) connection.

Data type:	String
Default:	High
Range	Low, Medium, High

Example 1: Configuring basic authentication and identity assertion

This example presents a pure Java client, C, that accesses a secure enterprise bean on server, S1, through user bob. The following steps take you through the configuration of C, S1, and S2.

About this task

The enterprise bean code on S1 accesses another enterprise bean on server, S2. This configuration uses identity assertion to propagate the identity of bob to the downstream server, S2. S2 trusts that bob already is authenticated by S1 because it trusts S1. To gain this trust, the identity of S1 also flows to S2 simultaneously and S2 validates the identity by checking the trustedPrincipalList list to verify that it is a valid server principal. S2 also authenticates S1.

Procedure

1. Configure the client C for message layer authentication with a Secure Sockets Layer (SSL) transport.
   a. Point the client to the `sas.client.props` file.

      Use the `com.ibm.CORBA.ConfigURL=file:/`*`profile_root`*` /properties/sas.client.props` property. The *profile_root* variable is the specific profile that you are working with. All further configuration involves setting properties within this file.
   b. Enable SSL.

      In this case, SSL is supported but not required:
      `com.ibm.CSI.performTransportAssocSSLTLSSupported=true,`
      `com.ibm.CSI.performTransportAssocSSLTLSRequired=false`
   c. Enable client authentication at the message layer.

      In this case, client authentication is supported but not required:
      `com.ibm.CSI.performClientAuthenticationRequired=false,`
      `com.ibm.CSI.performClientAuthenticationSupported=true`
   d. Use all of the remaining defaults in the `sas.client.props` file.
2. Configure the server, S1.

   In the administrative console, server S1 is configured for incoming requests to support message-layer client authentication and incoming connections to support SSL without client certificate authentication. Server S1 is configured for outgoing requests to support identity assertion.
   a. Configure S1 for incoming connections.
      1) Disable identity assertion.
      2) Enable user ID and password authentication.
      3) Enable SSL.

4) Disable SSL client certificate authentication.

b. Configure S1 for outgoing connections.

1) Enable identity assertion.

2) Disable user ID and password authentication.

3) Enable SSL.

4) Disable SSL client certificate authentication.

3. Configure the server, S2.

In the administrative console, server S2 is configured for incoming requests to support identity assertion and to accept SSL connections. Complete the following steps to configure incoming connections. Configuration for outgoing requests and connections are not relevant for this example.

a. Enable identity assertion.

b. Disable user ID and password authentication.

c. Enable SSL.

d. Disable SSL client authentication.

Example 2: Configuring basic authentication, identity assertion, and client certificates

This example is the same as example 1, except for the interaction from client C2 to server S2. Therefore, the configuration of example 1 still is valid, but you have to modify server S2 slightly and add a configuration for client C2. The configuration is not modified for C1 or S1.

About this task

Procedure

1. Configure client C2 for transport layer authentication (Secure Sockets Layer (SSL) client certificates).

a. Point the client to the `sas.client.props` file.

Use the `com.ibm.CORBA.ConfigURL=file:/profile_root /properties/sas.client.props` property. The *profile_root* variable is the specific profile that you are working with. All further configuration involves setting properties within this file.

b. Enable SSL.

In this case, SSL is supported but not required:

```
com.ibm.CSI.performTransportAssocSSLTLSSupported=true,
com.ibm.CSI.performTransportAssocSSLTLSRequired=false
```

c. Disable client authentication at the message layer.

```
com.ibm.CSI.performClientAuthenticationRequired=false,
com.ibm.CSI.performClientAuthenticationSupported=false
```

d. Enable client authentication at the transport layer where it is supported, but not required.

```
com.ibm.CSI.performTLClientAuthenticationRequired=false,
com.ibm.CSI.performTLClientAuthenticationSupported=true
```

2. Configure the server, S2.

In the administrative console, server S2 is configured for incoming requests to SSL client authentication and identity assertion. Configuration for outgoing requests is not relevant for this example.

You can mix and match these configuration options. However, a precedence exists as to which authentication features become the identity in the received credential:

a. Identity assertion

b. Message-layer client authentication (basic authentication or token)
c. Transport-layer client authentication (SSL certificates)

a. Enable identity assertion.
b. Disable user ID and password authentication.
c. Enable SSL.
d. Enable SSL client authentication.

Example 3: Configuring client certificate authentication and RunAs system

This example presents a pure Java client, C, accessing a secure enterprise bean on S1.

About this task

C authenticates to S1 using Secure Sockets Layer (SSL) client certificates. S1 maps the common name of the distinguished name (DN) in the certificate to a user in the local registry. The user in this case is bob. The enterprise bean code on S1 accesses another enterprise bean on S2. Because the RunAs mode is `system`, the invocation credential is set as server1 for any outbound requests.

Procedure

1. Configure client C for transport layer authentication (SSL client certificates).
   a. Point the client to the `sas.client.props` file.

      Use the `com.ibm.CORBA.ConfigURL=file:/`*profile_root* `/properties/sas.client.props` property. The *profile_root* variable is the specific profile that you are working with. All further configuration involves setting properties within this file.
   b. Enable SSL.

      In this case, SSL is supported but not required:
      `com.ibm.CSI.performTransportAssocSSLTLSSupported=true,`
      `com.ibm.CSI.performTransportAssocSSLTLSRequired=false`
   c. Disable client authentication at the message layer.
      `com.ibm.CSI.performClientAuthenticationRequired=false,`
      `com.ibm.CSI.performClientAuthenticationSupported=false`
   d. Enable client authentication at the transport layer. It is supported, but not required.
      `com.ibm.CSI.performTLClientAuthenticationRequired=false,`
      `com.ibm.CSI.performTLClientAuthenticationSupported=true`
2. Configure the S1 server. In the administrative console, S1 is configured for incoming connections to support SSL with client certificate authentication. The S1 server is configured for outgoing requests to support message layer client authentication.
   a. Configure S1 for incoming connections.
      1) Disable identity assertion.
      2) Disable user ID and password authentication.
      3) Enable SSL.
      4) Enable SSL client certificate authentication.
   b. Configure S1 for outgoing connections.
      1) Disable identity assertion.
      2) Disable user ID and password authentication.
      3) Enable SSL.
      4) Enable SSL client certificate authentication.
3. Configure the S2 server.

In the administrative console, the S2 server is configured for incoming requests to support message layer authentication over SSL. Configuration for outgoing requests is not relevant for this scenario.

a. Disable identity assertion.

b. Enable user ID and password authentication.

c. Enable SSL.

d. Disable SSL client authentication.

Example 4: Configuring TCP/IP transport using a virtual private network

This scenario illustrates the ability to choose TCP/IP as the transport when it is appropriate. In some cases, when two servers are on the same virtual private network (VPN), it can be appropriate to select TCP/IP as the transport for performance reasons because the VPN already encrypts the message.

About this task

Procedure

1. Configure client C for message layer authentication with an Secure Sockets Layer (SSL) transport.
   a. Point the client to the `sas.client.props` file.

      Use the `com.ibm.CORBA.ConfigURL=file:/`*profile_root*`/properties/sas.client.props` property. The *profile_root* variable is to the specific profile you are working with. All further configuration involves setting properties within this file.

   b. Enable SSL.

      In this case, SSL is supported but not required.`com.ibm.CSI.performTransportAssocSSLTLSSupported=true`, `com.ibm.CSI.performTransportAssocSSLTLSRequired=false`

   c. Enable client authentication at the message layer. In this case, client authentication is supported but not required. `com.ibm.CSI.performClientAuthenticationRequired=false`, `com.ibm.CSI.performClientAuthenticationSupported=true`

   d. Use the remaining defaults in the `sas.client.props` file.
2. Configure the S1 server. In the administrative console, the S1 server is configured for incoming requests to support message-layer client authentication and incoming connections to support SSL without client certificate authentication. The S1 server is configured for outgoing requests to support identity assertion.

   It is possible to enable SSL for inbound connections and disable SSL for outbound connections. The same is true in reverse.
   a. Configure S1 for incoming connections.
      1) Disable identity assertion.
      2) Enable user ID and password authentication.
      3) Enable SSL.
      4) Disable SSL client certificate authentication.
   b. Configure S1 for outgoing connections.
      1) Disable identity assertion.
      2) Enable user ID and password authentication.
      3) Disable SSL.
3. Configure the S2 server.

   In the administrative console, the S2 server is configured for incoming requests to support identity assertion and to accept SSL connections. Configuration for outgoing requests and connections are not relevant for this scenario.
   a. Disable identity assertion.

b. Enable user ID and password authentication.
c. Disable SSL.

Authentication protocol for EJB security

WebSphere Application Server Version 8.0 servers support the CSIv2 authentication protocol only. SAS is only supported between Version 6.0.x and earlier version servers that have been federated in a Version 8.0 cell. The option to select between SAS, CSIv2, or both is only available in the administration console when a Version 6.0.*x* or earlier release has been federated in a Version 8.0 cell.

SAS is the authentication protocol used by all previous releases of WebSphere Application Server and is maintained for backwards compatibility. The Object Management Group (OMG) has defined the authentication protocol called CSIv2 so that vendors can interoperate securely. CSIv2 is implemented in WebSphere Application Server with more features than SAS and is considered the strategic protocol.

Important: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

Invoking Enterprise Java Beans (EJB) methods in a secure WebSphere Application Server environment requires an authentication protocol to determine the level of security and the type of authentication that occur between any given client and server for each request. It is the job of the authentication protocol during a method invocation to merge the server authentication requirements that are determined by the object Interoperable Object Reference (IOR) with the client authentication requirements that are determined by the client configuration and come up with an authentication policy specific to that client and server pair.

The authentication policy makes the following decisions, among others, which are all based on the client and server configurations:
- What kind of connection can you make to this server--Secure Sockets Layer (SSL) or TCP/IP?
- If SSL is chosen, how strong is the encryption of the data?
- If SSL is chosen, do you authenticate the client using client certificates?
- Do you authenticate the client with a user ID and password? Does an existing credential exist?
- Do you assert the client identity to downstream servers?
- Given the configuration of the client and server, can a secure request proceed?

You can configure both protocols (SAS and CSIv2) to work simultaneously. If a server supports both protocols, it exports an IOR containing tagged components describing the configuration for SAS and CSIv2. If a client supports both protocols, it reads tagged components for both CSIv2 and SAS. If the client supports both and the server supports both, CSIv2 is used. However, if the server supports SAS (for example, it is a previous WebSphere Application Server release) and the client supports both, the client chooses SAS for this request because the SAS protocol is what both have in common.

Choose a protocol by specifying the `com.ibm.CSI.protocol` property on the client side and configuring through the administrative console on the server side. More details are included in the SAS and CSIv2 properties articles.

Common Secure Interoperability Specification, Version 2

The Common Secure Interoperability Specification, Version 2 (CSIv2) defines the Security Attribute Service (SAS) that enables interoperable authentication, delegation, and privileges. The CSIv2 SAS and SAS protocols are entirely different. The CSIv2 SAS is a subcomponent of CSIv2 that supports SSL and interoperability with the EJB Specification, Version 2.1.

Security Attribute Service

The Common Secure Interoperability Specification, Version 2 Security Attribute Service (CSIv2 SAS) protocol is designed to exchange its protocol elements in the service context of a General Inter-ORB Protocol (GIOP) request and reply messages that are communicated over a connection-based transport. The protocol is intended for use in environments where transport layer security, such as that available through Secure Sockets Layer (SSL) and Transport Layer Security (TLS), is used to provide message protection (that is, integrity and or confidentiality) and server-to-client authentication. The protocol provides client authentication, delegation, and privilege functionality that might be applied to overcome corresponding deficiencies in an underlying transport. The CSIv2 SAS protocol facilitates interoperability by serving as the higher-level protocol under which secure transports can be unified.

Connection and request interceptors

The authentication protocols that are used by WebSphere Application Server are add-on Interoperable Inter-ORB Protocol (IIOP) services. IIOP is a request-and-reply communications protocol that is used to send messages between two Object Request Brokers (ORBs). For each request made by a client ORB to a server ORB, an associated reply is made by the server ORB back to the client ORB. Prior to any request flowing, a connection between the client ORB and the server ORB must be established over the TCP/IP transport (SSL is a secure version of TCP/IP). The client ORB invokes the authentication protocol client connection interceptor, which is used to read the tagged components in the IOR of the object that is located on the server. As mentioned previously, the authentication policy is established here for the request. Given the authentication policy (a coalescing of the server configuration with the client configuration), the strength of the connection is returned to the ORB. The ORB makes the appropriate connection, usually over SSL.

After the connection is established, the client ORB invokes the authentication protocol client request interceptor, which is used to send security information other than what is established by the transport. The security information includes the user ID and password token that are authenticated by the server, an authentication mechanism-specific token that is validated by the server, or an identity assertion token. Identity assertion is a way for one server to trust another server without the need to re-authenticate or re-validate the originating client. However, some work is required for the server to trust the upstream server. This additional security information is sent with the message in a *service context*. A service context has a registered identifier so that the server ORB can identify which protocol is sending the information.

The fact that a service context contains a unique identity is another way for WebSphere Application Server to support both SAS and CSIv2 simultaneously because both protocols have different service context IDs. After the client request interceptor finishes adding the service context to the message, the message is sent to the server ORB.

When the message is received by the server ORB, the ORB invokes the authentication protocol server request interceptor. This interceptor looks for the service context ID known by the protocol. When both SAS and CSIv2 are supported by a server, two different server request interceptors are invoked and both interceptors look for different service context IDs.

However, only one finds a service context for any given request. When the server request interceptor finds a service context, it reads the information in the service context. A method is invoked to the security server to authenticate or validate client identity. The security server either rejects the information or returns a credential. A credential contains additional information about the client that is retrieved from the user registry so that authorization can make the appropriate decision. Authorization is the process of determining if the user can invoke the request based on the roles that are applied to the method and the roles given to the user.

If a service context is not found by the CSIv2 server request interceptor, the interceptor process looks at the transport connection to see if a client certificate chain is sent. This process is done when SSL client authentication is configured between the client and server.

If a client certificate chain is found, the distinguished name (DN) is extracted from the certificate and is used to map to an identity in the user registry. If the user registry is Lightweight Directory Access Protocol (LDAP), the search filters defined in the LDAP registry configuration determine how the certificate maps to an entry in the registry. If the user registry is local OS, the first attribute of the distinguished name (DN) maps to the user ID of the registry. This attribute is typically the common name.

If the certificate does not map, no credential is created and the request is rejected. When valid security information is not presented, the method request is rejected and a NO_PERMISSION exception is sent back with the reply. However, when no security information is presented, an unauthenticated credential is created for the request and the authorization engine determines if the method gets invoked. For an unauthenticated credential to invoke an Enterprise JavaBeans (EJB) method, either no security roles are defined for the method or a special Everyone role is defined for the method.

When the method invocation is completed in the EJB container, the server request interceptor is invoked again to complete server authentication and a new reply service context is created to inform the client request interceptor of the outcome. This process is typically for making the request *stateful*. When a stateful request is made, only the first request between a client and server requires that security information is sent. All subsequent method requests need to send a unique context ID only so that the server can look up the credential that is stored in a session table. The context ID is unique within the connection between a client and server.

Finally, the method request cycle is completed by the client request interceptor receiving a reply from the server with a reply service context providing information so that the client-side stateful context ID can be confirmed and reused.

Specifying a stateful client is done through the property com.ibm.CSI.performStateful (true/false). Specifying a stateful server is done through the administrative console configuration.

. *Authentication protocol flow*

Authentication policy for each request

The authentication policy of a given request determines the security protection between a client and a server. A client or server authentication protocol configuration can describe required features, supported features, and non-supported features. When a client requires a feature, it can talk only to servers that either require or support that feature. When a server requires a feature, it can talk only to clients that either require or support that feature. When a client supports a feature, it can talk to a server that supports or requires that feature, but can also talk to servers that do not support the feature. When a server supports a feature, it can talk to a client that supports or requires the feature, but can also talk to clients that do not support the feature or chose not to support the feature.

For example, for a client to support client certificate authentication, some setup is required to either generate a self-signed certificate or to get one from a certificate authority (CA). Some clients might not need to complete these actions, therefore, you can configure this feature as not supported. By making this decision, the client cannot communicate with a secure server that requires client certificate authentication. Instead, this client can choose to use the user ID and password as the method of authenticating itself to the server.

Typically, supporting a feature is the most common way of configuring features. It is also the most successful during runtime because it is more forgiving than requiring a feature. Knowing how secure servers are configured in your domain, you can choose the right combination for the client to ensure successful method invocations and still get the most security. If you know that all of your servers support both client certificate and user ID and password authentication for the client, you might want to require one and not support the other. If both the user ID and password and the client certificate are supported on the client and server, both are performed, but user ID and password take precedence at the server. This

action is based on the CSIv2 specification requirements.

Authentication protocol support

Use this page to reference information regarding supported authentication protocols.

Authentication protocol support

Beginning with WebSphere Application Server Version 8.0, the WebSphere Application Server Version 8.0 servers only support the Common Secure Interoperability Version 2 (CSIv2) authentication protocol. Secure Authentication Service (SAS) is only supported between Version 6.0.*x* and previous version servers that have been federated in a Version 8.0 cell. The option to select between SAS, CSIv2, or both will only be made available in the administration console when a Version 6.0.x or previous release has been federated in a Version 8.0 cell.

In future releases, IBM will no longer ship or support the Secure Authentication Service (SAS) IIOP security protocol. It is recommended that you use the Common Secure Interoperability version 2 (CSIv2) protocol.

You can configure both protocols to work simultaneously between Version 6.0.*x* and previous version servers that have been federated in a Version 8.0 cell. If a server supports both protocols, it exports an interoperable object reference (IOR) that contains tagged components describing the configuration for SAS and CSIv2. If a client supports both protocols, it reads tagged components for both CSIv2 and SAS. If the client and server support both protocols, CSIv2 is used. However, if the server supports SAS (for example, the server is a previous WebSphere Application Server release) and the client supports both protocols, the client chooses SAS for this request.

Choose a protocol using the com.ibm.CSI.protocol property on the client side and configure this protocol through the administrative console on the server side.

You can configure both protocols to work simultaneously. If a server supports both protocols, it exports an interoperable object reference (IOR) that contains tagged components describing the configuration for SAS and CSIv2. If a client supports both protocols, it reads tagged components for both CSIv2 and SAS. If the client and the server support both protocols, CSIv2 is used. However, if the server supports SAS (for example, it is a previous WebSphere Application Server release) and the client supports both protocols, the client chooses SAS for this request.

Common Secure Interoperability Version 2 features

The following Common Secure Interoperability Version 2 (CSIv2) features are available in IBM WebSphere Application Server: message layer authentication, identity assertion, and security attribute propagation.

- Identity Assertion

  Supports a downstream server in accepting the client identity that is established on an upstream server, without having to authenticate again. The downstream server trusts the upstream server.
- Message Layer Authentication

  Authenticates credential information and sends that information across the network so that a receiving server can interpret it.
- Security attribute propagation

  Supports the use of the authorization token to propagate serialized Subject contents and PropagationToken contents with the request. You can propagate these objects using a pure client or a server login that adds custom objects to the Subject. Propagating security attributes prevents downstream logins from having to make user registry calls to look up these attributes.

  Propagating security attributes is also useful when the security attributes contain information that is only available at the time of authentication. This information cannot be located using the user registry on downstream servers.

Identity assertion to the downstream server

When a client authenticates to a server, the received credential is set. When the authorization engine checks the credential to determine whether access is permitted, it also sets the *invocation* credential . *Identity assertion* is the invocation credential that is asserted to the downstream server.

When a client authenticates to a server, the received credential is set. When the authorization engine checks the credential to determine whether access is permitted, it also sets the *invocation* credential so that if the Enterprise JavaBeans (EJB) method calls another EJB method that is located on other servers, the invocation credential can be the identity used to invoke the downstream method. Depending on the RunAs mode for the enterprise beans, the invocation credential is set as the originating client identity, the server identity, or a specified different identity. Regardless of the identity that is set, when identity assertion is enabled, it is the invocation credential that is asserted to the downstream server.

The invocation credential identity is sent to the downstream server in an identity token. In addition, the sending server identity, including the password or token, is sent in the client authentication token when basic authentication is enabled. The sending server identity is sent through a Secure Sockets Layer (SSL) client certification authentication when client certificate authentication is enabled. Basic authentication takes precedence over client certificate authentication.

Both identity tokens are needed by the receiving server to accept the asserted identity. The receiving server completes the following actions to accept the asserted identity:

- The server determines whether the sending server identity, sent with a basic authentication token or with an SSL client certificate, is on the trusted principal list of the receiving server. The server determines whether the sending server can send an identity token to the receiving server.
- After it is determined that the sending server is on the trusted list, the server authenticates the sending server to verify its identity.
- The server is authenticated by comparing the user ID and password from the sending server to the receiving server. If the credentials of the sending server are authenticated and on the trusted principal list, then the server proceeds to evaluate the identity token.
- The downstream server checks its defined user registry for the presence of the asserted user ID to gather additional credential information for authorization purposes (for example, group memberships). Thus, the downstream user registry must contain all of the asserted user IDs. Otherwise, identity assertion is not possible. In a stateful server, this action occurs once for the sending server and the receiving server pair where the identity tokens are the same. Subsequent requests are made through a session ID.

  Note: When the downstream server does not have a user registry with access to the asserted user IDs in its repository, do not use identity assertion because authorization checks will fail. By disabling identity assertion, the authorization checks on the downstream server are not needed.

Evaluation of the identity token consists of the following four identity formats that exist in an identity token:

- Principal name
- Distinguished name
- Certificate chain
- Anonymous identity

The product servers that receive authentication information typically support all four identity types. The sending server decides which one is chosen, based on how the original client authenticated. The existing type depends on how the client originally authenticates to the sending server. For example, if the client uses Secure Sockets Layer (SSL) client authentication to authenticate to the sending server, then the identity token sent to the downstream server contains the certificate chain. With this information, the receiving server can perform its own certificate chain mapping and interoperability is increased with other vendors and platforms.

After the identity format is understood and parsed, the identity maps to a credential. For an ITTPrincipal identity token, this identity maps one-to-one with the user ID fields.

For an ITTDistinguishedName identity token, the mapping depends on the user registry. For Lightweight Directory Access Protocol (LDAP), the configured search filter determines how the mapping occurs. For LocalOS, the first attribute of the distinguished name (DN), which is typically the same as the common name, maps to the user ID of the registry.

Identity assertion is only available using the Common Secure Interoperability Version 2 (CSIv2) protocol.

Note: There is a restriction for using identity assertion with KRB token to downstream. If you use identity assertion with Kerberos enabled, the identity assertion does not have the Kerberos authentication token (KRBAuthnToken) when going to downstream servers. It uses LTPA for authentication instead.

Identity assertions with trust validation

If you want an application or system provider to perform an identity assertion with trust validation, it can be accomplished by use of the Java Authentication and Authorization Service (JAAS) login framework, where trust validation is performed in one login module and credential creation in another. These two custom login modules are used to create a JAAS login configuration that performs a login to an identity assertion.

Two custom login module are required:

- A user-implemented trust association login module. This login module performs whatever trust verification the user requires. When trust is verified, the trust verification status and the login identity must be placed in a map in the share state of the login module to enable the credential creation login module to use that information. The map must be stored in the com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.state property. State maps contain the following information:
  - com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.trusted – set to `true`, if trusted, and `false`, if not trusted.
  - com.ibm.wsspi.security.common.auth.module.IdenityAssertionLoginModule.principal – contains the principal of the identity.
  - com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.certificates – contains the certificate of the identity
- The com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule module performs the credential creation. It requires that the trust state information be in the login context's shared state. This login module is protected by the Java 2 security runtime permissions for the following:
  - com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.initialize
  - com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.login

IdentityAssertionLoginModule searches for the trust information in the shared state property, com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.state. This is a map that contains the trust status and the identity used to login. The map includes the following:

- com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.trusted – if set to `true` it is trusted, `false` if not trusted.
- com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.principal – if a principal is used, it contains the principal of the identity necessary to login.
- com.ibm.wsspi.security.common.auth.module.IdentityAssertionLoginModule.certificates – if a certificate is used, it contains an array of a certificate chain that includes the identity necessary to login.

A WSLoginFailedException is returned if the state, trust, or identity information is missing. The login module then performs a login of the identity. The subject now contains the new identity.

Message layer authentication

Defines the credential information and sends that information across the network so that a receiving server can interpret it.

When you send authentication information across the network using a token the transmission is considered message layer authentication because the data is sent with the message inside a service context.

A pure Java client uses Kerberos (KRB5) or basic authentication, or Generic Security Services Username Password (GSSUP), as the authentication mechanism to establish client identity.

However, a servlet can use either basic authentication (GSSUP) or the authentication mechanism of the server, Kerberos (KRB5) or Lightweight Third Party Authentication (LTPA), to send security information in the message layer. Use KRB5 or LTPA by authenticating or by mapping the basic authentication credentials to the security mechanism of the server.

The security token that is contained in a token-based credential is authentication mechanism-specific. The way that the token is interpreted is only known by the authentication mechanism. Therefore, each authentication mechanism has an object ID (OID) representing it. The OID and the client token are sent to the server, so that the server knows which mechanism to use when reading and validating the token. The following list contains the OIDs for each mechanism:

BasicAuth (GSSUP): oid:2.23.130.1.1.1
KRB5: OID: 1.2.840.113554.1.2.2
LTPA: oid:1.3.18.0.2.30.2
SWAM: No OID because it is not forwardable

Note: SWAM is deprecated in WebSphere Application Server Version 8.0 and will be removed in a future release.

On the server, the authentication mechanisms can interpret the token and create a credential, or they can authenticate basic authentication data from the client, and create a credential. Either way, the created credential is the *received* credential that the authorization check uses to determine if the user has access to invoke the method. You can specify the authentication mechanism by using the following property on the client side:

- com.ibm.CORBA.authenticationTarget

Basic authentication (BasicAuth) and KRB5 are currently the only valid values. You can configure the server through the administrative console.

Note: When **perform basic authentication** is enabled, if the client is not similarly configured (and does not pass a credential such as a user ID and password).

Configuring authentication retries

Situations occur where you want a prompt to display again if you entered your user ID and password incorrectly or you want a method to retry when a particular error occurs back at the client. If you can correct the error by information at the client side, the system automatically performs a retry without the client seeing the failure, if the system is configured appropriately.

Some of these errors include:
- Entering a user ID and password that are not valid
- Having an expired credential on the server
- Failing to find the stateful session on the server

By default, authentication retries are enabled and perform three retries before returning the error to the client. Use the com.ibm.CORBA.authenticationRetryEnabled property (`True` or `False`) to enable or disable authentication retries. Use the com.ibm.CORBA.authenticationRetryCount property to specify the number of retry attempts.

Using Microsoft Active Directory for authentication

WebSphere Application Server supports the Microsoft Active Directory. Many installations use the Microsoft Active Directory as their primary component for managing user authentication and user data. Authenticating a user across multiple repositories or across a distributed Lightweight Directory Access Protocol (LDAP), such as a Microsoft Active Directory forest can be challenging. In any search of the whole registry, if there is more than one match at run time, authentication fails because ambiguous matches result.

About this task

User IDs are guaranteed to be unique within a single domain, but there is no automatic guarantee that a given user ID is unique across a tree or a forest. The following figure exemplifies the condition of a given user ID not being unique across a tree or forest.

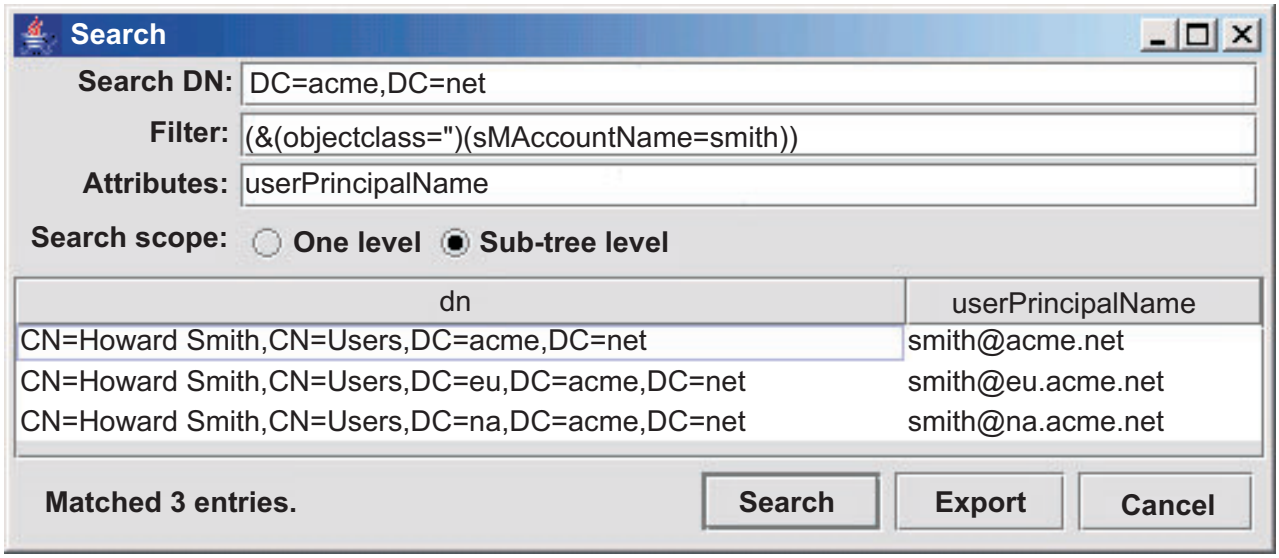

Figure 21. Forest search strategy.. Search illustration of a non-unique sAMAccountName across the entire forest.

Authenticating users across trees or forests can be a difficult task and the following steps should be performed.

Procedure

1. Analyze the Microsoft Active Directory construct that defines your installation. Your analysis can conclude with the following forms:
   - Single LDAP registry - Simple configuration.
   - Federated repository (a forest)- Typical configuration.
   - Merger of federated repositories (a merger of trees into a forest)- Less typical configuration
   - Combination of user and group forests - Rare configuration
2. Develop strategies for user look up that match your Microsoft Active Directory installation. Remember that user IDs are guaranteed to be unique within a single domain, but there is no automatic guarantee that a given user ID is unique across a tree or a forest.
3. Evaluate with testing to ensure that your authentication search strategies successfully authenticate users in your Microsoft Active Directory installation.

Results

You will be in the position to authenticate users with LDAP registries in a Microsoft Active Directory forest.

What to do next

gotcha: When you select any of these scenarios, consult appropriate Microsoft Active Directory information to completely understand any implications the scenarios might have on your configuation planning.

Authentication using Microsoft Active Directory

Many installations use the Microsoft Active Directory as their primary component for managing user authentication and user data. One portion of the Microsoft Active Directory provides a Lightweight Directory Access Protocol (LDAP) service. WebSphere Application Server supports LDAP and, therefore, WebSphere Application Server supports the Microsoft Active Directory.

While the Microsoft Active Directory is fully LDAP-compliant, it exposes LDAP information in ways that can make it difficult to obtain directory information for WebSphere Application Server.

WebSphere Application Server operates in a way that assumes that a single LDAP directory contains all the information necessary to operate. With complex Microsoft Active Directory configurations, this is not the case. WebSphere Application Server - Microsoft Active Directory installations must handle unique challenges because of the way data is spread throughout the domain controllers in a forest.

Microsoft Active Directory installations frequently incorporate the use of a forest. As such, security questions pertaining to user ID uniqueness, reliably obtaining user group information, and group membership spread across forests become important.

The following figure highlights a typical Microsoft Active Directory installation environment.

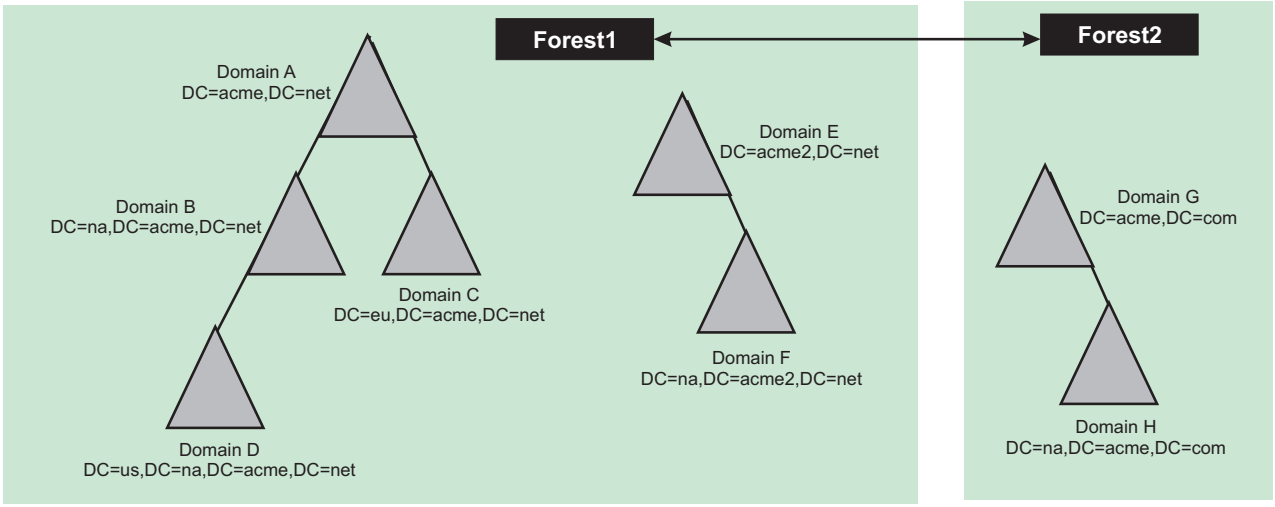

Figure 22. Microsoft Active Directory forests. An illustration of Microsoft Active Directory forests.

This figure illustrates two forests of one or more trees. A tree can contain one or more domains where the domain is the single atomic unit that forms the basis for the constructed environment. Each domain is made up of the primary domain components of the distinguished name (DN), for example, `dc=acme`, `dc=com`. A forest can extend trust to other forests (This trust is based on Kerberos.).

Microsoft Active Directory configurations with WebSphere Application Server

There can be a variety of Microsoft Active Directory configurations for WebSphere Application Server, which include:

- Simple configuration
- Typical configuration
- Less typical configurations
- Rare configurations

Simple configuration

The simplest configuration consists of a stand-alone LDAP registry representing a single domain. This configuration represents the closest fit between WebSphere Application Server and the Microsoft Active Directory. In this configuration, Microsoft Active Directory is supported through the WebSphere Application Server stand-alone LDAP user registry implementation. Alternatively, you can access this single Microsoft Active Directory domain through a federated repositories registry, which contains a single LDAP repository.

Typical Configuration

Beyond the simple single domain Microsoft Active Directory configuration, a typical Microsoft Active Directory configuration consists of a single tree in a forest where each branch of the tree is a domain. An example of this configuration, which consists of a single tree of four domains (A, B, C, D), is shown in the following example:

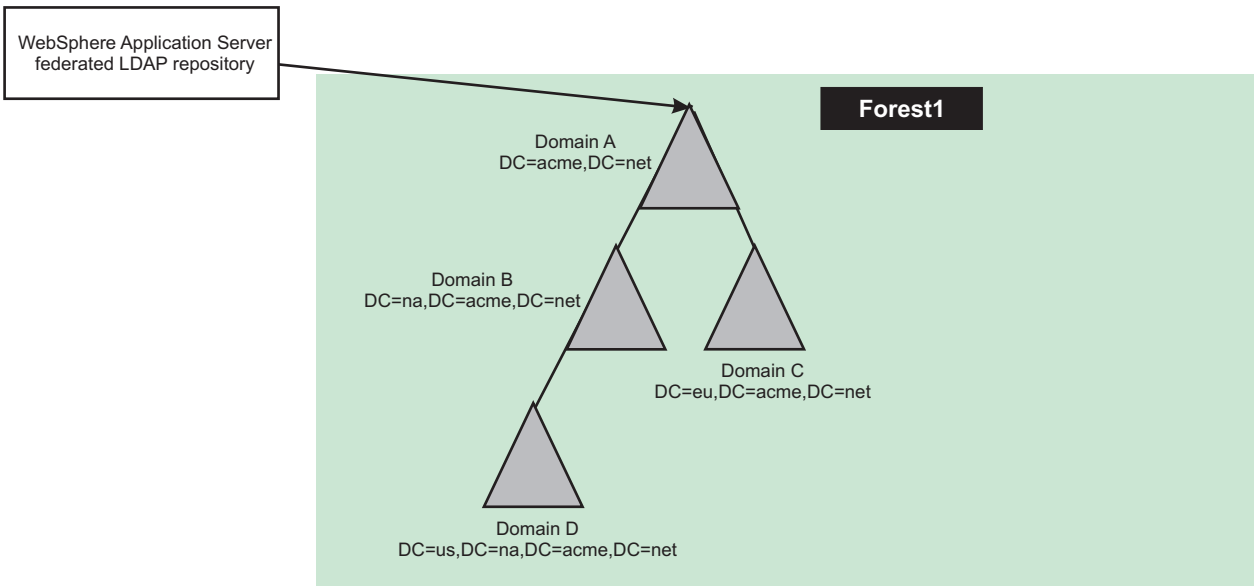

Figure 23. Typical forest configuration. An illustration of a typical forest configuration.

Configurations, such as this configuration, frequently have domains that are organized by geography or organizational unit. The WebSphere Application Server registry configuration that is necessary to use this "single tree" Microsoft Active Directory implementation needs to use the federated repositories. This configuration contains an LDAP registry to map entries from multiple individual user repositories into a single virtual repository. These configurations create a federated user repository with a single named realm and an LDAP subtree within the single repository. The root of the repository is mapped to a base entry

within the federated repository, which is the starting point within the hierarchical namespace of the virtual realm. LDAP searches in this configuration proceed with binding to the top domain object and following LDAP referrals.

gotcha: The stand-alone LDAP registry in WebSphere Application Server does not support LDAP referrals and cannot be used in a WebSphere Application Server - Microsoft Active Directory configuration.

Less typical configurations

Less typical WebSphere Application Server - Microsoft Active Directory configurations evolve from mergers of organizations units in a larger enterprise. Where a single forest of domains once served the enterprise, the merger of several new organizational units can add trees to the forest or even add more than a single forest to the environment. In this environment, the WebSphere Application Server LDAP configuration requires more careful design. You must use the federated repositories registry in such an environment with separate LDAP repositories mapped to the top of each tree in the forest. Again, if a Microsoft Active Directory tree exists under the top-level domain, LDAP referrals must be enabled for the LDAP registry. The forest resulting from a merger can look like the following figure:

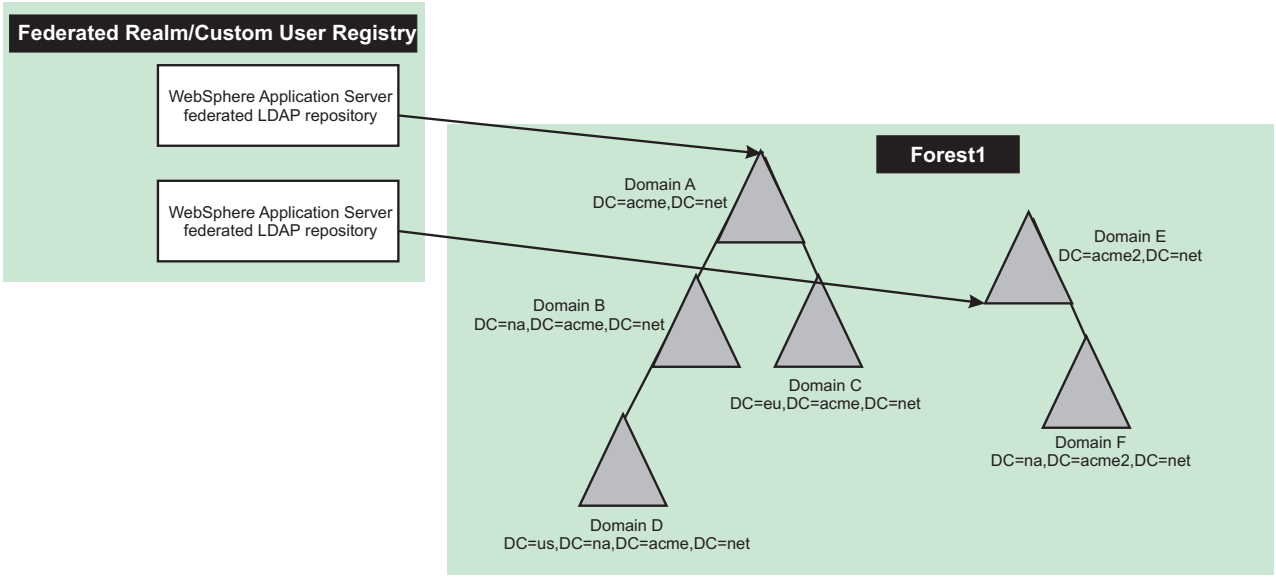

Figure 24. Less typical configurations. Less typical configurations that depict the merger of trees

Rare configurations

Rare configurations consist of Microsoft Active Directory domains that are configured where there is a combination of a user forest and a group forest. Users are imported as ForeignSecurityPrincipals objects in the group forest. The groups contain the distinguished names (DN) of the ForeignSecurityPrincipals objects as members.

In this form of configuration, direct group lookups do not occur. Lookups are relegated to a static group query across multiple registries. This configuration requires a custom user registry. However, WebSphere Application Server registries do not support this type of configuration. See the following figure.

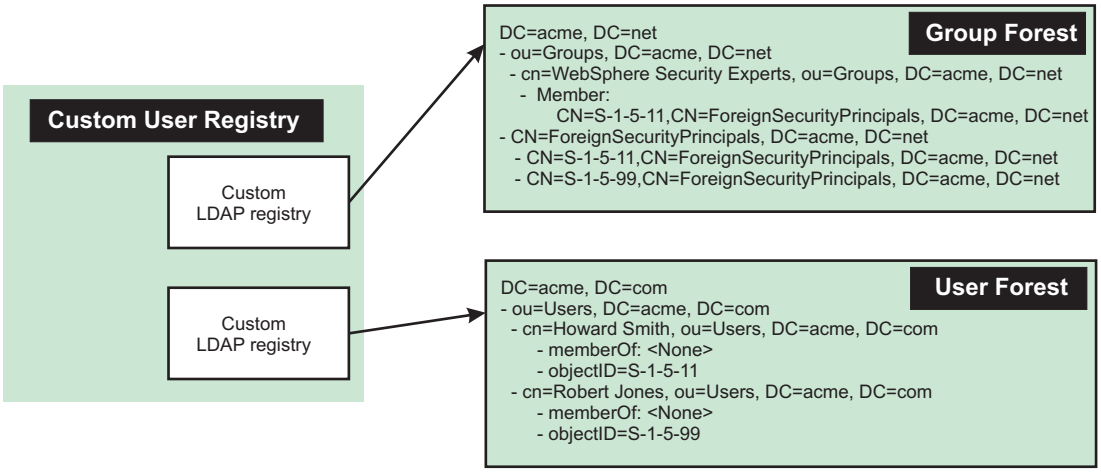

Figure 25. Resource model forest. An illustration of a resource model forest.

Using a Microsoft Active Directory forest as LDAP - user filter

Authenticating a user across multiple repositories, or across a distributed LDAP, such as a Microsoft Active Directory forest configuration can be challenging. In any search of the whole registry, authentication fails if there is more than one match at run time because ambiguous matches result. In multiple Microsoft Active Directory domain environment, the WebSphere Application Server administrator must consider that the default unique ID in the Microsoft Active Directory is the sAMAccountName attribute of a user. User IDs are guaranteed to be unique within a single domain, but it is not possible to guarantee that a given user ID is unique across a tree or a forest. See the topic, "Authenticating users with LDAP registries in a Microsoft Active Directory forest" to understand how to search for user IDs within a Microsoft Active Directory forest using the sAMAccountName attribute of a user.

gotcha: Before selecting any of these scenarios, consult appropriate Microsoft Active Directory information to completely understand any implications the scenarios might have on your configuation planning.

Groups spanning domains with Microsoft Active Directory

The domains and forests functional levels of the Microsoft Active Directory control which configurations are available for use. How you configure Microsoft Active Directory affects how group membership is determined within WebSphere Application Server. Using groups to configure your Microsoft Active Directory installation with the product allows flexible management.

A breakdown follows of applicable functional levels that apply to a Microsoft Active Directory installation with the product.

- Domain Functional Levels
  - Native
    - Supported by Windows Server 2008 and Windows Server 2008 R2
    - Default in Windows 2008

  You must use native domain functional levels to support group nesting, and universal groups. Forest functional levels do not directly affect group membership. The Windows 2008 operating system is the exception.
- Forest Functional Levels
  - Windows Server 2008 or Windows Server 2008 R2
    - All domains operate at the Windows Server 2008 **domain functional level**.

If the forest functional level is set to Windows Server 2008, then that also makes the domain functional level for all domains to be Windows Server 2008 Native level, which adds to the group nesting and Universal groups features to Microsoft Active Directory.

Microsoft Active Directory groups

In a domain, Microsoft Active Directory provides support for different types of groups and group scopes. Groups in Microsoft Active Directory are containers with other objects within them as members. Those objects can be user objects, other group objects, which is group nesting, and other objects types, such as computers. The group type determines the type of task that you manage with the group. The group scope determines whether the group can have members from multiple domains or a single domain. In summary:

- Groups are typically a collection of user accounts.
- Members receive permission given to groups.
- Users can be members of multiple groups.
- Groups can be members of other groups, which are nested groups.

gotcha: In WebSphere Application Server, security roles of the individual, which map to application permissions or authorizations, must be bound to either users or groups at application deployment time. From an administrative point of view, it is preferable to assign permissions once for a group instead of assigning permissions repeatedly for each user account. Then the ability to act in a given role is under the control of the directory administrator, instead of the WebSphere administrator. Because the job of the directory administrator is to create and delete users, change group memberships for users, and other tasks, this approach is generally the correct division of responsibilities.

Group types determine how the group is used. The Microsoft Active Directory group types are:

- **Security groups:** Microsoft Active Directory uses security groups for granting permissions to gain access to resources.
- **Distribution groups:** Distribution groups are used by Windows-based applications as lists for nonsecurity-related functions. Distribution groups are used for sending email messages to groups of users. You cannot grant Windows permissions to security groups.

Although WebSphere Application Server can use either type of group, security groups are typically bound to WebSphere Application Server security roles.

Group scopes describe which type of objects can be arranged together within a group. Group nesting describes when one group is a member of other groups. The Microsoft Active Directory group scopes are:

- **Domain local group:**
  - **Windows usage:** Members of this group can come from any domain, but can access Windows resources only in the local domain. Use this scope to grant permissions to domain resources that are located in the same domain in which you created the domain local group. Domain local groups can exist in all mixed, native, and interim functional level of domains and forests.
  - **Restriction:** You cannot define group nesting in a domain local group. A domain local group cannot be a member of another domain local group or any other group in the same domain.
  - **WebSphere usage:** Users are not typically placed in domain - local groups due to these restrictions. WebSphere Application Server security roles are not typically bound to domain local groups.
- **Global Group:**
  - **Windows usage:** Members of this group originate from a local domain, but can access Windows resources in any domain. The global group is used to organize users who share similar Windows network access requirements. You can add members only from the domain in which the global group is created. You can use this group to assign permissions to gain access to Windows resources that are located in any domain in the domain, tree, or forest.

You can group users with similar function under global scope and give permission to access a Windows resource, such as a printer or shared folder and files, that is available in local or another domain in the same forest. You can use global groups to grant permission to gain access to Windows resources that are located in any domain in a single forest as their memberships are limited. You can add user accounts and global groups only from the domain in which global group is created.

Nesting is possible for global groups within other groups as you can add a global group into another global group from any domain. Members of a global group can be members of a domain - local group. Global groups exist in all mixed, native, and interim functional levels of domains and forests.

WebSphere Application Server usage: Global groups are visible on every domain controller, but memberships are only visible for local users. That is, you can see your group memberships only if you query your home domain controller. A global group should contain groups of users. Global groups are intended to be included in universal groups.

- **Universal Group:**
  - **Windows usage:** Members in this group can come from any domain and access Windows resources in multiple domains. Universal group memberships are not limited like global groups. All domain user accounts and groups can be members of a universal group.
  - **Restrictions:**
    - Universal groups are available when the domain is at a Windows mixed functional level.
    - It can be expensive to replicate this data across the forest. Group definitions and deletions are relatively rare compared to the equivalent user actions, and nested group membership changes are typically rare compared to memberships of users within groups,

      gotcha: Consult appropriate Microsoft Active Directory information concerning any implications of replicating data across forests.
  - **WebSphere usage:**
    - Universal Groups and their memberships are visible on every domain controller in the forest.
    - Universal groups are also visible when using the Global Catalog. To be useful, all user objects must be directly in the universal group,

  Universal group guidelines

  1. Assign permissions to universal groups for Windows resources in any domain in the network.
  2. Use universal groups only when their membership is static. Changes in membership can cause excessive network traffic between domain controllers. Membership of universal groups can be replicated to many domain controllers.
  3. Add global groups from several domains to a universal group.
  4. Assign permissions for access to a Windows resource to the universal group and for use by WebSphere Application Server group membership resolution across multiple domains.
  5. Use a universal group in the same way as a domain local group to assign resource permissions.

gotcha: When you select any of these scenarios, consult the appropriate Microsoft Active Directory information to completely understand any implications the scenarios might have on your configuation planning.

Microsoft Active Directory Global Catalog

A *Global Catalog* is a Global Catalog Server. A Global Catalog holds a full set of attributes for the domain in which it resides and a subset of attributes for all objects in the Microsoft Active Directory Forest. The primary two functions of a Global Catalog within the Microsoft Active Directory are logon capability and Microsoft Active Directory queries.

A Global Catalog in a Microsoft Active Directory installation with the product is a single Lightweight Directory Access Protocol (LDAP) repository that contains a subset of user information from all the domains in the forest. This information includes user IDs, authentication information, and groups, but not all the group information.

You can use the Global Catalog on any domain controller in the forest, even in subdomains. The Global Catalog is a solution to the WebSphere Application Server limitation of a "single registry". There are limitations to the Global Catalog. Users from the local domain controller contain group "memberOf" information. Users from a foreign domain controller contain limited "memberOf" information because the global group information is not replicated to every domain controller.

Nested global groups in universal groups

This is a typical structure of group membership and consists of the following characteristics:

- Users are distributed across domain controllers in a forest containing multiple domain controllers.
- Users are defined in global groups within their own local domain controller.
- A universal group contains the global groups, which reflects a Java Platform Enterprise Edition (Java EE) role that maps to a set of users spread across *multiple* domain controllers.

The following figure illustrates nested global groups in universal groups.

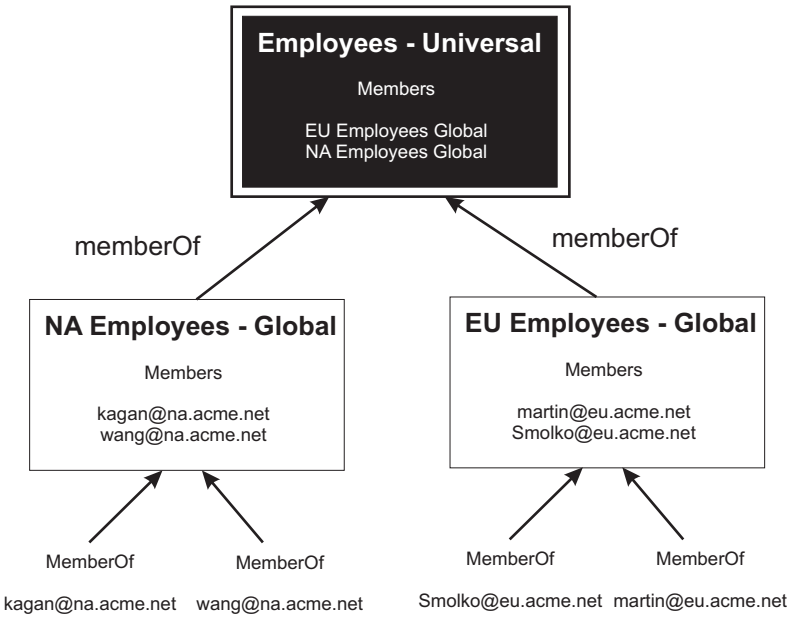

Figure 26. Nested global groups in universal groups. This figure illustrates nested global groups in universal groups.

It is a challenge to develop methods of configuring WebSphere Application Server to be able to find users and their group memberships when the information is spread across multiple domain controllers. One method requires that WebSphere Application Server follow LDAP referrals to find the home domain controller for each user and that WebSphere Application Server perform nested group queries.

gotcha: This approach does not use the Global Catalog.

Another method and the simplest approach has universal groups that contain users and uses a Global Catalog, which requires using referrals. The figure that follows illustrates this method.

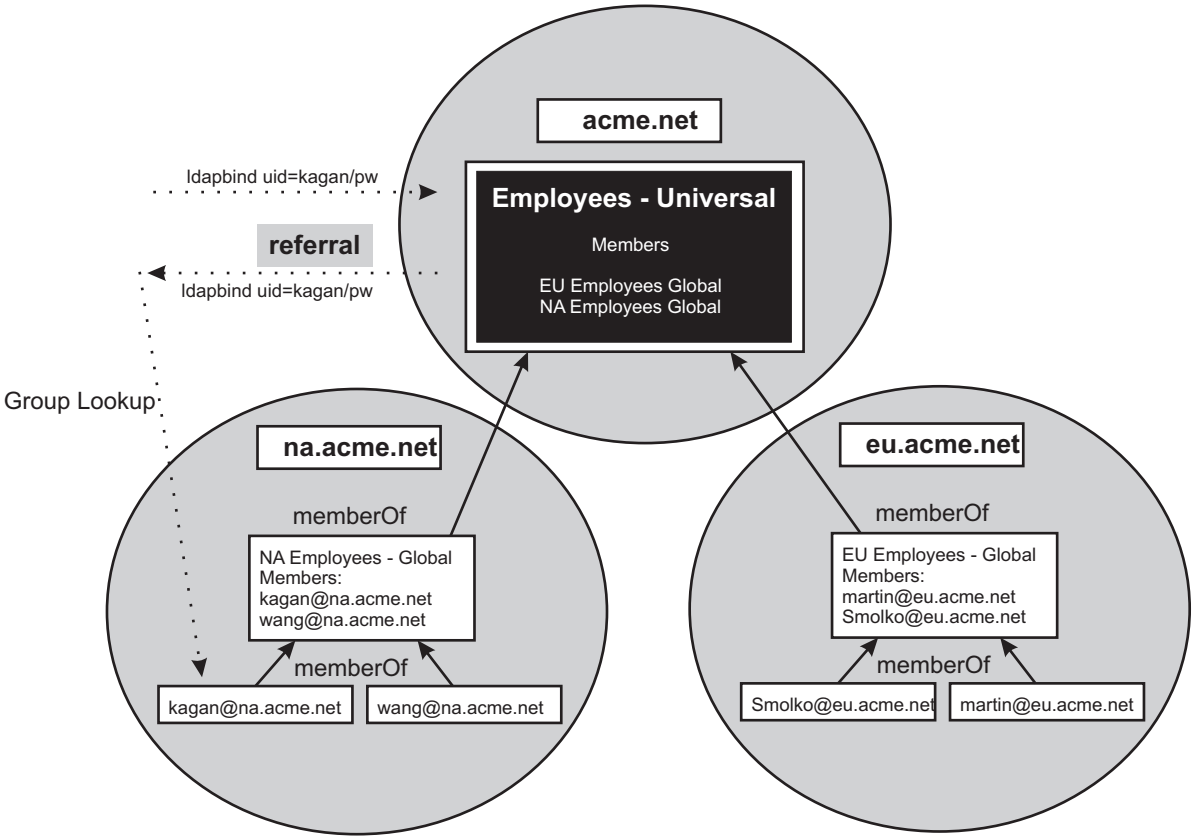

Figure 27. Locating group memberships. This figure illustrates the process of locating group memberships.

A variation on this method is to not use universal groups. You can use this approach when universal groups are not available.

gotcha: This approach does not use the Global Catalog.

You might consider using the Microsoft Active Directory Global Catalog as the WebSphere Application Server registry. There are three scenarios; however, the first two scenarios demonstrate how failures occur.

1. If you configure WebSphere Application Server to use Global Catalog as its LDAP registry and follow referrals, then individual users are visible in each domain controller. Because a user must exist only once in the registry, all logins fail.
2. If you configure WebSphere Application Server to use Global Catalog as its LDAP registry and do not follow referrals and the individual users are within global groups, then group membership is incomplete. See the following figure, which illustrates this limitation.

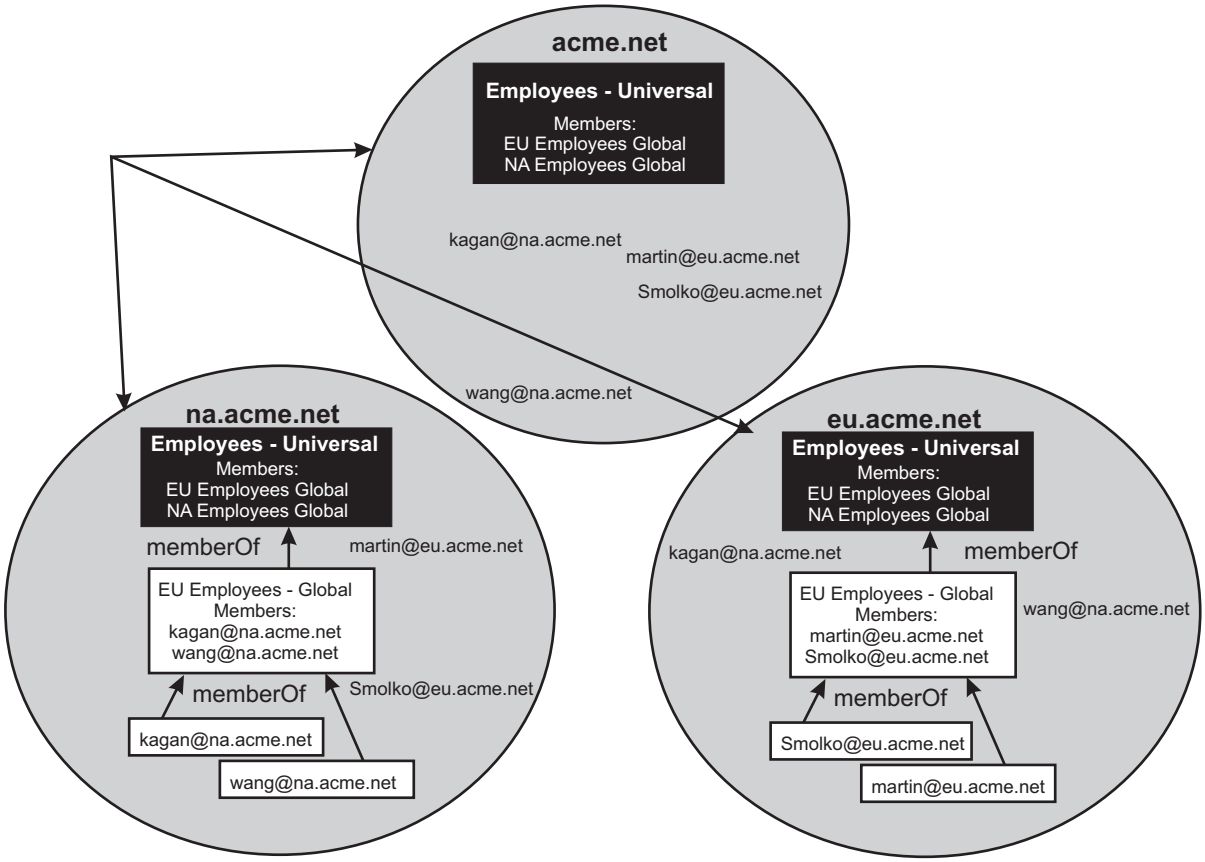

Figure 28. Global catalog (without using referrals). An illustration of a Global Catalog without using referrals

3. When you configure WebSphere Application Server to use Global Catalog as its LDAP registry, do not follow referrals, and users are directly contained within universal global groups, then group membership is complete.

gotcha: When you select any of these scenarios, consult appropriate Microsoft Active Directory information to completely understand any implications the scenarios might have on your configuation planning.

Options for finding group membership within a Microsoft Active Directory forest

Locating and finding group membership with the Microsoft Active Directory forest is necessary for authenticating users. There are several ways to approach finding group membership within the Microsoft Active Directory forest.

The following figure depicts an example of group membership with the Microsoft Active Directory forest. This figure is used to explain ways to find group membership.

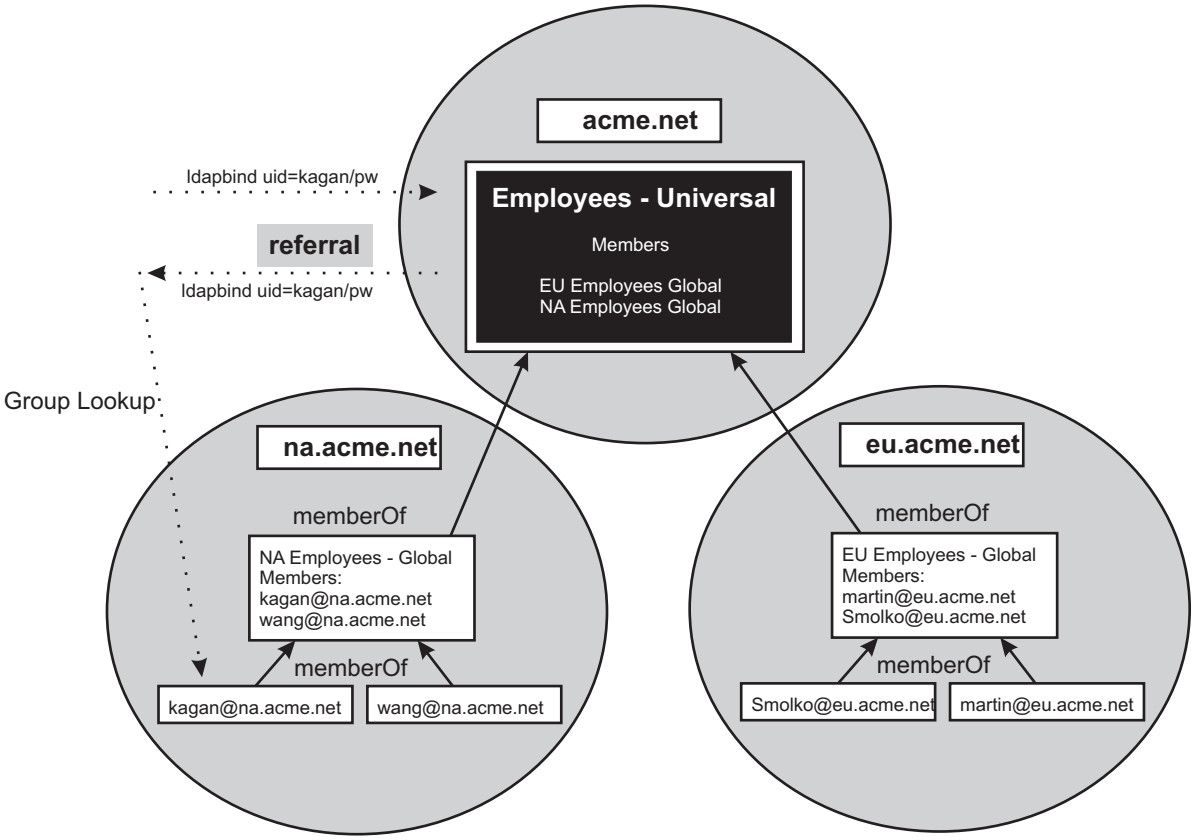

Figure 29. Finding group membership.. An illustration of ways to find group membership.

- **Option 1** does not use nested groups, and the following steps describe the process of locating group membership using a hypothetical organizational structure.
  - Create a global group of **NA employees**.
  - Create a global group of **EU employees**.
  - Map the Java Platform Enterprise Edition (Java EE) role to **NA employees** + **EU employees**. This mapping can become unmanageable if there are too many sub domains
  - Enable referrals.

    In WebSphere Application Server Version 6.1, use federated repositories, specifically:
    - Use a federated realm.
    - Add the Microsoft Active Directory top-level domain controller to the repository. Do not add sub-domain controllers. Doing this results in multiple matches when searches for user IDs occur. The multiple matches cause user logins to fail.
    - Select "**Support referrals to other LDAP servers**" = "follow".
- **Option 2** uses universal groups.
  - Put individual users into the universal group, **Employees**.

    Requirements:
    - The Windows 2003 Native domain functional levels is required.
    - Userids must be directly contained within universal groups.
  - Map Java EE role to **Employees**.
  - Connect to any global catalog in the forest.

Tip: This option reduces the amount of directory lookup traffic. WebSphere Application Server does not have to follow all the referrals across the directory tree. That is, each domain controller can fully resolve the group information locally.

- **Option 3** uses nested groups.
  - Create the universal group, **Employees**.
  - Create **NA Employees** and **EU Employees** as global groups and make them members in the **Employees** universal group.

    Requirements: Windows Native Domain functional levels.
  - Map Java JEE role to "Employees".
  - Enable referrals.

    For WebSphere Application Server Version 6.1, use federated repositories, specifically:
    - Use a federated realm.
    - Add the Active Directory top-level domain controller to the repository. Do not add sub-domain controllers, as this will result in multiple matches when searches for userids occur, and logins will fail.
    - Select "Support referrals to other LDAP servers" = "follow".
  - Enable nested groups.

Tip: This option offers the optimal approach when using WebSphere Application Server Versions 6.1 or later. Before WebSphere Application Server version 6.1, referrals were not officially supported.

Summary

The following table summarizes how to find group membership within a Microsoft Active Directory forest.

Table 122. Finding group membership.. The following table identifies group membership levels supported in a Microsoft Active Directory forest.

Group Membership	Map Java EE Roles To	Bind to Which LDAP	Enable	Supported in WebSphere Application Server Version	Comments
Global Groups	Collection of global groups	Top domain controller using port 389/636	Referrals	• Federated repositories in WebSphere Application Server	
Universal groups	Universal groups	Any Global catalog, using port 3268		All	
Global groups in universal groups	Universal groups	Top domain controller using port 389/636	referrals, nesting	• Federated repositories in WebSphere Application Server	Cannot use Windows mixed domain functional level

Configuring to use objectCategory attribute

A federated repository uses the `objectCategory` attribute by default for Active Directory user search filters. You can ensure that the federated repository is configured to use the objectCategory attribute. For example, the federated repositories configuration file, `wimconfig.xml`, should be as shown in the following example:

```
<supportedLDAPEntryType name="user" searchFilter="(objectCategory=user)"...>
<supportedLDAPEntryType name="Group" searchFilter="(objectCategory=Group)"...>
```

Configure the user filter and group filter (advanced properties) like the following example:

```
User Filter: (&(sAMAccountName=%v)(objectCategory=user))
Group Filter: (&cn=%v)(objectCategory=group)
```

Follow the following instructions from the administrative console to complete the search filter with the objectCategory attribute.

1. Click **Security**.
2. Select **Global security**.
3. Under Available realm definitions, use the drop-down list to select **Federated repositories**.
4. Click **Configure**.
5. Under Related items, click **Manage repositories**.
6. Select **Forest > LDAP entity types > PersonAccount**. Under General Properties, find the **Search filter** box.
7. Fill in the search filter.

   ```
   (objectCategory=user)
   ```

gotcha: When you select any of these scenarios to use, consult the appropriate Microsoft Active Directory information to completely understand any implications the scenarios might have on your configuation planning.

Authenticating users with LDAP registries in a Microsoft Active Directory forest

Authenticating a user across multiple repositories, or across a distributed Lightweight Directory Access Protocol (LDAP) repository, such as a Microsoft Active Directory forest can be challenging. In any search of the whole user registry, if there is more than one match at run time, authentication fails because of ambiguous match results.

Before you begin

In any multiple Microsoft Active Directory domain environment, the WebSphere Application Server administrator must consider that the default unique ID in the Microsoft Active Directory is the sAMAccountName attribute of a user.

About this task

User IDs are guaranteed to be unique within a single domain. However they are not guaranteed across a tree or a forest. For example, suppose the user ID, *smith*, is added in the forest and in each subdomain. The search for `sAMAccountName=smith` returns three matches. WebSphere Application Server does not authenticate this user when there is more than one possible match in the registry.

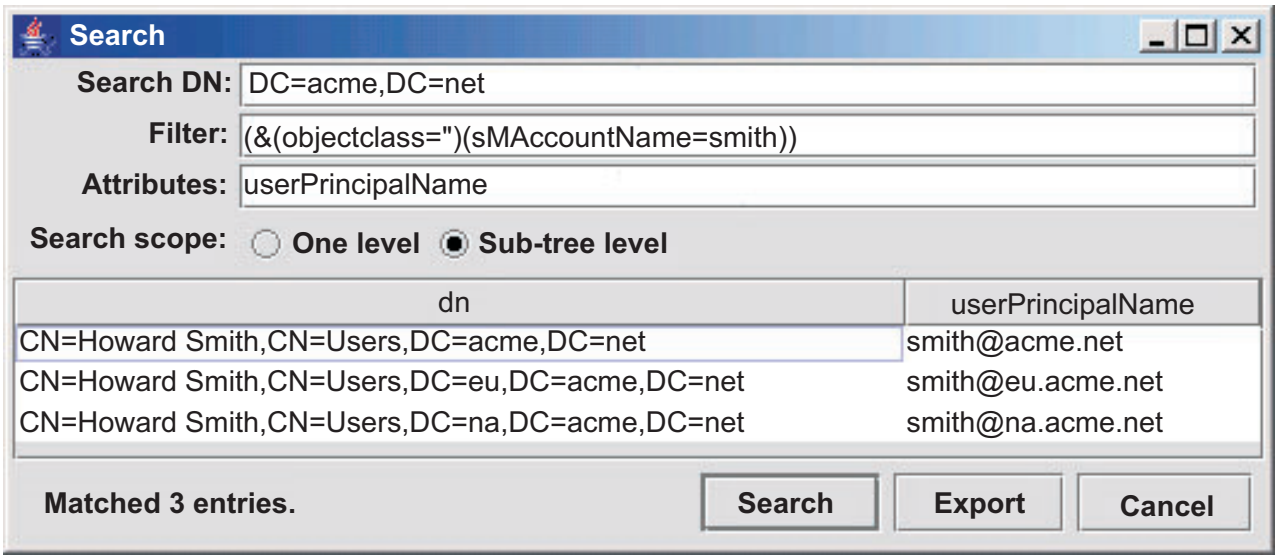

Figure 30. Forest search strategy.. Search illustration of a non-unique sAMAccountName across the entire forest.

You can mitigate this condition by changing the user filter to be based on the userPrincipalName attribute of the user, which is unique across the forest, instead of being based on their sAMAccountName attribute. However, users must then know to log in using their userPrincipalName, which they might not know.

The specific procedure to establish a user filter on a LDAP user registry depends on the type of LDAP registry. The following examples illustrate a procedure for a stand-alone LDAP registry and a procedure for a federated repository registry.

Procedure

1. **Establish a user filter on a stand-alone LDAP registry:** You can set the user filter on the Advance Lightweight Access Protocol (LDAP) user registry settings page to search for userPrincipalName instead of sAMAccountName value.

   For example:

   ```
   (&(objectClass=user)(userPrincipalName=%w))
   ```

2. **Establish a user filter on a federated repositories registry:** You can change the log-in property in the LDAP repository to `uid;cn`, for example, by using the administrative console.
   a. Click **Security**.
   b. Select **Global security**.
   c. Under Available realm definitions, use the drop-down list to select **Federated repositories**.
   d. Click **Configure**.
   e. Under Related items, click **Manage repositories**.
   f. Under General Properties, add the following information:

   Repository identifier
   forest

   Directory type
   Microsoft WIndows Server 2003 Active Directory

   Primary host name
   forest.acme.net

   Port 389

   Failover server used when primary is not available
   Delete

Bind distinguished name
cn=wasbind, CN=Users, DC=ib

Bind password
****

Login properties
uid;cn

3. Click **OK** and **Save** to save the changes to the master configuration.
4. Locate the `{WAS_HOME}\profiles\{profileName}\config\cells\{cellName}\wim\config\wimconfig.xml` or `profile_root/conf/cells/<cell>/wim/config/wimconfig.xml` file in the deployment manager configuration.
5. Edit the `wimconfig.xml` file.
   a. Find the `<config:attributeConfiguration>` attribute in the file.
   b. Add the following lines:

```
<config:attributes name="userPrincipalName" propertyName="cn">
<config:entityTypes>PersonAccount</config:entityTypes>
</config:attributes>
```

6. Save the `wimconfig.xml` file.
7. Run the `profile_root/bin/syncNode.bat` or `profile_root/syncNode.bar/sh` script on all of the nodes in the configuration.

Results

gotcha: When you select any of these scenarios, consult appropriate Microsoft Active Directory information to completely understand any implications the scenarios might have on your configuation planning.

Authorizing access to resources

WebSphere Application Server provides many different methods for authorizing accessing resources. For example, you can assign roles to users and configure a built-in or external authorization provider.

About this task

You can create an application, an Enterprise JavaBeans (EJB) module, or a web module and secure them using assembly tools.

To authorize user or group access to resources, read the following articles:

Procedure

1. Secure you application during assembly and deployment. For more information on how to create a secure application using an assembly tool, such as the IBM Rational Application Developer, see the information about securing applications during assembly and deployment.
2. Authorize access to Java Platform, Enterprise Edition (Java EE) resources. WebSphere Application Server supports authorization that is based on the Java Authorization Contract for Containers (JACC) specification in addition to the default authorization. When security is enabled in WebSphere Application Server, the default authorization is used unless a JACC provider is specified. For more information, see “Authorization providers” on page 1627.
3. Authorize access to administrative resources. You can assign users and groups to predefined administrative roles such as the monitor, configurator, operator, administrator, auditor and iscadmins roles. These roles determine which tasks a user can perform in the administrative console. For more information, see “Authorizing access to administrative roles” on page 1679.

What to do next

After authorizing access to resources, configure the Application Server for secure communication. For more information, see “Securing communications” on page 1700.

Authorization technology

Authorization information determines whether a user or group has the necessary privileges to access resources.

WebSphere Application Server supports many authorization technologies including the following:

- Authorization involving the web container and Java Platform, Enterprise Edition (Java EE) technology
- Authorization involving an enterprise bean application and Java EE technology
- Authorization involving web services and Java EE technology
- Java Message Service (JMS)
- Java Authorization Contract for Containers (JACC)

  WebSphere Application Server supports both a default authorization provider and an authorization provider that is based on the Java Authorization Contract for Containers (JACC) specification. The JACC-based authorization provider enables third-party security providers to handle the Java EE authorization. For more information, see “JACC support in WebSphere Application Server” on page 1627.
- Java Authentication and Authorization Service (JAAS)

  For more information, see “Java Authentication and Authorization Service” on page 1516.
- Java 2 security

  For more information, see “Java 2 security” on page 1176.
- Naming and administrative authorization
- Pluggable authorization

  WebSphere Application Server supports an authorization infrastructure that enables you to plug in an external authorization provider. For more information, see “Enabling an external JACC provider” on page 1649.

Administrative roles and naming service authorization

WebSphere Application Server extends the Java Platform, Enterprise Edition (Java EE) security role-based access control to protect the product administrative and naming subsystems.

Administrative roles

A number of administrative roles are defined to provide the degrees of authority that are needed to perform certain WebSphere Application Server administrative functions from either the administrative console or the system management scripting interface called wsadmin. The authorization policy is only enforced when administrative security is enabled. The following table describes the administrative roles:

Table 123. Administrative roles that are available through the administrative console and wsadmin.

This table lists administrative roles that are available through the administrative console and wsadmin.

Role	Description
Monitor	An individual or group that uses the monitor role has the least amount of privileges. A monitor can complete the following tasks: • View the WebSphere Application Server configuration. • View the current state of the Application Server.

Table 123. Administrative roles that are available through the administrative console and wsadmin (continued).

This table lists administrative roles that are available through the administrative console and wsadmin.

Role	Description
Configurator	An individual or group that uses the configurator role has the monitor privilege plus the ability to change the WebSphere Application Server configuration. The configurator can perform all the day-to-day configuration tasks. For example, a configurator can complete the following tasks: • Create a resource. • Map an application server. • Install and uninstall an application. • Deploy an application. • Assign users and groups-to-role mapping for applications. • Set up Java 2 security permissions for applications. • Customize the Common Secure Interoperability Version 2 (CSIv2), Secure Authentication Service (SAS), and Secure Sockets Layer (SSL) configurations. **Important:** SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.
Operator	An individual or group that uses the operator role has monitor privileges plus ability to change the runtime state. For example, an operator can complete the following tasks: • Stop and start the server. • Monitor the server status in the administrative console.
Administrator	An individual or group that uses the administrator role has the operator and configurator privileges plus additional privileges that are granted solely to the administrator role. For example, an administrator can complete the following tasks: • Modify the server user ID and password. • Configure authentication and authorization mechanisms. • Enable or disable administrative security. **Note:** In previous releases of WebSphere Application Server, the **Enable administrative security** option is known as the **Enable global security** option. • Enforce Java 2 security using the **Use Java 2 security to restrict application access to local resources** option. • Change the Lightweight Third Party Authentication (LTPA) password and generate keys. • Create, update, or delete users in the federated repositories configuration. • Create, update, or delete groups in the federated repositories configuration. **Note:** An administrator cannot map users and groups to the administrator roles.
Adminsecuritymanager	Only users who are granted this role can map users to administrative roles. Also, when fine-grained administrative security is used, only users who are granted this role can manage authorization groups. See “Administrative roles” on page 1623 for more information.
Deployer	Users who are granted this role can perform both configuration actions and runtime operations on applications.

Table 123. Administrative roles that are available through the administrative console and wsadmin (continued).

This table lists administrative roles that are available through the administrative console and wsadmin.

Role	Description
Auditor	Users granted this role can view and modify the configuration settings for the security auditing subsystem. For example, a user with the auditor role can complete the following tasks: • Enable and disable the security auditing subsystem. • Select the event factory implementation to be used with the event factory plug-in point. • Select and configure the service provide, or emitter. or both to be used with the service provider plug-in point. • Set the audit policy that describes the behavior of the application server in the event of an error with the security auditing subsystem. • Define which security events are to be audited. The auditor role includes the monitor role. This allows the auditor to view but not change the rest of the security configuration.

Table 124. Additional administrative role that is available through the administrative console.

This table lists an additional administrative role that is available through the administrative console.

Role	Description
iscadmins	This role is only available for administrative console users and not for wsadmin users. Users who are granted this role have administrator privileges for managing users and groups in the federated respositories. For example, a user of the iscadmins role can complete the following tasks: • Create, update, or delete users in the federated repositories configuration. • Create, update, or delete groups in the federated repositories configuration.

Table 125. Additional administrative role that is available through wsadmin.

This table lists an additional administrative role that is available through the administrative console.

Role	Description
Deployer	This role is only available for wsadmin users and not for administrative console users. Users who are granted this role can perform both configuration actions and run-time operations on applications.

When administrative security is enabled, the administrative subsystem role-based access control is enforced. The administrative subsystem includes the security server, the administrative console, the wsadmin scripting tool, and all the Java Management Extensions (JMX) MBeans. When administrative security is enabled, both the administrative console and the administrative scripting tool require users to provide the required authentication data. Moreover, the administrative console is designed so the control functions that display on the pages are adjusted, according to the security roles that a user has. For example, a user who has only the monitor role can see only the non-sensitive configuration data. A user with the operator role can change the system state.

When you are changing registries (for example, from a federated repository to LDAP), make sure you remove the information that pertains to the previously configured registry for console users and console groups.

When administrative security is enabled, WebSphere Application Servers run under the server identity that is defined under the active user registry configuration. Although it is not shown on the administrative console and in other tools, a special Server subject is mapped to the administrator role. The WebSphere Application Server runtime code, which runs under the server identity, requires authorization to runtime operations. If no other user is assigned administrative roles, you can log into the administrative console or to the wsadmin scripting tool using the server identity to perform administrative operations and to assign

other users or groups to administrative roles. Because the server identity is assigned to the administrative role by default, the administrative security policy requires the administrative role to perform the following operations:

- Change server ID and server password
- Enable or disable WebSphere Application Serveradministrative security
- Enforce Java 2 security using the **Use Java 2 security to restrict application access to local resources** option.
- Change the LTPA password or generate keys
- Assign users and groups to administrative roles

Primary administrative user name

The Version 6.1 release of WebSphere Application Server and subsequent releases require an administrative user, distinguished from the server user identity, to improve auditability of administrative actions. The user name specifies a user with administrative privileges that is defined in the local operating system.

Server user identity

The Version 6.1 release of WebSphere Application Server and subsequent releases distinguish the server identity from the administrative user identity to improve auditability. The server user identity is used for authenticating server-to-server communications.

Internal server ID

The internal server ID enables the automatic generation of the user identity for server-to-server authentication. Automatic generation of the server identity supports improved auditability for cells only for Version 6.1 or later nodes. In the Version 6.1 release of WebSphere Application Server, you can save the internally-generated server ID because the Security WebSphere Common Configuration Model (WCCM) model contains a new tag, internalServerId. You do not need to specify a server user ID and a password during security configuration except in a mixed-cell environment. An internally-generated server ID adds a further level of protection to the server environment because the server password is not exposed as it is in releases prior to Version 6.1. However, to maintain backwards compatibility, you must specify the server user ID if you use earlier versions of WebSphere Application Server.

When enabling security, you can assign one or more users and groups to naming roles. For more information, see Assigning users to naming roles. However, before assigning users to naming roles, configure the active user registry. User and group validation depends on the active user registry. For more information, see Configuring user registries.

Special subject

In addition to mapping users or groups, you can map a *special-subject* to the administrative roles. A special-subject is a generalization of a particular class of users. The AllAuthenticated or the AllAuhenticatedInTrustedRealms (when cross realm is involved) special subjects mean that the access check of the administrative role ensures that the user making the request is at least authenticated. The Everyone special subject means that anyone, authenticated or not, can perform the action as if security is not enabled.

Naming service authorization

CosNaming security offers increased granularity of security control over CosNaming functions. CosNaming functions are available on CosNaming servers such as the WebSphere Application Server. These functions affect the content of the WebSphere Application Server name space. Generally, you have two ways in

which client programs result in CosNaming calls. The first is through the Java Naming and Directory Interface (JNDI) call. The second is with common object request broker architecture (CORBA) clients invoking CosNaming methods directly.

Four security roles are introduced :

- CosNamingRead
- CosNamingWrite
- CosNamingCreate
- CosNamingDelete

The roles have authority levels from low to high:

CosNamingRead
: You can query the WebSphere Application Server name space, using, for example, the JNDI lookup method. The special-subject, Everyone, is the default policy for this role.

CosNamingWrite
: You can perform write operations such as JNDI bind, rebind, or unbind, and CosNamingRead operations. As a default policy, Subjects are not assigned this role.

CosNamingCreate
: You can create new objects in the name space through such operations as JNDI createSubcontext and CosNamingWrite operations. As a default policy, Subjects are not assigned this role.

CosNamingDelete
: You can destroy objects in the name space, for example using the JNDI destroySubcontext method and CosNamingCreate operations. As a default policy, Subjects are not assigned this role.

A Server special-subject is assigned to all of the four CosNaming roles by default. The Server special-subject provides a WebSphere Application Server process, which runs under the server identity, to access all the CosNaming operations. The Server special-subject does not display and cannot be modified through the administrative console or other administrative tools.

Special configuration is not required to enable the server identity as specified when enabling administrative security for administrative use because the server identity is automatically mapped to the administrator role.

Users, groups, or the special subjects AllAuthenticated and Everyone can be added or removed to or from the naming roles from the WebSphere Application Server administrative console at any time. However, a server restart is required for the changes to take effect.

A best practice is to map groups or one of the special-subjects, rather than specific users, to naming roles because it is more flexible and easier to administer in the long run. By mapping a group to a naming role, adding or removing users to or from the group occurs outside of WebSphere Application Server and does not require a server restart for the change to take effect.

The CosNaming authorization policy is only enforced when administrative security is enabled. When administrative security is enabled, attempts to do CosNaming operations without the proper role assignment result in an org.omg.CORBA.NO_PERMISSION exception from the CosNaming server.

Each CosNaming function is assigned to only one role. Therefore, users who are assigned the CosNamingCreate role cannot query the name space unless they have also been assigned CosNamingRead. And in most cases a creator needs to be assigned three roles: CosNamingRead, CosNamingWrite, and CosNamingCreate. The CosNamingRead and CosNamingWrite roles assignment for the creator example are included in the CosNamingCreate role. In most of the cases, WebSphere Application Server administrators do not have to change the roles assignment for every user or group when they move to this release from a previous one.

Although the ability exists to greatly restrict access to the name space by changing the default policy, unexpected org.omg.CORBA.NO_PERMISSION exceptions can occur at runtime. Typically, Java EE applications access the name space and the identity they use is that of the user that authenticated to WebSphere Application Server when accessing the Java EE application. Unless the Java EE application provider clearly communicates the expected naming roles, use caution when changing the default naming authorization policy.

Administrative roles for business level applications:

The Java 2 Platform, Enterprise Edition (J2EE) role-based authorization concept is extended to protect the WebSphere Application Server administrative subsystem. This protection applies to those administrative roles associated with business level applications.

Deploying business level applications on a server configured to hold business level applications requires a number of administrative roles that are defined to provide degrees of authority when performing certain administrative functions from either the Web-based administrative console or the system management scripting interface. The authorization policy is only enforced when administrative security is enabled. The following table describes the system management scripting command used for business level applications and the corresponding administrative role that is required in using the command:

Table 126. Business level application - administrative roles. Business level application - administrative roles

Command	Role Required
startBLA	Cell deployer, Cell operator, BLA deployer, BLA operator, Target deployer, Target operator
stopBLA	Cell deployer, Cell operator, BLA deployer, BLA operator, Target deployer, Target operator
createEmptyBLA	Cell configurator, Cell deployer
editBLA	Cell configurator, Cell deployer, BLA deployer
viewBLA	Cell monitor, BLA monitor
listBLAs	Cell monitor, BLA monitor(s)
deleteBLA	Cell configurator, Cell deployer, BLA developer

getBLAStatus	Cell monitor, BLA monitor
	Where: • BLA deployer specifies the deployer role for the BLA that is being managed. • BLA monitor specifies the monitor role for the BLA that is being managed. • BLA operator specifies the operator role for the BLA that is being managed. • Asset deployer specifies the deployer role for the asset that is being managed. • Asset monitor specifies the monitor role for the asset that is being managed. • Target deployer specifies the deployer for the target that the composition unit is being deployed to. • Target operator specifies the operator role for the target that the composition unit is being deployed to.

Role-based authorization

Use authorization information to determine whether a caller has the necessary privileges to request a service.

The following figure illustrates the process that is used during authorization.

Web resource access from a web client is handled by a web collaborator. The Enterprise JavaBeans (EJB) resource access from a Java client, whether an enterprise bean or a servlet, is handled by an EJB collaborator. The EJB collaborator and the web collaborator extract the client credentials from the object request broker (ORB) current object. The client credentials are set during the authentication process as received credentials in the ORB current object. The resource and the received credentials are presented to the WSAccessManager access manager to check whether access is permitted to the client for accessing the requested resource.

The access manager module contains two main modules:

- The resource permission module helps determine the required roles for a given resource. This module uses a resource-to-roles mapping table that is built by the security runtime during application startup. To build the resource-to-role mapping table, the security runtime reads the deployment descriptor of the enterprise beans or the Web module (`ejb-jar.xml` file or `web.xml` file)
- The authorization table module consults a role-to-user or group table to determine whether a client is granted one of the required roles. The role-to-user or group mapping table, also known as the *authorization table*, is created by the security runtime during application startup.

  To build the authorization table, the security run time reads the application binding file, the `ibm-application-bnd.xmi` file, or the `ibm-application-bnd.xml` file, as appropriate.

Note: For IBM extension and binding files, the .xmi or .xml file name extension is different depending on whether you are using a pre-Java EE 5 application or module or a Java EE 5 or later application or module. An IBM extension or binding file is named ibm-*-ext.xmi or ibm-*-bnd.xmi where * is the type of extension or binding file such as app, application, ejb-jar, or web. The following conditions apply:

- For an application or module that uses a Java EE version prior to version 5, the file extension must be .xmi.
- For an application or module that uses Java EE 5 or later, the file extension must be .xml. If .xmi files are included with the application or module, the product ignores the .xmi files.

However, a Java EE 5 or later module can exist within an application that includes pre-Java EE 5 files and uses the .xmi file name extension.

The `ibm-webservices-ext.xmi`, `ibm-webservices-bnd.xmi`, `ibm-webservicesclient-bnd.xmi`, `ibm-webservicesclient-ext.xmi`, and `ibm-portlet-ext.xmi` files continue to use the .xmi file extensions.

Use authorization information to determine whether a caller has the necessary privilege to request a service. You can store authorization information many ways. For example, with each resource, you can store an access-control list, which contains a list of users and user privileges. Another way to store the information is to associate a list of resources and the corresponding privileges with each user. This list is called a *capability list*.

WebSphere Application Server uses the Java 2 Platform, Enterprise Edition (J2EE) authorization model. In this model, authorization information is organized as follows:

During the assembly of an application, permission to invoke methods is granted to one or more roles. A role is a set of permissions; for example, in a banking application, roles can include teller, supervisor, clerk, and other industry-related positions. The teller role is associated with permissions to run methods that are related to managing the money in an account, such as the withdraw and deposit methods. The teller role is not granted permission to close accounts; this permission is given to the supervisor role. The application assembler defines a list of method permissions for each role. This list is stored in the deployment descriptor for the application.

Three *special subjects* are not defined by the J2EE model: AllAuthenticatedUsers, AllAuthenticatedInTrustedRealms, and Everyone. A special subject is a product-defined entity that is defined outside of the user registry. This entity is used to generically represent a class of users or groups in the registry.

- The AllAuthenticatedUsers subject permits all authenticated users to access protected methods. As long as the user can authenticate successfully, the user is permitted access to the protected resource.
- The AllAuthenticatedInTrustedRealms subject permits all authenticated foreign users (those that are bound to other realms) to access protected methods. As long as the user can authenticate successfully, the user is permitted access to the protected resource.
- The Everyone subject permits unrestricted access to a protected resource. Users do not have to authenticate to get access; this special subject provides access to protected methods as if the resources are unprotected.

During the deployment of an application, real users or groups of users are assigned to the roles. When a user is assigned to a role, the user gets all the method permissions that are granted to that role.

The application deployer does not need to understand the individual methods. By assigning roles to methods, the application assembler simplifies the job of the application deployer. Instead of working with a set of methods, the deployer works with the roles, which represent semantic groupings of the methods.

Users can be assigned to more than one role; the permissions that are granted to the user are the union of the permissions granted to each role. Additionally, if the authentication mechanism supports the grouping of users, these groups can be assigned to roles. Assigning a group to a role has the same effect as assigning each individual user to the role.

A best practice during deployment is to assign groups instead of individual users to roles for the following reasons:
- Improves performance during the authorization check. Typically far fewer groups exist than users.
- Provides greater flexibility, by using group membership to control resource access.
- Supports the addition and deletion of users from groups outside of the product environment. This action is preferred to adding and removing them to WebSphere Application Server roles. Stop and restart the enterprise application for these changes to take effect. This action can be very disruptive in a production environment.

At runtime, WebSphere Application Server authorizes incoming requests based on the user's identification information and the mapping of the user to roles. If the user belongs to any role that has permission to run a method, the request is authorized. If the user does not belong to any role that has permission, the request is denied.

The J2EE approach represents a declarative approach to authorization, but it also recognizes that you cannot deal with all situations declaratively. For these situations, methods are provided for determining user and role information programmatically. For enterprise beans, the following two methods are supported by WebSphere Application Server:
- **getCallerPrincipal**: This method retrieves the user identification information.
- **isCallerInRole**: This method checks the user identification information against a specific role.

For servlets, the following methods are supported by WebSphere Application Server:
- getRemoteUser
- isUserInRole
- getUserPrincipal

These methods correspond in purpose to the enterprise bean methods.

For more information on the J2EE security authorization model, see the following website: http://java.sun.com

Administrative roles

The Java Platform, Enterprise Edition (Java EE) role-based authorization concept is extended to protect the WebSphere Application Server administrative subsystem.

A number of administrative roles are defined to provide degrees of authority that are needed to perform certain administrative functions from either the Web-based administrative console or the system management scripting interface. The authorization policy is only enforced when administrative security is enabled. The following table describes the administrative roles:

Table 127. Administrative roles. Administrative roles

Role	Description
Monitor	An individual or group that uses the monitor role has the least amount of privileges. A monitor can complete the following tasks: • View the WebSphere Application Server configuration. • View the current state of the Application Server.

Table 127. Administrative roles (continued). Administrative roles

Configurator	An individual or group that uses the configurator role has the monitor privilege plus the ability to change the WebSphere Application Server configuration. The configurator can perform all the daily configuration tasks. For example, a configurator can complete the following tasks: • Create a resource. • Map an application server. • Install and uninstall an application. • Deploy an application. • Assign users and groups-to-role mapping for applications. • Set up Java 2 security permissions for applications. • Customize the Common Secure Interoperability Version 2 (CSIv2), Security Authentication Service (SAS), and Secure Sockets Layer (SSL) configurations. **Important:** SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.
Operator	An individual or group that uses the operator role has monitor privileges plus ability to change the runtime state. For example, an operator can complete the following tasks: • Stop and start the server. • Monitor the server status in the administrative console.
Administrator	An individual or group that uses the administrator role has the operator and configurator privileges, plus additional privileges that are granted solely to the administrator role. For example, an administrator can complete the following tasks: • Modify the server user ID and password. • Configure authentication and authorization mechanisms. • Enable or disable administrative security. • Enable or disable Java 2 security. • Change the Lightweight Third Party Authentication (LTPA) password and generate keys. • Create, update, or delete users in the federated repositories configuration. • Create, update, or delete groups in the federated repositories configuration. **Important:** An administrator cannot map users and groups to the administrator roles without also having the adminsecuritymanager role.
iscadmins	This role is only available for administrative console users, not for wsadmin users. Users who are granted this role have administrator privileges for managing users and groups in the federated repositories. For example, a user of the iscadmins role can complete the following tasks: • Create, update, or delete users in the federated repositories configuration. • Create, update, or delete groups in the federated repositories configuration.
Deployer	Users granted this role can complete both configuration actions and runtime operations on applications. See the “Deployer role” on page 1625 section for more details.
Admin Security Manager	You can assign users and groups to the Admin Security Manager role on the cell level through wsadmin scripts and the administrative console. Using the Admin Security Manager role, you can assign users and groups to the administrative user roles and administrative group roles. However, an administrator cannot assign users and groups to the administrative user roles and administrative group roles including the Admin Security Manager role. See the “Admin Security Manager role” on page 1626 section for more details.

Table 127. Administrative roles (continued). Administrative roles

Auditor	Users granted this role can view and modify the configuration settings for the security auditing subsystem. For example, a user with the auditor role can complete the following tasks: • Enable and disable the security auditing subsystem. • Select the event factory implementation to be used with the event factory plug-in point. • Select and configure the service provide, or emitter. or both to be used with the service provider plug-in point. • Set the audit policy that describes the behavior of the application server in the event of an error with the security auditing subsystem. • Define which security events are to be audited. The auditor role includes the monitor role. This allows the auditor to view but not change the rest of the security configuration. See the "Auditor role" on page 1626 section for more details.

The server ID that is specified and the administrative ID, if specified, when enabling administrative security is automatically mapped to the administrator role.

Users and groups can be added or removed from administrative roles using the WebSphere Application Server administrative console by a user given the appropriate authority. The Primary administrative user name must be used to log on to the administrative console to change the administrative user and group roles other than the auditor role. Only a user with the auditor role can change the auditor user and group roles. When security auditing is initially enabled, the Primary administrative user is also given the auditor role, and can manage all of the administrative user and group roles including the those in the auditor role. A best practice is to map a group or groups, rather than specific users, to administrative roles because it is more flexible and easier to administer.

In addition to mapping user or groups, a special-subject can also be mapped to the administrative roles. A special-subject subject is a generalization of a particular class of users. The AllAuthenticated special subject means that the access check of the administrative role ensures that the user making the request is at least authenticated. The Everyone special subject means that anyone, authenticated or not, can perform the action, as if security was not enabled.

Deployer role

A user that is granted a deployer role can complete all of the configuration and runtime operations on an application. A deployer role can be subsets of both configurator and operator roles. However, a user granted a deployer role cannot configure or operate any other resources, such as a server, node.

When fine-grained administrative security is used, only a user granted a deployer role to an application can configure and operate that application.

Cell-level configurators can configure applications. Cell-level operators can also operate (start and stop) applications. However, a user granted a deployer role at cell level can also complete configuration and operation on all applications.

Table 128. Deployer role capabilities.

This table lists the deployer role capabilities when fine-grained administrative security is used.

Operation	Required Roles (Any one)
Install application	Cell-configurator, target-deployer
Uninstall application	Cell-configurator, application-deployer, target-deployer
List application	Cell-monitor, application-monitor

Table 128. Deployer role capabilities (continued).

This table lists the deployer role capabilities when fine-grained administrative security is used.

Operation	Required Roles (Any one)
Edit, update and redeploy application	Cell-configurator, application-deployer
Export application	Cell-monitor, application-monitor
Start or stop application	Cell-operator, application-deployer

Where:

Cell-configurator
Specifies the configurator role at cell level.

Application-deployer
Specifies the deployer role for the application that is being managed.

Target-deployer
Specifies the deployer role for all servers or clusters for which an application is targeted. If you have a target-deployer role, you can install a new application on the target. However, to edit or update the installed application, you must be included in the authorization group of the installed application-deployer.

The target-deployer cannot explicitly start or stop a new application. However, when a target-deployer starts a server on a target, all of the applications that have their auto-start attribute set to `yes` are started when the server starts.

It is recommended that the application-deployer set this attribute to `true` if the application-deployer does not want the application to be started by the target-deployer.

Admin Security Manager role

The Admin Security Manager role separates administrative security administration from other application administration.

By default, serverId and adminID, if specified, are assigned to this role in the cell level authorization table. This role implies a monitor role. However, an administrator role does not imply the Admin Security Manager role.

When fine-grained admin security is used, only a user granted this role at cell level can manage administrative authorization groups. However, a user granted this role for each administrative authorization group can map users to administrative roles for those groups. The following list summarizes the capabilities of the Admin Security Manager role at different levels, such as the cell and administrative authorization group levels.

Table 129. Admin Security Manager role capabilities.

This table lists Admin Security Manager role capabilities.

Action	Role
Map users to administrative roles for cell level	Only the Admin Security Manager of the cell
Map users to administrative roles for an authorization group	Only the Admin Security Manager of that authorization group or the Admin Security Manager of the cell
Manage authorization groups, create, delete, add resource to an authorization group, or remove resource from an authorization group or list	Only the Admin Security Manager of the cell

Auditor role

The auditor role separates security auditing administration from administrative security and other application administration.

The auditor role was added to allow distinct separation of the authority of an auditor from the authority of the administrator. The auditor role can be granted to administrators to combine their authority. When security is first enabled, the auditor role is assigned to the primary administrator. If in your situation the separation of authority is required, administrators can remove the auditor role from themselves and assign the auditor role to other users.

A fine grained security for the auditor role is not implemented, which results in the auditor role requiring the monitor role. This process allows the auditor to read but not modify the panels managed by the administrator. The auditor has full authority to read and modify the panels associated with the security auditing subsystem. The administrator will have the monitor role for those panels, however, the administrator cannot modify those panels.

Authorization providers

WebSphere Application Server supports authorization that is based on the Java Authorization Contract for Containers (JACC) specification in addition to the default authorization.

JACC is a specification introduced in Java Platform, Enterprise Edition (Java EE)1.4. It enables third-party security providers to manage authorization in the application server.

Note: In WebSphere Application Server version 7.0, Java Authorization Contract for Containers (JACC) specification 1.4 was applied. In JACC specification 1.4, we support Java EE5 that includes Servlet 2.5 and EJB 3. The biggest functional change with the introduction of JACC specification 1.4 is the inclusion of annotations for propagating security policy information.

When security is enabled in WebSphere Application Server, the default authorization is used unless a JACC provider is specified. The default authorization does not require special setup, and the default authorization engine makes all of the authorization decisions. However, if a JACC provider is configured and set up for WebSphere Application Server to use, all of the enterprise beans and web authorization decisions are delegated to the JACC provider.

WebSphere Application Server supports security for Java EE applications and also for its administrative components. Java EE applications, such as Web and Enterprise JavaBeans (EJB) components are protected and authorized per the Java EE specification. The administrative components are internal to WebSphere Application Server and are protected by the role-based authorizer. The administrative components include the administrative console, MBeans, and other components such as naming and security. For more information on administrative security, see “Role-based authorization” on page 1621.

When a JACC provider is used for authorization in WebSphere Application Server, all of the Java EE application-based authorization decisions are delegated to the provider per the JACC specification. However, all administrative security authorization decisions are made by the WebSphere Application Server default authorization engine. The JACC provider is not called to make the authorization decisions for administrative security.

When a protected Java EE resource is accessed, the authorization decision to give access to the principal is the same whether using the default authorization engine or a JACC provider. Both of the authorization models satisfy the J2EE specification, and function the same. Choose a JACC provider only when you want to work with an external security provider such as Tivoli Access Manager. In this instance, the security provider must support the JACC specification and be set up to work with WebSphere Application Server. Setting up and configuring a JACC provider requires additional configuration steps, depending on the provider. Unless you have an external security provider that you can use with WebSphere Application Server, use the default authorization.

JACC support in WebSphere Application Server:

WebSphere Application Server supports the Java Authorization Contract for Containers (JACC) specification, which enables third-party security providers to handle the Java Platform, Enterprise Edition (Java EE) authorization.

The JACC specification requires that both the containers in the application server and the provider satisfy some requirements. Specifically, the containers are required to propagate the security policy information to the provider during the application deployment and to call the provider for all authorization decisions. The providers are required to store the policy information in their repository during application deployment. The providers then use this information to make authorization decisions when called by the container.

JACC access decisions

When security is enabled and an enterprise bean or web resource is accessed, the Enterprise JavaBeans (EJB) container or web container calls the security runtime to make an authorization decision on whether to permit access. When using an external provider, the access decision is delegated to that provider.

According to the Java Authorization Contract for Containers (JACC) specification, the appropriate permission object is created, the appropriate policy context handlers are registered, and the appropriate policy context identifier (contextID) is set. A call is made to the java.security.Policy object method that is implemented by the provider to make the access decision.

The following sections describe how the provider is called for both the enterprise bean and the web resources.

Access decisions for enterprise beans

When security is enabled, and an EJB method is accessed, the EJB container delegates the authorization check to the security runtime. If JACC is enabled, the security runtime uses the following process to perform the authorization check:

1. Creates the EJBMethodPermission object using the bean name, method name, interface name, and the method signature.
2. Creates the context ID and sets it on the thread by using the PolicyContext.setContextID(contextID) method.
3. Registers the required policy context handlers, including the Subject policy context handler.
4. Creates the ProtectionDomain object with principal in the Subject. If no principal exists, null is passed for the principal name.
5. The access decision is delegated to the JACC provider by calling the implies method of the Policy object, which is implemented by the provider. The EJBMethodPermission and the ProtectionDomain objects are passed to this method.
6. The isCallerInRole access check also follows the same process, except that an EJBRoleRefPermission object is created instead of an EJBMethodPermission object.

Access decisions for web resources

When security is enabled and configured to use a JACC provider, and when a web resource such as a servlet or a JavaServer Pages (JSP) file is accessed, the security runtime delegates the authorization decision to the JACC provider by using the following process:

1. A WebResourcePermission object is created to see if the URI is cleared. If the provider honors the Everyone subject it is also selected here.
   a. The WebResourcePermission object is constructed with the urlPattern and the HTTP method accessed.
   b. A ProtectionDomain object with a null principal name is created.

c. The JACC provider Policy.implies method is called with the permission and the protection domain. If the URI access is cleared or given access to the Everyone subject, the provider permits access (return `true`) in the implies method. Access is then granted without further checks.

2. If access is not granted in the previous step, a WebUserDataPermission object is created and used to see if the Uniform Resource Identifier (URI) is precluded, excluded or must be redirected using the HTTPS protocol.
   a. The WebUserDataPermission object is constructed with the urlPattern accessed, the HTTP method invoked, and the transport type of the request. If the request is over HTTPS, the transport type is set to CONFIDENTIAL; otherwise, null is passed.
   b. A ProtectionDomain object with a null principal name is created.
   c. The JACC provider Policy.implies method is called with the permission and the protection domain. If the request is using the HTTPS protocol and the implies method returns `false`, the HTTP 403 error is returned to imply excluded and precluded permission. In this case no further checks are performed. If the request is not using the HTTPS protocol, and the implies returns `false`, the request is redirected over HTTPS.
3. The security runtime attempts to authenticate the user. If the authentication information already exists (for example, LTPA token), it is used. Otherwise, the user's credentials must be entered.
4. After the user credentials are validated, a final authorization check is performed to see if the user is granted access privileges to the URI.
   a. As in Step 1, the WebResourcePermission object is created. The ProtectionDomain object now contains the Principal that is attempting to access the URI. The Subject policy context handler also contains the user's information, which can be used for the access check.
   b. The provider implies method is called using the Permission object and the ProtectionDomain object created previously. If the user is granted permission to access the resource, the implies method returns `true`. If the user is not granted access, the implies method returns `false`.

Even if the order listed previously is changed later (for example, to improve performance) the end result is the same. For example, if the resource is precluded or excluded, the end result is that the resource cannot be accessed.

For more information on these access permissions, see the JSR-000115 Java Authorization Contract for Containers (Final Release).

Using information from the Subject for access decision

If the provider relies on the WebSphere Application Server generated Subject for access decision, the provider can query the public credentials in the Subject to obtain the WSCredential credential. The WSCredential API is used to obtain information about the user, including the name and the groups that the user belongs to. This information is used to make the access decision.

If the provider adds the required information to the Subject, WebSphere Application Server can use the information to make the access decision. The provider might add the information by using the Trust Association Interface feature or by plugging login modules into the Application Server.

The security attribute propagation section contains additional documentation on how to add the WebSphere Application Server required information to the Subject. For more information, see “Propagating security attributes among application servers” on page 1549.

Dynamic module updates in JACC

WebSphere Application Server supports dynamic updates to web modules under certain conditions. If a web module is updated, deleted or added to an application, only that module is stopped and started as appropriate. The other existing modules in the application are not impacted, and the application itself is not stopped and then restarted.

When using the default authorization engine, any security policies are modified in the web modules and the application is stopped and then restarted. When using the Java Authorization Contract for Containers (JACC) based authorization, the behavior depends on the functionality that a provider supports. If a provider can handle dynamic changes to the web modules, then only the web modules are impacted. Otherwise, the entire application is stopped and restarted for the new changes in the web modules to take effect.

A provider can indicate if it supports the dynamic updates by configuring the **Supports dynamic module updates** option in the JACC configuration model (see “Authorizing access to Java EE resources using Tivoli Access Manager” on page 1644 for more information). This option can be enabled or disabled using the administrative console or by scripting. It is expected that most providers store the policy information in their external repository, which makes it possible for them to support these dynamic updates. This option should be enabled by default for most providers.

When the **Supports dynamic module updates** option is enabled, if a web module that contains security roles is dynamically added, modified, or deleted, only the specific web modules are impacted and restarted. If the option is disabled, the entire application is restarted. When dynamic updates are performed, the security policy information of the modules impacted are propagated to the provider. For more information about security policy propagation, see “JACC policy propagation” on page 1632.

Initialization of the JACC provider

If a Java Authorization Contract for Containers (JACC) provider requires initialization during server startup, for example, to enable the client code to communicate to the server code, the provider can implement the com.ibm.wsspi.security.authorization.InitializeJACCProvider interface. See “Interfaces that support JACC” on page 1662 for more information.

When this interface is implemented, it is called during server startup. Any custom properties in the JACC configuration model are propagated to the initialize method of this implementation. The custom properties can be entered using either the administrative console or by scripting.

During server shutdown, the cleanup method is called for any clean-up work that a provider requires. Implementation of this interface is strictly optional, and is used only if the provider requires initialization during server startup.

Mixed node environment and JACC

Authorization using Java Authorization Contract for Containers (JACC) is a new feature in WebSphere Application Server Version 6.0.*x*. Also, the JACC configuration is set up at the cell level and is applicable for all the nodes and servers in that cell.

If you are planning to use the JACC-based authorization, the cell must contain Version 6.0.*x* and later nodes only. This restriction implies that a mixed node environment containing a set of Version 5.*x* nodes in a Version 6.0.*x* or later cell is not supported.

JACC providers:

The Java Authorization Contract for Containers (JACC) is a specification that was first introduced in Java Platform, Enterprise Edition (Java EE) Version 1.4 through the Java Specifications Request (JSR) 115 process. JACC specification 1.4 is included for WebSphere Application Server version 7.0 for Java EE 5 support.. This specification defines a contract between Java EE 5 containers and authorization providers.

The contract enables third-party authorization providers to plug into Java EE 5 application servers, such as WebSphere Application Server, to make the authorization decisions when a Java EE 5 resource is accessed. The access decisions are made through the standard java.security.Policy object.

To plug in to WebSphere Application Server, the third-party JACC provider must implement the policy class, policy configuration factory class, and policy configuration interface, which are all required by the JACC specification.

The JACC specification does not specify how to handle the authorization table information between the container and the provider. It is the responsibility of the provider to provide some management facilities to handle this information. The container is not required to provide the authorization table information in the binding file to the provider.

WebSphere Application Server provides the RoleConfigurationFactory and the RoleConfiguration role configuration interfaces to help the provider obtain information from the binding file, as well as an initialization interface (InitializeJACCProvider). The implementation of these interfaces is optional. See "Interfaces that support JACC" on page 1662 for more information about these interfaces.

Tivoli Access Manager as the default JACC provider for WebSphere Application Server

The JACC provider in WebSphere Application Server is implemented by both the client and the server pieces of the Tivoli Access Manager. The client piece of Tivoli Access Manager is embedded in WebSphere Application Server. The server piece is located on a separate installable CD that is shipped as part of the WebSphere Application Server, Network Deployment (ND) package.

The JACC provider is not the default authorization. You must configure WebSphere Application Server to use the JACC provider.

JACC policy context handlers:

WebSphere Application Server supports all of the policy context handlers that are required by the Java Authorization Contract for Containers (JACC) specification. However, due to performance impacts, the Enterprise JavaBeans (EJB) arguments policy context handler is not activated unless it is specifically required by the provider. Performance impacts result if objects must be created for each argument of each EJB method.

If the provider supports and requires this context handler, select the **Requires the EJB arguments policy context handler for access decisions** check box in the External JACC provider link under the Authorization providers panel or by using scripting. Any changes to this option are effective after the servers are restarted. By default this option is disabled. Disable this option when using Tivoli Access Manager as the JACC provider, because the argument values are not required for access decisions.

JACC policy context identifiers (ContextID) format:

A policy context identifier is defined as a unique string that represents a policy context. A policy context contains all of the security policy statements as defined by the Java Contract for Containers (JACC) specification that affect access to the resources in a web or Enterprise JavaBeans (EJB) module.

During policy propagation to the JACC provider, a PolicyConfiguration object is created for each policy context. The object is populated with the policy statements, represented by the JACC permission objects that correspond to the context. The object is propagated to the JACC provider using the JACC specification APIs.

Note: The following information is include for planning purposes and is only applicable if you intend to federate in the future.

WebSphere Application Server makes the contextID unique by using the `href:cellName/appName/moduleName` string as the contextID format for the modules. The `href` part of the string indicates that a hierarchical name is passed as the context ID. The `cellName` represents the name of the deployment manager cell or the base cell where the application is installed.

The appName part of the string in the context ID represents the application name containing the module. The moduleName refers to the name of the module.

As an example, the context ID for the module Increment.jar file in an application named DefaultApplication that is installed in cell1 is the href:cell1/DefaultApplication/Increment.jar file.

JACC policy propagation:

When an application is installed or deployed in WebSphere Application Server, the security policy information in the application is propagated to the provider when the configuration is saved. The context ID for the application is saved in its application.xml file, that is used for propagating the policy to the Java Authorization Contract for Containers (JACC) provider, and also for access decisions for Java Platform, Enterprise Edition (Java EE) resources.

Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using SystemOut.log , SystemErr.log, trace.log, and activity.log files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

When an application is uninstalled, the security policy information in the application is removed from the provider when the configuration is saved.

If the provider implemented the RoleConfiguration interface, the security policy information that is propagated to the policy provider also contains the authorization table information. See “Interfaces that support JACC” on page 1662 for more information about this interface.

If an application does not contain security policy information, the PolicyConfiguration (and the RoleConfiguration, if implemented) objects do not contain any information. The existence of empty PolicyConfiguration and RoleConfiguration objects indicates that security policy information for the module does not exist.

After an application is installed, it can be updated without being uninstalled and reinstalled. For example, a new module can be added to an existing application, or an existing module can be modified. In this instance, the information in the impacted modules is propagated to the provider by default. A module is impacted when the deployment descriptor of the module or annotations within the module are changed as part of the update. If the provider supports the RoleConfiguration interfaces, the entire authorization table for that application is propagated to the provider.

If the security information is not propagated to the provider during application updates, you can set the com.ibm.websphere.security.jacc.propagateonappupdate Java virtual machine (JVM) property to false in the deployment manager, in a Network Deployment environment, or the unmanaged base application server. If this property is set to false, any updates to an existing application in the server are not propagated to the provider. You also can set this property on a per-application basis using the custom properties of an application. The wsadmin tool can be used to set the custom property of an application. If this property is set at the application level, any updates to that application are not propagated to the provider. If the update to an application is a full update, for example, a new application enterprise archive (EAR) file is used to replace the existing one, and the provider is refreshed with the entire application security policy information.

As mentioned earlier, the security policy information is propagated to the JACC provider during the save operation. The SystemOut.log file indicates the success or failure of the propagation to the provider. Check the log file after the installation to ensure that the propagation had no problems. If the propagation had any problems, access to the application fails when Tivoli Access Manager is used as the JACC provider.

If the security policy information for the application is successfully propagated to the provider, the audit statements with the message key SECJ0415I appear. However, if there was a problem propagating the security policy information to the provider (for example: network problems, JACC provider is not available), the `SystemOut.log` files contain the error message with the message keys SECJ0396E during install or SECJ0398E during modification. The installation of the application is not stopped due to a failure to propagate the security policy to the JACC provider. Also, in the case of failure, no exception or error messages appear during the save operation. When the problem causing this failure is fixed, run the **propagatePolicyToJaccProvider** tool to propagate the security policy information to the provider without reinstalling the application. For more information, see Propagating security policy of installed applications to a JACC provider using wsadmin scripting.

JACC registration of the provider implementation classes:

The JACC specification states that providers can plug in their provider using the javax.security.jacc.policy.provider and the javax.security.jacc.PolicyConfigurationFactory.provider system properties.

The javax.security.jacc.policy.provider property is used to set the policy object of the provider, while the javax.security.jacc.PolicyConfigurationFactory.provider property is used to set the provider PolicyConfigurationFactory implementation.

Although both system properties are supported in WebSphere Application Server, it is highly recommended that you use the configuration model that is provided. You can set these values using either the JACC configuration panel (see “Authorizing access to Java EE resources using Tivoli Access Manager” on page 1644 for more information) or by using wsadmin scripting. One of the advantages of using the configuration model instead of the system properties is that the information is entered in one place at the cell level, and is propagated to all nodes during synchronization. Also, as part of the configuration model, additional properties can be entered, as described in the JACC configuration panel.

Role-based security with embedded Tivoli Access Manager:

The Java Platform, Enterprise Edition (Java EE) role-based authorization model uses the concepts of roles and resources. An example is provided here.

Table 130. Roles.

This table is an example of role-based security with embedded Tivoli Access Manager.

	Methods		
Roles	**getBalance**	**deposit**	**closeAccount**
Teller	granted	granted	
Cashier	granted		
Supervisor			granted

In the example of the banking application that is conceptualized in the previous table, three roles are defined: teller, cashier, and supervisor. Permission to perform the getBalance, deposit, and closeAccount application methods are mapped to these roles. From the example, you can see that users assigned the role, Supervisor, can run the closeAccount method, whereas the other two roles are unable to run this method.

The term, principal, within WebSphere Application Sever security refers to a person or a process that performs activities. *Groups* are logical collections of principals that are configured in WebSphere Application Server to promote the ease of applying security. Roles can be mapped to principals, groups, or both.

Table 131. Roles methods. The entry that is invoked in the following table indicates that the principal or group can invoke any methods that are granted to that role.

	Roles		
Principal/Group	**Teller**	**Cashier**	**Supervisor**
TellerGroup	Invoke		
CashierGroup		Invoke	
SupervisorGroup			
Frank: A principal who is not a member of any of the previous groups		Invoke	Invoke

In the previous example, the principal Frank, can invoke the getBalance and the closeAccount methods, but cannot invoke the deposit method because this method is not granted either the Cashier or the Supervisor role.

At the time of application deployment, the Java Authorization Contract for Container (JACC) provider of Tivoli Access Manager populates the Tivoli Access Manager-protected object space with any security policy information that is contained in the application deployment descriptor and or annotations. This security information is used to determine access whenever the WebSphere Application Server resource is requested.

By default, the Tivoli Access Manager access check is performed using the role name, the cell name, the application name, and the module name.

Tivoli Access Manager access control lists (ACLs) determine which application roles are assigned to a principal. ACLs are attached to the applications in the Tivoli Access Manager-protected object space at the time of application deployment.

Principal-to-role mappings are managed from the WebSphere Application Server administrative console and are never modified using Tivoli Access Manager. Direct updates to ACLs are performed for administrative security users only.

The following sequence of events occur:

1. During application deployment, policy information is sent to the JACC provider of Tivoli Access Manager . This policy information contains permission-to-role mappings and role-to-principal and role-to-group mapping information.
2. The JACC provider of Tivoli Access Manager converts the information into the required format, and passes this information to the Tivoli Access Manager policy server.
3. The policy server adds entries to the Tivoli Access Manager-protected object space to represent the roles that are defined for the application and the permission-to-role mappings. A permission is represented as a Tivoli Access Manager-protected object and the role that is granted to this object is attached as an extended attribute.

Tivoli Access Manager integration as the JACC provider:

Tivoli Access Manager uses the Java Authorization Contract for Container (JACC) model in WebSphere Application Server to perform access checks.

Tivoli Access Manager consists of the following components:

- Run time
- Client configuration
- Authorization table support
- Access check
- Authentication using the PDLoginModule module

Tivoli Access Manager run-time changes that are used to support JACC

For the run-time changes, Tivoli Access Manager implements the PolicyConfigurationFactory and the PolicyConfiguration interfaces, as required by JACC. During the application installation, the security policy information in the deployment descriptor and the authorization table information in the binding files are propagated to the Tivoli provider using these interfaces. The Tivoli provider stores the policy and the authorization table information in the Tivoli Access Manager policy server by calling the respective Tivoli Access Manager application programming interfaces (API).

Tivoli Access Manager also implements the RoleConfigurationFactory and the RoleConfiguration interfaces. These interfaces are used to ensure that the authorization table information is passed to the provider with the policy information. See “Interfaces that support JACC” on page 1662 for more information about these interfaces.

Tivoli Access Manager client configuration

To configure the Tivoli Access Manager client, you can use either the administrative console or wsadmin scripting. You can access the administrative console panels for the Tivoli Access Manager client configuration by clicking **Security > Global security > External authorization providers**. Under Related Items, click **External JACC provider**. The Tivoli client must be set up to use the Tivoli Access Manager JACC Provider.

For more information about how to configure the Tivoli Access Manager client, see “Tivoli Access Manager JACC provider configuration” on page 1651.

Authorization table support

Tivoli Access Manager uses the RoleConfiguration interface to ensure that the authorization table information is passed to the Tivoli Access Manager provider when the application is installed or deployed. When an application is deployed or edited, the set of users and groups for the user or group-to-role mapping are obtained from the Tivoli Access Manager server, which shares the same Lightweight Directory Access Protocol (LDAP) server as WebSphere Application Server. This sharing is accomplished by plugging into the application management users or groups-to-role administrative console panels. The management APIs are called to obtain users and groups rather than relying on the WebSphere Application Server-configured LDAP registry.

Access check

When WebSphere Application Server is configured to use the JACC provider for Tivoli Access Manager , it passes the information to Tivoli Access Manager to make the access decision. The Tivoli Access Manager policy implementation queries the local replica of the access control list (ACL) database for the access decision.

Authentication using the PDLoginModule module

The custom login module in WebSphere Application Server can do the authentication. This login module is plugged in before the WebSphere Application Server-provided login modules. The custom login modules can provide information that can be stored in the Subject. If the required information is stored, no additional registry calls are made to obtain that information.

As part of the JACC integration, the Tivoli Access Manager-provided PDLoginModule module is also used to plug into WebSphere Application Server for Lightweight Third Party Authentication (LTPA), Kerberos (KRB5) and Simple WebSphere Authentication Mechanism (SWAM) authentication. The PDLoginModule module is modified to authenticate with the user ID or password. The module is also used to fill in the

required attributes in the Subject so that no registry calls are made by the login modules in WebSphere Application Server. The information that is placed in the Subject is available for the Tivoli Access Manager policy object to use for access checking.

Note: SWAM is deprecated in WebSphere Application Server Version 8.0 and will be removed in a future release.

Note: When using Kerberos authentication mechanism and Tivoli Access Manager, TAM loginModule creates the PDPrincipal without first going through the Tivoli Access Manager authentication process. Also when using Kerberos authentication mechanism and Tivoli Access Manager, the Tivoli Access Manager policy is not enforced starting in WebSphere Application Server Version 7.0.

Tivoli Access Manager security for WebSphere Application Server:

WebSphere Application Server provides embedded IBM Tivoli Access Manager client technology to secure your WebSphere Application Server-managed resources.

The benefits of using Tivoli Access Manager that are described here are only applicable when Tivoli Access Manager client code is used with the Tivoli Access Manager server:

- Robust container-based authorization
- Centralized policy management
- Management of common identities, user profiles, and authorization mechanisms
- Single-point security management for Java Platform, Enterprise Edition (Java EE) compliant and non-compliant Java EE resources using the administrative console for Tivoli Access Manager Web Portal Manager
- No requirements for coding or deployment changes to applications
- Easy management of users, groups, and roles using the WebSphere Application Server administrative console

WebSphere Application Server supports the Java Authorization Contract for Containers (JACC) specification. JACC details the contract requirements for Java EE containers and authorization providers. With this contract, authorization providers can perform the access decisions for resources in Java EE application servers such as WebSphere Application Server. The Tivoli Access Manager security utility that is embedded within WebSphere Application Server is JACC-compliant and is used to:

- Add security policy information when applications are deployed
- Authorize access to WebSphere Application Server-secured resources.

When applications are deployed, the embedded Tivoli Access Manager client takes any policy and or user and role information that is stored within the application deployment descriptor or using annotations and stores it within the Tivoli Access Manager Policy Server.

The Tivoli Access Manager JACC provider is also called when a user requests access to a resource that is managed by WebSphere Application Server.

Embedded Tivoli Access Manager client architecture

The previous figure illustrates the following sequence of events:

1. Users that access protected resources are authenticated using the Tivoli Access Manager login module that is configured for use when the embedded Tivoli Access Manager client is enabled.
2. The WebSphere Application Server container uses information from the Java EE application deployment descriptor and annotations to determine the required role membership.

3. WebSphere Application Server uses the embedded Tivoli Access Manager client to request an authorization decision from the Tivoli Access Manager authorization server. Additional context information, when present, is also passed to the authorization server. This context information is comprised of the cell name, Java EE application name, and Java EE module name. If the Tivoli Access Manager policy database has policies that are specified for any of the context information, the authorization server uses this information to make the authorization decision.
4. The authorization server consults the permissions that are defined for the specified user within the Tivoli Access Manager-protected object space. The protected object space is part of the policy database.
5. The Tivoli Access Manager authorization server returns the access decision to the embedded Tivoli Access Manager client.
6. WebSphere Application Server either grants or denies access to the protected method or resource, based on the decision that is returned from the Tivoli Access Manager authorization server.

At its core, Tivoli Access Manager provides an authentication and authorization framework. You can learn more about Tivoli Access Manager, including the information that is necessary to make deployment decisions, by reviewing the product documentation. The following guides are available in the IBM Tivoli Access Manager for e-business Information Center:

- *IBM Tivoli Access Manager for e-business Installation Guide*

  This guide describes how to plan, install, and configure a Tivoli Access Manager secure domain. Using a series of easy installation scripts, you can quickly deploy a fully functional secure domain. These scripts are very useful when prototyping the deployment of a secure domain.

  To access this guide in the IBM Tivoli Access Manager for e-business information center, click **Access Manager for e-business > Installation and upgrade information > Installation Guide**.
- *IBM Tivoli Access Manager for e-business Administration Guide*

  This document presents an overview of the Tivoli Access Manager security model for managing protected resources. This guide describes how to configure the Tivoli Access Manager servers that make access control decisions. In addition, detailed instructions describe how to perform important tasks, such as declaring security policies, defining protected object spaces, and administering user and group profiles.

  To access this guide in the IBM Tivoli Access Manager for e-business information center, click **Access Manager for e-business >Administration Information > Administration Guide**.

Tivoli Access Manager provides centralized administration of multiple servers.

The previous figure is an example architecture showing WebSphere Application Servers secured by Tivoli Access Manager.

The participating WebSphere Application Servers use a local replica of the Tivoli Access Manager policy database to make authorization decisions for incoming requests. The local policy databases are replicas of the master policy database. The master policy database is installed as part of the Tivoli Access Manager installation. Having policy database replicas on each participating WebSphere Application Server node optimizes performance when making authorization decisions and provides failover capability.

Although the authorization server can also be installed on the same system as WebSphere Application Server, this configuration is not illustrated in the diagram.

All instances of Tivoli Access Manager and WebSphere Application Server in the example architecture share the Lightweight Directory Access Protocol (LDAP) user registry on Machine E.

The LDAP registries that are supported by WebSphere Application Server are also supported by Tivoli Access Manager.

It is possible to have separate WebSphere Application Server profiles on the same host that is configured for different Tivoli Access Manager servers. Such an architecture requires that the profiles are configured for separate Java SE Runtime Environments (JRE 6) and therefore you need multiple JREs installed on the same host.

Note: Even though all WebSphere Application Server profiles on the same host share a single JRE 6, you can configure separate WebSphere Application Server profiles on the same host for different Tivoli Access Manager servers.

Security annotations:

Annotations are a powerful programming mechanism resulting from the JSR-175 recommendation. An annotation is a standard way to include supported security behaviors while allowing, the source code and configuration files to be generated automatically.

In Java Platform, Enterprise Edition (Java EE) 5 and above, The security roles and policies can be defined using annotations as well as within the deployment descriptor. During the installation of the application, the security policies and roles defined using annotations are merged with the security policies and roles defined within the deployment descriptor. This merge is performed by the Annotations Metadata Manager (AMM) facility. When the metadata is merged, the following inheritance rules are followed.

Table 132. Metadata merger inheritance rules.

This table lists the metadata merger inheritance rules.

Scenario	Rules
Security metadata in deployment descriptor only	No merge is needed, the security metadata from the deployment descriptor is propagated.
Security metadata in annotations only	No merge is needed, the security metadata defined with annotations is propagated.
Security metadata in deployment descriptor and annotations	The metadata from the deployment descriptor and annotations is merged. The metadata in annotations is overridden by the same type of data from the deployment descriptor.

Six security annotations are currently supported. For each annotation, a MergeAction implementation is defined.

- @DeclareRoles (Servlet 2.5 and greater and EJB 3)

  The MergeAction implementation finds all the classes annotated with the DeclareRoles annotation. Within each annotated class for each role name specified, if the security roles listed in the deployment descriptor does not contain a SecurityRole with the annotated role name, a new SecurityRole is created and added to this list of security roles.
- @RunAs (Servlet 2.5 and greater and EJB 3)

  The MergeAction implementation finds all the classes with the RunAs annotation. For each annotated class, it finds the Servlet or the Enterprise Java Bean (EJB) associated with the given class. It then determines if a run-as element is defined in the deployment descriptor for the servlet or EJB. If one is not found, a new run-as element is created and added to the deployment descriptor. If a run-as element is found, this run-as element will be used instead of creating a new one. The role name used in the RunAs annotation must be defined in the deployment descriptor.
- @DenyAll (EJB 3 only)

  The MergeAction implementation finds all the methods annotated with the DenyAll annotation. For each annotated method, if the method is not included in the deployment descriptor list of excluded methods, and a MethodPermission does not exist in the deployment descriptor, a new MethodElement is created and added to this list of excluded methods in the deployment descriptor.

- @PermitAll (EJB 3 only)

  The MergeAction implementation finds all the classes and the methods with the PermitAll annotation. For each annotated class, it finds the Enterprise Java Bean (EJB) associated with the given class. It then searches the subset of the MethodElements in the list of all the MethodPermissions defined in the deployment descriptor for this EJB. If a MethodElement with a wildcard method name ("*") is not found and a wildcard method does not exist in the list of excluded methods or in the list of MethodElements with security roles, a new MethodPermission and a new MethodElement are created. The new MethodPermission is marked unchecked and is added to the MethodPermission list in the deployment descriptor. The new MethodElement is added to the MethodElement list of the newly created unchecked MethodPermission. Similar action is done for all annotated methods. Instead of a wildcard MethodElement, the method signature must match exactly the signature of the annotated method.
- @RolesAllowed (EJB 3 only)

  The MergeAction implementation finds all of the classes and methods with the RolesAllowed annotation. For each annotated class, it finds the EJB associated with the given class. It then finds the subset of the MethodElements in the list of all the MethodPermissions defined in the deployment descriptor for this EJB. If a MethodElement with a wildcard method name ("*") is not found, and a wildcard method does not exist in the list of excluded methods or in the list of unchecked MethodElements, a new MethodPermission and MethodElement are created. If a MethodPermission for this EJB exists with exactly the same roles as those found in the annotation, this MethodPermission will be used instead of creating a new one. For each role name specified in the annotation, a new SecurityRole is created and added to the SecurityRole list in the MethodPermission, If the MethodPermission was newly created, it is added to the MethodPermission list in the deployment descriptor. The new MethodElement created is added to the MethodElement list of the MethodPermission. Similar processing is done for all annotated methods. Instead of a wildcard MethodElement, the method signature must exactly match the signature of the annotated method. Additionally, for each role name specified in the annotation, if the deployment descriptor list of security roles does not contain a SecurityRole with the annotated role name, a new SecurityRole is also created and added to this list of security roles.
- @ServletSecurity (Servlet 3.0 only)

  Note: Support for ServletSecurity annotation for Servlet 3.0 is new in this release of WebSphere Application Server.

  When an application deploys, the ServletSecurity MergeAction implementation finds all servlets with the ServletSecurity annotation. For each annotated servlet, it finds the servlet associated with the given class base on the WebServlet annotation. If RolesAllowed in the ServletSecurity annotation is not found in the deployment descriptor, it then creates a role-name attribute for the role in the deployment descriptor.

  When an application starts, the WebContainer inspects all servlets with the RunAs, declareRoles, and ServletSecurity annotations, and sets those annotations on the setServletSecurity() method of the ServletRegistration annotation. The WebContainer notifies the security component to inspect all ServletRegistration annotations that have URL patterns and security constraints. The security component then determines if a URL pattern is defined in the deployment descriptor. If one is not defined in the deployment descriptor, the security constraints and RunAs role in the URL pattern are created and then used. If an exact match is already defined in the deployment descriptor, the security constraints and RunAs role in the URL pattern of the deployment descriptor are used instead of the annotation data.

  Note: When the web authentication system property, com.ibm.wsspi.security.web.webAuthReq, is set to `persisting`, you can log into an unprotected URL if a valid username and password are provided.

  Note: ServletSecurity MergeAction and WebContainer require the WebServlet annotation to determine the servlet name of the URL pattern. The ServletSecurity annotation is omitted if the WebServlet annotation is missing, or if a URL pattern is not specified in the ServletSecurity annotation.

The Inherited servlet annotation is a metadata annotation. Do not specify the Inherited annotation in the class. If a subclass does not have security annotation, it automatically inherits security annotation from the parent class. The subclass can overwrite the parent security annotations by specifying its security annotations.

The following example is for all HTTP methods with no constraints:

```
@WebServlet ("/Example")
@ServletSecurity
public class Example extends HttpServlet {
       ......
}
```

The following example is for all HTTP methods with no <auth-constraint> element and confidential TransportGuarantee required:

```
@WebServlet ("/Example")
@ServletSecurity(@HttpConstraint(transportGuarantee =
                     TransportGuarantee.CONFIDENTIAL))
public class Example extends HttpServlet {
       ......
}
```

The following example is for all HTTP methods with all access denied:

```
@WebServlet ("/Example")
@ServletSecurity(@HttpConstraint(EmptyRoleSemantic.DENY))
public class Example extends HttpServlet {
       ......
}
```

The following example is for all HTTP methods except for the GET and POST values with no constraints. For GET, the <auth-constraint> element requires membership in ALL ROLE. For POST, all access is denied.

```
@WebServlet (name="Example", urlPatterns={"/Example"})
@ServletSecurity((httpMethodConstraints = {
 @HttpMethodConstraint(value = "GET", rolesAllowed = "ALL ROLE"),
 @HttpMethodConstraint(value="POST", emptyRoleSemantic =
EmptyRoleSemantic.DENY))
})
public class Example extends HttpServlet {
       ......
}
```

The following example is for all HTTP methods except GET, the <auth-constraint> element requires membership in ALL ROLE, and the GET method has no constraints.

```
@WebServlet (name="Example", urlPatterns={"/Example"})
@ServletSecurity(value = @HttpConstraint(rolesAllowed = "ALL ROLE"),
 httpMethodConstraints = @HttpMethodConstraint("GET"))
public class Example extends HttpServlet {
       ......
}
```

The following example is for all HTTP methods except TRACE, the <auth-constraint> element requires membership in ALL ROLE, and for TRACE, all access is denied.

```
@WebServlet (name="Example", urlPatterns={"/Example"})
@ServletSecurity(value = @HttpConstraint(rolesAllowed = "ALL ROLE"),
 httpMethodConstraints = @HttpMethodConstraint(value="TRACE",
 emptyRoleSemantic = EmptyRoleSemantic.DENY))
public class Example extends HttpServlet {
       ......
}
```

Java Servlet 3.0 support for security:

This release of WebSphere Application Server supports all security updates as defined in the Java Servlet 3.0 specification.

Note: This release of WebSphere Application Server supports all security updates as defined in the Java Servlet 3.0 specification (JSR-315), including the new servlet security annotations, use of new programmatic security APIs and the dynamic updating of the servlet security configuration.

A significant enhancement is the new annotation support for servlets. A developer can declare the security constraints using annotations as an alternative to declaring them as part of the web.xml file, which is used prior to Java Servlet 3.0. The `web.xml` file continues to function and overrides any conflicts defined as annotations.

The list of supported Java Servlet 3.0 updates for security includes the following:

- Support for the @ServletSecurity annotation
- Support for the dynamic updating of the @RunAs, @declareRoles, and @ServletSecurity servlet security annotations
- Support for the authenticate, login and logout servlet security methods
- The new com.ibm.websphere.security.displayRealm property specifies whether the HTTP basic authentication login window displays the realm name that is not defined in the application `web.xml` file.

The following discusses the Java Servlet 3.0 updates for security in more detail:

Support for the @ServletSecurity annotation:

When an application deploys, the ServletSecurity MergeAction implementation finds all servlets with the ServletSecurity annotation. For each annotated servlet, it finds the servlet associated with the given class base on the WebServlet annotation. If RolesAllowed in the ServletSecurity annotation is not found in the deployment descriptor, it then creates a role-name attribute for the role in the deployment descriptor.

When an application starts, the WebContainer inspects all servlets with the RunAs, declareRoles, and ServletSecurity annotations, and sets those annotations on the setServletSecurity() method of the ServletRegistration annotation. The WebContainer notifies the security component to inspect all ServletRegistration annotations that have URL patterns and security constraints. The security component then determines if a URL pattern is defined in the deployment descriptor. If one is not defined in the deployment descriptor, the security constraints and RunAs role in the URL pattern are created and then used. If an exact match is already defined in the deployment descriptor, the security constraints and RunAs role in the URL pattern of the deployment descriptor are used instead of the annotation data.

Read the Security annotations topic for more information.

Support for the dynamic updating of the @RunAs, @declareRoles, and @ServletSecurity servlet security annotations:

When an application starts, the web container inspects all servlets with the RunAs, declareRoles, and ServletSecurity annotations, and sets those annotations on the setServletSecurity() method of the ServletRegistration annotation. The web container notifies the security component to inspect all ServletRegistration annotations that have URL patterns and security constraints. The security component then determines if a URL pattern is defined in the deployment descriptor. If an exact match is already defined in the deployment descriptor, the security constraints and RunAs role in the URL pattern of the deployment descriptor are used instead of the dynamic data.

Read the Servlet security dynamic annotations topic for more information.

Note: WebSphere Application Server supports both a default authorization provider and an authorization provider that is based on the Java Authorization Contract for Containers (JACC) specification. The JACC-based authorization provider (for example, the Tivoli Access Manager), enables third-party security providers to handle the Java EE authorization. The RunAs, declareRoles, and ServletSecurity annotations are supported for both native authorization and for JACC.

Support for the authenticate, login and logout servlet security methods:

The authenticate method authenticates a user by using the WebSphere Application Server container login mechanism configured for the servlet context.

The login method authenticates a user to the WebSphere Application Server with a user ID and password. If authentication is successful, it creates a user subject on the thread and Lightweight Third Party Authentication (LTPA) cookies (if single sign-on (SSO) is enabled).

The logout method logs the user out of the WebSphere Application Server and invalidates the HTTP session.

Read the Servlet security methods topic for more information.

The new com.ibm.websphere.security.displayRealm property specifies whether the HTTP basic authentication login window displays the realm name that is defined in the application `web.xml` file:

If the realm name is not defined in the `web.xml` file, one of the following occurs:

- If the property is set to `false` (the default), the WebSphere realm name display is Default Realm.
- If the property is set to `true`, the WebSphere realm name display is the user registry realm name for the LTPA authentication mechanism or the Kerberos realm name for the Kerberos authentication mechanism.

Read the Security custom properties topic for more information.

Servlet security dynamic annotations:

When you use the programmatic APIs to add or to create a servlet, the security annotations, RunAs, declareRoles and ServletSecurity, can be dynamically updated through the setRunAsRole(), declareRoles() and setServletSecurity() methods respectively.

Note: Support for the dynamic updating of the RunAs, declareRoles, and ServletSecurity servlet security annotations is new in this release of WebSphere Application Server.

When an application starts, the web container inspects all servlets with the RunAs, declareRoles, and ServletSecurity annotations, and sets those annotations on the setServletSecurity() method of the ServletRegistration annotation. The web container notifies the security component to inspect all ServletRegistration annotations that have URL patterns and security constraints. The security component then determines if a URL pattern is defined in the deployment descriptor. If an exact match is already defined in the deployment descriptor, the security constraints and RunAs role in the URL pattern of the deployment descriptor are used instead of the dynamic data.

Note: If the dynamic security annotations, declareRoles, setRunAs and rolesAllowed, are used, the role name must be pre-defined, either through the deployment descriptor or through the declareRoles and or RunAs annotations in the servlet class. During deployment time, you can use the administrative console to map a user or group to this role.

If you have an exact URL pattern match for the ServletSecurity annotation in the security dynamic annotation, the security constraint of the URL pattern in the security dynamic annotation takes precedent. Also, if you call the setServletSecurity() method multiple times with the same URL pattern, the last one takes precedent.

- ServletRegistration.Dynamic.setRunAsRole(String roleName) sets the name of the RunAs role for this servlet registration.
- ServletContext.declareRoles(String roleNames) declares role names that are tested for the isUserInRole() method.
- ServletRegistration.Dynmaic.setServletSecurity(ServletSecurityElement constraint) sets the ServletSecurityElement for this servlet registration.

Note: When the web authentication system property, com.ibm.wsspi.security.web.webAuthReq, is set to `persisting`, you can log into an unprotected URL if a valid username and password are provided.

The following two examples can be used to set the security constraints and RunAs role for dynamic servlets by using the setServletSecurity() method.

In this example, all HTTP elements require membership in the Employee role except for the PUT method. For the PUT method, the <auth-constraint> element requires membership in the Manager role and TransportGuarantee is confidential.

```
HttpConstraintElement constraint = new HttpConstraintElement(TransportGuarantee.NONE,
new String[]{"Employee"});
List<HttpMethodConstraintElement> methodConstraints =
new ArrayList<HttpMethodConstraintElement>();
methodConstraints.add(new HttpMethodConstraintElement("PUT",
new HttpConstraintElement(TransportGuarantee.CONFIDENTIAL, new String[]{"Manager"})));
ServletSecurityElement servletSecurity =
new ServletSecurityElement(constraint, methodConstraints);
```

In this example, all HTTP methods are allowed except for the CUSTOM and GET methods. For the CUSTOM method, the <auth-constraint> element requires membership in the Manager role. For the GET method, the <auth-constraint> element requires membership in the Employee role, and TransportGuarantee is confidential.

```
HttpConstraintElement constraint = new HttpConstraintElement();
List<HttpMethodConstraintElement> methodConstraints =
new ArrayList<HttpMethodConstraintElement>();
methodConstraints.add(new HttpMethodConstraintElement("CUSTOM",
new HttpConstraintElement(TransportGuarantee.NONE, new String[]{"Manager"})));
methodConstraints.add(new HttpMethodConstraintElement("GET",
new HttpConstraintElement(TransportGuarantee.CONFIDENTIAL, new String[]{"Employee"})));
ServletSecurityElement servletSecurity = new ServletSecurityElement(constraint,
methodConstraints);
```

Delegations

Delegation is a process security identity propagation from a caller to a called object. As per the Java Platform, Enterprise Edition (Java EE) specification, a servlet and enterprise beans can propagate either the client or remote user identity when invoking enterprise beans, or they can use another specified identity as indicated in the corresponding deployment descriptor.

The extension supports enterprise bean propagation to the server ID when invoking other entity beans. Three types of delegations are possible:

- Delegate (RunAs) client identity
- Delegate (RunAs) specified identity
- Delegate (RunAs) system identity

Note: The RunAs system identity delegation only works when server ID and password are used. When the internalServerId feature is used, it does not work because runAs with system identity is not supported. You must specify RunAs roles. When internalServerID is used, use the RunAsSpecified with a user ID and password that is mapped to the administrator role. See “Administrative roles and naming service authorization” on page 1615 for more information about internalServerId.

The EJB specification only supports delegation (RunAs) at the Enterprise JavaBeans (EJB) level. But an extension allows EJB method-level RunAs specification. With an EJB method level, the RunAs specification can specify a different RunAs role for different methods within the same enterprise beans.

The RunAs specification is detailed in the deployment descriptor, which is the `ejb-jar.xml` file in the EJB module and the `web.xml` file in the web module. The extension to the RunAs specification is included in the `ibm-ejb-jar-ext.xml` file.

An IBM-specific binding file is available for each application that contains a mapping from the RunAs role to the user. This file is specified in the `ibm-application-bnd.xml` file.

These specifications are read by the runtime during application startup. The following figure illustrates the delegation mechanism, as implemented in the WebSphere Application Server security model.

Delegation Process

Two tables help in the delegation process:
- Resource to RunAs role mapping table
- RunAs role to user ID and password mapping table

Use the Resource to RunAs role mapping table to get the role that is used by a servlet or by enterprise beans to propagate to the next enterprise beans call.

Use the RunAsRole to user ID and password mapping table to get the user ID that belongs to the RunAs role and its password.

Delegation is performed after successful authentication and authorization. During this process, the delegation module consults the Resource to RunAs role mapping table to get the RunAs role (3). The delegation module consults the RunAs role to user ID and password mapping table to get the user that belongs to the RunAs role (4). The user ID and password is used to create a new credential using the authentication module, which is not shown in the figure.

The resulting credential is stored in the Object Request Broker (ORB) Current as an invocation credential (5). Servlet and enterprise beans when invoking other enterprise beans pick up the invocation credential from the ORB Current (6) and call the next enterprise beans (7).

Authorizing access to Java EE resources using Tivoli Access Manager

The Java Authorization Contract for Containers (JACC) defines a contract between Java Platform, Enterprise Edition (Java EE) containers and authorization providers. You can use the default authorization or an external JACC authorization provider. When security is enabled in WebSphere Application Server, the default authorization is used unless a JACC provider is specified.

Before you begin

JACC enables any third-party authorization providers to plug into a Java EE application server (such as WebSphere Application Server) to make the authorization decisions when a Java EE resource is accessed. By default, WebSphere Application Server implements the JACC provider by using Tivoli Access Manager as the external authorization provider.

Read the following articles for more detailed information about JACC before you attempt to configure WebSphere Application Server to use a JACC provider:

Procedure

- “JACC support in WebSphere Application Server” on page 1627
- “JACC providers” on page 1630
- “Tivoli Access Manager integration as the JACC provider” on page 1634

Using the built-in authorization provider

You can extend the capabilities of WebSphere Application Server by plugging in your own authorization provider. You can use the built-in authorization or an external JACC authorization provider.

About this task

For an explanation of the administrative console panels that support these capabilities, see:

Procedure

- Use the built-in authorization provider. It is recommended that you do not modify any settings on the authorization provider panels if you use the **Built-in authorization** option. For more information, see "External authorization provider settings."
- Use an external authorization provider. If you use the **External authorization using a JACC provider** option, the external providers must be based on the Java Authorization Contract for Containers (JACC) specification to handle the Java Platform, Enterprise Edition (Java EE) authorization. By default, WebSphere Application Server enables you to configure the Tivoli Access Manager Java Authorization Contract for Containers (JACC) provider as the default external JACC provider. For more information, see "External Java Authorization Contract for Containers provider settings" on page 1646 and "Tivoli Access Manager JACC provider settings" on page 1652.

External authorization provider settings:

Use this page to enable a Java Authorization Contract for Containers (JACC) provider for authorization decisions.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. Click **External authorization providers**.

The application server provides a default authorization engine that performs all of the authorization decisions. In addition, the application server also supports an external authorization provider using the JACC specification to replace the default authorization engine for Java Platform, Enterprise Edition (Java EE) applications.

JACC is part of the Java EE specification, which enables third-party security providers such as Tivoli Access Manager to plug into the application server and make authorization decisions.

Important: Unless you have an external JACC provider or want to use a JACC provider for Tivoli Access Manager that can handle Java EE authorizations based on JACC, and it is configured and set up to use with the application server, do not enable **External authorization using a JACC provider**.

Built-in authorization:

Use this option all the time unless you want an external security provider such as the Tivoli Access Manager to perform the authorization decision for Java EE applications that are based on the JACC specification.

External JACC provider: Use this link to configure the application server to use an external JACC provider. For example, to configure an external JACC provider, the policy class name and the policy configuration factory class name are required by the JACC specification.

The default settings that are contained in this link are used by Tivoli Access Manager for authorization decisions. If you intend to use another provider, modify the settings as appropriate.

External Java Authorization Contract for Containers provider settings:

Use this page to configure the application server to use an external Java Authorization Contract for Containers (JACC) provider. For example, the policy class name and the policy configuration factory class name are required by the JACC specification.

Use these settings when you have set up an external security provider that supports the JACC specification to work with the application server. The configuration process involves installing and configuring the provider server and configuring the client of the provider in the application server to communicate with the server. If the JACC provider is not enabled, these settings will be ignored.

To view this administrative console page, complete the following steps:

1. Click **Security > Global security**.
2. Click **External authorization providers**.
3. Under Authorization provider, click **External JACC provider**.

Use the default settings when you use Tivoli Access Manager as the JACC provider. Install and configure the Tivoli Access Manager server prior to using it with the application server. Use the Tivoli Access Manager properties link under Additional properties, and configure the Tivoli Access Manager client in the application server to use the Tivoli Access Manager server. If you intend to use another provider, modify the settings as appropriate.

Name:

Specifies the name that is used to identify the external JACC provider.

This field is required.

Data type: String

Description:

Provides an optional description for the provider.

Data type: String

Policy class name:

Specifies a fully qualified class name that represents the javax.security.jacc.policy.provider property as per the JACC specification. The class represents the provider-specific implementation of the java.security.Policy abstract methods.

The class file must reside in the class path of each application server process. These processes include the application server, node agents and the deployment manager.

Do not add the Java archive (JAR) file, which contains the class file, to the `<WAS_HOME>/lib` directory in a product environment as service releases overwrite files in this directory.

This class is used during authorization decisions. The default class name is for Tivoli Access Manager implementation of the policy file.

This field is required. For information on enabling the JACC provider using this field, see the "Enabling the JACC provider for Tivoli Access Manager" article in the information center.

Data type: String
Default: com.tivoli.pd.as.jacc.TAMPolicy

Policy configuration factory class name:

Specifies a fully qualified class name that represents the javax.security.jacc.PolicyConfigurationFactory.provider property as per the JACC specification. The class represents the provider-specific implementation of the javax.security.jacc.PolicyConfigurationFactory abstract methods.

The class file must reside in the class path of each application server process. These processes include the application server, node agents and the deployment manager.

Do not add the Java archive (JAR) file, which contains the class file, to the `<WAS_HOME>/lib` directory in a product environment as service releases overwrite files in this directory.

This class represents the provider-specific implementation of the PolicyConfigurationFactory abstract class. This class is used to propagate the security policy information to the JACC provider during the installation of the J2EE application. The default class name is for the Tivoli Access Manager implementation of the policy configuration factory class name.

This field is required.

Data type: String
Default: com.tivoli.pd.as.jacc.TAMPolicyConfigurationFactory

Role configuration factory class name:

Specifies a fully qualified class name that implements the com.ibm.wsspi.security.authorization.RoleConfigurationFactory interface.

The class file must reside in the class path of each application server process. These processes include the application server, node agents and the deployment manager.

Do not add the Java archive (JAR) file, which contains the class file, to the `<WAS_HOME>/lib` directory in a product environment as service releases overwrite files in this directory.

When you implement this class, the authorization table information in the binding file is propagated to the provider during the installation of the J2EE application. The default class name is for the Tivoli Access Manager implementation of the role configuration factory class name.

This field is optional. For information on enabling the JACC provider using this field, see the "Enabling the JACC provider for Tivoli Access Manager" article in the information center.

Data type: String
Default: com.tivoli.pd.as.jacc.TAMRoleConfigurationFactory

Provider initialization class name:

Specifies a fully qualified class name that implements the com.ibm.wsspi.security.authorization.InitializeJACCProvider interface.

The class file must reside in the class path of each application server process. These processes include the application server, node agents and the deployment manager.

Do not add the Java archive (JAR) file, which contains the class file, to the <WAS_HOME>/lib directory in a product environment as service releases overwrite files in this directory.

When implemented, this class is called at the start and the stop of all the application server processes. You can use this class for any required initialization that is needed by the provider client code to communicate with the provider server. The properties that are entered in the custom properties link are passed to the provider when the process starts up. The default class name is for the Tivoli Access Manager implementation of the provider initialization class name.

This field is optional. For information on enabling the JACC provider using this field, see the "Enabling the JACC provider for Tivoli Access Manager" article in the information center.

Data type: String
Default: com.tivoli.pd.as.jacc.cfg.TAMConfigInitialize

Requires the EJB arguments policy context handler for access decisions:

Specifies whether the JACC provider requires the EJBArgumentsPolicyContextHandler handler to make access decisions.

Because this option has an impact on performance, do not set it unless it is required by the provider. Normally, this handler is required only when the provider supports instance-based authorization. Tivoli Access Manager does not support this option for J2EE applications.

Default: Disabled

Supports dynamic module updates:

Specifies whether you can apply changes made to security policies of web modules in a running application, dynamically without affecting the rest of the application.

If this option is enabled, the security policies of the added or modified web modules are propagated to the JACC provider and only the affected web modules are started.

If this option is disabled, then the security policies of the entire application are propagated to the JACC provider for any module-level changes. The entire application is restarted for the changes to take effect.

Typically, this option is enabled for an external JACC provider.

Default: Enabled

Custom properties:

Specifies the properties that are required by the provider.

These properties are propagated to the provider during the startup process when the provider initialization class name is initialized. If the provider does not implement the provider initialization class name as described previously, the properties are not used.

The Tivoli Access Manager implementation does not require that you enter any properties in this link.

Tivoli Access Manager properties:

Specifies properties that are required by the Tivoli Access Manager implementation.

These properties are used to set up the communication between the application server and the Tivoli Access Manager server. You must install and configure the Tivoli Access Manager server before entering these properties.

Enabling an external JACC provider

Use this topic to enable an external JACC provider using the administrative console.

Before you begin

The Java Authorization Contract for Containers (JACC) defines a contract between Java Platform, Enterprise Edition (Java EE) containers and authorization providers. This contract enables any third-party authorization providers to plug into a Java EE 5 application server, such as WebSphere Application Server to make the authorization decisions when a Java EE resource is accessed.

Procedure

1. From the WebSphere Application Server administrative console, click **Security > Global security > External authorization providers**.
2. Under Related items, click **External JACC provider**.
3. The fields are set for Tivoli Access Manager by default. If you do not plan to use Tivoli Access Manager as the JACC provider, replace these fields with the details for your own external JACC provider.
4. If any custom properties are required by the JACC provider, click **Custom properties** under Additional properties and enter the properties. When using the Tivoli Access Manager, use the **Tivoli Access Manager properties** link instead of the Custom properties link. For more information, see "Configuring the JACC provider for Tivoli Access Manager using the administrative console."
5. On the External authorization providers panel, select the **External authorization using a JACC provider** option and click **OK**.
6. Complete the remaining steps to enable security. If you are using Tivoli Access Manager, you must select LDAP as the user registry and use the same LDAP server. For more information on configuring LDAP registries, see "Configuring Lightweight Directory Access Protocol user registries" on page 1260.
7. Restart all servers to make these changes effective.

Configuring the JACC provider for Tivoli Access Manager using the administrative console:

Use this task to configure Tivoli Access Manager as the Java Authorization Contract for Containers (JACC) provider using the administrative console.

Before you begin

Prior to completing the following steps, verify that you have previously created a security administrative user. For more information, see "Creating the security administrative user for Tivoli Access Manager" on page 1651.

About this task

The following configuration is performed on the management server. When you click either **Apply** or **OK**, configuration information is checked for consistency, saved, and applied if successful.

To configure Tivoli Access Manager as the JACC provider using the administrative console, complete the following steps:

Procedure

1. Start the WebSphere Application Server administrative console by clicking `http://`*`yourhost`*`.domain:`*`port_number`*`/ibm/console` after starting WebSphere Application Server. If security is

currently disabled, log in with any user ID. If security is currently enabled, log in with a predefined administrative ID and password. This ID is typically the server user ID that is specified when you configure the user registry.

2. Click **Security > Global security > External authorization providers**.
3. Under General properties, select **External authorization using a JACC provider**.
4. Under Related items, click **External JACC provider**.
5. Under Additional properties, click **Tivoli Access Manager Properties**. The Tivoli Access Manager JACC provider configuration screen is displayed.
6. Enter the following information:

   Enable embedded Tivoli Access Manager
   Select this option to enable Tivoli Access Manager.

   Ignore errors during embedded Tivoli Access Manager disablement
   Select this option when you want to unconfigure the JACC provider. Do not select this option during configuration.

   Client listening port set
   WebSphere Application Server must listen using a TCP/IP port for authorization database updates from the policy server. More than one process can run on a particular node or machine. More than one authorization server can be specified by separating the entries with commas. Specifying more than one authorization server at a time is useful for reasons of failover and performance. Enter the listening ports used by Tivoli Access Manager clients, separated by a comma. If a range of ports is specified, separate the lower and higher values by a colon (**:**) (for example, `7999, 9990:999`).

   Policy server
   Enter the name of the Tivoli Access Manager policy server and the connection port. Use the `policy_server:port` form. The policy communication port is set at the time of the Tivoli Access Manager configuration, and the default is 7135.

   Authorization servers
   Enter the name of the Tivoli Access Manager authorization server. Use the `auth_server:port:priority` form. The authorization server communication port is set at the time of the Tivoli Access Manager configuration, and the default is 7136. The priority value is determined by the order of the authorization server use (for example, `auth_server1:7136:1` and `auth_server2:7137:2`). A priority value of `1` is required when configuring against a single authorization server.

   Administrator user name
   Enter the Tivoli Access Manager administrator user name that was created when Tivoli Access Manager was configured; it is usually `sec_master`.

   Administrator user password
   Enter the Tivoli Access Manager administrator password.

   User registry distinguished name suffix
   Enter the distinguished name suffix for the user registry that is shared between Tivoli Access Manager and WebSphere Application Server, for example, `o=ibm, c=us`.

   Security domain
   You can create more than one security domain in Tivoli Access Manager, each with its own administrative user. Users, groups and other objects are created within a specific domain, and are not permitted to access resource in another domain. Enter the name of the Tivoli Access Manager security domain that is used to store WebSphere Application Server users and groups.

   If a security domain is not established at the time of the Tivoli Access Manager configuration, leave the value as `Default`.

Administrator user distinguished name

Enter the full distinguished name of the WebSphere Application Server security administrator ID (for example, `cn=wasdmin, o=organization, c=country`). The ID name must match the Server user ID on the Lightweight Directory Access Protocol (LDAP) User Registry panel in the administrative console. To access the LDAP User Registry panel, click **Security > Global security**. Under **User account repository**, choose **Standalone LDAP registry** as the available realm definition. Then click **Configure**.

7. When all information is entered, click **OK** to save the configuration properties. The configuration parameters are checked for validity and the configuration is attempted at the host server or cell manager.

Results

After you click **OK**, WebSphere Application Server completes the following actions:

- Validates the configuration parameters.
- Configures the host server or cell manager.

These processes might take some time depending on network traffic or the speed of your machine.

What to do next

If the configuration is successful, the parameters are copied to all subordinate servers, including the node agents. To complete the embedded Tivoli Access Manager client configuration, you must restart all of the servers, including the host server, and enable WebSphere Application Server security.

Creating the security administrative user for Tivoli Access Manager:

Enabling security requires the creation of a WebSphere Application Server administrative user. Use the Tivoli Access Manager command-line pdadmin utility to create the Tivoli Access Manager administrative user for WebSphere Application Server. This utility is available on the policy server host machine.

About this task

Follow these steps to use the pdadmin utility.

Procedure

1. From a command line, start the pdadmin utility as the Tivoli Access Manager administrative user, sec_master:

```
pdadmin -a sec_master -p sec_master_password
```

2. Create a WebSphere Application Server security user. For example, the following instructions create a new user, *wasadmin*. The command is entered as one continuous line:

```
pdadmin> user create wasadmin cn=wasadmin,o=organization,
c=country wasadmin wasadmin myPassword
```

   Substitute values for organization and country that are valid for your Lightweight Directory Access Protocol (LDAP) user registry.

3. Enable the account for the WebSphere Application Server security administrative user by issuing the following command:

```
pdadmin> user modify wasadmin account-valid yes
```

What to do next

Configure the Java Authorization Contract for Container (JACC) provider for Tivoli Access Manager. For more information, see “Tivoli Access Manager JACC provider configuration.”

Tivoli Access Manager JACC provider configuration:

You can configure the Java Authorization Contract for Containers (JACC) provider for Tivoli Access Manager to deliver authentication and authorization protection for your applications or for authentication only. Most deployments that use the JACC provider for Tivoli Access Manager to configure Tivoli Access Manager provide both authentication and authorization functionality.

If you want Tivoli Access Manager to provide authentication, but leave authorization as part of WebSphere Application Server's native security, add the `com.tivoli.pd.as.amwas.DisableAddAuthorizationTableEntry=true` property to the `amwas.amjacc.template.properties` file. The file is located in the *profile_root*`/config/cells/`*cell_name* directory.

After this property is set, perform the tasks for setting Tivoli Access Manager Security, as documented.

You can configure the JACC provider for Tivoli Access Manager using either the WebSphere Application Server administrative console or the **wsadmin** command-line utility.

- For details on configuring the JACC provider for Tivoli Access Manager using the administrative console, refer to "Configuring the JACC provider for Tivoli Access Manager using the administrative console" on page 1649.
- For details on configuring the Tivoli Access Manager JACC provider using the **wsadmin** command line utility, refer to Configuring the JACC provider for Tivoli Access Manager using the wsadmin utility.

The JACC configuration files are not common across multiple WebSphere Application profiles. The following property setting is added to the *profile_root*`/config/cells/`*cell_name*`/amwas.amjacc.template.properties` file to specify the location of the JACC configuration for each profile.

```
com.tivoli.pd.as.jacc.CommonFileLocation=USER_INSTALL_ROOT/etc/pd
```

The **wsadmin** command is available to reconfigure the Java Authorization Contract for Containers (JACC) Tivoli Access Manager interface:

```
$AdminTask reconfigureTAM -interactive
```

This command effectively prompts you through the process of unconfiguring the interface and then reconfiguring it.

Tivoli Access Manager JACC provider settings:

Use this page to configure the Java Authorization Contract for Container (JACC) provider for Tivoli Access Manager.

Note: When a third-party authorization such as Tivoli Access Manager or SAF for z/OS is used, the information in the administrative console panel might not represent the data in the provider. Also, any changes to the panel might not be reflected in the provider automatically. Follow the provider's instructions to propagate any changes made to the provider.

To view the JACC provider settings for Tivoli Access Manager, complete the following steps:

1. Click **Security > Global security**.
2. Under Authentication, click **External authorization providers**.
3. Under Authorization provider, click **External JACC provider**.
4. Click **Configure** to configure the properties for Tivoli Access Manager.

Enable embedded Tivoli Access Manager:

Enables or disables the embedded Tivoli Access Manager client configuration.

Default: Disabled

Range: Enabled or Disabled

Note: If you want to disable Tivoli Access Manager as the JACC provider, clear this option and also select **Default authorization**.

Ignore errors during embedded Tivoli Access Manager disablement:

Specifies whether to ignore error messages during the unconfiguration process.

If you check this check box and click **OK** or **Apply**, when you unconfigure the embedded Tivoli Access Manager, any unconfiguration errors are ignored and the process completes. If you do not check this check box, unconfiguration errors cause the unconfiguration process to stop.

This option is applicable only when re-configuring an embedded Tivoli Access Manager client or disabling an embedded Tivoli Access Manager.

Default: Disabled
Range: Enabled or Disabled

Client listening port set:

Enter the ports that are used as listening ports by Tivoli Access Manager clients.

The application server needs to listen on a TCP/IP port for authorization database updates from the policy server. More than one process can run on a particular node and machine, so a list of ports is required for use by the processes. If you specify a range of ports, separate the lower and higher values by a colon (:). The first 20% of the range is reserved for the deployment manager. Single ports and port ranges are specified on separate lines. An example list might look like the following example:

```
7999
 8900:8999
```

Policy server:

Enter the name, fully-qualified domain name, or IP address of the Tivoli Access Manager policy server and the connection port.

Use the form *policy_server*:*port*. The policy server communication port was set at the time of the Tivoli Access Manager configuration. The default is 7135.

Authorization servers:

Enter the name, fully-qualified domain name, or IP address of the Tivoli Access Manager authorization server. Use the form, *auth_server*:*port*:*priority*.

The authorization server communication port is set at the time of Tivoli Access Manager configuration. The default is 7136. You can specify more than one authorization server by entering each server on a new line. Configuring more than one authorization server provides for failover. The priority value is the order of authorization server use. For example:

```
auth_server1.mycompany.com:7136:1
auth_server2.mycompany.com:7137:2
```

A priority of 1 is still required when configuring a single authorization server.

Administrator user name:

Enter the Tivoli Access Manager administration user ID, as created at the time of Tivoli Access Manager configuration. This ID is usually, `sec_master`.

Administrator user password:

Enter the Tivoli Access Manager administration password for the user ID that is entered in the **Administrator user name** field.

User registry distinguished name suffix:

Enter the distinguished name suffix for the user registry to share between Tivoli Access Manager and the application server. For example: o=*organization*,c=*country*

Security domain:

Enter the name of the Tivoli Access Manager security domain that is used to store application server users and groups.

Specification of the Tivoli Access Manager domain is required because more than one security domain can be created in Tivoli Access Manager with its own administrative user. Users, groups, and other objects are created within a specific domain and are not permitted to access resources in another domain. If a security domain is not established at the time of Tivoli Access Manager configuration, leave the value as *Default*.

Default: Default

Administrator user distinguished name:

Enter the fully distinguished name of the security administrator ID for the application server. For example, cn=wasadmin,o=*organization*,c=*country*

JACC provider configuration properties for Tivoli Access Manager:

The JACC provider configuration properties detailed below may require configuration.

The Java property files are created in the WebSphere Application Server *profile_root* directory.

Two properties files might require configuration:

- `amwas.`*`node_name_server_name`*`.amjacc.properties` contains properties that are used by the JACC provider of Tivoli Access Manager.
- `amwas.`*`node_name_server_name`*`.pdjlog.properties` contains logging properties that are created from the `amwas.pdjlog.template.properties` file for the specific node and server combination at the time of configuration.

Use `amwas.`*`node_name_server_name`*`.amjacc.properties` file to configure static role caching, dynamic role caching, object caching, and role-based policy framework properties.

Static role caching properties:

The static role cache holds role memberships that do not expire.

These properties are in the *profile_root*`/etc/tam/amwas.`*`node_name_server_name`*`.amjacc.properties` file.

The *profile_root* directory is the value of the profilePath parameter at profile creation time.

com.tivoli.pd.as.cache.EnableStaticRoleCaching=true:

Enables or disables static role caching. Static role caching is enabled by default.

com.tivoli.pd.as.cache.StaticRoleCache=com.tivoli.pd.as.cache.StaticRoleCacheImpl:

This property holds the implementation class of the static role cache. You do not need to change this property, although the opportunity exists to implement your own cache, if necessary.

com.tivoli.pd.as.cache.StaticRoleCache.Roles=Administrator,Operator,Monitor,Deployer:

Defines the administration roles for WebSphere Application Server.

Tip: Enhance Application performance by adding the static roles: **CosNamingRead**, **CosNamingWrite**, **CosNamingCreate**, **CosNamingDelete**. These roles support for improved lookup performance within the application naming service.

Dynamic role caching properties:

The dynamic role cache holds role memberships that expire.

These properties are in the *profile_root*/etc/tam/amwas.*node_name_server_name*.amjacc.properties file.

The *profile_root* directory is the value of the profilePath parameter at profile creation time.

com.tivoli.pd.as.cache.EnableDynamicRoleCaching=true:

Enables or disables dynamic role caching. Dynamic role caching is enabled by default.

com.tivoli.pd.as.cache.DynamicRoleCache=com.tivoli.pd.as.cache.DynamicRoleCacheImpl:

This property holds the implementation class of the dynamic role cache. You do not need to change this property, although the opportunity exists to implement your own cache, if necessary.

com.tivoli.pd.as.cache.DynamicRoleCache.MaxUsers=100000:

The maximum number of users that the cache supports before a cache cleanup is performed. The default number of users is 100000.

com.tivoli.pd.as.cache.DynamicRoleCache.NumBuckets=20:

The number of tables that is used internally by the dynamic role cache. The default is 20. When a large number of threads use the cache, increase the value to tune and optimize cache performance.

com.tivoli.pd.as.cache.DynamicRoleCache.PrincipalLifeTime=10:

The period of time in minutes that a principal entry is stored in the cache. The default time is 10 minutes. The term, *principal*, here refers to the Tivoli Access Manager credential that is returned from a unique Lightweight Directory Access Protocol user.

com.tivoli.pd.as.cache.DynamicRoleCache.RoleLifetime=20:

The period of time in seconds that a role is stored in the role list for a user before it is discarded. The default is 20 seconds.

Object caching properties:

The object cache is used to cache all Tivoli Access Manager objects, including their extended attributes. This bypasses the need to query the Tivoli Access Manager authorization server for each resource request.

These properties are in the *profile_root*/etc/tam/amwas.*node_name_server_name*.amjacc.properties file.

The *profile_root* directory is the value of the profilePath parameter when the profile is created.

These object cache properties cannot be changed after configuration. If any require changing, it should be done before configuration of the nodes in the cell. Changes need to be made in the template properties file before any configuration actions are performed. Properties changed after configuration might cause access decisions to fail.

com.tivoli.pd.as.cache.EnableObjectCaching=true:

This property enables or disables object caching. The default value is true.

com.tivoli.pd.as.cache.ObjectCache=com.tivoli.pd.as.cache.ObjectCacheImpl:

This property is the class used to perform object caching. You can implement your own object cache if required. This can be done by implementing the *com.tivoli.pd.as.cache.IObjectCache* interface. The default is *com.tivoli.pd.as.cache.ObjectCacheImpl*.

com.tivoli.pd.as.cache.ObjectCache.NumBuckets=20:

This property specifies the number of buckets used to store object cache entries in the underlying hash table. The default is 20.

com.tivoli.pd.as.cache.ObjectCache.MaxResources=10000:

This property specifies the total number of entries for all buckets in the cache. This figure, divided by NumBuckets determines the maximum size of each bucket. The default is 10000.

com.tivoli.pd.as.cache.ObjectCache.ResourceLifeTime=20:

This property specifies the length of time in minutes that objects are kept in the object cache. The default is 20.

Role-based policy framework properties:

Although it is very unlikely that you will need to change these properties, use this file to reference supported properties within the role-based policy framework.

The role-based policy framework parameters are located in the Java Authorization Contract for Containers (JACC) configuration file and in the authorization configuration file. They are set at the time of JACC provider configuration and authorization server configuration. The role-based policy framework settings for the authorization table and the JACC provider can be modified separately for each WebSphere Application Server instance. The amwas.*node_server*.authztable.properties configuration file is generated from the authorization table. The amwas.*node_name_server_name*.amjacc.properties configuration file is generated from the JACC provider. Both files are stored in the *profile_root*/etc/tam directory. It is very unlikely that you might need to change these properties. The properties are described here for reference.

The settings cannot be changed after configuration. Make changes in the template properties file before any configuration actions are performed. Properties that are changed after configuration will cause access decisions to fail.

com.tivoli.pd.as.rbpf.AMAction=i:

This property is used to signify that a user is granted access to a role. This value is added to a Tivoli Access Manager access control list (ACL) and places invoke access on roles for users and groups.

com.tivoli.pd.as.rbpf.AMActionGroup=WebAppServer:

This property sets the Tivoli Access Manager action group that serves as a container for the action that is specified by the com.tivoli.pd.as.rbpf.AMAction property. The permission set in the `com.tivoli.pd.as.rbpf.AMAction` property goes into this action group.

com.tivoli.pd.as.rbpf.PosRoot=WebAppServer:

This property is used to determine where roles are stored in the protected object space.

com.tivoli.pd.as.rbpf.ProductId=deployedResources:

This property specifies the location under the root location that is specified in the posroot property to separate other products in the protected object space. Embedded Tivoli Access Manager objects are found in the `/WebAppServer/deployedResources` directory. The default value is `deployedResources`.

com.tivoli.pd.as.rbpf.ResourceContainerName=Resources:

This property specifies the Tivoli Access Manager object space container name for the protected resources. The default location is the `/WebAppServer/deployedResources/Resources` directory.

com.tivoli.pd.as.rbpf.RoleContainerName=Roles:

This property specifies the Tivoli Access Manager protected object space container name for the security roles. The default location is the `/WebAppServer/deployedResources/Roles` directory.

System-dependent configuration properties:

Do not change these system-dependent configuration properties. These properties are included in this article for reference only.

These properties are in the *profile_root*`/etc/tam/amwas.`*node_name_server_name*`.amjacc.properties` file.

The *profile_root* variable is the value of the profilePath parameter when the profile is created.

com.tivoli.pd.as.rbpf.AmasSession.CfgURL=file/:$WAS_HOME/profiles/profile_name/etc/tam/amwas.node_server.pdperm.properties:

This entry is generated by the Java Authorization Contract for Containers (JACC) provider configuration. This argument specifies the location of the file that contains information about the JACC provider of Tivoli Access Manager. Do not change this entry or the properties in the amwas.node_server.pdperm.properties file.

com.tivoli.pd.as.rbpf.AmasSession.CfgURL=file/:user_root/etc/tam/amwas.node_server.pdperm.properties:

This entry is generated by the Java Authorization Contract for Containers (JACC) provider configuration. It specifies the location of the file that contains information about the Tivoli Access Manager JACC provider. Do not change this entry or the properties in the amwas.node_server.pdperm.properties file.

com.tivoli.pd.as.rbpf.AmasSession.LoggingURL=file/:$WAS_HOME/profiles/profile_name/etc/tam/amwas.node_server.pdjlog.properties:

This entry contains the location of the logging configuration file for the JACC provider of Tivoli Access Manager. The referenced file is generated by the JACC provider of Tivoli Access Manager configuration. Do not change this entry.

com.tivoli.pd.as.rbpf.AmasSession.LoggingURL=file/:user_root/etc/tam/amwas.node_server.pdjlog.properties:

This entry contains the location of the logging configuration file for the Tivoli Access Manager JACC provider. The file referenced is generated by the Tivoli Access Manager JACC provider configuration. Do not change this entry.

Administering security users and roles with Tivoli Access Manager:

Use these steps to manage user-to-role mappings and user-to-group mappings for applications.

About this task

User-to-role mapping and user-to-group mapping for the JACC provider of Tivoli Access Manager are performed using the WebSphere Application Server administrative console.

Procedure

1. Click **Applications > Enterprise applications >** *application_name*.
2. Under Additional properties, click **Security role to user/group mapping**. The user and groups management screen is displayed.
3. Select the role that requires user or group management and use **Lookup users** or **Lookup groups** to manage the users or groups for the selected role. The native role mapping uses the MapRolesToUsers administrative task. If you are using Tivoli Access Manager, use the TAMMapRolesToUsers administrative task instead. The syntax and options for the Tivoli version are the same as those used in the native version. For more information, see “Role-based security with embedded Tivoli Access Manager” on page 1633 and “Configuring Tivoli Access Manager groups.”

Configuring Tivoli Access Manager groups:

Use these steps to configure the WebSphere Application Server administrative console to add objects of the accessGroup class to the list of object classes that represent user registry groups.

About this task

You can use the WebSphere Application Server administrative console to specify security policies for applications that run in the WebSphere Application Server environment. You can also use the WebSphere Application Server administrative console to specify security policies for other web resources, based on the entities that are stored in the user registry.

Tivoli Access Manager adds the accessGroup object class to the registry. Tivoli Access Manager administrators can use the pdadmin utility, which is available only on the policy server host in the PD.RTE fileset, to create new groups. These new groups are added to the registry as the accessGroup object class.

The WebSphere Application Server administrative console is not configured by default to recognize objects of the accessGroup class as user registry groups. You can configure the WebSphere Application Server administrative console to add this object class to the list of object classes that represent user registry groups. To do this configuration, complete the following instructions:

Procedure

1. From the WebSphere Application Server administrative console, access the advanced settings for configuring security by clicking **Security > Global security**.
2. Under User account repository, click the **Available realm definitions** drop-down list, select **Standalone LDAP registry**, and click **Configure**.
3. Under Additional properties, click **Advanced Lightweight Directory Access Protocol (LDAP) user registry settings**.
4. Modify the **Group Filter** field. Add the following entry: `(objectclass=accessGroup)`

   The Group Filter field looks like the following example:

   ```
   (&(cn=%w)(|(objectclass=groupOfNames)
   (objectclass=groupOfUniqueNames)(objectclass=accessGroup)))
   ```
5. Modify the **Group Member ID Map** field. Add the following entry: `accessGroup:member`. The Group Member ID Map field looks like the following example:

   ```
   groupOfNames:member;groupOfUniqueNames:uniqueMember;
   accessGroup:member
   ```
6. Stop and restart WebSphere Application Server.

Configuring additional authorization servers for Tivoli Access Manager:

Tivoli Access Manager secure domains can contain more than one authorization server. Having multiple authorization servers is useful for providing a failover capability as well as improving performance when the volume of access requests is large.

Procedure

1. Refer to the *Tivoli Access Manager Base Administration Guide* for details on installing and configuring authorization servers. This document is available in the IBM Tivoli Access Manager for e-business information center.
2. Re-configure the Java Authorization Contract for Containers (JACC) provider using the `$AdminTask reconfigureTAM interactive` **wsadmin** command. Enter all new and existing options. The following table lists the information that you are asked to provide for the reconfigureTAM command. The table also lists the properties that apply to the configureTAM and unconfigureTAM commands.

Table 133. Commands for configuring, reconfiguring, and unconfiguring Tivoli Access Manager. The following table lists the information that you are asked to provide for the configureTAM command. The table also lists the properties that apply to the unconfigureTAM and reconfigureTAM commands.

Property	Default	Relevant command	Description
Websphere Application Server node name	*	• configureTAM • reconfigureTAM • unconfigureTAM	Specify a single node on which to run the configuration task.
Tivoli Access Manager Policy Server	Default port: 7135	• configureTAM • reconfigureTAM	Enter the name of the Tivoli Access Manager policy server and the connection port. Use the format, *policy_server* **:** *port*. The policy server communication port is set at the time of Tivoli Access Manager configuration.
Tivoli Access Manager Authorization Server	Default port: 7136	• configureTAM • reconfigureTAM	Enter the name, port, and priority of each configured Tivoli Access Manager authorization server. Use the format *auth_server* **:** *port* **:** *priority*. The authorization server communication port is set at the time of Tivoli Access Manager configuration. You can specify more than one authorization server by separating the entries with commas. Having more than one authorization server configured is useful for failover and performance. The priority value is the order of authorization server use. For example: auth_server1**:**7136**:**1,auth_server2**:**7137**:**2. A priority of 1 is still required when you use a single authorization server.
Websphere Application Server administrator's distinguished name		• configureTAM • reconfigureTAM	Enter the full distinguished name of the security primary administrator ID for WebSphere Application Server as created in the "Creating the security administrative user" topic in the *Securing applications and their environment* PDF. For example: cn=wasadmin,o=*organization*,c=*country*
Tivoli Access Manager user registry distinguished name suffix		• configureTAM • reconfigureTAM	Enter the suffix that you have set up in the user registry to contain the user and groups for Tivoli Access Manager. For example: o=*organization*,c=*country*

Table 133. Commands for configuring, reconfiguring, and unconfiguring Tivoli Access Manager (continued). The following table lists the information that you are asked to provide for the configureTAM command. The table also lists the properties that apply to the unconfigureTAM and reconfigureTAM commands.

Property	Default	Relevant command	Description
Tivoli Access Manager administrator's user name	sec_master	• configureTAM • reconfigureTAM • unconfigureTAM	Enter the Tivoli Access Manager administration user ID that you created when you configured Tivoli Access Manager. This ID is usually sec_master.
Tivoli Access Manager administrator's user password		• configureTAM • reconfigureTAM • unconfigureTAM	Enter the password that is associated with the Tivoli Access Manager administration user ID.
Tivoli Access Manager security domain	Default	• configureTAM • reconfigureTAM	Enter the name of the Tivoli Access Manager security domain that is used to store users and groups. If a security domain is not already established at the time of Tivoli Access Manager configuration, click **Return** to accept the default.
Embedded Tivoli Access Manager listening port set	8900:8999	• configureTAM • reconfigureTAM	WebSphere Application Server needs to listen on a TCP/IP port for authorization database updates from the policy server. More than one process can run on a particular node and machine so a list of ports is required for the processes. Enter the ports that are used as listening ports by Tivoli Access Manager clients, separated by a comma. If you specify a range of ports, separate the lower and higher values by a colon. For example, 7999, 9990:9999.
Defer	No	• configureTAM • reconfigureTAM • unconfigureTAM	Set this option to *yes* if you want to defer the configuration of the management server until the next restart. Set the option to *no* if you want the configuration of the management server to occur immediately. Managed servers are configured on their next restart.
Force	No	• reconfigureTAM • unconfigureTAM	Set this value to *yes* if you want to ignore errors during the unconfiguration process and allow the entire process to complete. Set the value to *no* if you want errors to stop the unconfiguration process. This option is especially useful if the environment needs to be cleaned up and problems are occurring that do not allow the entire cleanup process to complete successfully.

Logging Tivoli Access Manager security:

Use this topic to enable the trace specification to indicate tracing at the required level.

About this task

The Java Authorization Contract for Containers (JACC) for Tivoli Access Manager provider messages are logged to the configured trace output location, and messages are written to standard out `SystemOut.log` file. When trace is enabled, all logging, both trace and messaging, is sent to the `trace.log` file.

Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

Procedure

1. The `amwas.`*`node_server`*`.pdjlog.properties` file must be updated and the **isLogging** attribute set to *true* for the required component. For example, to enable tracing for the JACC provider for Tivoli Access Manager, set the following line to *true*:
   `amwas.`*`node_server`*`.pdjlog.properties:baseGroup.AMWASWebTraceLogger.isLogging=true`
2. Enable tracing for the JACC provider of Tivoli Access Manager components in the WebSphere Application Server administrative console by completing the following steps:
   a. Click **Troubleshooting** > **Logs and Trace** > *server_name*.
   b. Under Logs and Trace tasks, click **Diagnostic trace**.
   c. Select the **Enable Log** option.
   d. Click **Apply**.
   e. Click **Troubleshooting** > **Logs and Trace** > *server_name*.

f. Click **Change Log Detail Levels**.

g. Click **Components**. Tracing for all components can be enabled using the **com.tivoli.pd.as.*** command. Tracing for separate components can be enabled using the following commands:
   - **com.tivoli.pd.as.rbpf.*** for role-based policy framework tracing
   - **com.tivoli.pd.as.jacc.*** for JACC provider tracing
   - **com.tivoli.pd.as.pdwas.*** for the authorization table
   - **com.tivoli.pd.as.cfg.*** for configuration
   - **com.tivoli.pd.as.cache.*** for caching

   For more information, see ../ae/utrb_loglevel.dita.

h. Click **Apply**.

What to do next

The trace specification now indicates that tracing is enabled at the required level. Save the configuration and restart the server for the changes to take effect.

Tivoli Access Manager loggers:

The Java Authorization Contract for Containers (JACC) provider for Tivoli Access Manager uses the JLog logging framework as does the Java runtime environment for Tivoli Access Manager. You can enable tracing and messaging selectively for specific JACC providers for Tivoli Access Manager components.

The JACC for Tivoli Access Manager provider messages are logged to the configured trace output location, and messages are written to standard out `SystemOut.log` file. When trace is enabled, all logging, both trace and messaging, is sent to the `trace.log` file.

Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

Tracing and message logging for the JACC provider for Tivoli Access Manager are configured in the `amwas.`*`node_server`*`.pdjlog.properties` properties file, which is located in the `profile_root/etc/tam` directory. This file contains logging properties from the `amwas.pdjlog.template.properties` template file for the specific node and server combination at the time of JACC provider for Tivoli Access Manager configuration.

The contents of this file let the user control:

- Whether tracing is enabled or disabled for the JACC provider of Tivoli Access Manager components.
- Whether message logging is enabled or disabled for the JACC provider of Tivoli Access Manager components.

The `amwas.`*`node_server`*`.pdjlog.properties` file defines several loggers, each of which is associated with one JACC provider of Tivoli Access Manager component. These loggers include:

Table 134. Tivoli Access Manager loggers. This table describes the Tivoli Access Manager loggers.

Logger Name	Description
AmasRBPFTraceLogger AmasRBPFMessageLogger	Logs messages and trace for the role-based policy framework. This underlying framework is used by embedded Tivoli Access Manager to make access decisions.
AmasCacheTraceLogger AmasCacheMessageLogger	Logs messages and trace for the policy caches that are used by the role-based policy framework.

Table 134. Tivoli Access Manager loggers (continued). This table describes the Tivoli Access Manager loggers.

Logger Name	Description
AMWASWebTraceLogger AMWASWebMessageLogger	Logs messages and trace for the WebSphere Application Server authorization plug-in.
AMWASConfigTraceLogger AMWASConfigMessageLogger	Logs messages and trace for the configuration actions of the JACC provider for Tivoli Access Manager .
JACCTraceLogger JACCMessageLogger	Logs messages and trace for the JACC provider activity of Tivoli Access Manager .

Note: Tracing can have a significant impact on system performance. Enable tracing only when diagnosing the cause of a problem.

The implementation of these loggers routes messages to the WebSphere Application Server logging sub-system. All messages are written to the WebSphere Application Server `trace.log` file.

For each logger, the `amwas.`*`node_server`*`.pdjlog.properties` file defines an isLogging attribute which, when set to *true*, enables logging for the specific component. A value of *false* disables logging for that component.

The `amwas.node_server.pdjlog.properties` file defines the parent loggers MessageLogger and TraceLogger that also have an isLogging attribute. If the child loggers do not specify this isLogging attribute, they inherit the value of their respective parent. When the JACC provider for Tivoli Access Manager is enabled, the isLogging attribute is set to *true* for the MessageLogger and set to *false* for the TraceLogger logger. Message logging is enabled for all components and tracing is disabled for all components, by default.

To turn on tracing for a JACC provider component, see Logging Tivoli Access Manager security.

Interfaces that support JACC:

WebSphere Application Server provides the RoleConfigurationFactory and the RoleConfiguration interfaces, which are similar to PolicyConfigurationFactory and PolicyConfiguration interfaces so the information that is stored in the bindings file can be propagated to the provider during installation. The implementation of these interfaces is optional.

RoleConfiguration interface

Use the RoleConfiguration interface to propagate the authorization information to the provider. This interface is similar to the PolicyConfiguration interface that is found in Java Authorization Contact for Containers (JACC).

```
RoleConfiguration
      - com.ibm.wsspi.security.authorization.RoleConfiguration

/**
 * This interface is used to propagate the authorization table information
 * in the binding file during application installation. Implementation of this interface is
 * optional. When a JACC provider implements this interface during an application, both
 * the policy and the authorization table information are propagated to the provider.
* If this is not implemented, only the policy information is propagated as per
 * the JACC specification.
 * @ibm-spi
 * @ibm-support-class-A1
 */

public interface RoleConfiguration

/**
 * Add the users to the role in RoleConfiguration.
 * The role is created, if it does not exist in RoleConfiguration.
 * @param role the role name.
 * @param users the list of the user names.
 * @exception RoleConfigurationException if the users cannot be added.
 */
 public void addUsersToRole(String role, List users)
 throws RoleConfigurationException
```

```
/**
 * Remove the users to the role in RoleConfiguration.
 * @param role the role name.
 * @param users the list of the user names.
 * @exception RoleConfigurationException if the users cannot be removed.
 */
 public void removeUsersFromRole(String role, List users)
 throws RoleConfigurationException

/**
 * Add the groups to the role in RoleConfiguration.
 * The role is created if it does not exist in RoleConfiguration.
 * @param role the role name.
 * @param groups the list of the group names.
 * @exception RoleConfigurationException if the groups cannot be added.
 */
 public void addGroupsToRole(String role, List groups)
 throws RoleConfigurationException

/**
 * Remove the groups to the role in RoleConfiguration.
 * @param role the role name.
 * @param groups the list of the group names.
 * @exception RoleConfigurationException if the groups cannot be removed.
 */
 public void removeGroupsFromRole( String role, List groups)
 throws RoleConfigurationException

/**
 * Add the everyone to the role in RoleConfiguration.
 * The role is created if it does not exist in RoleConfiguration.
 * @param role the role name.
 * @exception RoleConfigurationException if the everyone cannot be added.
 */
 public void addEveryoneToRole(String role)
 throws RoleConfigurationException

/**
 * Remove the everyone to the role in RoleConfiguration.
 * @param role the role name.
 * @exception RoleConfigurationException if the everyone cannot be removed.
 */
 public void removeEveryoneFromRole( String role)
 throws RoleConfigurationException

/**
 * Add the all authenticated users to the role in RoleConfiguration.
 * The role is created if it does not exist in RoleConfiguration.
 * @param role the role name.
 * @exception RoleConfigurationException if the authentication users cannot
 *  be added.
 */
 public void addAuthenticatedUsersToRole(String role)
 throws RoleConfigurationException

/**
 * Remove the all authenticated users to the role in RoleConfiguration.
 * @param role the role name.
 * @exception RoleConfigurationException if the authentication users cannot
 * be removed.
 */
 public void removeAuthenticatedUsersFromRole( String role)
 throws RoleConfigurationException

/**
 * This commits the changes in Roleconfiguration.
 * @exception RoleConfigurationException if the changes cannot be
 * committed.
 */
 public void commit( )
 throws RoleConfigurationException

/**
 * This deletes the RoleConfiguration from the RoleConfiguration Factory.
 * @exception RoleConfigurationException if the RoleConfiguration cannot
 * be deleted.
 */
 public void delete( )
 throws RoleConfigurationException

/**
 * This returns the contextID of the RoleConfiguration.
 * @exception RoleConfigurationException if the contextID cannot be
 * obtained.
 */
 public String getContextID( )
 throws RoleConfigurationException
```

RoleConfigurationFactory interface

The RoleConfigurationFactory interface is similar to the PolicyConfigurationFactory interface that is introduced by JACC, and is used to obtain RoleConfiguration objects based on the contextID IDs.

```
RoleConfigurationFactory
 - com.ibm.wsspi.security.authorization.RoleConfigurationFactory

/**
 * This interface is used to instantiate the com.ibm.wsspi.security.authorization.RoleConfiguration
 * objects based on the context identifier similar to the policy context identifier.
 * Implementation of this interface is required only if the RoleConfiguration interface is implemented.
 *
 * @ibm-spi
 * @ibm-support-class-A1
 */

public interface RoleConfigurationFactory
/**
 * This gets a RoleConfiguration with contextID from the
 * RoleConfigurationfactory. If the RoleConfiguration does not exist
 * for the contextID in the RoleConfigurationFactory, a new
 * RoleConfiguration with contextID is created in the
 * RoleConfigurationFactory. The contextID is similar to
 * PolicyContextID, but it does not contain the module name.
 * If remove is true, the old RoleConfiguration is removed and a new
 * RoleConfiguration is created, and returns with the contextID.
 * @return the RoleConfiguration object for this contextID
 * @param contextID the context ID of RoleConfiguration
 * @param remove true or false
 * @exception RoleConfigurationException if RoleConfiguration
 * cannot be obtained.
 **/
public abstract com.ibm.ws.security.policy.RoleConfiguration
         getRoleConfiguration(String contextID, boolean remove)
      throws RoleConfigurationException
```

InitializeJACCProvider provider

When implemented by the provider, this interface is called by every process where the JACC provider can be used for authorization. All additional properties that are entered during the authorization check are passed to the provider. For example, the provider can use this information to initialize client code to communicate with their server or repository. The cleanup method is called during server shutdown to clean up the configuration.

Declaration

public interface **InitializeJACCProvider**

Description

This interface has two methods. The JACC provider can implement the interface, and WebSphere Application Server calls it to initialize the JACC provider. The name of the implementation class is obtained from the value of the initializeJACCProviderClassName system property.

This class must reside in a Java archive (JAR) file on the class path of each server that uses this provider.

```
InitializeJACCProvider
   - com.ibm.wsspi.security.authorization.InitializeJACCProvider

  /**
   * Initializes the JACC provider
      * @return 0 for success.
   * @param props the custom properties that are included for this provider will
   * pass to the implementation class.
   * @exception Exception for any problems encountered.
   **/
  public int initialize(java.util.Properties props)
  throws Exception

  /**
   * This method is for the JACC provider cleanup and will be called during a process stop.
   **/
  public void cleanup()
```

Enabling the JACC provider for Tivoli Access Manager:

The Java Authorization Contract for Container (JACC) provider for Tivoli Access Manager is configured by default. Use this topic to enable the JACC provider for Tivoli Access Manager.

About this task

Restriction: Do not perform this task if you are configuring the JACC provider for Tivoli Access Manager to supply authentication services only. Only perform this task for installations that require both Tivoli Access Manager authentication and authorization protection.

The JACC provider for Tivoli Access Manager is configured by default. To enable the JACC provider for Tivoli Access Manager, complete the following steps:

Procedure

1. Click **Security > Global security > External authorization providers**.
2. Select the **External authorization using a JACC provider** option, then click **Apply**.
3. Under Related Items, click **External JACC provider**. The JACC provider settings for Tivoli Access Manager are displayed.
4. Verify that the correct settings are present to work with your Tivoli Access Manager configuration. The following list shows the JACC provider configuration settings for Tivoli Access Manager.

Table 135. JACC provider configuration settings for Tivoli Access Manager. This table describes the JACC provider configuration settings for Tivoli Access Manager.

Field	Value
Name	Tivoli Access Manager
Description	This field is optional and used as a reference.
J2EE policy class name	`com.tivoli.pd.as.jacc.TAMPolicy`
Policy configuration factory class name	`com.tivoli.pd.as.jacc.TAMPolicyConfigurationFactory`
Role configuration factory class name	`com.tivoli.pd.as.jacc.TAMRoleConfigurationFactory`
JACC provider initialization class name	`com.tivoli.pd.as.jacc.cfg.TAMConfigInitialize`
Requires the EJB arguments policy context handler for access decisions	false
Supports dynamic module updates	true

For more information, see “External Java Authorization Contract for Containers provider settings” on page 1646.

5. Under Additional properties, click **Tivoli Access Manager properties** and set the properties that are associated with the embedded Tivoli Access Manager. The following table explains the properties that are needed for the embedded Tivoli Access Manager. Some fields do not have default values.

Table 136. Tivoli Access Manger properties. This table lists the Tivoli Access Manger properties.

Name	Default value	Description
Enable embedded Tivoli Access Manager	Unchecked	When you select this check box, the embedded Tivoli Access Manager is configured or reconfigured. When you clear this check box, the embedded Tivoli Access Manager is unconfigured.
Ignore errors during embedded Tivoli Access Manager disablement	Unchecked	If you check this check box and click **OK** or **Apply**, when you unconfigure the embedded Tivoli Access Manager, any unconfiguration errors are ignored and the process completes. If you do not check this check box, unconfiguration errors cause the unconfiguration process to stop.
Client listening port	8900:8999	When the embedded Tivoli Access Manager is configured and running, it requires several ports to listen for updates to the access control list database for Tivoli Access Manager. The value in this field is a range of port numbers that Tivoli Access Manager can use for this purpose. The first 20% of this range is reserved for the deployment manager. You can enter multiple ranges or individual port numbers in a line separated list. For example: 8900:8999 9100:9200 9999

Table 136. Tivoli Access Manger properties (continued). This table lists the Tivoli Access Manger properties.

Name	Default value	Description
Policy server		This field value specifies the name and port number of the configure and running Tivoli Access Manager policy server. The format is server:port For example:`snapper.ibm.com:7135`
Authorization servers		This field contains the names, port numbers, and priorities of all of the configured and running Tivoli Access Manager authorization servers. This field must contain at least one authorization server. If multiple authorization servers are listed, those servers are used for failover. The server with priority 1 is used first with failover to server priority 2 and so on. The format is server:port:priority with each authorization server listed on a different line. For example: snapper.ibm.com:7136:1 turtle.ibm.com:7136:2
Authorization user name	sec_master	This field value specifies the administrative user name for Tivoli Access Manager.
Administrator user password		This field value specifies the password for Tivoli Access Manager.
User registry distinguished name suffix		This field value is the suffix that is set up in the user registry to contain the users and groups for Tivoli Access Manager. For example using IBM Tivoli Directory Server: o=ibm,c=au
Security domain	Default	This field value specifies the configured security domain to use for the embedded Tivoli Access Manager.
Administrator user distinguished name		This field specifies the fully distinguished user name of the primary administrative user for WebSphere Application Server security. For example using IBM Tivoli Directory Server: cn=wasadmin,o=ibm,c=au

For more information, see “Tivoli Access Manager JACC provider settings” on page 1652.

6. Click **OK**.
7. Save the settings by clicking **Save** at the top of the page.
8. Log out of the WebSphere Application Server administrative console.
9. Restart WebSphere Application Server. The security configuration is now replicated to managed servers and node agents. These other servers within a cell also require restarting before the security changes take effect.

Enabling embedded Tivoli Access Manager:

Embedded Tivoli Access Manager is not enabled by default, and you need to configure it for use.

About this task

Enabling Tivoli Access Manager security within WebSphere Application Server requires:

- A supported Lightweight Directory Access Protocol (LDAP) installed somewhere on your network. This user registry contains the user and group information for both Tivoli Access Manager and WebSphere Application Server.
- Tivoli Access Manager server exists and is configured to use the user registry. For details on the installation and configuration of Tivoli Access Manager, refer to the IBM Tivoli Access Manager for e-business information center.

Note: WebSphere Application Server contains an embedded client for Tivoli Access Manager. To use Tivoli Access Manager, you must also configure the Tivoli Access Manager server.

However, the server version must be the same version or later as the client version. For information on the supported version of Tivoli Access Manager, see WebSphere Application Server - Supported Prerequisites.

- WebSphere Application Server is installed either in a single server model or as WebSphere Application Server, Network Deployment.
- When administrative security is configured with a Federal Information Processing Standard (FIPS) provider, the Tivoli Access Manager server must be configured for FIPS as well

Complete the following steps to enable embedded Tivoli Access Manager security:

Procedure

1. Create the security administrative user.
   For more information, see the *Securing applications and their environment* PDF.
2. Configure the Java Authorization Contract for Containers (JACC) provider for Tivoli Access Manager .
   For more information, see the *Securing applications and their environment* PDF.
3. Enable WebSphere Application Server security. When you are using Tivoli Access Manager you must configure LDAP as the user registry.
   For more information, see the *Securing applications and their environment* PDF.
4. Enable the JACC provider for Tivoli Access Manager.
   For more information, see the *Securing applications and their environment* PDF.

TAMConfig command group for the AdminTask object:

You can use the Jython or Jacl scripting languages to configure embedded IBM Tivoli Access Manager with the wsadmin tool. The commands and parameters in the TAMConfig group can be used to configure or unconfigure Tivoli Access Manager.

The TAMConfig command group for the AdminTask object includes the following commands:

- "configureTAM"
- "listTAMSettings" on page 1668
- "modifyTAM" on page 1668
- "reconfigureTAM" on page 1669
- "unconfigureTAM" on page 1669

configureTAM

Use the configureTAM command to manually configure the Tivoli Access Manager.

Target object

None.

Required parameters

None.

Optional parameters

None.

Examples

Interactive mode example usage:

- Using Jacl:

```
$AdminTask configureTAM {-interactive}
```

- Using Jython:

```
AdminTask.configureTAM('-interactive')
```

listTAMSettings

The listSSLRepertoires command displays the current embedded Tivoli Access Manager configuration settings.

Target object

None.

Required parameters

None.

Optional parameters

None.

Examples

Interactive mode example usage:

- Using Jacl:

```
$AdminTask listTAMSettings {-interactive}
```

- Using Jython:

```
print AdminTask.listTAMSettings('-interactive')
```

modifyTAM

The modifyTAM command modifies embedded Tivoli Access Manager configuration settings.

Target object

None.

Required parameters

-adminPasswd
Specifies the Tivoli Access Manager administrator password. (String, required)

Optional parameters

-adminUid
Specifies the Tivoli Access Manager user name. (String, optional)

-nodeName
Specifies the target node or nodes. Set the value as the * asterisk character to specify all nodes. (String, optional)

Examples

Interactive mode example usage:

- Using Jacl:

```
$AdminTask modifyTAM {-adminPasswd my11password}
```

- Using Jython:

```
AdminTask.modifyTAM('-adminPasswd my11password')
```

- Using Jython list:

```
AdminTask.modifyTAM(['-adminPasswd', 'my11password'])
```

Interactive mode example usage:

- Using Jacl:

```
$AdminTask modifyTAM {-interactive}
```

- Using Jython:

```
AdminTask.modifyTAM('-interactive')
```

reconfigureTAM

The reconfigureTAM command reconfigures the Java Authorization Contract for Containers (JACC) Tivoli Access Manager settings.

Target object

None.

Required parameters

None.

Optional parameters

None.

Examples

Interactive mode example usage:

- Using Jacl:

```
$AdminTask reconfigureTAM {-interactive}
```

- Using Jython:

```
AdminTask.reconfigureTAM('-interactive')
```

unconfigureTAM

The unconfigureTAM command removes configuration data for the Java Authorization Contract for Containers (JACC) Tivoli Access Manager.

Required parameters

None.

Optional parameters

None.

Examples

Interactive mode example usage:

- Using Jacl:

```
$AdminTask unconfigureTAM {-interactive}
```

- Using Jython:

```
AdminTask.unconfigureTAM('-interactive')
```

configureTAMTAI

The configureTAMTAI command configures the embedded Tivoli Access Manager trust association interceptor (TAI) with classname TAMTrustAsociationInterceptorPlus.

Target object

None.

Required parameters

-policySvr
This property specifies the name of the Tivoli Access Manager policy server with which the application server communicates. The server is specified by a fully-qualified host name, the SSL port number, and the rank. The default SSL port number is 7135. For example: `myauth.mycompany.com:7135:1`.

-authSvrs
This property specifies the name of the Tivoli Access Manager authorization server with which the application server communicates. The server is specified by a fully-qualified host name, the SSL port number, and the rank. The default SSL port number is 7136. For example: `myauth.mycompany.com:7136:1`. You can specify multiple servers if the entries are separated by a comma (,).

-adminPasswd
This property specifies the password of the Tivoli Access Manager administrator user that is associated with the -adminUid parameter. The password restrictions depend upon the password policy for your Tivoli Access Manager configuration.

-loginId
The WebSEAL trusted user as created in "Creating a trusted user account in Tivoli Access Manager". See the Configuring single sign-on using trust association interceptor ++ article for more information. The format of the username is the short name representation.

Optional parameters

-adminUid
This property specifies the Tivoli Access Manager administrator name. If this option is not specified, `sec_master` is the default. A valid administrative ID is an alphanumeric, case-sensitive string. String values are expected to be characters that are part of the local code set. You cannot use a space in the administrative ID.

For example, for U.S. English, the valid characters are the letters a-Z, the numbers 0-9, a period (.), an underscore (_), a plus sign (+), a hyphen (-), an at sign (@), an ampersand (&), and an asterisk (*). The minimum and maximum lengths of the administrative ID, if there are limits, are imposed by the underlying registry.

-secDomain
This property specifies the Tivoli Access Manager domain name to which the administrator is authenticated. This domain must exist and an administrator ID and password must be valid for this domain. The application server is specified in this domain. If the application server is not specified, the default value is `Default`. The local domain value is retrieved from the configuration file.

A valid domain name is an alphanumeric, case-sensitive string. String values are expected to be characters that are part of the local code set. You cannot use a space in the domain name.

For example, for U.S. English, the valid characters for domain names are the letters a-Z, the numbers 0-9, a period (.), an underscore (_), a plus sign (+), a hyphen (-), an at sign (@), an ampersand (&), and an asterisk (*). The minimum and maximum lengths of the domain name, if there are limits, are imposed by the underlying registry.

-checkViaHeader

You can configure TAI so that the via header can be ignored when validating trust for a request. Set this property to `false` if none of the hosts in the via header need to be trusted. When set to false, you do not need to set the trusted host names and host ports properties. The only mandatory property to check when the via header is false is com.ibm.websphere.security.webseal.loginId. The default value of the check via header property is `false`. When using Tivoli Access Manager plug-in for web servers, set this property to false.

Note: The via header is part of the standard HTTP header that records the server names that the request passed through.

-id

This property specifies a comma-separated list of headers that exists in the request. If all of the configured headers do not exist in the request, trust cannot be established. The default value for the ID property is `iv-creds`. Any other values set in WebSphere Application Server are added to the list along with iv-creds, separated by commas.

-hostnames

Do not set this property if you are using the Tivoli Access Manager plug-in for web servers. This property specifies the host names (case-sensitive) that are both trusted and expected in the request header. Requests arriving from unlisted hosts might not be trusted. If the checkViaHeader property is not set, or is set to `false`, then the trusted host names property has no influence. If the checkViaHeader property is set to `true`, and the trusted host names property is not set, the TAI initialization fails.

-ports

Do not set this property if you are using the Tivoli Access Manager plug-in for web servers. This property is a comma-separated list of trusted host ports. Requests that arrive from unlisted ports might not be trusted. If the checkViaHeader property is not set, or is set to `false`, then this property has no influence. If the checkViaHeader property is set to `true`, and the trusted host ports property is not set in WebSphere Application Server, the TAI initialization fails.

-viaDepth

This property indicates a positive integer that specifies the number of source hosts in the via header to check for trust. By default, every host in the via header is checked, and if any host is not trusted, trust cannot be established. The viaDepth property is used when only some of the hosts in the via header have to be trusted. The setting indicates the number of hosts that are required to be trusted.

For example, consider the following header:

If in via: HTTP/1.1 webseal1:7002, 1.1 webseal2:7001If the viaDepth property is not set, is set to 2 or is set to 0, and a request with the previous via header is received then both webseal1:7002 and webseal2:7001 need to be trusted. The following configuration then applies:

```
com.ibm.websphere.security.webseal.hostnames = webseal1,webseal2
```

If in com.ibm.websphere.security.webseal.ports = 7002,7001If the viaDepth property is set to 1, and the previous request is received, then only the last host in the via header needs to be trusted. The following configuration then applies:

```
com.ibm.websphere.security.webseal.hostnames = webseal2
com.ibm.websphere.security.webseal.ports = 7001
```

The viaDepth property is set to 0 by default, which means that all of the hosts in the via header are checked for trust.

-ssoPwdExpiry
After trust is established for a request, the single sign-on user password is cached, eliminating the need to have the TAI re-authenticate the single sign-on user with Tivoli Access Manager for every request. You can modify the cache timeout period by setting the single sign-on password expiry property to the required time in seconds. If the password expiry property is set to 0, the cached password never expires. The default value for the password expiry property is 600.

-ignoreProxy
This property can be used to tell the TAI to ignore proxies as trusted hosts. If set to `true` the comments field of the hosts entry in the via header is checked to determine if a host is a proxy. Remember that not all proxies insert comments in the via header indicating that they are proxies. The default value of the ignoreProxy property is `false`. If the checkViaHeader property is set to false, then the ignoreProxy property has no influence in establishing trust.

-configURL
For the TAI to establish trust for a request, it requires that the SvrSslCfg task be run for the Java Virtual Machine on the Application Server and result in the creation of a properties file. If this properties file is not at the default URL, which is file://java.home/PdPerm.properties, the correct URL of the properties file must be set in the configuration URL property. If this property is not set, and the SvrSslCfg-generated properties file is not in the default location, the TAI initialization fails. The default value for the config URL property is `file://${WAS_INSTALL_ROOT}/java/jre/PdPerm.properties.`

-defer
This property indicates whether the Tivoli Access Manager configuration portion of this task should be run immediately or deferred until the startup of the WebSphere Application Server. The default value is `no`.

Note: The TAI properties are updated immediately regardless of this setting.

Examples

Interactive mode example usage:

- Using Jacl:

```
$AdminTask configureTAMTAI {-interactive}
```

- Using Jython:

```
AdminTask.configureTAMTAI('-interactive')
```

unconfigureTAMTAI

The unconfigureTAMTAI command unconfigures the embedded Tivoli Access Manager Trust Association Interceptor with classname TAMTrustAsociationInterceptorPlus. This task does not include removing any custom properties from the security configuration.

Target object

None.

Required parameters

-adminPasswd
Specifies the password of the Tivoli Access Manager administrator user that is associated with the -adminUid parameter. The password restrictions depend upon the password policy for your Tivoli Access Manager configuration.

Optional parameters

-adminUid
Specifies the Tivoli Access Manager administrator name. If this option is not specified, `sec_master` is

the default. A valid administrative ID is an alphanumeric, case-sensitive string. String values are expected to be characters that are part of the local code set. You cannot use a space in the administrative ID.

For example, for U.S. English the valid characters are the letters a-Z, the numbers 0-9, a period (.), an underscore (_), a plus sign (+), a hyphen (-), an at sign (@), an ampersand (&), and an asterisk (*). The minimum and maximum lengths of the administrative ID, if there are limits, are imposed by the underlying registry.

-force
Indicates whether or not this task should stop when an error is encountered. The default value is no.

-defer
Indicates whether this task should be run immediately or deferred until the startup of the WebSphere Application Server. The default value is no.

Examples

Interactive mode example usage:

- Using Jacl:

```
$AdminTask unconfigureTAMTAI {-interactive}
```

- Using Jython:

```
AdminTask.unconfigureTAMTAI('-interactive')
```

configureTAMTAIProperties

The configureTAMTAIProperties command adds the custom properties to the security configuration for the embedded Tivoli Access Manager Trust Association Interceptor with classname TAMTrustAsociationInterceptorPlus.

Target object

None.

Required parameters

-loginId
The WebSEAL trusted user is created as discussed in "Creating a trusted user account in Tivoli Access Manager". See the Configuring single sign-on using trust association interceptor ++ article for more information. The format of the username is the short name representation.

Optional parameters

-checkViaHeader
You can configure TAI so that the via header can be ignored when validating trust for a request. Set this property to false if none of the hosts in the via header need to be trusted. When set to `false` you do not need to set the trusted host names and host ports properties. The only mandatory property to check when via header is false is com.ibm.websphere.security.webseal.loginId. The default value of the check via header property is `false`. When using Tivoli Access Manager plug-in for web servers, set this property to false.

Note: The via header is part of the standard HTTP header that records the server names that the request passed through.

-id
This property indicates a comma-separated list of headers that exists in the request. If all of the

configured headers do not exist in the request, trust cannot be established. The default value for the ID property is `iv-creds`. Any other values set in WebSphere Application Server are added to the list along with iv-creds, separated by commas.

-hostnames
Do not set this property if using Tivoli Access Manager plug-in for web servers. The property specifies the host names (case-sensitive) that are both trusted and expected in the request header. Requests arriving from unlisted hosts might not be trusted. If the checkViaHeader property is not set, or is set to `false`, then the trusted host names property has no influence. If the checkViaHeader property is set to `true`, and the trusted host names property is not set, the TAI initialization fails.

-ports
Do not set this property if you are using the Tivoli Access Manager plug-in for web servers. This property is a comma-separated list of trusted host ports. Requests that arrive from unlisted ports might not be trusted. If the checkViaHeader property is not set, or is set to `false`, then this property has no influence. If the checkViaHeader property is set to `true`, and the trusted host ports property is not set in WebSphere Application Server, the TAI initialization fails.

-viaDepth
This property indicates a positive integer that specifies the number of source hosts in the via header to check for trust. By default, every host in the via header is checked, and if any host is not trusted, trust cannot be established. The viaDepth property is used only when some of the hosts in the via header have to be trusted. The setting indicates the number of hosts that are required to be trusted.

As an example, consider the following header:

If in via: HTTP/1.1 webseal1:7002, 1.1 webseal2:7001If the viaDepth property is not set, is set to 2 or is set to 0, and a request with the previous via header is received then both webseal1:7002 and webseal2:7001 need to be trusted. The following configuration then applies:

```
com.ibm.websphere.security.webseal.hostnames = webseal1,webseal2
```

If in com.ibm.websphere.security.webseal.ports = 7002,7001If the viaDepth property is set to 1, and the previous request is received, then only the last host in the via header needs to be trusted. The following configuration then applies:

```
com.ibm.websphere.security.webseal.hostnames = webseal2
com.ibm.websphere.security.webseal.ports = 7001
```

The viaDepth property is set to 0 by default, which means that all of the hosts in the via header are checked for trust.

-ssoPwdExpiry
This property can be used to tell the TAI to ignore proxies as trusted hosts. If set to true, the comments field of the hosts entry in the via header is checked to determine if a host is a proxy. Remember that not all proxies insert comments in the via header indicating that they are proxies. The default value of the ignoreProxy property is `false`. If the checkViaHeader property is set to false, then the ignoreProxy property has no influence in establishing trust

-viaDepth
This property indicates a positive integer that specifies the number of source hosts in the via header to check for trust. By default, every host in the via header is checked, and if any host is not trusted, trust cannot be established. The viaDepth property is used only when some of the hosts in the via header have to be trusted. The setting indicates the number of hosts that are required to be trusted.

-ssoPwdExpiry
After trust is established for a request, the single sign-on user password is cached, eliminating the need to have the TAI re-authenticate the single sign-on user with Tivoli Access Manager for every request. You can modify the cache timeout period by setting the single sign-on password expiry property to the required time in seconds. If the password expiry property is set to 0, the cached password never expires. The default value for the password expiry property is 600.

-ignoreProxy
This property can be used to tell the TAI to ignore proxies as trusted hosts. If set to `true`, the

comments field of the hosts entry in the via header is checked to determine if a host is a proxy. Remember that not all proxies insert comments in the via header indicating that they are proxies. The default value of the ignoreProxy property is `false`. If the checkViaHeader property is set to false, then the ignoreProxy property has no influence in establishing trust.

-configURL
For the TAI to establish trust for a request, it requires that the SvrSslCfg task be run for the Java Virtual Machine on the Application Server and result in the creation of a properties file. If this properties file is not at the default URL, which is `file://java.home/PdPerm.properties`, the correct URL of the properties file must be set in the configuration URL property. If this property is not set, and the SvrSslCfg-generated properties file is not in the default location, the TAI initialization fails. The default value for the config URL property is `file://${WAS_INSTALL_ROOT}/java/jre/PdPerm.properties`.

Examples

Interactive mode example usage:

- Using Jacl:

```
$AdminTask configureTAMTAIProperties {-interactive}
```

- Using Jython:

```
AdminTask.configureTAMTAIProperties('-interactive')
```

unconfigureTAMTAIProperties

The unconfigureTAMTAIProperties command removes the custom properties from the security configuration for the embedded Tivoli Access Manager Trust Association Interceptor with classname TAMTrustAsociationInterceptorPlus.

Target object

None.

Required parameters

None.

Optional parameters

None.

Examples

Interactive mode example usage:

- Using Jacl:

```
$AdminTask unconfigureTAMTAIProperties {-interactive}
```

- Using Jython:

```
AdminTask.unconfigureTAMTAIProperties('-interactive')
```

configureTAMTAIPdjrte

The configureTAMTAIPdjrte command performs the tasks necessary to fully configure the Tivoli Access Manager Runtime for Java. The specific tasks run are PDJrteCfg and SvrSslCfg.

Target object

None.

Required parameters

-policySvr
This property specifies the name of the Tivoli Access Manager policy server with which the application server communicates. The server is specified by fully qualified host name, the SSL port number, and the rank. The default SSL port number is 7135. For example: `myauth.mycompany.com:7135:1`.

-authSvrs
This property specifies the name of the Tivoli Access Manager authorization server with which the application server communicates. The server is specified by fully-qualified host name, the SSL port number, and the rank. The default SSL port number is 7136. For example: `myauth.mycompany.com:7136:1`. You can specify multiple servers if the entries are separated by a comma (,).

-adminPasswd
This property specifies the password of the Tivoli Access Manager administrator user that is associated with the -adminUid parameter. The password restrictions depend upon the password policy for your Tivoli Access Manager configuration.

Optional parameters

-adminUid
This property specifies the Tivoli Access Manager administrator name. If this option is not specified, `sec_master` is the default. A valid administrative ID is an alphanumeric, case-sensitive string. String values are expected to be characters that are part of the local code set. You cannot use a space in the administrative ID.

For example, for U.S. English. the valid characters are the letters a-Z, the numbers 0-9, a period (.), an underscore (_), a plus sign (+), a hyphen (-), an at sign (@), an ampersand (&), and an asterisk (*). The minimum and maximum lengths of the administrative ID, if there are limits, are imposed by the underlying registry.

-secDomain
This property specifies the Tivoli Access Manager domain name to which the administrator is authenticated. This domain must exist and an administrator ID and password must be valid for this domain. The application server is specified in this domain.

If this property is not specified, the default value is `Default`. The local domain value is retrieved from the configuration file.

A valid domain name is an alphanumeric, case-sensitive string. String values are expected to be characters that are part of the local code set. You cannot use a space in the domain name.

For example, for U.S. English, the valid characters for domain names are the letters a-Z, the numbers 0-9, a period (.), an underscore (_), a plus sign (+), a hyphen (-), an at sign (@), an ampersand (&), and an asterisk (*). The minimum and maximum lengths of the domain name, if there are limits, are imposed by the underlying registry.

-defer
This property indicates whether this task should be run immediately or deferred until the startup of the WebSphere Application Server. The default value is `no`.

Examples

Interactive mode example usage:

- Using Jacl:

```
$AdminTask configureTAMTAIPdjrte {-interactive}
```

- Using Jython:

```
AdminTask.configureTAMTAIPdjrte('-interactive')
```

unconfigureTAMTAIPdjrte

The unconfigureTAMTAIPdjrte command performs the tasks necessary to unconfigure the Tivoli Access Manager Runtime for Java. The specific tasks run are PDJrteCfg and SvrSslCfg.

Target object

None.

Required parameters

-adminPasswd
This property specifies the password of the Tivoli Access Manager administrator user that is associated with the -adminUid parameter. The password restrictions depend upon the password policy for your Tivoli Access Manager configuration.

Optional parameters

-adminUid
This property specifies the Tivoli Access Manager administrator name. If this option is not specified, `sec_master` is the default. A valid administrative ID is an alphanumeric, case-sensitive string. String values are expected to be characters that are part of the local code set. You cannot use a space in the administrative ID.

-force
This property indicates whether or not this task should stop when an error is encountered. The default value is `no`.

-defer
This property indicates whether this task should be run immediately or deferred until the startup of the WebSphere Application Server. The default value is `no`.

Examples

Interactive mode example usage:

- Using Jacl:

```
$AdminTask unconfigureTAMTAIPdjrte {-interactive}
```

- Using Jython:

```
AdminTask.unconfigureTAMTAIPdjrte('-interactive')
```

Disabling embedded Tivoli Access Manager client using the administrative console:

To unconfigure the JACC provider for Tivoli Access Manager, you can use the WebSphere Application Server administrative console.

Procedure

1. Click **Security > Global security > External authorization providers**.
2. Make sure that the default option, **Default authorization**, is checked, then click **OK**.
3. On the Global security panel, click **External authorization > External JACC provider**.
4. Under Additional properties, click **Tivoli Access Manager Properties**. The configuration screen for the JACC provider for Tivoli Access Manager is displayed.
5. Clear the **Enable embedded Tivoli Access Manager** option. If you want to ignore errors when unconfiguring, select the **Ignore errors during embedded Tivoli Access Manager disablement** option. Select this option only when the Tivoli Access Manager domain is in an irreparable state.
6. Click **OK**.
7. Optional: If you want security enabled without Tivoli Access Manager re-enable administrative security.

8. Restart all WebSphere Application Server instances for the changes to take effect.

Forcing the unconfiguration of the Tivoli Access Manager JACC provider:

If you find you cannot restart WebSphere Application Server after configuring the JACC provider for Tivoli Access Manager a utility is available to clear the security configuration and return WebSphere Application Server to an operable state.

About this task

The utility removes all of the PDLoginModuleWrapper entries as well as the Tivoli Access Manager authorization table from `security.xml` and `wsjaas.conf` files. This utility effectively removes the JACC provider for Tivoli Access Manager.

Procedure

1. Back up the `security.xml` and `wsjaas.conf` files.
2. Enter the following command as one continuous line.

```
java -classpath
"app_server_root/$WAS_HOME/plug-ins/com.tivoli.pd.amwas.core_6.1.0.jar"
com.tivoli.pd.as.jacc.cfg.CleanSecXML fully_qualified_path/security.xml
 fully_qualified_path/wsjaas.conf
```

Propagating security policies and roles for previously deployed applications:

Use this task to propagate security policies and roles to the external Java Authorization Contract for Containers (JACC) provider.

Before you begin

The external JACC provider must be configured before following these steps.

About this task

After switching to use the external JACC provider you can follow these steps to avoid having to redeploy your existing applications. Updating using these steps retrieves the security policy and roles from the deployed applications and propagates it to the external JACC provider removing the need for the applications to be redeployed.

Procedure

1. From the WebSphere Application Server administrative console, click **Security** > **Global security** > **External authorization providers**.
2. Select the appropriate security policy and role updating option.
   - Select **Don't update provider** to not propagate any security policies or roles
   - Select **Update with all applications** to propagate security policies and roles for all applications
   - Select **Update with application names listed** to propagate security policies and roles for the selected applications. If multiple applications should be updated, separate the application names with commas.
3. Click **Apply**.

Results

After completing this task your security policies and roles have been successfully propagated to the external JACC provider.

Authorizing access to administrative roles

You can assign users and groups to administrative roles to identify users who can perform WebSphere Application Server administrative functions.

Before you begin

Administrative roles enable you to control access to WebSphere Application Server administrative functions. Refer to the descriptions of these roles in “Administrative roles” on page 1623.

- Before you assign users to administrative roles, you must set up your user registry. For information on the supported registry types, see “Selecting a registry or repository” on page 1254.
- The following steps are needed to assign users to administrative roles.

About this task

You use the administrative console to assign users and groups to administrative roles and to identify users who can perform WebSphere Application Server administrative functions. In the administrative console,

Procedure

1. Click **Users and Groups**. Click either **Administrative User Roles** or **Administrative Group Roles**.
2. To add a user or a group, click **Add** on the Console users or Console groups panel.
3. To add a new administrator user, follow the instructions on the page to specify a user, and select the **Administrator** role. Once the user is added to the Mapped to role list, click **OK**. The specified user is mapped to the security role.
4. To add a new administrative group, follow the instructions on the page to specify either a group name or a Special subject, highlight the **Administrator** role, and click **OK**. The specified group or special subject is mapped to the security role.
5. To remove a user or group assignment, click **Remove** on the Console Users or the Console Groups panel. On the Console Users or the Console Groups panel, select the check box of the user or group to remove and click **OK**.
6. To manage the set of users or groups to display, click **Show filter function** on the User Roles or Group Roles panel. In the **Search term(s)** box, type a value, then click **Go**. For example, user* displays only users with the user prefix.
7. After the modifications are complete, click **Save** to save the mappings.
8. Restart the application server for changes to take effect.

Administrative user roles settings and CORBA naming service user settings

Use the Administrative User Roles page to give users specific authority to administer application servers through tools such as the administrative console or wsadmin scripting. The authority requirements are only effective when global security is enabled. Use the Common Object Request Broker Architecture (CORBA) naming service users settings page to manage CORBA naming service users settings.

To view the Console Users administrative console page, complete either of the following steps:

- Click **Security > Global security > Administrative User Roles**.
- Click **Users and Groups > Administrative User Roles**.

Note: If you are using local OS, the SIB administrative security panel's searches can use both the "?" and "*" search characters. However. if you switch to federated repositories, the searches will not work with the "?" character but will with the "*" character.

To view the CORBA naming service groups administrative console page, click **Environment > Naming > CORBA Naming Service Groups**.

Click **Refresh All** to automatically update the node agent and all of the nodes when a new user is created with the Administrator or Admin Security Manager role. When you click **Refresh All**, you do not need to manually restart the node agent under an existing Administrator before the new user is recognized with one of these roles. This button automatically invokes the AuthorizationManager refreshAll MBean method. To invoke this method manually, read about Fine-grained administrative security in heterogeneous and single-server environments.

User (Administrative user roles):

Specifies users.

The users that are entered must exist in the configured active user registry.

Data type: String

User (CORBA naming service users):

Specifies CORBA naming service users.

The users that are entered must exist in the configured active user registry.

Data type: String

Role (Administrative user roles):

Specifies user roles.

The following administrative roles provide different degrees of authority that are needed to perform certain application server administrative functions:

Administrator
The administrator role has operator permissions, configurator permissions, and the permission that is required to access sensitive data including server password, Lightweight Third Party Authentication (LTPA) password and keys, and so on.

Operator
The operator role has monitor permissions and can change the run-time state. For example, the operator can start or stop services.

Configurator
The configurator role has monitor permissions and can change the WebSphere Application Server configuration.

Deployer
The deployer role can complete both configuration actions and run-time operations on applications.

Monitor
The monitor role has the least permissions. This role primarily confines the user to viewing the application server configuration and current state.

adminsecuritymanager
The adminsecuritymanager role has privileges for managing users and groups from within the administrative console and determines who has access to modify users and groups using administrative role mapping. Only the adminsecuritymanager role can map users and groups to administrative roles, and by default, AdminId is granted to the adminsecuritymanager.

iscadmins
The iscadmins role has administrator privileges for managing users and groups from within the administrative console only.

Note: To manage users and groups, click **Users and Groups** in the console navigation tree. Click either **Manage Users** or **Manage Groups**.

Data type: String
Range: Administrator, Operator, Configurator, Deployer, Monitor, and iscadmins

Note: Other arbitrary administrative roles might also be visible in the administrative console collection table. Other contributors to the console might create these additional roles, which can be used for applications that are deployed to the console.

Role (CORBA naming service users):

Specifies naming service user roles.

A number of naming roles are defined to provide degrees of authority that are needed to perform certain application server naming service functions. The authorization policy is only enforced when global security is enabled. The following roles are valid: CosNamingRead, CosNamingWrite, CosNamingCreate, and CosNamingDelete.

The roles now have authority levels from low to high:

CosNamingRead
You can query the application server name space by using, for example, the Java Naming and Directory Interface (JNDI) lookup method. The EVERYONE special-subject is the default policy for this role.

CosNamingWrite
You can perform write operations such as JNDI bind, rebind, or unbind, plus CosNamingRead operations.

CosNamingCreate
You can create new objects in the name space through operations such as JNDI createSubcontext and CosNamingWrite operations.

CosNamingDelete
You can destroy objects in the name space, for example using the JNDI destroySubcontext method and CosNamingCreate operations.

Data type: String
Range: CosNamingRead, CosNamingWrite, CosNamingCreate and CosNamingDelete

Login status (Administrative user roles):

Specifies whether the user is active or inactive.

Administrative group roles and CORBA naming service groups

Use the Administrative Group Roles page to give groups specific authority to administer application servers through tools such as the administrative console or wsadmin scripting. The authority requirements are only effective when administrative security is enabled. Use the Common Object Request Broker Architecture (CORBA) naming service groups page to manage CORBA Naming Service groups settings.

To view the Console Groups administrative console page, complete either of the following steps:

- Click **Security > Global security > Administrative Group Roles**.
- Click **Users and Groups > Administrative Group Roles**.

To view the CORBA naming service groups administrative console page, click **Environment > Naming > CORBA Naming Service Groups**.

Click **Refresh All** to automatically update the node agent and all of the nodes when a new user is created with the Administrator or Admin Security Manager role. When you click **Refresh All**, you do not need to manually restart the node agent under an existing Administrator before the new user is recognized with one of these roles. This button automatically invokes the AuthorizationManager refreshAll MBean method. To invoke this method manually, read about Fine-grained administrative security in heterogeneous and single-server environments.

Group (CORBA naming service groups):

Identifies CORBA naming service groups.

In previous releases of WebSphere Application Server, there were two default groups: ALL AUTHENTICATED and EVERYONE. However, EVERYONE is now the only default group, and it provides CosNamingRead privileges only.

Data type: String
Range: EVERYONE

Role (CORBA naming service groups):

Identifies naming service group roles.

A number of naming roles are defined to provide the degrees of authority that are needed to perform certain application server naming service functions. The authorization policy is only enforced when global security is enabled.

Four name space security roles are available: CosNamingRead, CosNamingWrite, CosNamingCreate, and CosNamingDelete. The roles have authority levels from low to high:

Cos Naming Read
You can query the application server name space using, for example, the Java Naming and Directory Interface (JNDI) lookup method. The EVERYONE special-subject is the default policy for this role.

Cos Naming Write
You can perform write operations such as JNDI bind, rebind, or unbind, and CosNamingRead operations. The ALL_AUTHENTICATED special-subject is the default policy for this role.

Cos Naming Create
You can create new objects in the name space through operations such as JNDI createSubcontext and CosNamingWrite operations. The ALL_AUTHENTICATED special-subject is the default policy for this role.

Cos Naming Delete
You can destroy objects in the name space, for example using the JNDI destroySubcontext method and CosNamingCreate operations. The ALL_AUTHENTICATED special-subject is the default policy for this role.

Data type: String
Range: CosNamingRead, CosNamingWrite, CosNamingCreate, and CosNamingDelete

Group (Administrative group roles):

Specifies groups.

The ALL_AUTHENTICATED and the EVERYONE groups can have the following role privileges: Administrator, Configurator, Operator, and Monitor.

Data type:	String
Range:	ALL_AUTHENTICATED, EVERYONE

Role (Administrative group roles):

Specifies user roles.

The following administrative roles provide different degrees of authority needed to perform certain application server administrative functions:

Administrator
The administrator role has operator permissions, configurator permissions, and the permission that is required to access sensitive data, including server password, Lightweight Third Party Authentication (LTPA) password and keys, and so on.

Operator
The operator role has monitor permissions and can change the run-time state. For example, the operator can start or stop services.

Configurator
The configurator role has monitor permissions and can change the application server configuration.

Deployer
The deployer role can perform both configuration actions and runtime operations on applications.

Monitor
The monitor role has the least permissions. This role primarily confines the user to viewing the application server configuration and current state.

iscadmins
The iscadmins role has administrator privileges for managing users and groups from within the administrative console only.

Note: To manage users and groups, click **Users and Groups** in the console navigation tree. Click either **Manage Users** or **Manage Groups**.

Auditor
The auditor can view and modify the configuration settings for the security auditing subsystem. The auditor role includes the monitor role.

Data type:	String
Range:	Administrator, Operator, Configurator, Monitor, Deployer and iscadmins

Note: Other arbitrary administrative roles might also be visible in the administrative console collection table. Other contributors to the console might create these additional roles, which can be used for applications that are deployed to the console.

Assigning users to naming roles

Use this task to assign users to naming roles by using the administrative console.

About this task

The following steps are needed to assign users to naming roles. In the administrative console, click **Environment > Naming**, and click **CORBA Naming Service Users** or **CORBA Naming Service Groups**.

Procedure

1. Click **Add** on the CORBA Naming Service Users or the CORBA Naming Service Groups panel.

2. To add a new naming service user, follow the instructions on the page to specify a user, and select one or more roles. Once the user is added to the "Mapped to role" list, click **OK**. The specified user is mapped to one or more security roles.
3. To add a new naming service group, follow the instructions on the page to specify either a group name or a Special subject, highlight one or more roles, and click **OK**. The specified group or special subject are mapped to one or more the security roles
4. To remove a user or group assignment, go to the **CORBA Naming Service Users** or **CORBA Naming Service Groups** panel. Select the check box next to the user or group that you want to remove and click **Remove**.
5. To manage the set of users or groups to display, expand the **Filter** folder on the right panel, and modify the filter text box. For example, setting the filter to `user*` displays only users with the `user` prefix.
6. After modifications are complete, click **Save** to save the mappings. Restart the server for the changes to take effect.

Example

The default naming security policy is to grant all users read access to the CosNaming space and to grant any valid user the privilege to modify the contents of the CosNaming space. You can perform the previously mentioned steps to restrict user access to the CosNaming space. However, use caution when changing the naming security policy. Unless a Java Platform, Enterprise Edition (Java EE) application has clearly specified its naming space access requirements, changing the default policy can result in unexpected org.omg.CORBA.NO_PERMISSION exceptions at runtime.

Propagating administrative role changes to Tivoli Access Manager

These steps provide an example of how to migrate the `admin-authz.xml` file.

About this task

Additions and changes to console users and groups are not automatically added to the Tivoli Access Manager object space after the Java Authorization Contract for Containers (JACC) provider for Tivoli Access Manager is configured. Changes to console users and groups are saved in the `admin-authz.xml` file and this file must be migrated before any changes take effect. The JACC provider for Tivoli Access Manager includes the **migrateEAR** migration utility for incorporating console user and group changes into the Tivoli Access Manager object space.

Note: The **migrateEAR** utility is used to migrate the changes made to console users and groups after the JACC provider for Tivoli Access Manager is configured. The utility does not need to run for changes and additions to console users and groups made prior to the configuration of the JACC provider for Tivoli Access Manager because the changes made to the `admin-authz.xml` and `naming-authz.xml` files are automatically migrated at configuration time. Furthermore, the migration tool does not need to run before deploying standard Java Platform, Enterprise Edition (Java EE) applications; Java EE application policy deployment is also performed automatically.

For example, if you wanted to migrate the `admin-authz.xml` file, perform the following steps:

Procedure

1. Change to the *app_server_root*`/bin` directory where the `migrateEAR` utility is located.
2. Run the **migrateEAR** utility to migrate the data contained in the `admin-authz.xml` file. Use the parameter descriptions that are listed in “migrateEAR utility for Tivoli Access Manager” on page 1685.

   For example:

```
migrateEAR -profileName default
-j profile_root/config/cells/cell_name/xml_filename
-a sec_master
-p password
```

```
-w wsadmin
-d o=ibm,c=us
-c file:profile_root/etc/pd/PdPerm.properties
-z Roles
```

where *xml_filename* might be `admin-authz.xml` or `naming-authz.xml`.

- The `-j` parameter defaults to the file: *profile_root*`/config/cells/`*cell_name*`/admin-authz.html`
- The `-c` parameter defaults to the file: *profile_root*`/etc/pd/PdPerm.properties`. The output of the utility is logged in the `pdwas_migrate.log` file. The `pdwas_migrate.log` file is created in the *profile_root*`/logs` directory.
- The *-profile_name* parameter is optional and defaults to the default profile name.
- The `-z Roles` parameter is optional and when specified adds a subdirectory under the current directory structure in which to store the role mapping. For example,

```
/WebAppServer/deployedResouces/Roles
```

If `-z Roles` is not specified, the role mapping is stored in the current directory structure. For example,

```
/WebAppServer/deployedResouces
```

A status message is displayed when the migration completes. Output of the utility is logged to the `pdwas_migrate.log` file, which is created in the directory where the utility is run. Check the log file after each migration. If the log file displays errors, check the last recorded transaction, correct the source of the error, and rerun the migration utility. If the migration is unsuccessful, verify that you supplied the correct values for the `-c` and `-j` options.

3. WebSphere Application Server does not require a restart for the changes to take effect.

migrateEAR utility for Tivoli Access Manager

The **migrateEAR** utility migrates changes made to console users and groups in the `admin-authz.xml` and `naming-authz.xml` files into the Tivoli Access Manager object space.

Syntax

```
migrateEAR -profile_name default
-j fully_qualified_filename
-a Tivoli_Access_Manager_administrator_ID
-p Tivoli_Access_Manager_administrator_password
-w WebSphere_Application_Server_administrator_user_name
-d user_registry_domain_suffix
-c PdPerm.properties_file_location
[-z role_mapping_location]
```

Attention:

- The `-j` parameter defaults to the file: *profile_root*`/config/cells/`*cell_name*`/admin-authz.html`
- The `-c` parameter defaults to: `file:`*profile_root*`/etc/pd/PdPerm.properties`. The output of the utility is logged in the `pdwas_migrate.log` file. The `pdwas_migrate.log` file is created in the *profile_root*`/logs` directory.
- The *-profile_name* parameter is optional and defaults to the default profile name.

Parameters

-a*Tivoli_Access_Manager_administrator_ID*

The administrative user identifier. The administrative user must have the privileges required to create users, objects, and access control lists (ACLs). For example, `-a sec_master`.

This parameter is optional. When the parameter is not specified, you are prompted to supply it at run time.

-c *PdPerm.properties_file_location*

The Uniform Resource Indicator (URI) location of the `PdPerm.properties` file that is configured by the pdwascfg utility. When WebSphere Application Server is installed in the default location, the URI is:

file:*profile_root*/etc/pd/PdPerm.properties

-d *user_registry_domain_suffix*
The domain suffix for the user registry to use. For example, for Lightweight Directory Access Protocol (LDAP) user registries, this value is the domain suffix, such as: "o=ibm,c=us"

You can use the **pdadmin user show** command to display the distinguished name (DN) for a user.

-j *fully_qualified_pathname*
The fully qualified path and file name of the Java 2 Platform, Enterprise Edition application archive file ,admin-authz.xml or the roles definitions file naming-authz.xml that is used for a naming operation authorization. Optionally, this path can also be a directory of an expanded enterprise application. For example, when WebSphere Application Server is installed in the default location, the path to the data files to migrate includes:

profile_root/config/cells/*cell_name*

-p *Tivoli_Access_Manager_administrator_password*
The password for the Tivoli Access Manager administrative user. The administrative user must have the privileges that are required to create users, objects, and access control lists (ACLs). For example, you can specify the password for the -a sec_master administrative user as -p myPassword.

When this parameter is not specified, the user is prompted to supply the password for the administrative user name.

-w *WebSphere_Application_Server_administrator_user_name*
The user name that is configured in the WebSphere Application Server security user registry field as the administrator. This value matches the account that you created or imported in “Creating the security administrative user for Tivoli Access Manager” on page 1651. Access permission for this user is needed to create or update the Tivoli Access Manager protected object space.

When the WebSphere Application Server administrative user does not already exist in the protected object space, it is created or imported. In this case, a random password is generated for the user and the account is set to not valid. Change this password to a known value and set the account to valid.

A protected object and access control list (ACL) are created. The administrative user is added to the pdwas-admin group with the following ACL attributes:

T Traverse permission

i Invoke permission

WebAppServer
You can overwrite the action group name. The default name is WebAppServer. This action group name and the matching root object space can be overwritten when the migration utility is run with the **-r** option.

-z *role_mapping_location*
The location where the role mapping is to be stored when migrating administration applications. The default location is to place the role mapping in the current directory structure, such as:

/WebAppServer/deployedResouces

Specifying the -z option adds another directory level in which to store the role mapping. For example, if you specify -z Roles in the migrateEAR utility, the role mapping is stored in the directory structure as follows:

/WebAppServer/deployedResouces/Roles

Comments

This utility migrates security policy information from deployment descriptors or enterprise archive files to Tivoli Access Manager for WebSphere Application Server. The script calls com.tivoli.pdwas.migrate.Migrate the Java class.

Before you invoke the script, you must run the **setupCmdLine** script from the Qshell command line. You can find this file in the *profile_root*/bin directory, where *profile_root* is your installation path. In a default installation, *profile_root* is *app_server_rootBase*.

The script is dependent on finding the correct environment variables for the location of prerequisite software.

To enable a new user access to the administrative group in WebSphere Application Server, it is recommended that the user be added to the pdwas-admin group after JACC has been enabled. You can enter the administrative primary ID (adminID) in the group. This is required when the serverID is not the same as the adminID.

The following is an example of this command:

```
pdadmin> group modify pdwas-admin add adminID
```

Return codes

The utility can return the following exit status codes:

0 The command completed successfully.

1 The command failed.

Assigning users from a foreign realm to the admin-authz.xml

Operating with the administrative agent and job manager topology allows more situations where you might need to add an administrative user from a different registry into your administrative authorization table (admin-authz.xml). Each administrative user that needs to be added requires the "accessID" format of the user from the remote registry. When that user finally is active in the local cell, the authorization table will already have that accessID that is required. This task demonstrates how this assignment of users is performed.

Procedure

1. You need to determine the accessId for a user on the remote registry. To do this, you call the following wsadmin task and query based on a user filter. The following example illustrates a query from the registry realm "BIRKT60" with a userFilter of "localuser*". This query returns any user from this realm that begins with "localuser". The resulting accessId is the one you need to specify in the target administrative authorization table in the following step. Connect to the sending administrative process:

   ```
   wsadmin> $AdminTask listRegistryUsers {-securityRealmName BIRKT60 -displayAccessIds true -userFilter localuser*}
   {name BIRKT60\localuser@BIRKT60}
   {accessId user:BIRKT60/S-1-5-21-3033296400-14683092-2821094880-1007}
   ```

2. Add "localuser" to the target admin-authz.xml using the following wsadmin task. Connected to the receiving administrative process:

   ```
   wsadmin> $AdminTask mapUsersToAdminRole {-roleName administrator -userids {localuser }
   -accessids {user:BIRKT60/S-1-5-21-3033296400-14683092-2821094880-1007 }}
   ```

3. Save the changes.

Results

This task updates the admin-authz.xml in the receiving administrative process to allow a "cross-realm authorization" to succeed. The example illustrated here was for a LocalOS registry user. Performing the same task for an LDAP accessId produces results that look more like a realm and distinguished name (DN).

Note: If you change your realm you must repeat this process with the new realm name.

Fine-grained administrative security

In releases prior to WebSphere Application Server version 6.1, users granted administrative roles could administer all of the resources under the cell. WebSphere Application Server is now more fine-grained, meaning that access can be granted to each user per resource.

For example, users can be granted configurator access to a specific instance of a resource only (an application, an application server or a node). Users cannot access any other resources outside of the resources assigned to them. The administrative roles are now per resource rather than to the entire cell. However, there is a cell-wide authorization group for backward compatibility. Users assigned to administrative roles in the cell-wide authorization group can still access all of the resources within the cell.

Note: Nodes prior to WebSphere Application Server Version 6.1 in a mixed cell environment are filtered out of resource mapping.

To achieve this instance-based security or fine-grained security, resources that require the same privileges are placed in a group called the *administrative authorization group* or *authorization group*. Users can be granted access to the authorization group by assigning to them the required administrative role.

Fine-grained administrative security can also be used in single-server environments. Various applications in the single server can be grouped and placed in different authorization groups. Therefore, there are different authorization constraints for different applications. Note that the server itself cannot be part of any authorization group in a single-server environment.

You can assign users and groups to the adminsecuritymanager role on the cell level through wsadmin scripts and the administrative console. Using the adminsecuritymanager role, you can assign users and groups to the administrative user roles and administrative group roles.

When fine grained administrative security is used, users granted the adminsecuritymanager role can manage authorization groups. See “Administrative roles and naming service authorization” on page 1615 for detailed explanations of all administrative roles.

An administrator cannot assign users and groups to the administrative user roles and administrative group roles, including the adminsecuritymanager role. See “Administrative roles” on page 1623 for more details.

There are several administrative security commands that can be used to create authorization groups, map resources to authorization groups, and to assign users to administrative roles within the authorization groups. Following are some examples using wsadmin:

- **Create a new authorization group:**

```
$AdminTask createAuthorizationGroup {-authorizationGroupName authGroup1}
```

- **Deleting an authorization group:**

```
$AdminTask deleteAuthorizationGroup {-authorizationGroupName groupName}
```

- **Add resources to an authorization group:**

```
$AdminTask addResourceToAuthorizationGroup
{-authorizationGroupName groupName -resourceName Application=app1}
```

- **Remove resources from an authorization group:**

```
$AdminTask removeResourceFromAuthorizationGroup
{-authorizationGroupName groupName -resourceName Application=app1}
```

- **Add user IDs to roles in an authorization group:**

```
$AdminTask mapUsersToAdminRole {-authorizationGroupName groupName
-roleName administrator -userids user1}
```

- **Add group IDs to roles in an authorization group:**

```
$AdminTask mapGroupsToAdminRole {-authorizationGroupName groupName
-roleName administrator -groupids group1}
```

- **Remove user IDs from roles in an authorization group:**

```
AdminTask removeUsersFromAdminRole {-authorizationGroupName
groupName -roleName administrator -userids user1}
```

- **Remove group IDs from roles in an authorization group:**

```
$AdminTask removeGroupsFromAdminRole {-authorizationGroupName
groupName -roleName administrator -groupids group1}
```

Resources that can be added to an authorization group

You can add only resources of the following types to an authorization group:

- Cell
- Node
- ServerCluster
- Server
- Application
- NodeGroup

If a resource is not one of the types listed above, its parent resource will be used.

A resource can only belong to one authorization group. However, there is a containment relationship among resources. If a parent resource belongs to a different authorization group than that of its child resource, the child resource implicitly will belong to multiple authorization groups. You cannot add the same resource to more than one authorization group.

The following diagram shows the containment relationship among resources:

The privileges required for actions on resources depend on two factors:

- The authorization group of the administrative resource. If a user is granted access to an authorization group, all of the resources in that group will be included.
- The containment relationship of the resource. If a user is granted access to a parent resource, all of the children resources will be included.

Keystore management requires a user to have cell-level administrative privileges because they are created and managed at the cell level. Fine-grained security access to a specific resource does not allow management of the associated keystores.

Table 137. Privileges required to access various administrative resources. The privileges required to access various administrative resources are shown in the following table:

Resource	Action	Required roles
Server	Start, stop, runtime operations	Server-operator, node-operator, cell-operator
Server	New, delete	Node-configurator, cell-configurator
Server	Edit configuration	Server-configurator, node-configurator, cell-configurator
Server	View configuration, runtime status	Server-monitor, node-monitor, cell-monitor
Node	Restart, stop, sync	Node-operator, Cell-operator
Node	Add, delete	Cell-configurator
Node	Edit configuration	Node-configurator, cell-configurator
Node	View configuration, runtime status	Node-monitor, cell-monitor
Cluster	Start, stop, runtime operations	Cluster-operator, cell-operator
Cluster	New, delete	Cell-configurator
Cluster	Edit configuration	Cluster-configurator, cell-configurator

Table 137. Privileges required to access various administrative resources (continued). The privileges required to access various administrative resources are shown in the following table:

Resource	Action	Required roles
Cluster	View configuration, runtime status	Cluster-monitor, cell-monitor
Cluster member	Start, stop, runtime operations	Server-operator, cluster-operator, node-operator, cell-operator
Cluster member	New, delete	Node-configurator, cell-configurator
Cluster member	Edit configuration	Server-configurator, cluster-configurator, node-configurator, cell-configurator
Cluster member	View configuration, runtime status	Server-monitor, cluster-monitor, node-monitor, cell-monitor
Application	All operations	Refer to the section "Deployer roles" in “Administrative roles” on page 1623.
Node, cluster	Add, delete	Cell-configurator

The *server-operator* role is the operator role of the authorization group to which the server instance is part of. Similarly, the *node-operator* role is in the operator role of the authorization group to which the node instance is part of.

To use fine-grained administrative security in the administrative console, a user should be granted a monitor role at the cell level at minimum. However, to login using wsadmin, a user should be granted a monitor role for any authorization group.

Example: Using fine-grained security.

The following scenarios describe the use of fine-grained administrative security, particularly the new deployment role.

Deployment role scenario 1.

In the following scenario, there are four applications configured on server S1, as shown in the following table. Each application must be isolated so that the administrator of one application cannot modify another application. Assume that only user1 can manage application A1, user2 can manage applications A2 and A3, and only user3 can manage application A4.

Note: It is not recommended to have an application in one group and its target server in another group. However, that is not always possible. It is common to have many applications on one server. It is still sometimes necessary to isolate the administration of applications running on the same server.

One example is an Application Service Provider (ASP), where a single application server can have multiple vendor applications. In this instance the server administrator is responsible for installing all of the vendor applications. Once applications are installed, each vendor can manage their own application without interfering with other vendor's applications.

Table 138. Deployment role scenario 1 applications.

This table lists the Deployment role scenario 1 applications.

Application	Server	Node
A1	S1	N1
A2	S1	N1
A3	S1	N1
A4	S1	N1

We can configure authorization groups as shown in the diagram below:

In the diagram, application A1 is in authorization group G1, applications A2 and A3 are in authorization group G2, and application A4 is in authorization group G3.

A deployer role is assigned from authorization group G1 to user1, from authorization group G2 to user2, and from authorization group G3 to user3.

Consequently, user1 can perform all of the operations on application A1, user2 on applications A2 and A3, and user3 on application A4. Since all applications share the same server, we cannot put the same server on all authorization groups. Only a cell-level administrator can install an application. After the installation of an application is complete, the deployer of each application can modify their own. To start and stop the server, cell-level administrative authority is required. This type of scenario is useful in an ASP environment.

Deployment role scenario 2.

In the following scenario, a group of applications require the same administrative roles to one server. In this example, applications A1 and A2 are related applications, and can be administrated by one set of administrators. They are running on the same server (S1). Applications A3 and A4 require a different set of administrators, and are running on servers S2 and S3 respectively.

Table 139. Deployment role scenario 2 applications.

This table lists the Deployment role scenario 2 applications.

Application	Server	Node
A1	S1	N1
A2	S1	N1
A3	S2	N2
A4	S3	N3

Scenarios that can be applied directly in customer environments.

Each developer must be able to modify the configuration for their server, and they must be able to install their application onto that server. They also must be able to start and stop the server as well as the application on the server.

Developers also must be able to configure the server so that they can debug any problems they run into. They must have the ability to update or modify the application being developed. The administrative authorization group for this developer includes at least one server and any applications that the developer installs on that server.

In the following example, developers of authorization group G1 have a new application (A11). They can install and target that new application only on servers within authorization group G1. Also, they can place that new application in their authorization group (G1).

ASP environment scenario.

In this scenario, the customer is an ASP. They have their own customers to whom they provide application serving function. They want to enable their customers to administer and monitor their applications, but not to see or administer applications for different customers. In this example, however, the ASP has internal staff administrators whose job it is to maintain the servers.

This internal ASP staff administrator might need to move an application from one server to another to ensure that an application remains available. The internal ASP staff administrator should be able to stop and start the servers and to change their configuration.

In contrast, the ASP customer administrator should not be able to stop or start servers. However, the ASP customer administrator should be able to update their applications running on those servers. The administrative authorization group for the internal ASP administrator can be the whole cell or can include a subset of servers, nodes, clusters and applications. The administrative authorization group for the customer administrator only includes those applications that the customer has paid to have served by this ASP.

When updating the configuration repository, run the admin scripts from the deployment manager so that the fine grain admin security rules will be in effect when admin scripts are run from the deployment manager side.

The following diagram contains a scenario where two different customers have two different types of applications, and can manage their own applications. However, the servers and nodes on which the applications are running are isolated from their customers. The servers and nodes can only be maintained by the internal administrators. In addition, the customers cannot target their applications on a different server. This can only be performed by the internal administrator or internal deployers.

Regional organization scenario.

In this scenario, the customer is a large global company. The company's nodes and servers are organized so as to provide application serving for different regions (or alternatively, different lines of business). They want representatives from the different regional areas to be able to monitor and administer the nodes and servers associated with that region. However, they do not want the regional administer to be able to effect any node and server associated with a different region.

The administrative authorization group for each regional representative includes the nodes, servers, clusters and applications associated with that region.

For example, consider a company that provides multiple services, such as a financial institution that provides services like credit card accounts, brokerage accounts, banking accounts, or travel accounts. Each of these services can be separate applications, and the administrator for each of these applications must also be different. The following figure shows one way to configure such a system:

The following figure shows how the resources in such a system can be grouped to isolate administrators from each other:

Note that the nodes are not part of any authorization group. Therefore, a trade application administrator cannot stop a server on any of the nodes, and is prevented from stopping a travel application.

The same system can be configured in another way as shown below:

The following figure shows how the resources in such a system can be grouped to isolate administrators from each other:

New Administrative Authorization Group

Use this page to create a new administrative authorization group and to specify the associated administrative resources.

To view this administrative console page, click **Security** > **Administrative Authorization Groups** > **New**.

You must be logged into the administrative console with cell-level **AdminSecurityManager** authority, or the primary administrative ID can make these changes as well.

Name:

Use to identify the new administrative authorization group. The name should be descriptive of the group's role, or purpose, and should be unique in the cell structure. Using a non-unique name results in an error and a failure to create the new administrative authorization group. This is a required field.

Resources:

Select the resources from the Resource section to which you want the new administrative authorization group to control access.

Resources that are displayed in black text are available for selection.

Resources that are displayed in grey are already members of a different administrative authorization group. Therefore, these resources are not available for inclusion in the new administrative authorization group. When a resource is a member of a different authorization group, the name of the group displays next to the resource name. For example: server_1 (group_1)

The available filtering options are the following. Each option includes all the resources that are associated with that specific filtering option.

All scopes
The default view that displays the authorization group tree.

Clusters
All of the resources associated with the clusters.

Web Servers
All of the resources associated with the web servers.

Business-level applications
All of the resources associated with the business-level applications.

Servers
All of the resources associated with the servers.

Nodes
All of the resources associated with the nodes.

Applications
All of the resources associated with the applications.

Assets
All of the resources associated with the assets.

Node Groups
All of the resources associated with the node groups.

Assigned scopes
Displays all of the scopes explicitly assigned to the current authorization group.

Administrative Authorization Group collection
Use this page to create, delete or to edit an existing administrative authorization group.

To view this administrative console page, click **Security** > **Administrative Authorization Groups**.

You must be logged into the administrative console with cell-level **AdminSecurityManager** authority, or the primary administrative ID can make these changes as well.

Name:

The name field specifies the current name of the administrative authorization group. You can edit the name of the administrative authorization group during the creation process only. After the authorization group is created, you cannot modify the name. The specified name must be unique within the cell structure. Otherwise, a non-unique name results in an error.

New:

Select to create a new administrative authorization group.

Delete:

Select to remove an existing administrative authorization group.

Note: You must select an administrative authorization group before selecting **Delete**.

Creating a fine-grained administrative authorization group using the administrative console
You can create a fine-grained administrative authorization group by selecting administrative resources to be part of the authorization group. You can assign users or groups to this new administrative authorization group and also give them access to the administrative resources contained within.

Before you begin

You must be logged into the administrative console with cell-level **Admin Security Manager** authority, or the primary administrative ID can make these changes as well.

Procedure
1. Navigate to **Security** > **Administrative Authorization Groups** > **New**.
2. Type a name for the administrative authorization group into the **Name** field. This is a required field. The name must be unique within the cell structure. If the name is not unique then the new administrative authorization group is not created at the end of this procedure.
3. Select the resources from the Resource section to which you want the new administrative authorization group to control access.

   Resources that are displayed in black text are available for selection.

   Resources that are displayed in grey are already members of a different administrative authorization group. Therefore, these resources are not available for inclusion in the new administrative authorization group. When a resource is a member of a different authorization group, the name of the group displays next to the resource name. For example: server_1 (group_1)

Your filtering options include the following:

- Nodes. (All of the resources associated with the nodes.)
- Servers. (All of the resources associated with the servers.)
- Web servers. (All of the resources associated with the web servers.)
- Clusters. (All of the resources associated with the clusters.)
- Applications. (All of the resources associated with the applications.)
- Node groups. (All of the resources associated with the Node Groups.)
- All scopes. (The default view that displays the authorization group tree.)
- Assigned scopes. (Displays all of the scopes explicitly assigned to the current authorization group.)

4. Click **OK** or **Apply**.
5. If you want to associate a user role to this new administrative authorization group, do the following:
   a. Click **Administrative user roles** located under the Additional Properties section. The available user roles are the following:

      Administrator

      An individual or group that uses the administrator role has the operator and configurator privileges plus additional privileges that are granted solely to the administrator role. For example, an administrator can complete the following tasks:

      - Modify the server user ID and password.
      - Configure authentication and authorization mechanisms.
      - Enable or disable administrative security.
      - Enable or disable Java 2 security.
      - Change the Lightweight Third Party Authentication (LTPA) password and generate keys.
      - Create, update, or delete users in the federated repositories configuration.
      - Create, update, or delete groups in the federated repositories configuration.

      Note: An administrator cannot map users and groups to the administrator roles.
      .

      Configurator

      An individual or group that uses the configurator role has the monitor privilege plus the ability to change the WebSphere Application Server configuration. The configurator can perform all the day-to-day configuration tasks. For example, a configurator can complete the following tasks:

      - Create a resource.
      - Map an application server.
      - Install and uninstall an application.
      - Deploy an application.
      - Assign users and groups-to-role mapping for applications.
      - Set up Java 2 security permissions for applications.
      - Customize the Common Secure Interoperability Version 2 (CSIv2), Secure Authentication Service (SAS), and Secure Sockets Layer (SSL) configurations.

        Important: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

      Deployer

      Users granted this role can perform both configuration actions and runtime operations on applications..

Operator

An individual or group that uses the operator role has monitor privileges plus ability to change the runtime state. For example, an operator can complete the following tasks:

- Stop and start the server.
- Monitor the server status in the administrative console.

Monitor

An individual or group that uses the monitor role has the least amount of privileges. A monitor can complete the following tasks:

- View the WebSphere Application Server configuration.
- View the current state of the Application Server.

Admin Security Manager

Using the Admin Security Manager role, you can assign users and groups to the administrative user roles and administrative group roles. However, an administrator cannot assign users and groups to the administrative user roles and administrative group roles including the Admin Security Manager roles.

b. Click **Add...**. The New User page is displayed.

c. Select the appropriate role(s) from the **Role(s)** list box.

d. Select a user or users by entering text in the **Search string** field, and then click **Search.**. Click the arrow to add the available user or users to the **Mapped to role** field. You can select multiple users and roles by clicking **Select All**.

e. Click **OK**. You are returned to the Administrative User Roles page. The new users are displayed in the Administrative User Roles table along with their appropriate roles.

f. Repeat steps B through E for each new user to whom you want to map a role.

6. If you want to associate a group to this new user role, do the following:

   a. Click **Administrative group roles** located under the Additional Properties section.

   b. Click **Add...**. The New Group page is displayed.

   c. Select the appropriate role or roles from the **Role(s)** list box.

   d. Select a user or users by entering text in the **Search string** field, and then click **Search.**. Click the arrow to add the available user or users to the **Mapped to role** field. You can select multiple users and roles by clicking **Select All**.

   e. Select either the **Select from special subjects** or **Map Groups As Specified Below** option.

      If you select the **Select from special subjects** option, you can select the EVERYONE, ALL AUTHENTICATED, or ALL AUTHENTICATED IN TRUSTED REALMS values.

      A list of user groups and roles are displayed in the **Available** and **Mapped to role** fields. Select the user groups from the **Available** field and then select the roles from the **Mapped to role** field to which you want the group or groups associated. You can select multiple groups and roles.

   f. Click **OK**. You are returned to the Administrative Group Roles page. The new group is displayed in the Administrative Group Roles table along with the role of the new group.

   g. Repeat steps B through E for each new group to whom you want to map a role.

7. If you want to create another administrative authorization group, click **Apply**. The current administrative authorization group is created. Repeat steps 2 through 6 to create another administrative authorization group.

8. If you do not want to create another administrative authorization group, click **OK**.

Editing a fine-grained administrative authorization group using the administrative console

You can add or remove administrative resources to an administrative authorization group or edit an existing one.

Before you begin

You must be logged into the administrative console with the cell-level **AdminSecurityManager** authority or as the primary administrative user.

Procedure

1. Navigate to **Security** > **Administrative Authorization Groups**. The Administrative Authorization Groups page displays a table that lists all of the current administrative authorization groups available in the cell.
2. Click on the administrative authorization group in the table that you want to edit.
3. To add or remove resources from the administrative authorization group, select or clear them in the Resource section of the edit page. Resources displayed in black text are available for selection or clearing. Resources displayed in grey text are members of a different administrative authorization group and therefore cannot be edited for the current administrative authorization group.

   The available filtering options are the following. Each option includes all the resources that are associated with that specific filtering option.

   - All scopes. (The default view that displays the authorization group tree.)
   - Clusters. (All of the resources associated with the clusters.)
   - Web servers. (All of the resources associated with the Web servers.)
   - Business-level applications. (All of the resources associated with the business-level applications.)
   - Servers. (All of the resources associated with the servers.)
   - Nodes. (All of the resources associated with the nodes.)
   - Applications. (All of the resources associated with the applications.)
   - Assets. (All of the resources associated with the assets.)
   - Node groups. (All of the resources associated with the node groups.)
   - Assigned scopes. (Displays all of the scopes explicitly assigned to the current authorization group).

   Nodes prior to WebSphere Application Server Version 6.1 in a mixed cell environment are filtered out of resource mapping.
4. To remove a user or a group, do the following:
   a. To delete users, click **Administrative user roles** under the Additional Properties section. To delete groups, click **Administrative group roles** under the Additional Properties section. The appropriate edit page displays a table that lists all of the current users or groups and their associated roles, along with the user's login status.
   b. Click the check box beside the name of the current user or group and then click **Remove**. The current user or group is no longer associated with the role and the role is no longer listed in the table. It is now ready to have a new user or group assigned to it.
5. If you want to add or to reassign a user or group role to this administrative authorization group, do the following:
   a. To add a user, click **Administrative user roles** under the Additional Properties section. To add a group, click **Administrative group roles** located under the Additional Properties section. The appropriate edit page displays a table that lists all of the current users or groups and their associated roles. The available roles are:

      Administrator

      An individual or group that uses the administrator role has the operator and configurator privileges plus additional privileges that are granted solely to the administrator role. For example, an administrator can complete the following tasks:

      - Modify the server user ID and password.
      - Configure authentication and authorization mechanisms.
      - Enable or disable administrative security.

- Enable or disable Java 2 security.
- Change the Lightweight Third Party Authentication (LTPA) password and generate keys.
- Create, update, or delete users in the federated repositories configuration.
- Create, update, or delete groups in the federated repositories configuration.

Note: An administrator cannot map users and groups to the administrator roles.

Configurator
An individual or group that uses the configurator role has the monitor privilege plus the ability to change the WebSphere Application Server configuration. The configurator can perform all the day-to-day configuration tasks. For example, a configurator can complete the following tasks:

- Create a resource.
- Map an application server.
- Install and uninstall an application.
- Deploy an application.
- Assign users and groups-to-role mapping for applications.
- Set up Java 2 security permissions for applications.
- Customize the Common Secure Interoperability Version 2 (CSIv2), Security Authentication Service (SAS), and Secure Sockets Layer (SSL) configurations.

Important: SAS is supported only between Version 6.0.x and previous version servers that have been federated in a Version 6.1 cell.

Deployer
Users granted this role can perform both configuration actions and runtime operations on applications.

Operator
An individual or group that uses the operator role has monitor privileges plus ability to change the runtime state. For example, an operator can complete the following tasks:

- Stop and start the server.
- Monitor the server status in the administrative console.

.

Monitor
An individual or group that uses the monitor role has the least amount of privileges. A monitor can complete the following tasks:

- View the WebSphere Application Server configuration.
- View the current state of the Application Server.

Admin Security Manager
Using the Admin Security Manager role, you can assign users and groups to the administrative user roles and administrative group roles. However, an administrator cannot assign users and groups to the administrative user roles and administrative group roles including the Admin Security Manager role.

b. Click **Add...**.

c. To add a new user or group, follow the instructions on the page to specify either a user name, group name, or Special subject. Highlight the desired role(s), and click **OK**. The specified users, groups, or Special subject are mapped to the security roles.

Fine-grained administrative security in heterogeneous and single-server environments

Fine-grained administrative security can be used in heterogeneous or single-server environments with some restrictions.

Fine-grained administrative security in a heterogeneous environment

Fine-grained administrative security in a heterogeneous environment has the following restrictions:

- Only nodes that are running WebSphere Application Server Version 8.0 can be part of an administrative authorization group.
- Only servers that are running in a WebSphere Application Server Version 8.0 node can be part of an administrative authorization group.
- Only applications that are targeted on servers running on WebSphere Application Server Version 8.0 can be part of an administrative authorization group.
- If a cluster spans nodes of multiple releases, it cannot be part of an administrative authorization group.
- If a cluster spans nodes of multiple releases, none of its members can be part of an administrative authorization group.
- If an application is targeted on a cluster that spans multiple releases, that application cannot be part of an administrative authorization group.

Fine-grained administrative security in a single-server environment

You can also use fine-grained administrative security in a single-server environment. Various applications in the single server can be grouped and placed in different authorization groups. Therefore, different authorization constraints might exist for different applications.

Life cycle of fine-grained administrative resource

An administrative resource that was once part of an authorization group continues to be part of that authorization group until one of the following events occurs:

- The administrative resource is removed from the authorization group. In this instance, the administrative resource belongs to the cell-level authorization group.
- The administrative resource is removed from the configuration. In this instance, the administrative resource does not exist in the configuration, but still exists in the authorization group. Remove this administrative resource from the authorization group.

After the administrative resource is removed from the authorization group, the administrative authorizer runtime must be notified by using the AuthorizationManager refreshAll MBean method.

The **refreshAll** command must be invoked after AdminConfig.save() and sync nodes. For example:

JACL:

```
// get AuthorizationGroup Mbean
wsadmin> set agBean [$AdminControl queryNames
type=AuthorizationGroupManager,process=dmgr,*]

wsadmin> $AdminControl invoke &agBean refreshAll
```

JYTHON:

```
// get AuthorizationGroup Mbean
wsadmin> set agBean
AdminControl.queryNames('type=AuthorizationGroupManager,process=dmgr,*')

wsadmin> AdminControl.invoke(agBean, 'refreshAll')
```

The server restart is no longer needed.

Securing communications

WebSphere Application Server provides several methods to secure communication between a server and a client.

About this task

Note: WebSphere Application Server provides several methods for securing communication between a server and a client. New in this release are functions that ensure secure communication between a server and a client. These functions focus on certificate management, authentication, and ensuring trust among the application server, administrative agent, and job manager. The new functions include:

- Creating and using a certificate authority (CA) clients to enable a CA to request, query, and revoke certificates.
- Creating and using chained personal certificates to allow a certificate to be signed with a longer life span.
- Creating and revoking certificate authority (CA) certificates to ensure secure communication between the CA client and the CA server.

The following topics are covered in this section:

Procedure

- Secure communications using Secure Sockets Layer
- Creating an SSL configuration
- Creating a keystore configuration
- Creating a certificate authority (CA) client
- Deleting a certificate authority (CA) client
- Viewing or Modifying a certificate authority (CA) client
- Creating a keystore configuration for a preexisting keystore file
- Creating a self-signed certificate
- Creating a certificate authority request
- Extracting a signer certificate from a personal certificate
- Retrieving signers from a remote SSL port
- Adding a signer certificate to a keystore
- Adding a signer certificate to the default signers keystore
- Exchanging signer certificates in a keystore
- Configuring certificate expiration monitoring
- Key management for cryptographic uses
- Creating a key set configuration
- Creating a key set group configuration

Secure communications using Secure Sockets Layer (SSL)

The Secure Sockets Layer (SSL) protocol provides transport layer security including authenticity, data signing, and data encryption to ensure a secure connection between a client and server that uses WebSphere Application Server. The foundation technology for SSL is *public key cryptography*, which guarantees that when an entity encrypts data using its public key, only entities with the corresponding private key can decrypt that data.

WebSphere Application Server uses Java Secure Sockets Extension (JSSE) as the SSL implementation for secure connections. JSSE is part of the Java 2 Standard Edition (J2SE) specification and is included in

the IBM implementation of the Java Runtime Extension (JRE). JSSE handles the handshake negotiation and protection capabilities that are provided by SSL to ensure secure connectivity exists across most protocols. JSSE relies on X.509 certificate-based asymmetric key pairs for secure connection protection and some data encryption. Key pairs effectively encrypt session-based secret keys that encrypt larger blocks of data. The SSL implementation manages the X.509 certificates.

Managing X.509 certificates

Secure communications for WebSphere Application Server require digitally-signed X.509 certificates. The contents of an X.509 certificate, such as its distinguished name and expiration, are either signed by a certificate authority (CA), signed by a root certificate in **NodeDefaultRootStore** or **DmgrDefaultRootStore**, or are self-signed. When a trusted CA signs an X.509 certificate, WebSphere Application Server identifies the certificate and freely distributes it. A certificate must be signed by a CA because the certificate represents the identity of an entity to the general public. Server-side ports that accept connections from the general public must use CA-signed certificates. Most clients or browsers already have the signer certificate that can validate the X.509 certificate so signer exchange is not necessary for a successful connection.

You can trust the identity of a self-signed X.509 certificate only within a peer in a controlled environment, such as internal network communications, accepts the signer certificate. To complete a trusted handshake, you must first send a copy of the entity certificate to every peer that connects to the entity.

CA, chained, and self-signed X.509 certificates reside in Java *keystores*. JSSE provides a reference to the keystore in which a certificate resides. You can select from many types of keystores, including Java Cryptographic Extension (JCE)-based and hardware-based keystores. Typically, each JSSE configuration has two Java keystore references: a keystore and a *truststore*. The keystore reference represents a Java keystore object that holds personal certificates. The truststore reference represents a Java keystore object that holds signer certificates.

A personal certificate without a private key is an X.509 certificate that represents the entity that owns it during a handshake. Personal certificates contain both public and private keys. A signer certificate is an X.509 certificate that represents a peer entity or itself. Signer certificates contain just the public key and verify the signature of the identity that is received during a peer-to-peer handshake.

For more information, see “Extracting a signer certificate from a personal certificate” on page 1818

For more information about keystores, see “Keystore configurations for SSL” on page 1715.

Signer exchange

When you configure an SSL connection, you can exchange signers to establish trust in a *personal certificate* for a specific entity. Signer exchange enables you to extract the X.509 certificate from the peer keystore and add it into the truststore of another entity so that the two peer entities can connect. The signer certificate also can originate from a CA as a root signer certificate or a chained certificate's root signer certificate or an intermediate signer certificate. You can also extract a *signer certificate* directly from a self-signed certificate, which is the X.509 certificate with the public key.

Figure 1 illustrates a hypothetical keystore and truststore configuration. An SSL configuration determines which entities can connect to other entities, and the peer connections that are trusted by an SSL handshake. If you do not have the necessary signer certificate, the handshake fails because the peer cannot be trusted.

Figure 31. Signer exchange

In this example, the truststore for Entity A contains three signers. Entity A can connect to any peer as long as one of the three signers validates its personal certificate. For example, Entity A can connect to Entity B or Entity C because the signers can trust both signed personal certificates. The truststore for Entity-B contains one signer. Entity B is able to connect to Entity C only, and only when the peer endpoint is using certificate Entity-C Cert 1 as its identity. The ports that use the other personal certificate for Entity C are not trusted by Entity B. Entity C can connect to Entity A only.

In the example, the self-signed configuration seems to represent a one-to-one relationship between the signer and the certificate. However, when a CA signs a certificate, it typically signs many at a time. The advantage of using a single CA signer is that it can validate personal certificates that are generated by the CA for use by peers. However, if the signer is a public CA, you must be aware that the signed certificates might have been generated for another company other than your target entity. For your internal communications, private CAs and self-signed certificates are preferable to public CAs because they enable you to isolate the connections that you want to occur and prevent those that you do not want to occur.

SSL configurations

An SSL configuration comprises a set of configuration attributes that you can associate with an *endpoint* or set of endpoints in the WebSphere Application Server topology. The SSL configuration enables you to create an SSLContext object, which is the fundamental JSSE object that the server uses to obtain SSL socket factories. You can manage the following configuration attributes:

- An alias for the SSLContext object
- A handshake protocol version
- A keystore reference
- A truststore reference
- A key manager
- One or more trust managers
- A security level selection of a cipher suite grouping or a specific cipher suite list
- A certificate alias choice for client and server connections

To understand the specifics of each SSL configuration attribute, see “SSL configurations” on page 1706.

Selecting SSL configurations

In previous releases of WebSphere Application Server, you can reference an SSL configuration only by selecting the SSL configuration alias directly. Each secure endpoint was denoted by an alias attribute that references a valid SSL configuration within a repertoire of SSL configurations. When you made a single configuration change, you had to re-configure many alias references across the various processes. Although the current release still supports direct selection, this approach is no longer recommended.

The current release provides improved capabilities for managing SSL configurations and more flexibility when you select SSL configurations. In this release, you can select from the following approaches:

Programmatic selection

You can set an SSL configuration on the running thread prior to an outbound connection. WebSphere Application Server ensures that most system protocols, including Internet Inter-ORB Protocol (IIOP), Java Message Service (JMS), Hyper Text Transfer Protocol (HTTP), and Lightweight Directory Access Protocol (LDAP), accept the configuration. See “Programmatically specifying an outbound SSL configuration using JSSEHelper API” on page 1772

Dynamic selection

You can associate an SSL configuration dynamically with a specific target host, port, or outbound protocol by using a predefined selection criteria. When it establishes the connection, WebSphere Application Server checks to see if the target host and port match a predefined criteria that includes the domain portion of the host. Additionally, you can predefine the protocol for a specific

outbound SSL configuration and certificate alias selection. See “Dynamic outbound selection of Secure Sockets Layer configurations” on page 1717 for more information.

Dynamic outbound selection of Secure Sockets Layer configurations is based on connection information being available for the server so that the server can match up the outbound protocol, host, or port when the creation of the client socket takes place in com.ibm.websphere.ssl.protocol.SSLSocketFactory. For WebSphere admin connectors like SOAP and Remote Method Invocation (RMI), connection information is placed on the thread and is available for dynamic outbound selection to take place. The dynamic outbound selection process replies on connection information being setup when SSL properties are retrieved similar to what is described in “Programmatically specifying an outbound SSL configuration using JSSEHelper API” on page 1772.

When the outbound connection is being made from customer written applications, parts of the connection information may not be available. Some of these applications make API calls to a protocol to make the connection. The API ultimately then calls one of the createSocket() methods in com.ibm.websphere.ssl.protocol.SSLSocketFactory to complete the process. gotcha: All of the connection information for dynamic outbound selection might not be available, and you may have to adjust the dynamic outbound selection connection filter and fill in an asterisk (*) for the missing part of the connection information. As an example, the openConnection() call on a URL object ultimately calls `createSocket(java.net.Socket socket, String host, int port, boolean autoClose)`. The connection information can be built with the host and port provided, but there is no protocol provided. In this case, a wild card, asterisk (*), should be used for the protocol part of the dynamic selection connection information.

Most of the createSocket() methods take a host or IP address and a port as parameters. The dynamic outbound selection connection filter can be built with the host and port. The default method, createSocket(), without any parameters does not contain any information to build the outbound selection connection filter unless the socket factory was instantiated with connection information, If no connection information is available, then you should consider using one of the other methods of selecting a SSL configuration describes in this topic, "Programmatic selection" can be good choice.

Direct selection

You can select an SSL configuration by using a specific alias, as in past releases. This method of selection is maintained for backwards compatibility because many applications and processes rely on alias references.

Scope selection

You can associate an SSL configuration and its certificate alias, which is located in the keystore associated with that SSL configuration, with a WebSphere Application Server management scope. This approach is recommended to manage SSL configurations centrally. You can manage endpoints more efficiently because they are located in one topology view of the cell. The inheritance relationship between scopes reduces the number of SSL configuration assignments that you must set.

Each time you associate an SSL configuration with a cell scope, the node scope within the cell automatically inherits the configuration properties. However, when you assign an SSL configuration to a node, the node configuration overrides the configuration that the node inherits from the cell. Similarly, all of the application servers for a node automatically inherit the SSL configuration for that node unless you override these assignments. Unless you override a specific configuration, the topology relies on the rules of inheritance from the cell level down to the endpoint level for each application server.

Note: If your applications are relying on SSL configurations that were set as individual settings for each SSL configuration in the topology, but your application servers have inherited the SSL configuration as deployed from the cell level down to the endpoint level, then there is the

possibility of communication errors occurring among servers (for example, handshake errors). You need to ensure that your applications are operating consistent with the central management of SSL configurations.

The topology view displays an inbound tree and outbound tree. You can make different SSL configuration selections for each side of the SSL connection based on what that server connects to as an outbound connection and what the server connects to as an inbound connection. See "Central management of SSL configurations" on page 1718 for more information.

The runtime uses an order of precedence for determining which SSL configuration to choose because you have many ways to select SSL configurations. Consider the following order of precedence when you select a configuration approach:

1. Programmatic selection. If an application sets an SSL configuration on the running thread using the com.ibm.websphere.ssl.JSSEHelper application programming interface (API), the SSL configuration is guaranteed the highest precedence.
2. Dynamic selection criteria for outbound host and port or protocol.
3. Direct selection.
4. Scope selection. Scope inheritance guarantees that the endpoint that you select is associated with an SSL configuration and is inherited by every scope beneath it that does not override this selection.

Default chained certificate configuration

By default, WebSphere Application Server creates a unique chained certificate for each node. The chained certificate is signed with a root, a self-signed certificate stored in the **DmgrDefaultRootStore** or **NodeDefaultRootStore**. WebSphere Application Server no longer relies on a self-signed certificate or the default or dummy certificate that is shipped with the product. The `key.p12` default keystore and the trust.p12 truststore are stored in the configuration repository within the node directory. The default root certificate is stored in the root-key.p12 in the configuration repository under the node directory.

All of the nodes put their signer certificates from the default root certificate in this common truststore (`trust.p12`). Additionally, after you federate a node, the default SSL configuration is automatically modified to point to the common truststore, which is located in the cell directory. The node can now communicate with all other servers in the cell.

All default SSL configurations contain a keystore with the name suffix DefaultKeyStore, a truststore with the name suffix DefaultTrustStore and a rootstore with the name suffix DefaultRootStore. These default suffixes instruct the WebSphere Application Server runtime to add the root signer of the personal certificate to the common truststore. If a truststore name does not end with DefaultKeyStore, the keystores root signer certificates are not added to the common truststore when you federate the server. You can change the default SSL configuration, but you must ensure that the correct trust is established for administrative connections, among others.

For more information, see "Default chained certificate configuration in SSL" on page 1724.

Certificate expiration monitoring

Certificate monitoring ensures that the default chained certificate for each node is not allowed to expire. The certificate expiration monitoring function issues a warning before certificates and signers are set to expire. Those certificates and signers that are located in keystores managed by the WebSphere Application Server configuration can be monitored. You can configure the expiration monitor to automatically replace a certificate. A chained certificate will be recreated based on the same data used for the initial creation and sign it with the same root certificate that signed the original certificate. A self-signed certificate or chained certificate is also recreated based upon the same data that is used for the initial creation.

The monitor also can automatically replace old signers with the signers from the new chained or self-signed certificates in keystores that are managed by WebSphere Application Server. The existing signer exchanges that occurred by the runtime during federation and by administration are preserved. For more information, see “Certificate expiration monitoring in SSL” on page 1732.

The expiration monitor is configured to replace chained personal certificates that are signed by a root certificate in **DmgrDefaultRootStore** or **NodeDefaultRootStore**. The certificate is renewed using the same root certificate that was used to sign the original certificate.

The monitor also can automatically replace old signers with the signers from the new self-signed certificates in keystores that are managed by WebSphere Application Server. The existing signer exchanges that occurred by the runtime during federation and by administration are preserved. For more information, see “Certificate expiration monitoring in SSL” on page 1732.

WebSphere Application Server clients: signer-exchange requirements

A new chained certificate is generated for each node during its initial startup. To ensure trust, clients must be given the root signers to establish a connection. The introduction of chained certificates in the current release makes this process simpler. Rather than exchanging the signer of a short lived self-signed certificate, you can exchange the long lived root signer which will allow for preserved trust across personal certificate renewals. In addition, you can gain access to the signer certificates of various nodes to which the client must connect with any one of the following options (for more information, see “Secure installation for client signer retrieval in SSL” on page 1727):

- A signer exchange prompt enables you to import signer certificates that are not yet present in the truststores during a connection to a server. By default, this prompt is enabled for administrative connections and can be enabled for any client SSL configuration. When this prompt is enabled, any connection that is made to a server where the signer is not already present offers the signer of the server along with the certificate information and a Secure Hash Algorithm (SHA) digest of the certificate for verification. The user is given a choice whether to accept these credentials. If the credentials are accepted, the signer is added to the truststore of the client until the signer is explicitly removed. The signer exchange prompt does not occur again when connecting to the same server unless the personal certificate changes.

  Attention: It is unsafe to trust a signer exchange prompt without verifying the SHA digest. An unverified prompt can originate from a browser when a certificate is not trusted.
- You can run a retrieveSigners administrative script from a client prior to making connections to servers. To download signers, no administrative authority is required. To upload signers, you must have Administrator role authority. The script downloads all of the signers from a specified server truststore into the specified client truststore and can be called to download only a specific alias from a truststore. You can also call the script to upload signers to server truststores. When you select the CellDefaultTrustStore truststore as the specified server truststore and common truststore for a cell, all of the signers for that cell are downloaded to the specified client truststore, which is typically ClientDefaultTrustStore. For more information, see “retrieveSigners command” on page 1730.
- You can physically distribute to clients the trust.p12 common truststore that is located in the cell directory of the configuration repository. When doing this distribution, however, you must ensure that the correct password has been specified in the `ssl.client.props` client SSL configuration file. The default password for this truststore is `WebAS`. Change the default password prior to distribution. Physical distribution is not as effective as the previous options. When changes are made to the personal certificates on the server, automated exchange can fail.

Dynamic SSL configuration changes

The SSL runtime for WebSphere Application Server maintains listeners for most SSL connections. A change to the SSL configuration causes the inbound connection listeners to create a new SSLContext object. Existing connections continue to use the current SSLContext object. Outbound connections automatically use the new configuration properties when they are attempted.

Make dynamic changes to the SSL configuration during off-peak hours to reduce the possibility of timing-related problems and to prevent the possibility of the server starting again. If you enable the runtime to accept dynamic changes, then change the SSL configuration and save the `security.xml` file. Your changes take effect when the new `security.xml` file reaches each node.

Note: If configuration changes cause SSL handshake failures, administrative connectivity failures also can occur, which can lead to outages. In this case, you must re-configure the SSL connections then perform manual node synchronization to correct the problem. You must carefully complete any dynamic changes. It is highly recommended that you perform changes to SSL configurations on a test environment prior to making the same changes to a production system. For more information, see “Dynamic configuration updates in SSL” on page 1735.

Built-in certificate management

Certificate management that is comparable to iKeyMan functionality is now integrated into the keystore management panels of the administrative console. Use built-in certificate management to manage personal certificates, certificate requests, and signer certificates that are located in keystores. Additionally, you can remotely manage keystores. For example, you can manage a file-based keystore that is located outside the configuration repository on any node from the deployment manager. You also can remotely manage hardware cryptographic keystores from the deployment manager.

With built-in certificate management, you can replace a chained or self-signed certificate along with all of the signer certificates scattered across many truststores and retrieve a signer from a remote port by connecting to the remote SSL host and port and intercepting the signer during the handshake. The certificate is first validated according to the certificate SHA digest, then the administrator must accept the validated certificate before it can be placed into a truststore.

When you make a certificate request, you can send it to a certificate authority (CA). When the certificate is returned, you can accept it within the administrative console. For more information, see “Certificate management in SSL” on page 1736.

Tip: Although iKeyMan functionality still ships with WebSphere Application Server, configure keystores from the administrative console using the built-in certificate management functionality. iKeyMan is still an option when it is not convenient to use the administrative console. For more information, see “Certificate management using iKeyman prior to SSL” on page 1735.

AdminTask configuration management

The SSL configuration management panels in the administrative console rely primarily on administrative tasks, which are maintained and enhanced to support the administrative console function. You can use wsadmin commands from a Java console prompt to automate the management of keystores, SSL configurations, certificates, and so on.

SSL configurations

Secure Sockets Layer (SSL) configurations contain attributes that enable you to control the behavior of both the client and the server SSL endpoints. You can assign SSL configurations to have specific management scopes. The scope that an SSL configuration inherits depends upon whether you create it using a cell, node, server, or endpoint link in the configuration topology.

When you create an SSL configuration, you can set the following SSL connection attributes:

- Keystore
- Default client certificate for outbound connections
- Default server certificate for inbound connections
- Truststore
- Key manager for selecting a certificate

- Trust manager or managers for establishing trust during the handshake
- Handshaking protocol
- Ciphers for negotiating the handshake
- Client authentication support and requirements

You can manage an SSL configuration using any of the following methods:
- Central management selection
- Direct reference selection
- Dynamic outbound connection selection
- Programmatic selection

Using the administrative console, you can manage all of the SSL configurations for WebSphere Application Server. From the administrative console, click **Security > SSL certificates and key management > Manage endpoint security configurations > Inbound | Outbound >** *SSL_configuration*. You can view an SSL configuration at the level it was created and in the inherited scope below that point in the topology. If you want the entire cell to view an SSL configuration, you must create the configuration at the cell level in the topology.

SSL configuration in the security.xml file

The attributes defining an SSL configuration repertoire entry for a specific management scope are stored in the `security.xml` file. The scope determines the point at which other levels in the cell topology can see the configuration, as shown in the following example:

```
<repertoire xmi:id="SSLConfig_1" alias="NodeDefaultSSLSettings"
managementScope="ManagementScope_1" type="JSSE">
<setting xmi:id="SecureSocketLayer_1" clientAuthentication="false"
clientAuthenticationSupported="false" securityLevel="HIGH" enabledCiphers=""
jsseProvider="IBMJSSE2" sslProtocol="SSL_TLS" keyStore="KeyStore_1"
trustStore="KeyStore_2" trustManager="TrustManager_1" keyManager="KeyManager_1"
clientKeyAlias="default" serverKeyAlias="default"/>
</repertoire>
```

The SSL configuration attributes from the previous code sample are described in Table 1.

Table 140. security.xml Attributes. This table lists the security.xml Attributes.

security.xml attribute	Description	Default	Associated SSL property
xmi:id	The xml:id attribute represents the unique identifier for this XML entry and determines how the SSL configuration is linked to other XML objects, such as SSLConfigGroup. This system-defined value must be unique.	The administrative configuration service defines the default value.	None. This value is used only for XML associations.
alias	The alias attribute defines the name of the SSL configuration. Direct selection uses the alias attribute and the node is not prefixed to the alias. Rather, the management scope takes care of ensuring that the name is unique within the scope.		com.ibm.ssl.alias
managementScope	The managementScope attribute defines the management scope for the SSL configuration and determines the visibility of the SSL configuration at runtime.		The managementScope attribute is not mapped to an SSL property. However, it confirms whether or not the SSL configuration is associated with a process.

Table 140. security.xml Attributes (continued). This table lists the security.xml Attributes.

security.xml attribute	Description	Default	Associated SSL property
type	The type attribute defines the Java Secure Socket Extension (JSSE) or System Secure Sockets Layer (SSSL) configuration option. JSSE is the SSL configuration type for most secure communications within WebSphere Application Server.	The default is JSSE.	com.ibm.ssl.sslType
clientAuthentication	The clientAuthentication attribute determines whether SSL client authentication is required.	The default is false.	com.ibm.ssl.clientAuthentication
clientAuthenticationSupported	The clientAuthenticationSupported attribute determines whether SSL client authentication is supported. The client does not have to supply a client certificate if it does not have a client certificate. **Attention:** When you set the clientAuthentication attribute to `true`, you override the value that is set for the clientAuthenticationSupported attribute.	The default is false.	com.ibm.ssl.client.AuthenticationSupported
securityLevel	The securityLevel attribute determines the cipher suite group. Valid values include STRONG (128-bit ciphers), MEDIUM (40-bit ciphers), WEAK (for all ciphers without encryption), and CUSTOM (if the cipher suite group is customized. When you set the enabledCiphers attribute with a specific list of ciphers, the system ignores this attribute.	The default is STRONG.	com.ibm.ssl.securityLevel
enabledCiphers	You can set the enabledCiphers attribute to specify a unique list of cipher suites. Separate each cipher suite in the list with a space.	The default is the securityLevel attribute for cipher suite selection.	com.ibm.ssl.enabledCipherSuites
jsseProvider	The jsseProvider attribute defines a specific JSSE provider.	The default is IBMJSSE2.	com.ibm.ssl.contextProvider
sslProtocol	The sslProtocol attribute defines the SSL handshake protocol. Valid options include: SSLv2 (client-side only), SSLv3, SSL, SSL_TLS, TLSv1, and TLS values. The SSL option includes SSLv2 and SSLv3 values. The TLS option includes the TLSv1 value. SSL_TLS, which is the most interoperable protocol, includes all these values and defaults to a Transport Layer Security (TLS) handshake.	The default is SSL_TLS.	com.ibm.ssl.protocol

Table 140. security.xml Attributes (continued). This table lists the security.xml Attributes.

security.xml attribute	Description	Default	Associated SSL property
keyStore	The keyStore attribute defines the keystore and attributes of the keyStore instance that the SSL configuration uses for key selection.		For more information, see Keystore configurations.
trustStore	The trustStore attribute defines the key store that the SSL configuration uses for certificate signing verification.		A trustStore is a logical JSSE term. It signifies a key store that contains signer certificates. Signer certificates validate certificates that are sent to WebSphere Application Server during an SSL handshake.
keyManager	The keyManager attribute defines the key manager that WebSphere Application Server uses to select keys from a key store. A JSSE key manager controls the javax.net.ssl.X509KeyManager interface. A custom key manager controls the javax.net.ssl.X509KeyManager and the com.ibm.wsspi.ssl.KeyManagerExtendedInfo interfaces. The com.ibm.wsspi.ssl.KeyManagerExtendedInfo interface provides more information from WebSphere Application Server.	The default is IbmX509.	com.ibm.ssl.keyManager defines a well-known key manager and accepts the algorithm and algorithm|provider formats, for example IbmX509 and IbmX509|IBMJSSE2. com.ibm.ssl.customKeyManager defines a custom key manager and takes precedence over the other keyManager properties. This class must implement javax.net.ssl.X509KeyManager and can implement com.ibm.wsspi.ssl.KeyManagerExtendedInfo. For more information, see "Key manager control of X.509 certificate identities" on page 1711
trustManager	The trustManager determines which trust manager or list of trust managers to use for determining whether to trust the peer side of the connection. A JSSE trust manager implements the javax.net.ssl.X509TrustManager interface. A custom trust manager might also implement com.ibm.wsspi.ssl.TrustManagerExtendedInfo interface to get more information from the WebSphere Application Server environment.	The default is IbmPKIX, which can be configured for certificate revocation list (CRL) verification when the certificate contains a CRL distribution point. The other option is IbmX509.	com.ibm.ssl.trustManager defines a well-known trust manager, which is required for most handshake situations. com.ibm.ssl.trustManager performs certificate expiration checking and signature validation. You can define com.ibm.ssl.customTrustManagers with additional custom trust managers that are called during an SSL handshake. Separate additional trust managers with the vertical bar (|) character. For more information, see "Trust manager control of X.509 certificate trust decisions"

Client SSL configurations are managed using the `ssl.client.props` properties file. The `ssl.client.props` file is located in the ${USER_INSTALL_ROOT}/properties directory for each profile. For more information about configuring this file, see the "ssl.client.props client configuration file" on page 1783. Specifying any javax.net.ssl system properties will override the corresponding property in the `ssl.client.props` file.

Trust manager control of X.509 certificate trust decisions:

The role of the trust manager is to validate the Secure Sockets Layer (SSL) certificate that is sent by the peer, which includes verifying the signature and checking the expiration date of the certificate. A Java Secure Socket Extension (JSSE) trust manager determines if the remote peer can be trusted during an SSL handshake.

WebSphere Application Server has the ability to call multiple trust managers during an SSL connection. The default trust manager does the standard certificate validation; custom trust manager plug-ins run customized validation such as host name verification. For more information, see "Example: Developing a custom trust manager for custom SSL trust decisions" on page 1765

When a trust manager is configured in a server-side SSL configuration, the server calls the isClientTrusted method. When a trust manager is configured in a client-side SSL configuration, the client calls the isServerTrusted method. The peer certificate chain is passed to these methods. If the trust manager chooses not to trust the peer information, it might produce an exception to force a handshake failure.

Optionally, WebSphere Application Server provides the com.ibm.wsspi.ssl.TrustManagerExtendedInfo interface so that additional information can be passed to the trust manager. For more information, see the com.ibm.wsspi.ssl.TrustManagerExtendedInfo interface.

Default IbmX509 trust manager

The default IbmX509 trust manager, which is used in the following code sample, establishes trust by performing standard certificate validation.

```
<trustManagers xmi:id="TrustManager_1132357815717" name="IbmX509" provider="IBMJSSE2"
algorithm="IbmX509" managementScope="ManagementScope_1132357815717"/>
```

The trust manager provides a signer certificate to verify the peer certificate that is sent during the handshake. The signers who are added to the truststore for the SSL configuration must be trustworthy. If you do not trust the signers or do not want to allow others to connect to your servers, consider removing default root certificates from certificate authorities (CA). You might also remove any certificates if you cannot verify their origination.

Default IbmPKIX trust manager

You can use the default IbmPKIX trust manager to replace the IbmX509 trust manager, which is shown in the following code sample:

```
<trustManagers xmi:id="TrustManager_1132357815719" name="IbmPKIX" provider="IBMJSSE2"
algorithm="IbmPKIX" trustManagerClass="" managementScope="ManagementScope_1132357815717">
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_1132357815717"
name="com.ibm.security.enableCRLDP" value="true" type="boolean"/>
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_1132357815718"
name="com.ibm.jsse2.checkRevocation" value="true" type="boolean"/>
  </trustManagers>

<trustManagers xmi:id="TrustManager_managementNode_2" name="IbmPKIX" provider=
"IBMJSSE2" algorithm="IbmPKIX" trustManagerClass=""
managementScope="ManagementScope_managementNode_1">
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_1" name="com.ibm.se
curity.enableCRLDP" value="false" type="boolean" displayNameKey="" nlsRangeKey="
" hoverHelpKey="" range="" inclusive="false" firstClass="false"/>
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_2" name="com.ibm.js
se2.checkRevocation" value="false" type="boolean" displayNameKey="" nlsRangeKey=
"" hoverHelpKey="" range="" inclusive="false" firstClass="false"/>
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_3" name="ocsp.enabl
e" value="false" type="String" displayNameKey="" nlsRangeKey="" hoverHelpKey=""
range="" inclusive="false" firstClass="false"/>
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_4" name="ocsp.respo
nderURL" value="http://ocsp.example.net:80" type="String" displayNameKey=""
nlsRangeKey="" hoverHelpKey="" range="" inclusive="false" firstClass="false"/>
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_5" name="ocsp.respo
nderCertSubjectName" value="" type="String" displayNameKey="" nlsRangeKey="" hov
erHelpKey="" range="" inclusive="false" firstClass="false"/>
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_6" name="ocsp.respo
nderCertIssuerName" value="" type="String" displayNameKey="" nlsRangeKey="" hove
rHelpKey="" range="" inclusive="false" firstClass="false"/>
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_7" name="ocsp.respo
nderCertSerialNumber" value="" type="String" displayNameKey="" nlsRangeKey="" ho
verHelpKey="" range="" inclusive="false" firstClass="false"/>
</trustManagers>
```

See “Example: Enabling certificate revocation checking with the default IbmPKIX trust manager” on page 1712 for additional information in using the default IbmPKIX trust manager.

In addition to its role of standard certificate verification, the IbmPKIX trust manager checks for OCSP properties and for certificates that contain certificate revocation list (CRL) distribution points. This process is known as extended CRL checking. When you select a trust manager, its associated properties are automatically set as Java System properties so that the IBMCertPath and IBMJSSE2 providers are aware that CRL checking is enabled.

Custom trust manager

You can define a custom trust manager to perform additional trust checking, which is based upon the needs of the environment. For example, in one environment, you might enable connections from the same Transmission Control Protocol (TCP) subnet only. The com.ibm.wsspi.ssl.TrustManagerExtendedInfo interface provides extended information about the connection that is not provided by the standard Java Secure Sockets Extension (JSSE) javax.net.ssl.X509TrustManager interface. The configured trustManagerClass attribute determines which class is instantiated by the runtime, as shown in the following code sample:

```
<trustManagers xmi:id="TrustManager_1132357815718" name="CustomTrustManager"
trustManagerClass="com.ibm.ws.ssl.core.CustomTrustManager"
managementScope="ManagementScope_1132357815717"/>
```

The trustManagerClass attribute must implement the javax.net.ssl.X509TrustManager interface and, optionally, can implement the com.ibm.wsspi.ssl.TrustManagerExtendedInfo interface.

Disabling the default trust manager

In some cases, you might not want to perform the standard certificate verification that is provided by the IbmX509 and IbmPKIX default trust managers. For example, you might be working with an internal automated test infrastructure that is not concerned with SSL client or server authentication, integrity, or confidentiality. The following sample code shows a basic custom trust manager such as com.ibm.ws.ssl.core.CustomTrustManager whose property is set to `true`.

```
com.ibm.ssl.skipDefaultTrustManagerWhenCustomDefined=true
```

You can set this property in the global properties at the top of the `ssl.client.props` file for clients or in the `security.xml` custom properties file for servers. You must configure a custom trust manager when you disable the default trust manager to prevent the server from calling the default trust manager even though it is configured. Disabling the default trust manager is not a common practice. Be sure to test the system with the disabled default trust manager in a test environment first. For more information on setting up a custom trust manager, see “Creating a custom trust manager configuration for SSL” on page 1761

Key manager control of X.509 certificate identities:

The role of a Java Secure Socket Extension (JSSE) key manager is to retrieve the certificate that is used to identify the client or server during a Secure Sockets Layer (SSL) handshake.

WebSphere Application Server provides a default key manager that can select a certificate from a keystore when you define the following SSL configuration properties:

com.ibm.ssl.keyStoreClientAlias
: Defines the alias that is chosen from the keystore for the client side of a connection. This alias must be present in the keystore.

com.ibm.ssl.keyStoreServerAlias
: Defines the alias that is chosen from the keystore for the server side of a connection. This alias must be present in the keystore.

These two properties are set automatically when you use the administrative console because the default key manager is already configured.

With WebSphere Application Server, you can configure only one key manager at a time for a given SSL configuration. If you want custom certificate selection logic on the client side, you must write a new custom key manager. The custom key manager could provide function that prompts the user to choose a certificate dynamically. Also, you can implement an extended interface so that a key manager can provide information during connection time. For more information on the extended interface, see the com.ibm.wsspi.ssl.KeyManagerExtendedInfo interface. For more information on custom key manager development, see “Creating a custom key manager for SSL” on page 1766.

Default IbmX509 key manager

The default IbmX509 key manager chooses a certificate to serve as the identity for an SSL handshake. The key manager is called to enable client authentication on either side of the SSL handshake; frequently on the server-side, and less frequently on the client side according to client and server requirements. If a keystore is not configured on the client-side and SSL client authentication is enabled, the key manager cannot select a certificate to send to the server. Therefore, the handshake fails.

The following sample code shows the key manager configuration in the `security.xml` file for an IbmX509 key manager.

```
<keyManagers xmi:id="KeyManager_1" name="IbmX509"
provider="IBMJSSE2" algorithm="IbmX509" keyManagerClass=""
managementScope="ManagementScope_1"/>
```

You do not specify the keyManagerClass class because the key manager is provided by the IBMJSSE2 provider. However, you can specify whether the key manager is a custom class implementation, in which case you must specify the keyManager class, or an algorithm name that WebSphere Application Server can start from the Java security provider framework.

Custom key manager

The following sample code shows the key manager configuration in the `security.xml` file for a custom class.

```
<keyManagers xmi:id="KeyManager_2" name="CustomKeyManager"
keyManagerClass="com.ibm.ws.ssl.core.CustomKeyManager"
managementScope="ManagementScope_1"/>
```

The custom class must implement the javax.net.ssl.X509KeyManager interface and, optionally, implement the com.ibm.wsspi.ssl.KeyManagerExtendedInfo interface to retrieve additional WebSphere Application Server information. This interface replaces the function of the default key manager because you can configure only one key manager at a time. Therefore, the custom key manager has sole responsibility for selecting the alias to use from the configured keystore. The benefit of a custom key manager is its ability, on the client side, to prompt for an alias. This process enables the user to decide which certificate to use in situations where the user knows the client certificate identity. For more information, see “Creating a custom key manager for SSL” on page 1766.

Example: Enabling certificate revocation checking with the default IbmPKIX trust manager:

The IbmPKIX trust manager is enabled in the WebSphere Application Server by default. The IbmPKIX trust manager allows certificate revocation checking to occur. You enable certificate revocation checking by using the administrative console or by manually updating the `ssl.client.props` file.

The default IbmPKIX trust manager

The IbmPKIX trust manager is enabled by default, but revocation checking is not enabled by default. The following trust manager definition for IbmPKIX reflects the default condition:

```
<trustManagers xmi:id="TrustManager_managementNode_2" name="IbmPKIX" provider=
"IBMJSSE2" algorithm="IbmPKIX" trustManagerClass=""
managementScope="ManagementScope_managementNode_1">
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_1" name="com.ibm.se
curity.enableCRLDP" value="false" type="boolean" displayNameKey="" nlsRangeKey="
" hoverHelpKey="" range="" inclusive="false" firstClass="false"/>
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_2" name="com.ibm.js
se2.checkRevocation" value="false" type="boolean" displayNameKey="" nlsRangeKey=
"" hoverHelpKey="" range="" inclusive="false" firstClass="false"/>
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_3" name="ocsp.enable
e" value="false" type="String" displayNameKey="" nlsRangeKey="" hoverHelpKey=""
range="" inclusive="false" firstClass="false"/>
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_4" name="ocsp.respo
nderURL" value="http://ocsp.example.net:80" type="String" displayNameKey=""
```

```
nlsRangeKey="" hoverHelpKey="" range="" inclusive="false" firstClass="false"/>
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_5" name="ocsp.respo
nderCertSubjectName" value="" type="String" displayNameKey="" nlsRangeKey="" hov
erHelpKey="" range="" inclusive="false" firstClass="false"/>
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_6" name="ocsp.respo
nderCertIssuerName" value="" type="String" displayNameKey="" nlsRangeKey="" hove
rHelpKey="" range="" inclusive="false" firstClass="false"/>
<additionalTrustManagerAttrs xmi:id="DescriptiveProperty_7" name="ocsp.respo
nderCertSerialNumber" value="" type="String" displayNameKey="" nlsRangeKey="" ho
verHelpKey="" range="" inclusive="false" firstClass="false"/>
</trustManagers>
```

Enabling certificate revocation checking with the default IbmPKIX trust manager

You can view and change IbmPKIX Trust Manager Custom Properties using the administrative console.

To do this,

- Click **Security > SSL certificate and key management**.
- Under Related Items, click **Trust managers**.
- Click **IbmPKIX**.
- Under Additional Properties, click **Custom properties**.

IbmPKIX custom properties

com.ibm.jsse2.checkRevocation

This property configures revocation checking for the Java Virtual Machine (JVM). This property is set to false by default because the default WebSphere certificates used for SSL communication do not contain certificate revocation list (CRL) distribution points or Online Certificate Status Protocol (OCSP) information.

Note: Since this property is a JVM property, this value is in effect for the entire application server. If the property is defined in trust managers at different scopes, the value in effect is used from the most specifically scoped IbmPKIX trust manager. For example, the property for an IbmPKIX trust manager defined at the node level overrides the property for an IbmPKIX trust manager defined at the cell level. This property is ignored for the IbmX509 trust manager.

default
false

com.ibm.security.enableCRLDP

This property configures CRL distribution point checking for the PKIX trust manager.

Note: If you enable CRL distribution point revocation checking, the certificates used for secure sockets layer (SSL) must contain a valid distribution point and the distribution point must be accessible or else SSL communication will fail and the server will not function correctly.

default
false

For certificates that do not contain an internal CRL distribution point, the following properties can used so the revocation status will be checked against a remote LDAP server containing the CRL.

com.ibm.security.ldap.certstore.host

This property specifies the LDAP server host name containing trusted certificates or certificate revocation lists. The target LDAP server host is used to obtain CA certificates or certificate revocation lists when validating a certificate and the local truststore does not contain the required certificate. The local truststore must contain the required certificates if an LDAP server is not

specified. In cases when an LDAP server is used, the root CA certificates must also be located in the local truststore as the LDAP server is not a trusted certificate store.

Note: Enabling this property in addition to the com.ibm.jsse2.checkRevocation property enables revocation checking. The remote LDAP server must contain a valid certificate revocation list and the server must be accessible. If the revocation status cannot be determined then the check will fail and SSL communication will fail and the server will not function correctly.

default
none

com.ibm.security.ldap.certstore.port
This property specifies the LDAP server port. A port value of 389 will be used by default if no LDAP server port is specified.

default
389

The following Java Development Kit (JDK) properties apply to enabling certificate revocation checking with the default IbmPKIX trust manager:

- ocsp.enable
- ocsp.responder
- ocsp.responderCertSubjectName
- ocsp.responderCertIssuerName
- ocsp.responderCertSerialNumber

These JDK properties can be set using the administrative console. You should reference Java(TM) Certification Path API Programmer's Guide - SDK 6.0 for descriptions of these properties and their allowable settings.

Note: In addition to its role of standard certificate verification, the IbmPKIX trust manager checks for certificates that contain CRL distribution points. This process is known as extended CRL checking. By default, CRL distribution point revocation checking is disabled. To enable CRL distribution point revocation checking, you must set the following properties to `true` using the administrative console:

- com.ibm.security.enableCRLDP
- com.ibm.jsse2.checkRevocation

OCSP properties and CRL properties affect certificate revocation checking. By default OCSP properties are checked first. If there is an error validating the certificate with OCSP, then validation uses a CRL distribution point instead.

When you select a trust manager, its associated properties are automatically set as Java system properties so that the IBMCertPath and IBMJSSE2 providers are aware that CRL checking is enabled or disabled. Similarly, the same applies for OCSP properties, which are java.security.Security properties.

Client considerations

You can also enable revocation checking for WebSphere application and administrative clients by directly setting the properties in the `ssl.client.props` file. An example of the `ssl.client.props` file follows:

```
#-------------------------------------------------------------------------
# Default Revocation Checking Properties
# These properties are used for certificate revocation checking with the IBM
# PKIX TrustManager.
#
# To enable CRL Distribution Points extension checking, use the system property
# com.ibm.security.enableCRLDP.
```

```
#
# OCSP checking is not enabled by default. It is enabled by setting the
# ocsp.enable property to "true".  Use of the other ocsp properties is optional.
#
# Note: Both OCSP and CRLDP checking is only effective if revocation checking
# has also been enabled by setting com.ibm.jsse2.checkRevocation to "true".
#
#-------------------------------------------------------------------------
com.ibm.jsse2.checkRevocation=false
com.ibm.security.enableCRLDP=false
#ocsp.enable=true
#ocsp.responderURL=http://ocsp.example.net
#ocsp.responderCertSubjectName=CN=OCSP Responder, O=XYZ Corp
#ocsp.responderCertIssuerName=CN=Enterprise CA, O=XYZ Corp
#ocsp.responderCertSerialNumber=2A:FF:00
```

Note: In order for these properties to be effective, you must ensure that the IbmPKIX trust manager is initialized by setting `com.ibm.ssl.trustManager=IbmPKIX`.

In addition, for revocation checking to be processed successfully on the client, you are required to turn off the signer exchange prompt. To do this, change the value of the **com.ibm.ssl.enableSignerExchangePrompt** property to `false`, in the ssl.client.props file.

For more information on these properties, see Java(TM) Certification Path API Programmer's Guide - SDK 6.0.

Keystore configurations for SSL

Use keystore configurations to define how the runtime for WebSphere Application Server loads and manages keystore types for Secure Sockets Layer (SSL) configurations.

By default, the java.security.Security.getAlgorithms("KeyStore") attribute does not display a predefined list of keystore types in the administrative console. Instead, WebSphere Application Server retrieves all of the KeyStore types that can be referenced by the java.security.KeyStore object, including hardware cryptographic, z/OS platform, IBM i platform, IBM Java Cryptography Extension (IBMJCE), and Java-based content management system (CMS)-provider keystores. If you specify a keystore provider in the `java.security` file or add it to the provider list programmatically, WebSphere Application Sever also retrieves custom keystores. The retrieval list depends upon the java.security configuration for that platform and process.

IBMJCE file-based keystores (JCEKS, JKS, and PKCS12)

A typical IBMJCE file-based keystore configuration is shown in the following sample code:

```
<keyStores xmi:id="KeyStore_1" name="NodeDefaultKeyStore"
password="{xor}349dkckdd=" provider="IBMJCE"
location="${USER_INSTALL_ROOT}/config/cells/myhostNode01Cell
/nodes/myhostNode01/key.p12" type="PKCS12" fileBased="true"
hostList="" initializeAtStartup="true" readOnly="false"
description="Default key store for myhostNode01" usage="SSLKeys"
managementScope="ManagementScope_1"/>
```

For more information about default keystore configurations, see “Default chained certificate configuration in SSL” on page 1724.

Table 1 describes the attributes that are used in the sample code.

Table 141. keystore configurations. This table describes the keystore configurations.

Attribute name	Default	Description
xmi:id	Varies	A value that issued to reference the keystore from another area in the configuration, for example, from an SSL configuration. Make this value unique within the `security.xml` file.

Table 141. keystore configurations (continued). This table describes the keystore configurations.

Attribute name	Default	Description
name	For Java Secure Socket Extension (JSSE) keystore: NodeDefaultKeyStore. For JSSE truststore: NodeDefaultTrustStore.	A name that is used to identify the keystore by sight. The name can determine if the keystore is a default keystore based upon whether the name ends with DefaultKeyStore or DefaultTrustStore.
password	The default keystore password is `WebAS`. It is recommended that this be changed as soon as possible. See Updating default key store passwords using scripting for more information.	The password that is used to access the keystore name is also the default that is used to store keys within the keystore.
description	No default	A description of the keystore.
usage	An attribute specifying what the keystore is used for.	Valid values are: SSLKeys, KeySetKeys, RootKeys, DeletedKeys, DefaultSigners, RSATokenKeys.
provider	The default provider is IBMJCE.	The Java provider that implements the type attribute (for example, PKCS12 type). The provider can be left unspecified and the first provider that implements the keystore type specified is used.
location	The default varies, but typically references a `key.p12` file or a `trust.p12` file in the node or cell directories of the configuration repository. These files are PKCS12 type keystores.	The keystore location reference. If the keystore is file-based, the location can reference any path in the file system of the node where the keystore is located. However, if the location is outside of the configuration repository, and you want to manage the keystore remotely from the administrative console or from the **wsadmin** utility, then specify the hostList attribute that contains the host name of the node where it resides.
type	The default Java crypto device keystore type is `PKCS12`.	This type specifies the keystore. Valid types can be those returned by the java.security.Security.getAlgorithms("KeyStore") attribute. These types include the following keystore types, and availability depends on the process and platform `java.security` configuration: • JKS • JCEKS • PKCS12 • PKCS11 (Java crypto device) • CMSKS • IBMi5OSKeyStore • JCERACFKS • JCECCAKS keystores (replacing JCE4758KS) - (z/OS crypto device)
fileBased	The default is `true`.	This option is required for default keystores. It indicates a file-system keystore so you can use a FileInputStream or FileOutputStream for loading and storing the keystore.
hostList	The hostList attribute is used to specify a remote hostname so that the keystore can be remotely managed. There are no remotely managed keystores by default. All default keystores are managed locally in the configuration repository and synchronized out to each of the nodes.	The option manages a keystore remotely. You can set the host name of a valid node for a keystore. When you use either the administrative console or the wsadmin utility to manage certificates for this keystore, an MBean call is made to the node where the keystore exists for the approved operation. You can specify multiple hosts, although synchronization of the keystore operations are not guaranteed. For example, one of the hosts that is listed might be down when a specific operation is performed. Therefore, use multiple hosts in this list.
initializeAtStartup	The default is `true`.	This option informs the runtime to initialize the keystore during startup. This option can be important for hardware cryptographic device acceleration.
readOnly	The default is `false`.	This option informs the configuration that you cannot write to this keystore. That is, certain update operations on the keystore cannot be attempted and are not allowed. An example of a read-only keystore type is JCERACFKS on the z/OS platform. This type is read-only from the WebSphere certificate management standpoint, but you can also update it using the keystore management facility for RACF.
managementScope	The default scope is the node scope for a base Application Server environment and the cell scope for a Network Deployment environment.	This option references a particular management scope in which you can see this keystore. For example, if a hardware cryptographic device is physically located on a specific node, then create the keystore from a link to that node in the topology view under **Security > Security Communications > SSL configurations**. You can also use management scope to isolate a keystore reference. In some cases, you might need to allow only a specific application server to reference the keystore; the management scope is for that specific server.

CMS keystores

You can set some provider-specific attributes in CMS keystores.

When you create a CMS keystore, the CMS provider is `IBMi5OSJSSEProvider`, and the CMS type is `IBMi5OSKeyStore`, as shown in the following sample code:

```
<keyStores xmi:id="KeyStore_1132071489571" name="CMSKeyStore"
password="{xor}HRYNFAtrbxEwOzpvbhw6MzM=" provider="IBMi5OSJSSEProvider"
location="${USER_INSTALL_ROOT}\profiles\AppSrv01/config/cells/myhostCell01
/nodes/myhostNode01/servers/webserver1/plugin-key.kdb" type="IBMi5OSKeyStore"
fileBased="true" createStashFileForCMS="true"
managementScope="ManagementScope_1132071489569"/>
```

Note: The IBM i keystore type `IBMi5OSKeyStore` does not recognize or generate `.sth` password stash files. Instead it keeps an internal record of the password for the `.kdb` keystore file where it is created. If the `.kdb` file is moved, the password is no longer associated with the keystore. In that case, the Digital Certificate Manager (DCM) must be used to recreate the internal record of the password for the `.kdb` key store file. For more information, see “Recreating the .kdb keystore internal password record” on page 1793.

Attention: When you create chained personal certificates or use the requestCACertificate task with the IBMi5OSKeyStore, the IBMi5OSJSSEProvider requires that the signer for each part of the chain be present in the keystore prior to creation of the new certificate. Therefore, you must import the signer into the IBMi5OSKeyStore keystore before creating the new certificate.

Hardware cryptographic keystores

For cryptographic device configuration, see “Key management for cryptographic uses” on page 1834.

You can add a slot either as the custom property, com.ibm.ssl.keyStoreSlot, or as the configuration attribute, `slot="0"`. The custom property is read before the attribute for backwards compatibility.

Dynamic outbound selection of Secure Sockets Layer configurations

WebSphere Application Server provides dynamic outbound selection that enables you to choose a specific Secure Sockets Layer (SSL) configuration and certificate alias for each outbound protocol, target host, target port, or any combination of these attributes. You can specify the dynamic selection information for outbound connections from a pure client or from a server that is acting as a client.

Before the SSL runtime for WebSphere Application Server starts an outbound connection, the runtime attempts to match the outbound protocol, target host, and target port attributes with the dynamic outbound selection information that is associated with an SSL configuration and certificate alias in the configuration.

The runtime caches both selection misses and selection hits, so the impact on performance can be minimal. However, a relationship exists between the amount of dynamic outbound selection information and its impact on the initial connection performance.

Target information during outbound connections

The dynamic outbound selection configurations are only effective when the outbound protocol uses the JSSEHelper application programming interface (API) when you select an SSL configuration with a specified connectionInfo hash map. This hash map must contain the following properties:

com.ibm.ssl.direction
The value for outbound connections is OUTBOUND.

com.ibm.ssl.remoteHost
The format should match what the protocol provides. Typically this is the canonical Domain Name Space (DNS), but it also could be the IP address.

com.ibm.ssl.remotePort
The port is target port.

com.ibm.ssl.endPointName
The value for an outbound connection must be one of the following protocol strings:

- IIOP
- HTTP
- SIP
- LDAP
- ADMIN_IPC
- ADMIN_SOAP
- BUS_TO_BUS
- BUS_CLIENT
- BUS_TO_WEBSPHERE_MQ
- WEBSPHERE_MQ_CLIENT

Central management of SSL configurations

By default, Secure Sockets Layer (SSL) configurations for servers are managed from a central location in the topology view of the administrative console. You can associate an SSL configuration and certificate alias with a specific management scope. This method is the most efficient method to manipulate and modify configurations when the server topology changes.

In prior releases, SSL configurations are managed for each process. You have to maintain individual settings for each SSL configuration in the topology. In this release of WebSphere Application Server, management control of your SSL configurations offers more options and additional flexibility. You are able to make coarse-grained changes for the entire topology using the cell-scope and also make fine-grained changes using a particular endpoint name for a specific application server process. Because the SSL configuration associations manifest an inheritance behavior, you can simplify the number of associations by referencing only the highest level management scope that needs a unique configuration.

The topology view provides the scoping mechanism. The SSL configuration inherits its scope, which can be seen as its display in the topology. The scope encompasses the level where you created the configuration and all the levels below that point. For example, when you create an SSL configuration at a specific node, that configuration can be seen by that node agent and by every application server that is part of that node. Any application server or node that is not part of this particular node can not see this SSL configuration.

Your security environment influences issues such as the uniqueness of the SSL configurations, as well as the SSL configuration and the certificate alias placement in the topology. You are also able to configure different certificate aliases and different SSL configurations for inbound connections versus outbound connections.

To configure the inbound and outbound topologies, which must be done separately in the administrative console, click **Security > SSL certificates and key management > Manage endpoint security configurations > Inbound | Outbound**.

Default centrally managed SSL configuration

The default management scope is the node scope. When a node is federated into a cell, the default SSL configurations for the node are maintained, as shown in the following sample code for the sslConfigGroups and management scopes attributes:

```
<sslConfigGroups xmi:id="SSLConfigGroup_1" name="myhostNode01"
direction="inbound" certificateAlias="default" sslConfig="SSLConfig_1"
managementScope="ManagementScope_1"/>
```

```
<sslConfigGroups xmi:id="SSLConfigGroup_2" name="myhostNode01"
direction="outbound" certificateAlias="default" sslConfig="SSLConfig_1"
managementScope="ManagementScope_1"/>

<managementScopes xmi:id="ManagementScope_1"
scopeName="(cell):myhostNode01Cell:(node):myhostNode01" scopeType="node"/>
```

The SSL configuration xmi:id "SSLConfig_1" is also federated and applicable:

```
<repertoire xmi:id="SSLConfig_1" alias="NodeDefaultSSLSettings"
managementScope="ManagementScope_1">
<setting xmi:id="SecureSocketLayer_1" clientAuthentication="true"
securityLevel="HIGH" enabledCiphers="" jsseProvider="IBMJSSE2"
sslProtocol="SSL_TLS" keyStore="KeyStore_1" trustStore="KeyStore_2"
trustManager="TrustManager_1" keyManager="KeyManager_1"/>
</repertoire>
```

The keystores that are associated with the SSLConfig_1 SSL configuration are also federated, and `key.p12` is located in the node directory of the configuration repository:

```
<keyStores xmi:id="KeyStore_1" name="NodeDefaultKeyStore"
password="{xor}HRYNFAtrbxEwOzpvbhw6MzM=" provider="IBMJCE"
location="${USER_INSTALL_ROOT}/config/cells/myhostNode01Cell/nodes
/myhostNode01/key.p12" type="PKCS12" fileBased="true" hostList=""
initializeAtStartup="true" managementScope="ManagementScope_1"/>
<keyStores xmi:id="KeyStore_2" name="NodeDefaultTrustStore"
password="{xor}HRYNFAtrbxEwOzpvbhw6MzM=" provider="IBMJCE"
location="${USER_INSTALL_ROOT}/config/cells/myhostNode01Cell
/nodes/myhostNode01/trust.p12" type="PKCS12" fileBased="true"
hostList="" initializeAtStartup="true" managementScope="ManagementScope_1"/>
```

Secure Sockets Layer node, application server, and cluster isolation

Secure Sockets Layer (SSL) enables you to ensure that any client that attempts to connect to a server during the handshake first performs server authentication. Using SSL configurations at the node, application server, and cluster scopes, you can isolate communication between severs that should not be allowed to communicate with each other over secure ports.

Before you attempt to isolate communications controlled by WebSphere Application Server, you must have a good understanding of the deployment topology and application environment. To isolate a node, application server, or cluster, you must be able to control the signers that are contained in the truststores that are associated with the SSL configuration. When the client does not contain the server signer, it cannot establish a connection to the server. By default, WebSphere uses chained certificates and each node has a unique root certificate signer. Because they the node shares the same root signer, all of the server in that node can connect to each other because they share the same root signer. However, if you use self-signed certificates, the server that created the personal certificate controls the signer, although you do have to manage the self-signed certificates. If you obtain certificates from a certificate authority (CA), you must obtain multiple CA signers because all of the servers can connect to each other if they share the same signer.

Authenticating only the server-side of a connection is not adequate protection when you need to isolate a server. Any client can obtain a signer certificate for the server and add it to its trust store. SSL client authentication must also be enabled between servers so that the server can control its connections by deciding which client certificates it can trust. For more information, see “Enabling Secure Sockets Layer client authentication for a specific inbound endpoint” on page 1777, which applies as well to enabling SSL client authentication at the cell level.

Isolation also requires that you use centrally managed SSL configurations for all or most endpoints in the cell. Centrally managed configurations can be scoped, unlike direct or end point configuration selection, and they enable you to create SSL configurations, key stores, and trust stores at a particular scope. Because of the inheritance hierarchy of WebSphere Application Server cells, if you select only the properties that you need for an SSL configuration, only these properties are defined at your selected

scope or lower. For example, if you configure at the node scope, your configuration applies to the application server and individual end point scopes below the node scope. For more information, see “Associating Secure Sockets Layer configurations centrally with inbound and outbound scopes” on page 1774, “Selecting an SSL configuration alias directly from an endpoint configuration” on page 1775, and “Associating a Secure Sockets Layer configuration dynamically with an outbound protocol and remote secure endpoint” on page 1771

When you configure the key stores, which contain cryptographic keys, you must work at the same scope at which you define the SSL configuration and not at a higher scope. For example, if you create a key store that contains a certificate whose host name is part of the distinguished name (DN), then store that keystore in the node directory of the configuration repository. If you decide to create a certificate for the application server, then store that keystore on the application server in the application server directory.

When you configure the trust stores, which control trust decisions on the server, you must consider how much you want to isolate the application servers. You cannot isolate the application servers from the node agents or the deployment manager. However, you can configure the SOAP connector end points with the same personal certificate or to share trust. Naming persistence requires IIOP connections when they pass through the deployment manager. Because application servers always connect to the node agents when the server starts, the IIOP protocol requires that WebSphere Application Server establish trust between the application servers and the node agents.

Establishing node SSL isolation

By default, WebSphere Application Server installation uses a single chained certificate for each node so you can isolate nodes easily. A common trust store, which is located in the cell directory of the configuration repository, contains all of the signers for each node that is federated into the cell. After federation, each cell process trusts all of the other cell processes because every SSL configuration references the common trust store.

You can modify the default configuration so that each node has its own trust store, and every application server on the node trusts only the node agent that uses the same personal certificate. You must also add the signer to the node trust store so that WebSphere Application Server can establish trust with the deployment manager. To isolate the node, ensure that the following conditions are met:

- The deployment manager must initiate connections to any process
- The node agent must initiate connections to the deployment manager and its own application servers
- The application servers must initiate connections to the applications servers on the same node, to its own node agent, and the deployment manager

Figure 1 shows Node Agent A contains a key.p12 keystore and a trust.p12 trust store at the node level of the configuration repository for node A.

Figure 32.

When you associate an SSL configuration with this keystore and truststore, you break the link with the cell-scoped trust store. To isolate the node completely, repeat this process for each node in the cell. WebSphere Application Server SSL configurations override the cell scope and use the node scope instead so that each process at this scope uses the SSL configuration and certificate alias that you selected at this scope. You establish proper administrative trust by ensuring that nodeA signer is in the common trust store and the cell signer is in the nodeA trust store. The same logic applies to node B as well. For more information, see “Associating Secure Sockets Layer configurations centrally with inbound and outbound scopes” on page 1774.

Establishing application server SSL isolation

Isolating application server processes from one another is more challenging than isolating nodes. You must consider the following application design and topology conditions:

- An application server process might need to communicate with the node agent and deployment manager
- Isolating application server processes from each other might disable single sign-on capabilities for horizontal propagation

If you configure outbound SSL configurations dynamically, you can accommodate these conditions. When you define a specific outbound protocol, target host, and port for each different SSL configuration, you can override the scoped configuration.

Figure 2 shows how you might isolate an application server completely, although in practice this approach would be more complicated.

Figure 33.

The dynamic configuration enables server1 on Node A to communicate with server 1 on Node B only over IIOP. The dynamic outbound rule is IIOP,nodeBhostname,*. For more information, see “Associating a Secure Sockets Layer configuration dynamically with an outbound protocol and remote secure endpoint” on page 1771

Establishing cluster SSL isolation

You can configure application servers into clusters instead of scoping them centrally at the node or dynamically at the server to establish cluster SSL isolation. While clustered servers can communicate with each other, application servers outside of the cluster cannot communicate with the cluster, thus isolating the clustered servers. For example, you might need to separate applications from different departments while maintaining a basic level of trust among the clustered servers. Using the dynamic outbound SSL configuration method described for servers above, you can easily extend the isolated cluster as needed.

Figure 3 shows a sample cluster configuration where cluster 1 contains a key.p12 with its own self-signed certificate, and a trust.p12 that is located in the config/cells/<cellname>/clusters/<clustername> directory.

Figure 34.

In the example, cluster1 might contain web applications, and cluster2 might contain EJB applications. Considering the various protocols, you decide to enable IIOP traffic between the two clusters. Your task is to define a dynamic outbound SSL configuration at the cluster1 scope with the following properties:

```
IIOP,nodeAhostname,9403|IIOP,nodeAhostname,9404|IIOP,nodeBhostname,9403|IIOP,nodeBhostname,9404
```

You must create another SSL configuration at the cluster1 scope that contains a new trust.p12 file with the cluster2 signer. Consequently, outbound IIOP requests go either to nodeAhostname ports 9403 and 9404 or to nodeBhostname ports 9403 and 9404. The IIOP SSL port numbers on these two application server processes in cluster2 identify the ports.

As you review Figure 3, notice the following features of the cluster isolation configuration:

- The trust.p12 for cluster1 contains signers that allow communications with itself (cluster1 signer), between both node agents (nodeAsigner and nodeBsigner), and with the deployment manager (cell signer).
- The trust.p12 for cluster2 contains signers that allow communications with itself (cluster2 signer), between both node agents (nodeAsigner and nodeBsigner), and with the deployment manager (cell signer).

- Node agent A and Node agent B can communicate with themselves, the deployment manager, and both clusters.

For more information, see “Associating a Secure Sockets Layer configuration dynamically with an outbound protocol and remote secure endpoint” on page 1771.

Although this article presents an overview of isolation methods from an SSL perspective, you must also ensure that non-SSL ports are closed or applications require the confidentiality constraint in the deployment descriptor. For example, you can set the CSIv2 inbound transport panel to require SSL and disable the channel ports that are not secure from the server ports configuration.

Also, you must enable SSL client authentication for SSL to enforce the isolation requirements on both sides of a connection. Without mutual SSL client authentication, a client can easily obtain a signer for the server programmatically and thus bypass the goal of isolation. With SSL client authentication, the server would require the client's signer for the connection to succeed. For HTTP/S protocol, the client is typically a browser, a web service, or a URL connection. For the IIOP/S protocol, the client is typically another application server or a Java client. WebSphere Application Server must know the clients to determine if SSL client authentication enablement is possible. Any applications that are available through a public protocol must not enable SSL client authentication because the client may fail to obtain a certificate to authenticate to the server.

Note: It is beyond the scope of this article to describe all of the factors you must consider to achieve complete isolation.

Certificate options during profile creation

Starting in WebSphere Application Server Version 7.0, you have several options available during profile creation concerning the default certificate and root certificate of the server.

The new certificate options enable you to:

- Import the default certificate of the server
- Import the root certificate of the server
- Customize the default certificate subjectDN and validity period of the server
- Customize the root certificate subjectDN and validity period of the server

Two new panels are available during profile creation that enable you to make decisions about the default certificate and root certificate of the server.

The first panel, titled Security Certificate (Part 1), enables you to choose to import a certificate or to have WebSphere Application Server create the default certificate or the default root certificate of the server for you.

The second panel, titled Security Certificate (Part 2), either displays the information from the certificate imported from the previous panel, or, if you choose to have WebSphere Application Server create the certificate, enables you to change the subjectDN and the certificate validity period.

Customization of certificates can also be performed by using the manageprofile command and from a silent install response file.

Importing the default certificate of the server during profile creation

If the default certificate of the server is imported during profile creation, it is added to NodeDefaultKeyStore if on a stand-alone application server, or to CellDefaultKeyStore if on a deployment manager. The imported certificate signer is added to NodeDefaultTrustStore or CellDefaultTrustStore.

To import the default certificate of the server, you must have a personal certificate stored and a keystore that you have access to. You must know the location, type and password of the keystore. On the Security Certificate (Part 1) panel, do the following:

1. Select **Import an existing default personal certificate**.
2. Type or select the keystore file name.
3. Enter the password of the keystore.
4. Select a keystore type from the pull-down list.
5. If you have correctly filled in all information from the previous 3 steps, you are able to select a certificate alias from the pull-down list.

The certificate you choose is imported to the default keystore of the server. The next panel, Security Certificate (Part 2) displays the issuedTo and issuedBy certificate information.

If you use the manageprofiles command to import the default certificate, the options are:

-importPersonalCertKS keystore_path
the keystore file location

-importPersonalCertKSType keystore_type
the type of the keystore

-importPersonalCertKSPassword keystore_password
the password to open the keystore

-importPersonalCertKSAlias keystore_alias
the alias of the certificate used from the keystore

Importing the root certificate of the server during profile creation

If the server root certificate is imported during profile creation, the certificate is added to NodeDefaultRootStore on a stand-alone application server or to DmgrDefaultRootStore on a deployment manager. The signer is pulled from the imported root certificate and added to NodeDefaultTrustStore or CellDefaultTrustStore. The root certificate is used by WebSphere Application Server to sign any chained certificates it creates. If no default certificate is provided during profile creation, WebSphere Application Server uses the root certificate to sign the default certificate of the server.

To import the default certificate of the server, you must have a personal certificate stored and a keystore that you have access to. You must know the location, type and password of the keystore. On the Security Certificate (Part 1) panel, do the following:

1. Select **Import an existing root signing certificate**.
2. Type or select the keystore file name.
3. Enter the password of the keystore.
4. Select a keystore type from the pull-down list.
5. If you have correctly filled in all information from the previous 3 steps, you are able to select a certificate alias from the pull-down list.

The certificate you choose is imported to the root keystore of the server. The next panel, Security Certificate (Part 2) displays the issuedTo and issuedBy certificate information.

If you use the manageprofiles command to import the root certificate, the options are:

-importSigningICertKS keystore_path
the keystore file location

-importSigningCertKSType keystore_type
the type of the keystore

-importSigningCertKSPassword keystore_password
the password to open the keystore

-importSigningCertKSAlias keystore_alias
the alias of the certificate used from the keystore

Customizing the default certificate created by WebSphere Application Server

If you choose to let WebSphere Application Server create the default certificate of the server, you can customize the subject distinguished name (DN) and the life span of the certificate.

To customize the default certificate of the server on the Security Certificate (Part 1) panel, do the following:

1. Select **Create a new default personal certificate**.
2. On the next panel, Security Certificate (Part 2), the Issued to distinguished name field contains the WebSphere Application Server default DN. Replace this with your customized DN.
3. In Expiration period in years, select the number of years you want the certificate to be valid for.

If you use the manageprofiles command to customize the default certificate, the options are:

-personalCertDN distinguished_name
the DN to give to the certificate

-personalCertValidityPeriod validity_period
the life span to give to the certificate

Customizing the root certificate created by WebSphere Application Server

If you choose to let WebSphere Application Server create the root certificate, you can customize the DN of the certificate and the life span of the certificate.

To customize the root certificate of the server on the Security Certificate (Part 1) panel, do the following:

1. Select **Create a new root signing certificate**.
2. On the next panel, Security Certificate (Part 2), the Issued by distinguished name field contains the WebSphere Application Server default root certificate DN. Replace this with your customized DN.
3. In Expiration period in years, select the number of years you want the root certificate to be valid for.

If you use the manageprofiles command to customize the root certificate, the options are:

-signingCertDN distinguished_name
the DN to give to the root certificate

-signingCertValidityPeriod validity_period
the life span to give to the root certificate

Default chained certificate configuration in SSL

When a WebSphere Application Server process starts for the first time, the Secure Sockets Layer (SSL) runtime initializes the default keystores and truststores that are specified in the SSL configuration.

The chained certificates created during profile creation have a 1 year life span by default. The default root certificate used to signer the default chained certificate has a life span of 15 years. The life span of the default and the root certificates can be customized during profile creation. An advantage in this type of chained certificate is that only the signer from the root certificate is needed to establish trust. When the chained certificate is regenerated with the same root certificate, clients using that root signer certificate for trust do not lose their trust.

Default keystore and truststore properties
WebSphere Application Server creates the `key.p12` default keystore file and the `trust.p12` default truststore file during profile creation. A default, chained certificate is also created in the **key.p12**

file. The root signer, or public key, of the chained certificate is extracted from the **key.p12** file and added to the **trust.p12** file. If the files do not exist during process startup, they are recreated during startup.

You can identify keystore and truststore defaults because of their suffixes: **DefaultKeyStore** and **DefaultTrustStore**. Also, in the SSL configuration, you must set the **fileBased** attribute to `true` so that the runtime only uses the default keystores and truststore.

On a base application server, default key and truststores are stored in the node directory of the configuration repository. For example, the default `key.p12` and `trust.p12` stores are created with the AppSrv01 profile name, the myhostNode01Cell name, and the myhostNode01 node name. The keystore and truststore are located in the following directories:

- C:\WebSphere\AppServer\profiles\AppSrv01\config\cells\myhostNode01Cell \nodes\myhostNode01\key.p12
- C:\WebSphere\AppServer\profiles\AppSrv01\config\cells\myhostNode01Cell \nodes\myhostNode01\trust.p12

The default password is **WebAS** for all default keystores generated by WebSphere Application Server. Change the default password after the initial configuration for a more secure environment.

Default chained certificate

The default chained certificate of the server along with a root self-signed certificate used to sign the default chained certificate are created during profile creation.

You can recreate the certificates with different information simply by deleting the `*.p12` files in `/config` and `/etc`. Change the four properties in the next code example to the values you want the certificates to contain, then restart the processes. This causes the server certificate in `/config` and the client certificate in `/etc` to differ.

The certificate properties in the next code example exist in the **ssl.client.props** file, but do not exist in the server configuration. However, you can use these values in the server configuration by adding them as custom security properties in the administrative console. Click **Security** > **Global securit**y > **Custom properties** to change the following properties:

```
com.ibm.ssl.defaultCertReqAlias=default_alias
com.ibm.ssl.defaultCertReqSubjectDN=cn=${hostname},ou=myhostNode01,ou=myhostNode01Cell,o=IBM,c=US
com.ibm.ssl.defaultCertReqDays=365
com.ibm.ssl.defaultCertReqKeySize=1024
com.ibm.ssl.rootCertSubjectDN=cn=${hostname},ou=Root Certificate, ou=myhostNode01,
ou=myhostNode01Cell,o=IBM,c=US
com.ibm.ssl.rootCertValidDays=7300
com.ibm.ssl.rootCertAlias=root
com.ibm.ssl.rootCertKeySize=1024
```

After changing the properties, complete the following actions:

1. Delete the default key.p12 keystore and trust.p12 truststore files for the application server, which contain the default chained certificate. If the keystore and truststore file do not exist, WebSphere Application Server automatically generates them and creates new default certificates using the previously listed property values.
2. Delete the root keystore, which is the root-key.p12 file, to regenerate the root certificate with the previously listed properties.
3. Restart the application server.

If a `default_alias` value already exists, the runtime appends `_#`, where the number sign (#) is a number that increases until it is unique in the keystore. `${hostname}` is a variable that is resolved to the host name where it was originally created. The default expiration date of chained certificates is one year from their creation date.

The runtime monitors the expiration dates of chained certificates using the certificate expiration monitor. These chained certificates are automatically replaced along with any signer certificates when they are within the expiration threshold, which is typically 30 days before expiration. You can

increase the default key size beyond 1024 bits only when the Java runtime environment policy files are unrestricted (that is, not exported). For more information, see “Certificate expiration monitoring in SSL” on page 1732.

Default keystore and truststore configurations for new Base Application Server processes

The following sample code shows the default SSL configuration for a base application server. References to the default keystores and truststores files are highlighted.

```
<repertoire xmi:id="SSLConfig_1" alias="NodeDefaultSSLSettings"
managementScope="ManagementScope_1">
<setting xmi:id="SecureSocketLayer_1" clientAuthentication="false"
securityLevel="HIGH" enabledCiphers="" jsseProvider="IBMJSSE2" sslProtocol="SSL_TLS"
keyStore="KeyStore_1" trustStore="KeyStore_2" trustManager="TrustManager_1"
keyManager="KeyManager_1"/>
</repertoire>
```

Default keystore

In the following sample code, the keystore object that represents the default keystore is similar to the XML object.

```
<keyStores xmi:id="KeyStore_1" name="NodeDefaultKeyStore"
password="{xor}349dkckdd=" provider="IBMJCE" location="${WAS_INSTALL_ROOT}/config
/cells/myhostNode01Cell/nodes/myhostNode01/key.p12" type="PKCS12" fileBased="true"
hostList="" initializeAtStartup="true" managementScope="ManagementScope_1"/>
```

The **NodeDefaultKeyStore** keystore contains the personal certificate that represents the identity of the secure endpoint. Any keystore reference can use the ${WAS_INSTALL_ROOT} variable, which is expanded by the runtime. The PKCS12 default keystore type is in the most interoperable format, which means that it can be imported into most browsers. The myhostNode01Cell password is encoded. The management scope determines which server runtime loads the keystore configuration into memory, as shown in the following code sample:

```
<managementScopes xmi:id="ManagementScope_1" scopeName="
(cell):myhostNode01Cell:(node):myhostNode01" scopeType="node"/>
```

Any configuration objects that are stored in the **security.xml** file whose management scopes are outside the current process scope are not loaded in the current process. Instead, the management scope is loaded by servers that are contained within the myhostNode01 node. Any application server that is on the specific node can view the keystore configuration.

When you list the contents of the **key.p12** file to show the chained certificate, note that the common name (CN) of the distinguished name (DN) is the host name of the resident machine. This listing enables you to verify the host name by its URL connections. Additionally, you can verify the host name from a custom trust manager. For more information, see “Trust manager control of X.509 certificate trust decisions” on page 1709.

Contents of default keystore

The following sample code shows the contents of the default **key.p12** file in a keytool list:

```
keytool -list -v -keystore c:\WebSphere\AppServer\profile\AppSrv01\profiles\config
\cells\myhostNode01Cell\nodes\myhostNode01\key.p12 -storetype PKCS12 -storepass *****

Keystore type: PKCS12
Keystore provider: IBMJCE

Your keystore contains 1 entry

Alias name: default
Creation date: Dec 31, 1969
Entry type: keyEntry
Certificate chain length: 2
Certificate[1]:
Owner: CN=myhost.austin.ibm.com, OU=myhostNode01Cell, OU=myhostNode01, O=IBM, C=US
Issuer: CN=myhost.austin.ibm.com, OU=Root Certificate, OU=myhostNode01Cell, OU=myhostNode01, O=IBM, C=US
Serial number: 4e48f29aafea6
Valid from: 2/7/08 1:03 PM until: 2/6/09 1:03 PM
Certificate fingerprints:
  MD5:  DB:FE:65:DB:40:13:F4:48:A4:CE:2F:4F:60:A5:FF:2C

*******************************************
*******************************************
```

The default alias name and the keyEntry entry type indicate that the private key is stored with the public key, which represents a complete personal certificate. The certificate is owned by`CN=myhost.austin.ibm.com, OU=myhostNode01Cell, OU=myhostNode01, O=IBM, C=US` and it is issued by the default root certificate, which is owned by`CN=myhost.austin.ibm.com, OU=Root Certificate, OU=myhostNode01Cell, OU=myhostNode01, O=IBM, C=US` By default, the certificate is valid for one year from the date of creation.

Additionally, in some signer-exchange situations, the certificate fingerprint ensures that the sent certificate has not been modified. The fingerprint, which is a hash algorithm output for the certificate, is displayed by the WebSphere Application Server runtime during an automated signer exchange on the client side. The client fingerprint must match the fingerprint that is displayed on the server. The runtime typically uses the SHA1 hash algorithm to generate certificate fingerprints.

Default truststore

In the following sample code, the keystore object represents the default `trust.p12` truststore. The truststore contains signer certificates that are necessary for making trust decisions:

```
<keyStores xmi:id="KeyStore_2" name="NodeDefaultTrustStore"
password="{xor}349dkckdd=" provider="IBMJCE" location="${WAS_INSTALL_ROOT}
/config/cells/myhostNode01Cell/nodes/myhostNode01/trust.p12" type="PKCS12"
fileBased="true" hostList="" initializeAtStartup="true" managementScope="ManagementScope_1"/>
```

Contents of default truststore

The following sample code shows the contents of the default `trust.p12` truststore in a keytool listing. By default, for the sample chained certificate, the root certificate signer is included in the trust store. The root signer alias name and the trustedCertEntry entry type indicate that the certificate is the public key. The private key is not stored in this truststore. In addition, all truststores contain the default DataPower certificate.

```
keytool -list -v -keystore c:\WebSphere\AppServer\profile\AppSrv01\profiles\config\cells\myhostNode01Cell
\nodes\myhostNode01\trust.p12 -storetype PKCS12 -storepass *****
```

```
Keystore type: PKCS12
Keystore provider: IBMJCE

Your keystore contains 2 entries

```

Secure installation for client signer retrieval in SSL:

Each profile in the WebSphere Application Server environment contains a unique chained certificate signed by a unique long lived root certificate that was created when the profile was created. This certificate replaces the default self-signed certificate that ships with WebSphere Application Server Version 6.1 as

well as the default dummy certificate that ships in releases prior to Version 6.1. When a profile is federated to a deployment manager, the signer for the root signing certificate is added to the common truststore for the cell, establishing trust for all certificates signed by that root certificate.

Note: Do not use the dummy keystore and truststore files, which are referenced in this topic, in a production environment. These files contain the same certificates and are used everywhere, which is not secure. Also, change the passwords for the keystore and truststore so that it does not use the `WebAS` default password.

By default, clients do not trust servers from different profiles in the WebSphere Application Server environment. That is, they do not contain the root signer for these servers. There are some things that you can do to assist in establishing this trust:

1. Enable the signer exchange prompt to except the signer during the connection attempt.
2. Run the **retrieveSigners** utility to download the signers from that system prior to making the connection.
3. Copy the `trust.p12` file from the `/config/cells/<cell_name>/nodes/<node_name>` directory of the server profile to the `/etc` directory of the client. Update the SSL configuration to reflect the new file name and password, if they are different. Copying the file provides the client with a `trust.p12` that contains all signers from servers in that cell. Also, you might need to perform this step for back-level clients that are still using the `DummyClientTrustFile.jks` file. In this case, you might need to change the `sas.client.props` or `soap.client.props` file to reflect the new truststore, truststore password, and truststore type (`PKCS12`).

For clients to perform an in-band signer exchange, you must specify the `ssl.client.props` file as a com.ibm.SSL.ConfigURL property in the SSL configuration. For managed clients, this is done automatically. Signers are designated either as in-band during the connection or out-of-band during runtime. You must also set the com.ibm.ssl.enableSignerExchangePrompt attribute to `true`.

Tip: You can configure a certificate expiration monitor to replace server certificates that are about to expire. For more information about how clients can retrieve the new signer from the configuration, see “Certificate expiration monitoring in SSL” on page 1732.

Using the signer exchange prompt to retrieve signers from a client

When the client does not already have a signer to connect to a process, you can enable the signer exchange prompt. The signer exchange prompt displays once for each unique certificate and for each node. After the signer for the node is added, the signer remains in the client truststore. The following sample code shows the signer exchange prompt retrieving a signer from a client:

```
/QIBM/UserData/WebSphere/AppServer/V8/Express/profiles/default/bin/serverStatus -all ADMU0116I:
Tool information is being logged in file
/QIBM/UserData/WebSphere/AppServer/V8/Express/profiles/default/logs/serverStatus.log ADMU0128I:
Starting tool with the default profile ADMU0503I: Retrieving server status for all servers
ADMU0505I: Servers found in
configuration: ADMU0506I: Server name: server1
*** SSL SIGNER EXCHANGE PROMPT *** SSL signer from target host 192.168.1.5
is not found in truststore
/QIBM/UserData/WebSphere/AppServer/V8/Express/profiles/default/etc/trust.p12.
Here is the signer information
(verify the digest value matches what is  displayed at the server):

Add signer to the truststore now? (y/n) y A retry of the request may need to occur.
ADMU0508I: The Application Manager "server1" is STARTED
```

To automate this process, see “retrieveSigners command” on page 1730.

When a prompt occurs to accept the signer, a socket timeout can occur and the connection might be broken. For this reason, the message `A retry of the request may need to occur.` displays after answering the prompt. The message informs the user to resubmit the request. This problem should not happen frequently, and it might be more prevalent for some protocols than others.

A retry of the request may need to occur if the socket times out while waiting for a prompt response. If the retry is required, note that the prompt will not be re-displayed if `(y)` is entered, which indicates the signer has already been added to the trust store.

Verify the displayed SHA-1 digest, which is the signature of the certificate that is sent by the server. If you look at the certificate on the server, verify that the same SHA-1 digest displays.

You can disable the prompt when you do not want it to display by running the **retrieveSigners** utility to retrieve all of the signers for a particular cell. You can download or upload the signers from any remote keystore to any local keystore by referencing a common truststore with this client script. For more information, see “Default chained certificate configuration in SSL” on page 1724.

Using the retrieveSigners utility to download signers for a client

You can run the **retrieveSigners** utility to retrieve all of the signers from the remote keystore for a specified client keystore. The truststore contains the signers that enable the client to connect to its processes. The **retrieveSigners** utility can point to any keystore in the target configuration, within the scope of the target process, and can download the signers (certificate entries only) to any client keystore in the `ssl.client.props` file.

Obtaining signers for clients and servers from a previous release

Note: When a client from a release prior to version 7.0 connects to the current release, the client must obtain signers for a successful handshake. Clients using previous releases of WebSphere Application Server cannot obtain signers as easily as in the current release. You can copy the deployment manager *common* truststore to your back-level client or server, and then re-configure the SSL configuration to directly reference that truststore. This common truststore of type `PKCS12` is located in the `/config/cells/<cell_name>/nodes/<node_name>` directory in the configuration repository and has a default password of `WebAS`.

To collect all of the signers for the cell in a single `trust.p12` keystore file, complete following steps:

1. Copy the trust.p12 keystore file on the server and replicate it on the client. The client references the file directly from the `sas.client.props` and `soap.client.props` files that specify the SSL properties for previous releases.
2. Change the client-side keystore password so that it matches the default cell name that is associated with the copied keystore.
3. Change the default keystore type for the `trust.p12` file to `PKCS12` in the client configuration.

The following two code samples show you a before and an after view of the changes to make.

Default SSL configuration of sas.client.props for a previous release

```
com.ibm.ssl.protocol=SSL com.ibm.ssl.keyStore=/QIBM/UserData/WebSphere/AppServer/V8/Base/
profiles/default/
etc/DummyClientKeyFile.jks
com.ibm.ssl.keyStorePassword={xor}CDo9Hgw\= com.ibm.ssl.keyStoreType=JKS com.ibm.ssl.trustStore=
/QIBM/UserData/WebSphere/AppServer/
V8/Base/profiles/default/etc/DummyClientTrustFile.jks com.ibm.ssl.trustStorePassword={xor}CDo9Hgw\=
com.ibm.ssl.trustStoreType=JKS
```

SSL configuration changes that are required to common truststore file in the /etc directory of the client

```
com.ibm.ssl.protocol=SSL com.ibm.ssl.keyStore=/QIBM/UserData/WebSphere/AppServer/V8/Base/
profiles/default/etc/
DummyClientKeyFile.jks com.ibm.ssl.keyStorePassword={xor}CDo9Hgw\= com.ibm.ssl.keyStoreType=JKS
com.ibm.ssl.trustStore=/QIBM/UserData/WebSphere/AppServer/V8/Base/profiles/default/etc/trust.p12
com.ibm.ssl.trustStorePassword=myhostNode01Cell com.ibm.ssl.trustStoreType=PKCS12
```

Tip: You can run the **PropsFilePasswordEncoder** script, which is located in the `/bin` directory to encode the password.

You can also make these changes in the `soap.client.props` file and specify the `key.p12` file in place of the `DummyClientKeyFile.jks` file. However, you must also change the keyStorePassword and keyStoreType values to match those in the default `key.p12` file.

In releases of WebSphere Application Server prior to Version 7.0, you must edit the SSL configuration on the server to replace the common truststore. The `trust.p12` file, which is used by the server, also must contain the default dummy certificate signer for connections among servers at previous release levels. You might need to manually extract the default certificate from the `DummyServerKeyFile.jks` file and then import the certificate into the `trust.p12` file that you added to the configuration.

retrieveSigners command:

The retrieveSigners command creates a new client self-signed certificate, keystore, and SSL configuration in the ssl.client.props file. Using this command you can optionally extract the signer to a file.

For more information about where to run this command, read about Using command tools.

Syntax

Use the following command syntax to create a new client self-signed certificate, keystore, and SSL configuration in the ssl.client.props file.

```
retrieveSigners <remoteKeyStoreName> <localKeyStoreName> [options]
```

The <remoteKeyStoreName> and <localKeyStoreName> parameters are required. The following optional parameters are available:

```
[-remoteAlias aliasFromRemoteStore]
[-localAlias storeAsAlias]
[-listRemoteKeyStoreNames][-listLocalKeyStoreNames]
[-autoAcceptBootstrapSigner][-uploadSigners] [-host host]
[-port port][-conntype JSR160RMI|RMI|SOAP|IPC][-user user]
[-password password]
[-trace] [-logfile filename]
[-replacelog] [-quiet] [-help]
```

Parameters

The following parameters are available for the **retrieveSigners** command:

-remoteKeyStoreName
The name of a truststore that is located in the server configuration from which to retrieve the signers. This parameter is typically the CellDefaultTrustStore file for a managed environment or the NodeDefaultTrustStore file for an unmanaged environment.

-localKeyStoreName
The name of the truststore that is located in the ssl.client.props file for the profile to which the retrieved signers is added. This parameter is typically the ClientDefaultTrustStore file for either a managed or unmanaged environment.

-remoteAlias <aliasFromRemoteStore>
Specifies one alias from the remote truststore that you want to retrieve. Otherwise, all signers from the remote truststore are retrieved.

-localAlias <storeAsAlias>
Determines the name of the alias stored in the local truststore. This option is only valid if you specify the –remoteAlias option. If you do not specify the -localAlias option, then the alias name from the remote truststore is used, if possible. If an alias clash occurs, then the alias name is used and has an incremented number appended to the end of it until a unique alias is found.

-listRemoteKeyStoreNames
Sends a remote request to the server to list all keystores that you can specify for the remoteKeyStoreName parameter. Use this command when you are unsure of the name of the remote truststore from which you want to download the signers.

-listLocalKeyStoreNames
Lists the keystores located in the ssl.client.props file that you can specify for the localKeyStoreName parameter. This truststore receives the signers from the server. Use this parameter when you are unsure of the name of the local truststore into which you want to retrieve the signers. The default name of the truststore is ClientDefaultTrustStore and is located in the ssl.client.props file.

-autoAcceptBootstrapSigner
Automatically adds a signer to make a secure connection to the server. The purpose of the option is to support automation of the command so that you do not need to accept the signer. After the signer is added to the local truststore, an SHA hash prints so that you can verify the certificate.

-uploadSigners
Converts the signer download into a signer upload. The signers from the localKeyStoreName parameter is sent to the remoteKeyStoreName parameter instead.

-host <host>
Specifies the target host from which the signers are retrieved.

-port <port>
Specifies the target administrative port to which you want to connect. You must specify the port based on the -conntype parameter. If the conntype is SOAP, the default port is 8879. This value can vary for different servers. If the conntype is RMI, the default port is 2809.

-conntype <JSR160RMI|IPC|RMI|Soap>
Determines the administrative connector type that is used for the MBean call to retrieve the signers.

Note: Eventually switch from the RMI connector to the JSR160RMI connector because support for the RMI connector is deprecated.

-user <user>
When the -uploadSigners flag is used, you are required to specify this option to supply the user name that is authenticated for the MBean operation. If you do not specify this parameter when the -uploadSigners flag is used, then you are prompted for credentials by default.

-password <password>
When the -uploadSigners flag is used, you are required to specify this option to supply the password that is authenticated for the MBean operation. The password goes along with the –user parameter.

-trace
When specified, this parameter enables tracing of the trace specification necessary to debug this component. By default, the trace is located in the profiles/*profile_name*/log/retrieveSigners.log file.

-logfile <filename>
Overrides the default trace file. By default, the trace will appear in the profiles/*profile_name*/log/retrieveSigners.log file.

-replacelog
Causes the existing trace file to be replaced when the command runs.

-quiet
Suppresses most messages from printing to the console.

-help
Prints a usage statement.

-? Prints a usage statement.

Usage scenario

The following examples demonstrate correct syntax for using the **retrieveSigners** command:

- The following example lists remote and local keystores:

```
retrieveSigners -listRemoteKeyStoreNames -listLocalKeyStoreNames -conntype RMI -port 2809
```

Example output

```
CWPKI0306I: The following remote keystores exist on the specified server:
          CMSKeyStore, NodeLTPAKeys, NodeDefaultTrustStore, NodeDefaultKeyStore
CWPKI0307I: The following local keystores exist on the client:
          ClientDefaultKeyStore, ClientDefaultTrustStore
```

- The following example retrieves all signers from NodeDefaultTrustStore:

```
retrieveSigners NodeDefaultTrustStore ClientDefaultTrustStore -autoAcceptBootstrapSigner
-conntype RMI -port 2809
```

Example output

```
CWPKI0308I: Adding signer alias "CN=BIRKT40.austin.ibm.com, O=IBM, C=US" to
          local keystore "ClientDefaultTrustStore" with the following SHA
          digest: 40:20:CF:BE:B4:B2:9C:F0:96:4D:EE:E5:14:92:9E:37:8D:51:A5:47
```

Certificate expiration monitoring in SSL:

The certificate expiration monitor administrative task is a scheduled task that cycles through all the keystores in the security configuration and reports on any certificates that are expired, certificates that fall within the expiration threshold, and certificates that fall within the pre-notification period.

Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

The certificate expiration monitor also replaces self-signed and chained certificates that have a root in the root keystore if configured to do so. If the monitor is configured to replace certificates, then certificates that are expired or fall in the expiration threshold are replaced. Certificates that are imported from an external Certificate authority (CA) are reported but not replaced.

Certificate expiration monitoring relies on the following definitions:

Expired certificates
Certificates are created with a finite life span. Self-signed or chained certificates that have reached the end of their life span are reported and replaced, if possible. Certificate authority signed certificates cannot be replaced but will be reported. Replacing CA-signed certificates is the responsibility of the administrator.

Certificates within the expiration threshold

There is a period of time before a certificate expires. A certificate in this period of time is one within the expiration threshold. The server replaces certificates within the expiration threshold so that the certificate does not expire and cause outages. By default the expiration threshold is 60 days, but can be configured as required.

Pre-notification period

Before a certificate falls within the expiration threshold there are warnings issued that indicate that the certificate will be replaced, when the expiration threshold date is reached. The period of time prior to the expiration threshold date is called the pre-notification period and is set at 90 days for the certificate.

The certificate expiration monitor performs the following:

1. Clears out the **NodeDefaultDeletedStore** or **DmgrDefaultDeletedStore**. This operation is performed silently without reporting that the certificates are deleted.
2. Checks the root key stores, **DmgrDefaultRootStore** or **NodeDefaultRootStore** and the **DmgrRSATokenRootStore** or **NodeRSATokenRootStore**. If any root certificates are expired, falls in the threshold period, or the pre-notification period, then the certificate is noted in the report.
3. If there are any root certificates that are expired or fall in the threshold period that root certificate is recreated using all the information used to create the original one. Any signer certificates from the original root certificate are replaced with the signers from the new root certificate.
4. If a root certificate is replaced, then all the keystores are checked to see if there are any chained certificates signed with the original root certificate. If there are, then the chain certificate is renewed (recreated with the new root certificate). Any signer certificate from the original certificate is replaced with the signer from the recreated certificate.
5. After all root keystores are processed, the rest of the keystores are checked for expired certificates, certificates in the expiration threshold, or certificates in the pre-notification period. Any certificate falling in any one of these categories is noted in the report.
6. If there are any expired certificates or certificates in the expiration threshold period and these certificates are self-signed certificates or chained certificates created by WebSphere, then they are replaced. If the chained certificates root is not in the root key store then it will be recreated as a default root certificate. Any signer certificates from the original certificate are replaced with the signer from the new certificate."
7. A report is generated and returned, written to a log file, or mailed.

The server default certificate is a chained certificate with a 365 day life span. It is signed with the default root certificate which has a 15 year life span.

You can configure this monitor task to run according to a particular schedule. The schedule produces the next start date that persists in the configuration and, when the date is reached, WebSphere Application Server starts the monitor to check all of the keystores for certificates that meet the expiration threshold. You can start the task manually to run at any time.

The following `security.xml` configuration object specifies when the monitor task starts, determines the certificate expiration threshold, and indicates whether you are notified in an email using Simple Mail Transfer Protocol (SMTP) or in a message log.

```
<wsCertificateExpirationMonitor xmi:id="WSCertificateExpirationMonitor_1"
name="Certificate Expiration Monitor" daysBeforeNotification="30"
isEnabled="true" autoReplace="true" deleteOld="true"
wsNotification="WSNotification_1" wsSchedule="WSSchedule_2"
nextStartDate="1134358204849"/>
```

The expiration monitor replaces self-signed certificates and chained personal certificates that are signed by a root certificate in **DmgrDefaultRootStore** or **NodeDefaultRootStore**. Self-signed certificates are renewed using all the information that was used to create the original self-signed certificate. A chained certificate is renewed using the same root certificate that was used to sign the original certificate.

The expiration monitor automatically replaces only self-signed certificates and chained certificates that are expired or that meet the expiration threshold criteria. To replace all of the signers from the old certificate with the signer that belongs to the new certificate in all the keystores in the configuration for that cell, set the autoReplace attribute to `true`. When the deleteOld attribute is `true`, the old personal certificate and old signers also are deleted from the keystores. The isEnabled attribute determines whether the expiration monitor task runs based upon the nextStartDate attribute that is derived from the schedule. The nextStartDate attribute is derived from the schedule in milliseconds since 1970, and is identical to the System.currentTimeMillis(). If the nextStartDate has already passed when an expiration monitor process begins, and the expiration monitor is enabled, the task is started, but a new nextStartDate value is established based on the schedule.

The following sample the schedule object shows the frequency attribute as the number of days between each run of the certificate monitor.

```
<wsSchedules xmi:id="WSSchedule_2" name="ExpirationMonitorSchedule"
frequency="30" dayOfWeek="1" hour="21" minute="30"/>
```

The dayOfWeek attribute adjusts the schedule to run on a specified day of the week, which is always the same day regardless of whether the frequency is set to 30 or 31 days. Based on 24-hour clock, the hour and minute attributes determine when the expiration monitor is started on the specified day.

The following sample code of the notification object shows the notification configuration, which notifies you after the expiration monitor runs.

```
<>wsNotifications xmi:id="WSNotification_1" name="MessageLog" logToSystemOut="true" emailList=""/
```

For expiration monitor notifications, you can select message log, email using SMTP server, or both methods of notification. When you configure the email option, use the format `user@domain@smtpserver`. If you do not specify an SMTP server, WebSphere Application Server defaults to the same domain as the email address. For example, if you configure joeuser@ibm.com, WebSphere Application Server attempts to call smtp-server.ibm.com. To specify multiple email addresses using scripting, you must add a pipe (I) character between entries. When you specify the logToSystemOut attribute, the expiration monitor results are sent to the message log for the environment, which is typically the `SystemOut.log` file.

The expiration monitor clears out the deleted certificates keystore. The monitor first clears out the deleted keystore. Due to the nature of the PKCS12 keystore, there must be at lease one entry in the keystore so the signer certificates from the dummy key store will remain in the deleted keystore. There is no reporting on the certificate being deleted from the deleted keystore.

Important: When the expiration monitor replaces certificates, this can dynamically affect the runtime when the following configuration option is enabled:

Security > **SSL certificate and key management**. Under configuration settings, check the checkbox for **Dynamically update the run time when SSL configuration changes occur**.

When enabled, any certificates that are replaced causes the client SSL runtime to begin using the new certificates immediately, which in turn, flushes SSL and keystore caches and causes some ports using SSLServerSockets (RMI/IIOP on distributed and Admin SOAP) to restart. Restarting ports breaks existing connections. These connections can be reconnected after the port restart is completed. Endpoints using the channel framework (HTTP, BUS, RMI/IIOP on z/OS) leave existing connections unaffected but still use the new certificates for new connections.

When the dynamic change property is disabled and before the new certificates become effective, the administrator needs to recycle all processes in the entire cell after each node has the synchronized configuration. Regardless of which method is chosen, you should always check the health of your cell after the certificate expiration monitor has run (based on the

schedule specified). The schedule should be set to run the certificate expiration monitor during a maintenance period so that if a restart is required after the certificate replacement, it will not cause unexpected outages.

Dynamic configuration updates in SSL

During the Secure Sockets Layer (SSL) runtime, dynamic configuration updates affect both inbound and outbound SSL endpoints. For inbound SSL endpoints, the changes that are implemented by the SSL channel are only affected by dynamic changes. For outbound SSL endpoints, all outbound connections inherit the new configuration changes.

In this release, dynamic update functionality provides you with greater flexibility and efficiency. You can change SSL configurations without restarting WebSphere Application Server for the changes to take effect.

To make dynamic changes, in the administrative console click **Security > SSL certificates and key management**, then select the **Dynamically update the runtime when SSL configuration changes occur** check box. You must save your changes and then synchronize the `security.xml` file with remote systems. A remote system must be able to confirm that `dynamicallyUpdateSSLConfig=true` is in the `security.xml` file.

The SSL runtime reloads the modified SSL configuration and creates a new SSLEngine for the modified connections that are associated with inbound endpoints. New outbound connections use the new configuration while existing connections continue to use the old SSLEngine object and are not affected.

Tip: Make dynamic changes to the SSL configuration during off-peak hours. Synchronization delays can negatively affect connections when you update SSL configurations during peak hours.

You can turn on and off the dynamicallyUpdateSSLConfig attribute in the `security.xml` file to ensure successful updates by doing the following actions:

1. Set dynamicallyUpdateSSLConfig=On.
2. Save the updated configuration.
3. Synchronize the `security.xml` file with remote systems.
4. Set the dynamicallyUpdateSSLConfig attribute to `Off`.

You must verify that all of the nodes receive the changes before turning off the dynamicallyUpdateSSLConfig attribute. Test the changes in a test environment before updating the production environment.

Tip: Some SSL changes, especially administrative SSL changes, can cause server outages if you fail to test them first. When a change prevents trust between two endpoints, the endpoints cannot communicate with each other. Additionally, if administrative SSL connection updates cause system outages, you might need to disable the nodes after you make corrective changes using the deployment manager. From the command line, you can manually synchronize the server to retrieve the new SSL changes, then restart the nodes.

Certificate management using iKeyman prior to SSL

Starting in WebSphere Application Server Version 6.1, you can manage your certificates from the administrative console. When using versions of WebSphere Application Server prior to Version 6.1, use iKeyman for certificate management. iKeyman is a key management utility.

WebSphere Application Server certificate management requires that you define the keystores in your WebSphere Application Server configuration. With iKeyman, you need access to the keystore file only. You can read a keystore file with personal certificates and signers that is created in iKeyman. A keystore file can be read into the WebSphere Application Server configuration by using the **createKeyStore** command.

The majority of certificate management functions are the same between WebSphere Application Server and iKeyman, especially for personal certificates and signer certificates. However, certificate requests are

special. The underlying behavior is different in the two certificate management schemes. Because of the different behavior, when a certificate request is generated from iKeyman, the process must be completed in iKeyman. For example, a certificate that is generated by a certificate request that originated in iKeyman must be received in iKeyman as well.

The same is true for WebSphere Application Server. For example, when a certificate is generated from a certificate request that originated in WebSphere Application Server, the certificate must be received in WebSphere Application Server.

You can perform the following certificate operations using iKeyman:

Table 142. Available certificate operations using iKeyman. This table describes the available certificate operations using iKeyman.

Types of certificates	Functions	Description
Personal certificates	Create a self-signed certificate	Creates a self-signed certificate and stores it in a keystore.
	List personal certificates	Lists all the personal certificates in a keystore.
	Get information about a personal certificate	Gets information about a personal certificate.
	Delete a personal certificate	Deletes a personal certificate from a keystore.
	Import a certificate	Imports a certificate from a keystore to a keystore.
	Export a certificate	Exports a certificate from a keystore to another keystore.
	Extract a certificate	Extracts the signer part of a personal certificate to a file.
	Receive a certificate	Reads a certificate that comes from a certificate authority (CA) into a keystore.
Signer certificates	Add a signer certificate	Adds a signer certificate from a file to a keystore.
	List signer certificates	Lists all the signer certificates in a keystore.
	Get information about a signer certificate	Gets information about a signer certificate.
	Delete a signer certificate	Deletes a signer certificate from a keystore.
	Extract a signer certificate	Extracts a signer certificate from a keystore, and stores the certificate in a file.
Certificate requests	Create a certificate request	Creates a certificate request that can be sent to a CA.
	List certificate requests	Lists the certificate requests in a keystore.
	Get information about a certificate request	Gets information about a certificate request.
	Delete a certificate request	Deletes a certificate request from a keystore.
	Extract a certificate request	Extracts a certificate request to a file.

Certificate management in SSL

You can manage certificate operations that involve personal certificates, signer certificates, and personal certificate requests on the administrative console.

Types of certificates

WebSphere Application Server uses the certificates that reside in keystores to establish trust for a Secure Sockets Layer (SSL) connection. Click **Security > SSL certificate and key management > Manage**

endpoint security configurations > Inbound | Outbound > *SSL_configuration_name* > Key stores and certificates, then select an existing or create a new keystore. After selecting a keystore, and depending on the type of certificate you need, choose one of the following types of certificates under Related Items:

- Personal certificate
- Signer certificate
- Certificate Authority (CA) certificates
- Personal certificate request

Table 143. Certificate operations. The following table describes the certificate operations that you can perform on the administrative console

Types of certificates	Functions	Description
Personal certificates	Create a self-signed certificate	Creates a self-signed certificate and stores it in a keystore.
	List personal certificates	Lists all the personal certificates in a keystore.
	Get information about a personal certificate	Gets information about a personal certificate.
	Delete a personal certificate	Deletes a personal certificate from a keystore.
	Import a certificate	Imports a certificate from a keystore to a keystore.
	Export a certificate	Exports a certificate from a keystore to another keystore.
	Extract a certificate	Extracts the signer part of a personal certificate to a file.
	Exchange signer certificates	Exchange signer part of a personal certificate between key store.
	Receive a certificate	Reads a certificate that comes from a certificate authority (CA) into a keystore.
	Replace a certificate	Replaces all occurrences of a personal certificate alias in the WebSphere Application Server configuration with another certificate. Also, replaces all occurrences of the personal certificates signer with the new personal certificate signer.
	Create a chained certificate	Creates a chained certificate and stores it in a keystore.
	Renew a certificate	Renews a certificate with a new public/private key pair and stores it in a keystore.
	Request a CA certificate	Makes a request to a CA using a CA client to obtain a CA certificate.
Certificate authority (CA) certificates	Create CA certificate	Sends a certificate request to an external certificate authority (CA).
	Revoke CA certificate	Sends a revocation request to an external certificate authority (CA).
Signer certificates	Add a signer certificate	Adds a signer certificate from a file to a keystore.
	List signer certificates	Lists all the signer certificates in a keystore.
	Get information about a signer certificate	Gets information about a signer certificate.
	Delete a signer certificate	Deletes a signer certificate from a keystore.
	Extract a signer certificate	Extracts a signer certificate from a keystore, and stores the certificate in a file.

Table 143. Certificate operations (continued). The following table describes the certificate operations that you can perform on the administrative console

Types of certificates	Functions	Description
	Retrieve a signer from a port	Retrieves a signer certificate from a port, and stores it in a key store.
Certificate requests	Create a certificate request	Creates a certificate request that can be sent to a CA.
	List certificate requests	Lists the certificate requests in a keystore.
	Get information about a certificate request	Gets information about a certificate request.
	Delete a certificate request	Deletes a certificate request from a keystore.
	Extract a certificate request	Extracts a certificate request to a file.

Personal certificates

Table 144. Personal certificate operations. The following table lists the operations that you can perform on personal certificates, the AdminTask object that you can use to perform that operation, and how to navigate to the certificate on the console:

Function	AdminTask object	Administrative console
Create a self-signed certificate	createSelfSignedCertificate	**Security > Secure Communications > Key store and certificates >** *key store* **> Create a Self-Signed Certificate**
List personal certificates	listPersonalCertificates	**Security > Secure Communications > Key store and certificates >** *key store* **> personal certificates**
Get information about a personal certificate	getPersonalCertificate	**Security > Secure Communications > Key store and certificates >** *key store* **> personal certificates >** *alias*
Delete a personal certificate	deletePersonalCertificate	**Security > Secure Communications > Key store and certificates >** *key store* **> personal certificates > delete**
Import a certificate	importCertificate	**Security > Secure Communications > Key store and certificates >** *key store* **> personal certificates > import**
Export a certificate	exportCertificate	**Security > Secure Communications > Key store and certificates >** *key store* **> personal certificates > export**
Extract a certificate	extractCertificate	**Security > Secure Communications > Key store and certificates >** *key store* **> personal certificates > extract**
Exchange signer certificates	exchangeSignerCertificates	**Security > Secure Communications > Key store and certificates > Exchange signers**
Create a chained certificate	createChainedCertificate	**Security > SSL certificate and key management > Key store and certificates >** ***keystore name*** **> Personal certificates**. Click **Create** button and select **Chained certificate**
Renew a certificate	renewChainedCertificate	**Security > SSL certificate and key management > Key store and certificates >** ***keystore name*** **> Personal certificates**. Select a certificate. Click **Renew** button.
Create a chained Certificate	createChainedCertificate	**Security > Secure communications > Key store and certificates > keystore > Create a chained certificate**.

Table 144. Personal certificate operations (continued). The following table lists the operations that you can perform on personal certificates, the AdminTask object that you can use to perform that operation, and how to navigate to the certificate on the console:

Function	AdminTask object	Administrative console
Request a CA certificate	requestCACertificate	**Security > Secure communications > Key store and certificates > keystore > Request a CA certificate**.

Certificate authority (CA) certificates

Table 145. CA certificate operations. The following table lists the operations that you can perform on CA certificates, the AdminTask object that you can use to perform that operation, and how to navigate to the certificate on the console:

Function	AdminTask object	Administrative console
Create a CA certificate	createCACertificate	**Security > Secure Communications > Key store and certificates >** *key store* **> Personal certificates > Create > CA-signed certificate**
Revoke a CA certificate	revokeCACertificate	**Security > Secure Communications > Key store and certificates >** *key store* **> Personal certificates** *personal certificate* **> Revoke**

Signer certificates

Table 146. Signer certificate operations. The following table lists the operations that you can perform with signer certificates, the AdminTask object that you can use to perform the operation, and how to navigate to the certificate on the console:

Function	AdminTask object	Administrative console
Add a signer certificate	addSignerCertificate	**Security > Secure communications > Key store and certificates >** *key store* **> signer certificates > Add**
List signer certificates	listSignerCertificates	**Security > Secure communications > Key store and certificates >** *key store* **> signer certificates**
Get information about a signer certificate	getSignerCertificate	**Security > Secure communications > Key store and certificates >** *key store* **> signer certificates >** *alias*
Delete a signer certificate	deleteSignerCertificate	**Security > Secure communications > Key store and certificates >** *key store* **> signer certificate >delete**
Extract a signer certificate to a file	extractSignerCertificate	**Security > Secure communications > Key store and certificates >** *key store* **> signer certificates > extract**
Retrieve a signer certificate from a port	retrieveSignerFromPort	**Security > Secure communications > Key store and certificates >** *key store* **> signer certificates > retrieve from port**

Personal certificate requests

Table 147. Personal certificate request operations. The following table lists the operations that you can perform on personal certificate requests, the AdminTask object that you can use to perform that operation, and how to navigate to the certificate request on the console:

Function	AdminTask object	Administrative console
Create a personal certificate request	createCertificateRequest	**Security > Secure communications > Key store and certificates >** *key store* **> Personal certificate Requests > Add**

Table 147. Personal certificate request operations (continued). The following table lists the operations that you can perform on personal certificate requests, the AdminTask object that you can use to perform that operation, and how to navigate to the certificate request on the console:

Function	AdminTask object	Administrative console
List personal certificate requests	listCertificateRequests	**Security > Secure communications > Key store and certificates >** *key store* **> Personal certificate requests**
Get information about a personal certificate request	getCertificateRequest	**Security > Secure communications > Key store and certificates >** *key store* **> Personal certificate requests >** *alias*
Delete a personal certificate request	deleteCertificateRequest	**Security > Secure communications > Key store and certificates >** *key store* **> Personal certificate requests > delete**
Extract a personal certificate request to a file	extractCertificateRequest	**Security > Secure communications > Key store and certificates >** *key store* **> Personal certificate requests > Extract**

Using the retrieveSigners command in SSL to enable server to server trust

You can add a signer certificate to a server's `trust.p12` file, allowing that server to securely communicate with another server. This can be done using the **retrieveSigners** command to add a signer to a server's `trust.p12` file after making changes to the `ssl.client.props` file.

Before you begin

The server that will be communicating as a client must be identified before the server to server trust can be established. You will make change to the `ssl.client.props` file and run the **retrieveSigners** command on the server communicating as a client. If both servers will be acting as a client , these steps will be required for both servers.

About this task

The `ssl.client.props` file is setup by default to configure Secure Socket Layer (SSL) communication for clients. This makes the default behavior of the **retrieveSigners** command work on the client's `trust.p12` file and `key.p12` file in the *profile_root*`/etc` directory. You can add a signer certificate to a server's `trust.p12` file, allowing that server to act as a client communicating to another server. Using the **retrieveSigners** command to add a signer to a server's `trust.p12` file requires some changes to the `ssl.client.props` file.

Procedure

1. Open the `ssl.client.props` file. The `ssl.client.props` file is located in *profile_root*`/properties` ditrectory.
2. Uncomment the section of `ssl.client.props` that starts with com.ibm.ssl.alias=AnotherSSLSettings property.
3. Uncomment the section of `ssl.client.props` that starts with com.ibm.ssl.trustStoreName=AnotherTrustStore property.
4. Enter the location of the trust store that the signer should be added. If you are using the server trust store for a deployment manager then it is located in *profile_root*`/config/cells/`*cell name*`/trust.p12`. If using the trust store for an application server, it is located in *profile_root*`/config/cells/`*cell name*`/nodes/`*node name*`/trust.p12`.
5. Update the remaining properties in this section with the values associated with the trust store being used. A description of the properties can be found in ssl.client.props client configuration file.
6. Optional: Uncomment and update section that starts with com.ibm.ssl.trustStoreName=AnotherKeyStore property. Most scenarios only require a signer to be

added to the trust store. This example only adds a signer to the trust store, but you can also add a signer to the key store by updating the properties as you did for the trust store in steps 3 through 5.

7. Save the changes made to `ssl.client.props`.
8. Run the **retrieveSigners** command. For more information see the page about the retrieveSigners command.

```
retrieveSigners NodeDefaultTrustStore AnotherTrustStore -host ademyers.austin.ibm.com -port 8879
```

Example output:

```
CWPKI0308I: Adding signer alias "default_1" to local keystore
                    "AnotherTrustStore" with the following SHA digest:
                    F4:71:97:79:3E:C1:DC:E7:9F:8F:3D:F0:A0:15:1E:D1:44:73:2C:06
```

Results

After the steps have been successfully completed. the server acting as a client has the signing certificate of the other server. This allows that server to establish a SSL connection to the other server.

Example

The example shows the modified section of the `ssl.client.props` file assuming that the server's `trust.p12` file is being used. Any trust store existing trust store can be used if the properties are provided for that trust store.

```
#-------------------------------------------------------------------------
com.ibm.ssl.alias=AnotherSSLSettings
com.ibm.ssl.protocol=SSL_TLS
com.ibm.ssl.securityLevel=HIGH
com.ibm.ssl.trustManager=IbmX509
com.ibm.ssl.keyManager=IbmX509
com.ibm.ssl.contextProvider=IBMJSSE2
com.ibm.ssl.enableSignerExchangePrompt=true
#com.ibm.ssl.keyStoreClientAlias=default
#com.ibm.ssl.customTrustManagers=
#com.ibm.ssl.customKeyManager=
#com.ibm.ssl.dynamicSelectionInfo=
#com.ibm.ssl.enabledCipherSuites=

# KeyStore information
#com.ibm.ssl.keyStoreName=AnotherKeyStore
#com.ibm.ssl.keyStore=${user.root}/etc/key.p12
#com.ibm.ssl.keyStorePassword={xor}CDo9Hgw=
#com.ibm.ssl.keyStoreType=PKCS12
#com.ibm.ssl.keyStoreProvider=IBMJCE
#com.ibm.ssl.keyStoreFileBased=true

# TrustStore information
com.ibm.ssl.trustStoreName=AnotherTrustStore
com.ibm.ssl.trustStore=${user.root}/config/cells/localhostCell01/trust.p12
com.ibm.ssl.trustStorePassword={xor}CDo9Hgw=
com.ibm.ssl.trustStoreType=PKCS12
com.ibm.ssl.trustStoreProvider=IBMJCE
com.ibm.ssl.trustStoreFileBased=true
```

What to do next

After the signer has been added, edit the `ssl.client.props` file to comment out the sections that were to used to add the signer certificate.

Creating a Secure Sockets Layer configuration

Secure Sockets Layer (SSL) configurations contain the attributes that you need to control the behavior of client and server SSL endpoints. You create SSL configurations with unique names within specific management scopes on the inbound and outbound tree in the configuration topology. This task shows you how to define SSL configurations, including quality of protection and trust and key manager settings.

Before you begin

You must decide at which scope you need to define an SSL configuration, for instance, the cell, node group, node, server, cluster, or endpoint scope, from the least specific to the most specific scope. When

you define an SSL configuration at the node scope, for example, only those processes within that node can load the SSL configuration; however, any processes at the endpoint in the cell can use an SSL configuration at the cell scope, which is higher in the topology.

You must also decide which scope to associate with the new SSL configuration, according to the processes that the configuration affects. For example, an SSL configuration for a hardware cryptographic device might require a keystore that is available only on a specific node, or you might need an SSL configuration for a connection to a particular SSL host and port. For more information, see “Dynamic outbound selection of Secure Sockets Layer configurations” on page 1717.

gotcha: The security.xml file is restricted. Therefore, if you need to make changes to the security.xml file, verify that your user ID has administrator role authorization. If you are using a user ID with operator role authorization, you can perform a node synchronization, but any changes that you made to the security.xml file are not synchronized.

About this task

Complete the following steps in the administrative console:

Procedure

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations**.
2. Select an SSL configuration link on either the Inbound or Outbound tree, depending on the process you are configuring.
   - If the scope is already associated with a configuration and alias, the SSL configuration alias and certificate alias are noted in parentheses.
   - If the parenthetical information is not included, then the scope is not associated. Instead, the scope inherits the configuration properties of the first scope above it that is associated with an SSL configuration and certificate alias.

   The cell scope must be associated with an SSL configuration because it is at the top of the topology and represents the default SSL configuration for the inbound or outbound connection.
3. Click **SSL configurations** under Related Items. You can view and select any of the SSL configurations that are configured at this scope. You can also view and select these configuration at every scope that is lower on the topology.
4. Click **New** to display the SSL configuration panel. You cannot select links under Additional Properties until you type a configuration name and click **Apply**.
5. Type an SSL configuration name. This field is required. The configuration name is the SSL configuration alias. Make the alias name unique within the list of SSL configuration aliases that are already created at the selected scope. The new SSL configuration uses this alias for other configuration tasks.
6. Select a truststore name from the drop-down list. A truststore name refers to a specific truststore that holds signer certificates that validate the trust of certificates sent by remote connections during an SSL handshake. If there is no truststore in the list, see “Creating a keystore configuration for a preexisting keystore file” on page 1792 to create a new truststore, which is a keystore whose role is to establish trust during the connection.
7. Select a keystore name from the drop-down list. A keystore contains the personal certificates that represent a signer identity and the private key that WebSphere Application Server uses to encrypt and sign data.
   - If you change the keystore name, click **Get certificate aliases** to refresh the list of certificates from which you can choose a default alias. WebSphere Application Server uses a server alias for inbound connections and a client alias for outbound connections.
   - If there is no keystore in the list, see “Creating a keystore configuration for a preexisting keystore file” on page 1792 to create a new keystore.

8. Choose a default server certificate alias for inbound connections. Select the default only when you have not specified an SSL configuration alias elsewhere and have not selected a certificate alias. A centrally managed SSL configuration tree can override the default alias. For more information, see “Central management of SSL configurations” on page 1718.
9. Choose a default client certificate alias for outbound connections. Select the default only when the server SSL configuration specifies an SSL client authentication.
10. Review the identified management scope for the SSL configuration. Make the management scope in this field identical to the link you selected in Step 2. If you want to change the scope, you must click a different link in the topology tree and continue at Step 3.
11. Click **Apply** if you intend to configure Additional Properties. If not, go to Step 24.
12. Click **Quality of protection (QoP) settings** under Additional Properties. QoP settings define the strength of the SSL encryption, the integrity of the signer, and the authenticity of the certificate.
13. Select a client authentication setting to establish an SSL configuration for inbound connections and for clients to send their certificates, if appropriate.
    - If you select **None**, the server does not request that a client send a certificate during the handshake.
    - If you select **Supported**, the server requests that a client send a certificate. However, if the client does not have a certificate, the handshake might still succeed.
    - If you select **Required**, the server requests that a client send a certificate. However, if the client does not have a certificate, the handshake fails.

    Important: The signer certificate that represents the client must be in the truststore that you select for the SSL configuration. By default, servers within the same cell trust each other because they use the common truststore, `trust.p12`, that is located in the cell directory of the configuration repository. However, if you use keystores and truststores that you create, perform a signer exchange before you select either **Supported** or **Required**.
14. Select a protocol for the SSL handshake.
    - The default protocol, SSL_TLS, supports client protocols TLSv1, SSLv3, and SSLv2.
    - The TLSv1 protocol supports TLS and TLSv1. The SSL server connection must support this protocol for the handshake to proceed.
    - The SSLv3 protocol supports SSL and SSLv3. The SSL server connection must support this protocol for the handshake to proceed.

    Important: Do not use the SSLv2 protocol for the SSL server connection. Use it only when necessary on the client side.
15. Select one of the following options:
    - A predefined Java Secure Socket Extension (JSSE) provider. The IBMJSSE2 provider is recommended for use on all platforms which support it. It is required for use by the channel framework SSL channel. When Federal Information Processing Standard (FIPS) is enabled, IBMJSSE2 is used in combination with the IBMJCEFIPS crypto provider.
    - A custom JSSE provider. Type a provider name in the **Custom provider** field.
16. Select from among the following cipher suite groups:
    - **Strong**: WebSphere Application Server can perform 128-bit confidentiality algorithms for encryption and support integrity signing algorithms. However, a strong cipher suite can affect the performance of the connection.
    - **Medium**: WebSphere Application Server can perform 40-bit encryption algorithms for encryption and support integrity signing algorithms.
    - **Weak**: WebSphere Application Server can support integrity signing algorithms but not to perform encryption. Select this option with care because passwords and other sensitive information that cross the network are visible to an Internet Protocol (IP) sniffer.

- **Custom**: you can select specific ciphers. Any time you change the ciphers that are listed from a specific cipher suite group, the group name changes to Custom.

17. Click **Update selected ciphers** to view a list of the available ciphers for each cipher strength.
18. Click **OK** to return to the new SSL configuration panel.
19. Click **Trust and key managers** under Additional Properties.
20. Select a default trust manager for the primary SSL handshake trust decision.
    - Choose **IbmPKIX** when you require certificate revocation list (CRL) checking using CRL distribution points in the certificates or the online certificate status protocol (OCSP).
    - Choose **IbmX509** when you do not require CRL checking but do need increased performance. You can configure a custom trust manager to perform CRL checking, if necessary.
21. Define a custom trust manager, if appropriate. You can define a custom trust manager that runs with the default trust manager you select. The custom trust manager must implement the JSSE javax.net.ssl.X509TrustManager interface and, optionally, the com.ibm.wsspi.ssl.TrustManagerExtendedInfo interface to obtain product-specific information.
    a. Click **Security > SSL certificate and key management > Manage endpoint security configurations > *SSL_configuration* > Trust and key managers > Trust managers > New**.
    b. Type a unique trust manager name.
    c. Select the **Custom** option.
    d. Type a class name.
    e. Click **OK**. When you return to the Trust and key managers panel, the new custom trust manager displays in the **Additional ordered trust managers** field. Use the left and right list boxes to add and remove custom trust managers.
22. Select a key manager for the SSL configuration. By default, IbmX509 is the only key manager unless you create a custom key manager.

    Important: If you choose to implement your own key manager, you can affect the alias selection behavior because the key manager is responsible for selecting the certificate alias from the keystore. The custom key manager might not interpret the SSL configuration as the WebSphere Application Server key manager IbmX509 does. To define a custom key manager, click **Security > Secure communications > SSL configurations > *SSL_configuration* > Trust and key managers > Key managers > New**.
23. Click **OK** to save the trust and key manager settings and return to the new SSL configuration panel.
24. Click **Save** to save the new SSL configuration.

Results

Important: You can override the default trust manager when you configure at least one custom trust manager and set the com.ibm.ssl.skipDefaultTrustManagerWhenCustomDefined property to `true`. Click **Custom Property** on the SSL configuration panel. However, if you change the default, you leave all the trust decisions to the custom trust manager, which is not recommended for production environments. In test environments, use a dummy trust manager to avoid certificate validation. Remember that these environment are not secure.

What to do next

In this release of WebSphere Application Server, you can associate SSL configurations with protocols using one of the following methods:

- Set the SSL configuration on the thread programmatically
- Associate the SSL configuration with an outbound protocol, and target host and port. For more information, see “Associating a Secure Sockets Layer configuration dynamically with an outbound protocol and remote secure endpoint” on page 1771

- Associate the SSL configuration directly using the alias. For more information, see “Selecting an SSL configuration alias directly from an endpoint configuration” on page 1775
- Manage the SSL configurations centrally by associating them with SSL configuration groups or zones that are scoped for endpoints. For more information, see “Associating Secure Sockets Layer configurations centrally with inbound and outbound scopes” on page 1774.

SSL certificate and key management

Use this page to configure security for Secure Socket Layer (SSL) and key management, certificates, and notifications. The SSL protocol provides secure communications between remote server processes or endpoints. SSL security can be used for establishing communications inbound to and outbound from an endpoint. To establish secure communications, a certificate and an SSL configuration must be specified for the endpoint.

To view this administrative console page, click **Security > SSL certificate and key management**.

Configuration settings:

Specifies the following administrative console tasks:

- Manage endpoint security configurations
- Manage certificate expiration

Use Federal Information Processing Standard (FIPS) algorithms:

Specifies the Federal Information Processing Standard (FIPS)-compliant Java cryptography engine is enabled.

- Does not affect the SSL cryptography that is performed by the application server for z/OS System Secure Sockets Layer (SSSL).
- Does not change the JSSE provider if this cell includes any Application Server versions before the application server for z/OS Version 6.0.x.

When you select the **Use the Federal Information Processing Standard (FIPS)** option, the Lightweight Third Party Authentication (LTPA) implementation uses IBMJCEFIPS. IBMJCEFIPS supports the Federal Information Processing Standard (FIPS)-approved cryptographic algorithms for Data Encryption Standard (DES), Triple DES, and Advanced Encryption Standard (AES). Although the LTPA keys are backwards compatible with prior releases of the application server, the LTPA token is not compatible with prior releases. In prior releases, the application server did not generate the LTPA token using a FIPS-approved algorithm.

The IBMJSSE2 JSSE provider does not perform cryptographic functions directly, and therefore does not need to be FIPS-approved. Instead, the IBMJSSE2 JSSE provider uses the JCE framework for cryptographic functions and uses IBMJCEFIPS when FIPS mode is enabled.

Default: Disabled

Dynamically update the runtime when SSL configuration changes occur:

Specifies that all of the SSL-related attributes and LTPA keys that change must be read from the configuration dynamically after they have been saved, then reused for new connections. To avoid customer impact, it is recommended that changes to production servers be made during off-peak periods.

Default: Enabled

When this option is selected, the configuration is updated each time you configure an SSL communication.

SSL configurations for selected scopes

Use this page to display Secure Socket Layer (SSL) configurations for selected scopes, such as a cell, node, server, or cluster. From this page you can navigate to configuration panels for the following: SSL configurations, dynamic inbound and outbound endpoint SSL configurations, key stores, key sets, key set groups, key managers, and trust managers.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***.

Name:

Specifies the SSL configuration scope, which is derived from the selected object in the hierarchy.

Data type: Text

Direction:

Specifies the direction for which the SSLConfig applies. Inbound refers to any listener port. Outbound refers to outbound end point connections.

Data type: Text

SSL configuration:

Specifies the SSL configuration that is used by requests at this scope.

Data type: Text

Update certificate alias list:

Specifies the certificate aliases contained in the key store for this SSL configuration can be selected from the **Certificate alias in key store** list. You must update the certificate list after choosing a different SSL configuration alias. If you do not update the list, you will save a certificate alias that is not contained in the SSL configuration.

Manage certificates:

Specifies to open the keystore panel for the key store in this SSL configuration, which enables you to manage personal certificates, signers, and certificate requests.

Certificate alias in key store:

Specifies the certificate to use in the key store.

If you select **None**, the Java Secure Sockets Extension (JSSE) key manager determines which certificate is used. If multiple certificates exist in the key store, the key manager might not consistently select the same certificate.

Data type: Text

SSL configurations collection

Use this page to define a list of Secure Sockets Layer (SSL) configurations.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***. Under Related items, click **SSL configurations**.

Table 148. SSL configurations buttons. This table lists the SSL configurations buttons.

Button	Resulting action
New	The Java Secure Socket Extension (JSSE) repertoire is for Java-based SSL communications. You can define a new JSSE configuration that can be used to create an SSLContext, URLStreamHandler, SSLSocketFactory, SSLServerSocketFactory, and so on, using the com.ibm.websphere.ssl.JSSEHelper API.
Delete	Deletes an existing JSSE configuration (administrator only). Be careful that any references to the SSL configuration have been removed prior to deleting this SSL configuration.

Name:

Specifies the unique name of the SSL configuration in the management scope.

SSL configuration settings

Use this page to define Secure Sockets Layer (SSL) configuration properties.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *nodes name***. Under Related items, click **SSL configurations > New**.

Name:

Specifies the unique name of the SSL configuration within the management scope in which it resides. For ways to programmatically access the properties that are configured for this SSL configuration, see the com.ibm.websphere.ssl.JSSEHelper application programming interface (API).

Data type: Text

Trust store name:

Specifies a reference to a specific trust store used by Java Secure Sockets Extension (JSSE). The trust store holds signer certificates that validate the trust of certificates sent by remote connections during an SSL handshake.

Data type: Text
Default: *selected trust store*

Key store name:

Specifies a reference to a specific key store. The key store holds personal certificates that represent the identity of one side of a connection. The public key of this personal certificate is sent to the other side of the connection to establish trust during the handshake. The remote side of the connection needs the root certificate authority (CA) certificate or self-signed public key (signer) to be in the trust store to validate this personal certificate.

Data type: Text
Default: *selected key store*

Get certificate aliases:

Queries the keystore for the aliases of all the personal certificates in the keystore from which to choose.

Default server certificate alias:

Specifies the certificate alias used as the identity for this SSL configuration if one has not been specified elsewhere.

If you select **None**, the Java Secure Sockets Extension (JSSE) key manager determines which certificate is used. If multiple certificates exist in the key store, the key manager might not consistently select the same certificate.

Data type: Text

Default client certificate alias:

Specifies the certificate alias to be used if this configuration is to be used as a client.

If you select **None**, the Java Secure Sockets Extension (JSSE) key manager determines which certificate is used. If multiple certificates exist in the key store, the key manager might not consistently select the same certificate.

Data type: Text

Management scope:

Specifies the scope where this SSL configuration is visible. For example, if you choose a specific node, then the configuration is visible only on that node and on any servers that are part of that node.

Data type: Text

Secure Sockets Layer client certificate authentication

Client software that wants to establish a secure connect to a server by using Secure Socket Layer (SSL) protocol initiates by leveraging SSL protocol or the enhanced protocol called Transport Layer Security (TLS) to perform a SSL handshake with SSL certificates. A personal certificate can represent the server or it can represent a particular client, and is signed by a Certificate Authority (CA) to ensure that the personal certificate is correctly identified.

SSL ensures that the administrator has the CA signer certificate available that is used to sign the personal certificate, and that it is stored in both the client and or the server trusted store. SSL client certificate authentication takes place during the connection handshake by using SSL certificates.

The following events must occur during this process:

- The server side must determine if client authentication is going to take place. The client authentication must be enabled in the SSL configuration of the server and the Common Secure Interoperability version 2 (CSIv2) configuration if Inter-ORB Protocol (IIOP) is used.
- The CSIv2 configuration must take place in global security, not in a security domain.
- The signer certificate of the client must be extracted from the key store of the client and added to the trust store of the server.
- The signer certificate of the server must to be extracted from the key store of the server and added to the trust store of the client.

Configuring a WebSphere server for client authentication

Client certificate authentication occurs if the server side requests that the client side send a certificate. A Websphere server can be configured for client certificate authentication on the SSL configuration. However, if client authentication is needed for IIOP then it must be configured on the CSIv2 configuration.

To configure client certificate authentication on the SSL configuration using the administrative console:

1. Click **Security > SSL certificate and key management > SSL configurations**.
2. Select a SSL configuration.
3. Under Additional Properties, select **Quality of protection (QoP) settings**.
4. Under Client authentication, select **Required**.
5. Click **OK** to save the changes.

Note: You can also use the modifySSLConfig command with the -clientAuthentication flag set to `true` to enable client authentication. See SSLConfigCommands command group for the AdminTask object for more information about this command.

.

To configure client certificate authentication on a CSIv2 inbound connection using the administrative console:

1. Click **Security > Global Security**.
2. Under RMI/IIOP security, select **CSIv2 inbound communications**.
3. In the CSIv2 Transport Layer section, and under Client certificate authentication, select **Required**.
4. Click **OK** to save the changes

Note: You can also use the configureCSIInbound command with the -clientCertAuth flag set to `Required` to enable client authentication on CSIv2. Read SecurityConfigurationCommands command group for the AdminTask object for more information about this command.

If the client side is set up for client authentication, the signer certificate of the client must be added to the trust store of the server. When you have a certificate from the client in a certificate file it can be added to the trust store of the server.

To add a signer to the trust store of the server using the administrative console:

1. Click **Security > SSL certificate and key management > Key stores and certificates**.
2. Select the trust store that is configured for client authentication.
3. Under Additional Properties, select **Signer Certificates**.
4. Click **Add**.
5. In the Alias field, type an alias name under which to store the certificate.
6. In the File name box, type the full path to the certificate file.
7. Click **OK** to save the changes

Note: You can also use the addSignerCertificate command to add a signer to the trust store of the server. Read SignerCertificateCommands command group for the AdminTask object for more information about this command.

Note: If you are using client authentication in a cluster environment, client authentication must be configured for each node that the servers in the cluster are located in.

Setting up the client side for client authentication

Clients:

Administrative clients, thin clients or pure clients must have a personal certificate in their key stores. The WebSphere client default key store that is created when WebSphere Application Server is installed already has a personal certificate in it. This key store can be found in the **ssl.client.props** file in the com.ibm.ssl.keyStore property. The client key stores are not managed by WebSphere Application Server, so the Key Management utility (iKeyman) or Java keytool utility can be used to extract the certificate to a certificate file.

To extract a certificate using iKeyman:

1. Start iKeyman.
2. Select **Key Database File > open**.
3. Enter the path to the keystore file. You can obtain this from the **ssl.client.props** file.
4. Click **OK**.
5. Enter the password to the key store and click **OK**
6. Under Personal Certificates, select the client default certificate.
7. Enter a path and file name for the certificate file and click **OK**.

The file that contains the extracted certificate can be used to add the signer to the trust store of the server. Follow the steps in the "Configuring a WebSphere server for client authentication" section to add that signer to the server trust store.

If the communication is over IIOP, the following properties must be set in the **sas.client.props** file.

- Enable SSL:

  ```
  com.ibm.CSI.performTransportAssocSSLTLSSupported=true
  com.ibm.CSI.performTransportAssocSSLTLSRequired=false
  ```

- Disable client authentication at the message layer:

  ```
  com.ibm.CSI.performClientAuthenticationRequired=false
  com.ibm.CSI.performClientAuthenticationSupported=false
  ```

- Enable client authentication at the transport layer (this is supported, but not required):

  ```
  com.ibm.CSI.performTLClientAuthenticationRequired=false
  com.ibm.CSI.performTLClientAuthenticationSupported=true
  ```

Thin clients and pure clients might not use the WebSphere Application Server SSL properties file, **ssl.client.props**. They most likely use the Java system properties to set the client key store and trust store. The signer certificate of the server must be added to the trust store that is specified with the java.net.ssl.trustStore system property. Keytool or iKeyman can be used to add the signer certificate. The signer must be extracted from the personal certificate in the key store specified by the javax.net.ssl.keyStore system property, and added to the trust store of the server.

For example:

```
javax.net.ssl.keyStore
javax.net.ssl.keyStorePassword
javax.net.ssl.keyStoreType
javax.net.ssl.trustStore
javax.net.ssl.trustStorePassword
javax.net.ssl.trustStoreType
```

Server acting as a client:

The client can be a WebSphere server acting as a client. If so, determine which SSL configuration is being used as the client side of the communication, extract it's certificate's signer and add it to the server side trust store. It is recommended that the root certificate signer be used.

To extract the root certificate using the administrative console:

1. Click **Security > SSL certificate and key management > Key stores and certificates**.

2. Under the Keystore usages pull-down, select **Root certificate keystore**.
3. Select either **DmgrDefaultRootStore** (for a network deployment server) or **NodeDefaultRootStore** (for an application server).
4. Under Additional Properties, select **Personal certificates**.
5. Select the default root certificate (usually called *root*), and then click **Extract**.
6. In the Certificate file name box, type a full path to the file in which to hold the certificate.
7. Click **OK** to save.

Note: You can also use the extractCertificate command to extract the root certificate. Read PersonalCertificateCommands command group for the AdminTask object for more information about this command.

The certificate file that is created can be carried to the server side and added to the trust store of the server.

When a server acts as a client, the client side server requires the signer from the destination server. The signer can be retrieved using the signer certificate **Retrieve from port** option.

To retrieve the signer from the port using the administrative console:
1. Click **Security > SSL certificate and key management > Key stores and certificates**.
2. Select the trust store of the server from the collection.
3. Under Additional Properties, select **Signer certificates**.
4. Click **Retrieve from port**.
5. Enter a destination host name and a destination port name.
6. Enter an alias name for the certificate.
7. Click **Retrieve signer information**.
8. Click **OK** to save.

You can also use the retrieveSignerFromPort command to retrieve the signer from the port. Read SignerCertificateCommands command group for the AdminTask object for more information about this command.

Setting up a browser for client authentication:

When WebSphere Application Server is configured for client certificate authentication, and an attempt is made to access the server from a browser, the browser must have a certificate for the client certificate authentication. If the default SSL configuration of the server was modified to enable client certificate authentication you are unable to login to the administrative console.

You can create a certificate for the browser by using the administrative console. You must first create a key store and then create a chained certificate. After the certificate is created, use the instructions for your browser to import a certificate. Browsers require that each part of the chain be added to verify the certificate, so the root certificate must be extracted and added to the browser. Follow the instructions in the "Setting up the client side for client authentication" section for information about extracting the root certificate.

To create a key store using the administrative console:
1. Click **Security > SSL certificate and key management > Key stores and certificates**.
2. Click **New**.
3. Enter a name for the key store.
4. Enter the full path to the key store file.

5. Enter a password for the key store and then confirm.
6. Click **OK** to save.

To create a chained certificate using the administrative console:
1. Click **Security > SSL certificate and key management > Key stores and certificates**.
2. Select the key store you created previously.
3. Under Additional Properties, click **Personal certificates**.
4. In the pull-down list under the Create button, select **Chained Certificate**.
5. Enter an alias name for the certificate.
6. Provide a common name for the certificate. The name is the "CN=" part of the subject DN.
7. You can enter information in any of the remaining fields to build the subject DN of the chained certificate.
8. Click **OK** to save.

You can also use the createKeyStore command to create a key store. Read KeyStoreCommands command group for the AdminTask object for more information about this command.

You can also use the createChainedCertificate command to create a chained certificate. Read PersonalCertificateCommands command group for the AdminTask object for more information about this command.

Note: When client certificate authentication is enabled, web certificate authentication can then be performed as discussed in the next section.

Web certificate authentication

Certificate base authentication can be performed on Java 2 Platform, Enterprise Edition (J2EE) web modules when the module is configured for client certificate authentication. This enables a user to login to a web module using a certificate to authenticate, and to map that certificate to a user from the registry.

Enabling web certificate authentication requires that the SSL configuration of the server be configured for client certificate authentication on the server where the module is installed.

The server side determines that client authentication is to take place. See the "Configuring a WebSphere server for client authentication" section for information about how to configure client authentication. The client side must have the signer from the server to add to the client truststore. See the "Setting up the client side for client authentication" section for more information.

The **web.xml** file of the web module must have the authentication method set to CLIENT-AUTH in the login-config section of the **web.xml** file:

```
<login-config>
<auth-method>CLIENT-CERT</auth-method>
</login-config>
```

The certificate must map to a user in the registry or you are unable to login to that web module.

For localOS user registries, the CN value of the certificate subject DN must map to a user in the local OS user registry. For example, if the certificate subject DN is `CN=tester,o=ibm,c=us`, then `tester` is the user searched for in the local user registry. If that user does not exist in the local registry then the authentication fails.

The Lightweight Directory Access Protocol (LDAP) user registry provides more options for mapping a certificate to a user identity. The default certificate mapping mode in LDAP is used for an exact DN match between the entry in the LDAP registry and the subject DN in the certificate. For example, if the certificate

DN is `CN=user1,o=ibm,c=us`, then there must be an entry in the LDAP registry with that exact value. The LDAP user registry also has a certificate filter option that can provide a match to a particular part of the certificate subject DN against entries in the LDAP repository. For more detail on LDAP certificate mapping, read "Lightweight Directory Access Protocol repository configuration settings".

A federated repository file-based registry does not support certificate mapping, but the federated repository LDAP registry does. It uses the same mapping rules and properties that the LDAP user registry uses.

Custom user registry can map certificates to a user if the custom registry implemented the mapCertificate() method.

Certificate authority (CA) client configuration

Use this page to create, modify, and configure a certificate authority (CA) client.

To view this administrative console page, click **Security > SSL Configurations and key management** . Under Related Items, click **Certificate Authority (CA) client configurations**. Then click either the **New** button or select an existing CA client by clicking on its <client_name>.

Name:

Specifies the unique name of the CA client configuration. This is the name to identify the CA client object. This name needs to be unique to the scope.

Data type: String

Implementation class:

Specifies the name of the module that implements the com.ibm.wsspi.ssl.WSKPIClient interface that is used to act as a client to a CA. This implementation class connects to the CA server and performs a certificate create, revoke, or replace.

Default: String

CA server host name:

Specifies the host name of the CA server, if the implementation requires a host name.

Data type: String

Port:

Specifies the port where the CA server will communicate, if the implementation requires a port.

Data type: String

User name:

Specifies the user Id used to connect to the CA server, if the implementation requires a user to login to the CA.

Data type: String

Password:

Specifies the password for the connection to the CA server.

Data type: String

Confirm password:

Confirms the password that is provided in the password field.

Data type: String

Number of times to poll:

Specifies the number of times to check the CA server to see if the certificate is complete. This poll number applies to the CA that does not return certificates right away.

Default: 5

Polling interval when requesting certificates:

Specifies the amount of time, in minutes, between checks to the CA server to see if the certificate is complete.

Default: 10

Custom properties:

Specifies arbitrary name and value pairs of data. The name is a property key, and the value is a string value that can be used to set internal system configuration properties.

Data type: string

Certificate authority (CA) client configuration collections

Use this page to define and manage certificate authority (CA) clients or view and modify existing CA clients.

This panel allows you to create a certificate authority (CA) client object in the configuration. You can also view and modify existing CA clients. The information in the CA client object can then be used by the runtime to connect to a CA server to request, revoke, or query a certificate.

To view this administrative console page, click **Security > SSL Configurations and key management >** . Under Related Items, click **Certificate Authority (CA) client configurations**.

Table 149. CA client configuration buttons.

This table describes the CA client configuration buttons.

Button	Resulting action
New	Adds a new CA client object that can be referenced by Secure Sockets Layer (SSL) configurations.
Delete	Deletes an existing CA client object.

Name:

Identifies the unique name of the CA client configuration.

Implementation class:

Identifies the name of the module that implements the **com.ibm.wsspi.ssl.WSKPIClient** interface that is used to act as a client to a CA.

Management Scope:

Identifies the scope where this secure sockets layer (SSL) configuration is visible.

Creating a chained personal certificate in SSL

A chained personal certificate is a personal certificate that is created by using another personal certificate to sign it. This chaining allows a certificate to be signed with a certificate (a root certificate) that has a long life span. Root certificates are stored in the **DmgrDefaultRootStore** or **NodeDefaultRootStore**. The server's default personal certificate is a chained certificate created when the profile is created. Chained certificates can also be created after profile creation

Before you begin

You use the administrative console to create a chained personal certificate.

Procedure

1. Click **Security > SSL certificate and key management**.
2. Under Related Items, click **Key stores and certificates**.
3. Click a **<keystore name>** to which you want to add the chained personal certificate.
4. Under Additional Properties, click **Personal certificates** .
5. Click the **Create** button and select **Chained Certificate** The **listCertificates** AdminTask can be used to generate the list of root certificates available to sign the certificate.
6. Fill in the following information to the General Properties section as follows:
   - Supply an alias name.
   - Select Root certificate from the pull down list.
   - Key size
   - Common name
   - Validity period
   - Organization
   - Organization Unit
   - Locality
   - State/Province
   - Zip code
   - Country or region
   -
7. Click **Apply** then **OK**.

Results

The certificate is created, signed by the root certificate specified, and stored in the keystore. Once a chained personal certificate is created, the certificate can be used by the runtime for SSL communication.

Recovering deleted certificates in SSL

The SSL configuration contains a keystore created to hold personal certificates that were deleted from other keystores in the configuration. Perform this task to recover deleted certificates.

Before you begin

The SSL configuration contains a keystore created to hold personal certificates that were deleted from other keystores in the configuration. On a stand alone application server the keystore is called `NodeDefaultDeletedStore` and on a deployment manager the keystore is called `DmgrDefaultDeletedStore`.

When a personal certificate is deleted from a keystore using the administrative console or in a script using the deleteCertificate AdminTask, a copy of the certificate is stored in the `DmgrDeletedKeyStore` or `NodeDeletedKeyStore`. The personal certificate takes the alias of <keystore>_<alias> > in the deleted keystore. If the alias name is already used in that deleted keystore a <unique number> is appended to the alias.

A personal certificate can be recovered from the deleted keystore by importing or exporting the personal certificate to a keystore in the configuration. To recover a personal certificate using the administrative console perform the following steps:

Procedure

1. Click **Security > SSL certificate and key management**.
2. Under Related Items, click **Key stores and certificates**.
3. From the Keystore usages drop-down list, select "Deleted certificates keystore".
4. Click **DmgrDefaultDeletedStore** or **NodeDefaultDeletedStore**.
5. Under Additional Properties, click **Personal certificates**.
6. Select a certificate.
7. Select **Export**
8. Click **OK**.
9. Perform the following:
   - • Enter the keystore password of the deleted keystore.
   - • Enter The alias to be assigned to the certificate (in the key store that will receive the certificate).
   - • Select the ‘Managed key store’ radio button.
   - • Select the key store from the drop down list that will receive the certificate.
   - Click **Apply** then **OK**.

Results

Note: To recover a personal certificate you can also use the exportCertToManagedKS AdminTask command.

Renewing a certificate in SSL

If a personal certificate has been compromised or is about to expire, then it should be renewed. Renewing a certificate recreates the certificate with all the information from the original certificate, but with a new expiration period and public/private key pair. Only self-signed certificates and chained certificates created by WebSphere can be renewed. If the certificate used to sign the chained certificate is not in the root keystore then the default root certificate is used to renew the certificate.

Before you begin

You use the administrative console to renew the certificate.

Procedure

1. Click **Security > SSL certificate and key management**.
2. Under Related Items, click **Key stores and certificates**.
3. Click the appropriate **<keystore name>** to which you want to add the new certificate.

Note: Only self-signed certificates and chained certificates signed with root certificates from the root keystore can be renewed.

4. Under Additional Properties, click **Personal certificates** to list the personal certificates.
5. Select a personal certificate from the list.
6. Click the **Renew** button.
7. Click **Apply** then **OK**.

Results

The certificate is renewed in the key store selected in the path to this panel . If the certificate is not a self-signed certificate or a chained certificate signed with a root certificate from the default root store, an error is returned.

Note: If this command is used with a CA certificate, an error occurs.

Revoking a CA certificate in SSL

If a certificate authority (CA) certificate is compromised and the servers cannot trust it anymore that CA certificate can be revoked. To revoke a CA certificate, you perform the following task.

Before you begin

You use the administrative console to replace or revoke a CA certificate.

Procedure

1. Click **Security > SSL certificate and key management**.
2. Under Related Items, click **Key stores and certificates**.
3. Click a **<keystore name>** to which you want to add the new CA certificate.
4. Under Additional Properties, click **Personal certificates** to list the personal certificates.
5. Select a certificate to revoke (a CA certificate)
6. Click the **Revoke** button.
7. Fill in the following information to the CA certificate section.
   - Revocation password
   - Revocation reason
8. Click **Apply** then **OK**.

Results

The certificate is revoked in the key store selected in the path. If the certificate selected was not a CA certificate, then an error is returned.

What to do next

Using a CA client to create a personal certificate to be used as the default personal certificate

An external certificate authority (CA) certificate can be used as the server default personal certificate. The CA certificate can be created using a CA client.

Before you begin

What you need to have before you perform this task is as follows:

- A certificate authority (CA) to make the certificate request to.

- A module that implements the **com.ibm.wsspi.ssl.WSPKIClient** interface. This module is needed to connect to the CA server and request a certificate.

You use the administrative console to view or modify a CA client.

Procedure

1. Click **Security > SSL certificate and key management**.
2. Under Related Items, click **Certificate Authority (CA) client configurations**. A panel displaying the existing CA clients appears.
3. Click the **New** button.
4. Enter the CA client information as required.
   - Name of the CA client.
   - The management scope (selected from the drop-down list.
   - Implementation class.
   - CA server host name.
   - User name.
   - Password.
   - Confirm of password.
   - Number of times to poll.
   - Polling interval (in minutes) when requesting certificates.
   - Custom properties.
5. Click **Apply** then **Save**.
6. Navigate to the Server default key store personal certificate. **Security > SSL configuration and certificate management > Key stores and certificates > <server_default_keystore>** . Under Additional properties, click **Personal certificates**
7. Click the **Create** button and select **CA-signed certificate**
8. Fill in the following information to the CA certificate section.
   - Revocation password
   - Confirm password.
   - Select the CA client that applies to this CA certificate.

     Note: You can create a new CA client to apply to this CA authority by clicking the **New** button.
   - Fill in the following information to the Request Specification section:
     – Select the radio button for Predefined request alias if you have a predefined alias.
     – If you do not have a predefined alias, fill in the following fields:
       - Type an alias name in the Alias field. The alias identifies the certificate request in the keystore.
       - Type a common name (CN) value. This value is the CN value in the certificate distinguished name (DN).
       - **Optional:** Type an organization value. This value is the O value in the certificate DN.
       - **Optional:** Select a key size value. The valid key size values are 512, 1024, 2048, 4096, and 8192. The default key size value is 2048 bits.
       - Locality
       - **Optional:** Type the State or Province value. This value is the ST value in the certificate DN.
       - **Optional:** Type a zip code value. The zip code value is the POSTALCODE value in the certificate DN.
       - **Optional:** Type a country or region value from the list. This country value is the C= value in the certificate request DN.

- Validity period

9. Click **Apply** then **Save**.
10. Navigate to the Server Default Key store's personal certificates **Security > SSL configuration and certificate management > Key stores and certificates > <server_default_keystore>** . Under Additional properties, click **Personal certificates**
11. Select the server default personal certificate and click the **Replace** button.
12. Select the CA certificate alias from the list of aliases.
13. Click **Apply** then **Save**.

Results

The CA certificate alias replaces the alias of the default certificate in places where it is referenced in the configuration. All signer certificates from the default certificate are replaced with the signer certificate from the CA certificate.

Creating a CA certificate in SSL

Certificates can be created by a certificate authority (CA) when a CAClient object is configured to connect to the CA to create the certificate. Certificates created by a certificate authority (CA) with a CA client are tracked in the security configuration in an object called `CACertificate`. The certificate is stored in a keystore and a `CACertificate` object is added to the configuration to reference the certificate. CA certificates are personal certificates.

Before you begin

Before you begin, a CA client must be created to connect to the CA server. You then use the administrative console to create a CA certificate.

Note: In this release of WebSphere Application Server, the valid key size values are 512, 1024, 2048, 4096, and 8192. The default key size value is 2048 bits.

Procedure

1. Click **Security > SSL certificate and key management**.
2. Under Related Items, click **Key stores and certificates**.
3. Click a **<keystore name>** to which you want to add the new CA certificate.
4. Under Additional Properties, click **Personal certificates** to create a new CA certificate in the configuration.

   Note: You can also create a CA certificate by using the **requestCACertificate** AdminTask .
5. Click the **Create** button and select **CA-signed Certificate**
6. Fill in the following information to the CA certificate section.
   - Revocation password
   - Confirm password.
   - Select the CA client from the pull down list.

     Note: You can create a new CA client to apply to this CA authority by clicking the **New** button.
   - Fill in the following information to the Request Specification section:
     – Select the radio button for a predefined request alias if a certificate request is already created.
     – If you do not have a predefined certificate request alias, fill in the following fields:
       a. Type an alias name in the Alias field. The alias identifies the certificate request in the keystore.

b. Type a common name (CN) value. This value is the CN value in the certificate distinguished name (DN).
c. **Optional:** Type an organization value. This value is the O value in the certificate DN.
d. **Optional:** Select a key size value. The valid key size values are 512, 1024, 2048, 4096, and 8192. The default key size value is 2048 bits.
e. Locality
f. **Optional:** Type the State or Province value. This value is the ST value in the certificate DN.
g. **Optional:** Type a zip code value. The zip code value is the POSTALCODE value in the certificate DN.
h. **Optional:** Type a country or region value from the list. This country value is the C= value in the certificate request DN.

7. Click **Apply** then **OK**.

Results

The certificate is stored in the keystore selected in the path to this panel and a CACertificate configuration object is created. Once a CA certificate is created the certificate can be used by the runtime for SSL communication.

An existing certificate request can be used to create the CA certificate or a new certificate request can be created. This panel uses the requestCAClient AdminTask to create the CA certificate.

Developing the WSPKIClient interface for communicating with a certificate authority

Implementing the WSPKIClient interface enables WebSphere Application Server security to communicate with a remote certificate authority (CA).

Procedure

1. Initialize the WSPKIClient method, with init(java.util.HashMap).

   ```
   public void init(java.util.HashMap initAttrs) throws WSPKIException;
   ```

   This method is called by WebSphere Application Server runtime to set up connection information to a CA.

2. • Request a certificate with requestCertificate(byte[], X500Principal, byte[], java.util.HashMap).

   ```
   public X509Certificate[] requestCertificate(byte[] certReq,
   X500Principal SubjectDN, byte[] revocationPassword,
   java.util.HashMap customAttrs) throws WSPKIException;
   ```

   This method is called by WebSphere Application Server runtime to connect to a CA and requests a certificate signed by the authority. A X509Certificate[] is returned if the requested certificate is created. If a null is returned then queryCertificate() is called to check if the certificate is ready. This method is used when the CA requires manual intervention to process a certificate request.

   You can invoke this operation from the administrative console using the “Creating a CA certificate in SSL” on page 1759 task and from a client using the requestCertificate script.

3. • Revoke a certificate with revokeCertificate(X509Certiifcate[], byte[], String, java.util.HashMap).

   ```
   public void revokeCertificate(X509Certificate[] cert, byte[] revocationPassword,
   String revocationReason, java.util.HashMap customAttrs) throws WSPKIException;
   ```

   This method called by WebSphere Application Server runtime to submit a request to a CA to revoke a certificate.

   You can invoke this operation from the administrative console using the revoke CA certificate task, “Revoking a CA certificate in SSL” on page 1757, or using the revokeCertificate script.

4. • Query a certificate with queryCertificate(X509Certiifcate[], byte[], java.util.HashMap).

```
public X509Certificate[] queryCertificate(byte[] certReq,
java.util.HashMap customAttrs) throws WSPKIException;
```

This method is called by WebSphere Application Server runtime to query if certificate creation is completed on the CA. A X509Certificate[] is returned if certificate request is complete. A null is returned if the certificate request is pending.

You perform this operation from the administrative console using the Query (link to usec_sslperscertreqs.html) option, see “Personal certificate requests collection” on page 1811and from a client using the queryCertificate script.

Results

the WSPKIClient interface for communicating with a certificate authority (CA) is implemented.

Creating a custom trust manager configuration for SSL

You can create a custom trust manager configuration at any management scope and associate the new trust manager with a Secure Sockets Layer (SSL) configuration.

Before you begin

You must develop, package, and locate a Java Archive JAR file for a custom key manager in the `was.install.root/lib/ext` directory on WebSphere Application Server. For more information, see “Example: Developing a custom trust manager for custom SSL trust decisions” on page 1765.

About this task

Complete the following steps in the administrative console:

Procedure

1. Decide whether you want to create the custom trust manager at the cell scope or below the cell scope at the node, server, or cluster, for example.

   Important: When you create a custom trust manager at a level below the cell scope, you can associate it only with a Secure Sockets Layer (SSL) configuration at the same scope or higher. An SSL configuration at a scope lower than the trust manager does not see the trust manager configuration.

   - To create a custom trust manager at the cell scope, click **Security > SSL certificate and key management > Trust managers**. Every SSL configuration in the cell can select the trust manager at the cell scope.
   - To create a custom trust manager at a scope below the cell level, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration* > Trust managers**.
2. Click **New** to create a new custom trust manager.
3. Type a unique trust manager name.
4. Select the **Custom** implementation setting. The custom setting enables you to define a Java class with an implementation of the javax.net.ssl.X509TrustManager Java interface and, optionally, the com.ibm.wsspi.ssl.TrustManagerExtendedInfo WebSphere Application Server interface.

   Note: The standard implementation setting applies only when the trust manager is already defined in the Java security provider list as a provider and an algorithm, which is not the case for a custom trust manager.
5. Type a class name, for example, com.ibm.test.CustomTrustManager.
6. Select one of the following actions:

- Click **Apply**, then click **Custom properties** under Additional Properties to add custom properties to the new custom trust manager. When you are finished adding custom properties, click **OK** and **Save**, then go to the next step.
- Click **OK** and **Save**, then go to the next step.

7. Click **SSL certificate and key management** in the page navigation at the top of the panel.
8. Select one of the following actions:
   - Click **SSL configurations** under Related Items for a cell-scoped SSL configuration.
   - Click **Manage endpoint security configurations** to select an SSL configuration at a lower scope.
9. Click the link for the existing SSL configuration that you want to associate with the new custom trust manager. You can create a new SSL configuration instead of associating the custom trust manager with an existing configuration. For more information, see "Creating a Secure Sockets Layer configuration" on page 1741.
10. Click **Trust and Key managers** under Additional Properties. If the new custom trust manager is not listed in the **Additional ordered trust managers** list, verify that you selected an SSL configuration scope that is at the same level or below the scope that you selected in Step 8.
11. Click **Add**. This action adds the new trust manager to the list of custom trust managers.
12. Click **OK** and **Save**.

Results

You have created a custom trust manager configuration that references a JAR file in the install directory of WebSphere Application Server and associates it with an SSL configuration during the connection handshake.

What to do next

You can create a custom trust manager for a pure client. For more information, see the TrustManagerCommands command group for the AdminTask object topic.

Trust and key managers settings:

Use this page to specify trust and key managers for the selected SSL configuration.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***. Under **Related items** click **SSL configurations >** *SSL_configuration_name*. Under **Additional Properties** click **Trust and key managers**.

Attention: The application server checks the default trust managers first before checking the additional ordered trust managers in descending order.

Default trust manager:

Specifies the default trust manager. The default trust manager is IbmPKIX, which can be selected when certificate revocation checks must be made using the X509Certificate CRL distribution list. The other default trust manager is IbmX509.

Data type:	Text
Default:	ibmPKIX

Additional ordered trust managers:

Specifies additional trust managers that are used in the order shown for this SSL configuration.

Add:

Specifies to add the selection to the **Additional ordered trust managers** right-hand list.

Remove:

Specifies to remove the selection from the **Additional ordered trust managers** right-hand list.

Key manager:

Specifies the key manager that runs for this SSL configuration.

Data type: Text
Default: IbmX509

Trust managers collection:

Use this page to define the implementation settings for the trust manager. A trust manager is a class that is invoked during a Secure Sockets Layer (SSL) handshake to make trust decisions about the remote end point. A default trust manager is used to validate the signature and expiration of the certificate. Custom trust managers can be plugged in to perform an extended certificate and host name check.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***. Under Related items, click **Trust managers**.

Table 150. Trust managers buttons. This table describes the trust manager buttons.

Button	Resulting action
New	Adds a new trust manager that can be selected by an SSL configuration. A trust manager is invoked during an SSL handshake and can decide whether the handshake should be accepted based on the information it knows about the remote certificate and host.
Delete	Deletes an existing trust manager. Make sure the trust manager is not referenced by any SSL configuration before you delete it.

Name:

Specifies the name of the trust manager. This name is used as a selection in the SSL configuration panel.

Class name:

Specifies a class that implements the javax.net.ssl.X509TrustManager interface. Optionally, the class can implement the com.ibm.wsspi.ssl.TrustMangerExtendedInfo interface to get extended information about the connection. The class can use the information to verify the host name and so on.

Algorithm:

Specifies the algorithm name of the trust manager that is implemented by the selected provider.

Trust managers settings:

This page enables you to view and set definitions for trust manager implementation settings. A trust manager is a class that gets invoked during a Secure Sockets Layer (SSL) handshake to make trust decisions about the remote end point. A default trust manager is used to validate the signature and expiration of the certificate. Custom trust managers can be plugged in to perform an extended certificate and hostname check.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration*** . Under Related items click **Trust managers > New** .

Name:

Specifies the name of the trust manager.

Data type: Text
Default: ibmX509TrustManager

Management scope:

Specifies the scope where this Secure Sockets Layer (SSL) configuration is visible. For example, if you choose a specific node, then the configuration is only visible on that node and any servers that are part of that node.

This field is not editable and provides information only.

Standard:

Specifies that the trust manager selection is available from a Java provider that is installed in the java.security file. This provider might be shipped by the Java Secure Sockets Extension (JSSE) or might be a custom provider that implements the javax.net.ssl.X509TrustManager interface.

Default: Enabled

Provider:

Specifies the provider name that has an implementation of the javax.net.ssl.X509TrustManager interface. This provider is typically set to IBMJSSE2.

Enabled when **Standard** is selected.

Default IBMJCE

Algorithm:

Specifies the algorithm name of the trust manager implemented by the selected provider.

Enabled when **Standard** is selected.

Default ibmX509 or IbmPKIX
Range ibmX509, IbmPKIX

Custom:

Specifies that the trust manager selection is based on a custom implementation class that implements the javax.net.ssl.X509TrustManager interface and optionally the com.ibm.wsspi.ssl.TrustManagerExctendedInfo interface to obtain additional connection information that is not otherwise available.

Default: Disabled

Class name:

Specifies a class that implements the javax.net.ssl.X509TrustManager interface. Optionally, the class can implement the com.ibm.wsspi.ssl.TrustMangerExtendedInfo interface to get extended information about the connection. The class can use the information to verify the host name and so on.

Enabled when **Custom** is selected.

Data type: Text

Example: Developing a custom trust manager for custom SSL trust decisions:

The following example is of a sample custom trust manager. The custom trust manager makes no trust decisions but instead uses the information in the X.509 certificate that it references to make decisions.

After you build and package the custom trust manager, configure it either from the `ssl.client.props` file for a pure client or the SSLConfiguration TrustManager link in the administrative console. See "Trust manager control of X.509 certificate trust decisions" on page 1709 for more information about trust managers.

Note: This example should only be used as a sample, and is not supported.

```
import java.security.cert.X509Certificate;
import javax.net.ssl.*;
import com.ibm.wsspi.ssl.TrustManagerExtendedInfo;

public final class CustomTrustManager implements X509TrustManager,
TrustManagerExtendedInfo
{
    private static ThreadLocal threadLocStorage = new ThreadLocal();
    private java.util.Properties sslConfig = null;
    private java.util.Properties props = null;

    public CustomTrustManager()
    {
    }

    /**
     * Method called by WebSphere Application Server run time to set the target
     * host information and potentially other connection info in the future.
     * This needs to be set on ThreadLocal since the same trust manager can be
     * used by multiple connections.
     *

        {
            System.out.println("Server certificate information:");
            System.out.println("  Subject DN: " + chain[j].getSubjectDN());
            System.out.println("  Issuer DN: " + chain[j].getIssuerDN());
            System.out.println("  Serial number: " + chain[j].getSerialNumber());
            System.out.println("");
        }
    }

    /**
     * Return an array of certificate authority certificates which are trusted
     * for authenticating peers. You can return null here since the IbmX509
     * or IbmPKIX will provide a default set of issuers.
     *
     * See API documentation for javax.net.ssl.X509TrustManager.
     */
    public X509Certificate[] getAcceptedIssuers()
    {
        return null;
    }
}
```

Creating a custom key manager for SSL

You can create a custom key manager configuration at any management scope and associate the new key manager with a Secure Sockets Layer (SSL) configuration.

Before you begin

You must develop, package, and locate a Java Archive (.JAR) file for a custom key manager in the `was.install.root/lib/ext` directory on WebSphere Application Server.

About this task

Complete the following steps in the administrative console:

Procedure

1. Decide whether you want to create the custom key manager at the cell scope or below the cell scope at the node, server, or cluster, for example.

   Important: When you create a custom key manager at a level below the cell scope, you can associate it only with a Secure Sockets Layer (SSL) configuration at the same scope or higher. An SSL configuration at a scope lower than the key manager does not see the key manager configuration.

   - To create a custom key manager at the cell scope, click **Security > SSL certificate and key management > Key managers**. Every SSL configuration in the cell can select the key manager at the cell scope.
   - To create a custom key manager at a scope below the cell level, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > *SSL_configuration* > Key managers**.
2. Click **New** to create a new key manager.
3. Type a unique key manager name.
4. Select the **Custom** implementation setting. With the custom setting, you can define a Java class that has an implementation on the Java interface javax.net.ssl.X509KeyManager and, optionally, the com.ibm.wsspi.ssl.KeyManagerExtendedInfo WebSphere Application Server interface. The standard implementation setting applies only when the key manager is already defined in the Java security provider list as a provider and an algorithm, which is not the case for a custom key manager. The typical standard key manager is `algorithm = IbmX509, provider = IBMJSSE2`.
5. Type a class name. For example, com.ibm.test.CustomKeyManager.
6. Select one of the following actions:
   - Click **Apply**, then click **Custom properties** under Additional Properties to add custom properties to the new custom key manager. When you are finished adding custom properties, click **OK** and **Save**, then go to the next step.
   - Click **OK** and **Save**, then go to the next step.
7. Click **SSL certificate and key management** in the page navigation at the top of the panel.
8. Select one of the following actions:
   - Click **SSL configurations** under Related Items for a cell-scoped SSL configuration.
   - Click **Manage endpoint security configurations** to select an SSL configuration at a lower scope.
9. Click the link for the existing SSL configuration that you want to associate with the new custom key manager. You can create a new SSL configuration instead of associating the custom key manager with an existing configuration. For more information, see example below.
10. Click **Trust and Key managers** under Additional Properties.
11. Select the new custom key manager in the **Key manager** drop-down list. If the new custom key manager is not listed, verify that you selected an SSL configuration scope that is at the same level or below the scope that you selected in Step 8.
12. Click **OK** and **Save**.

Results

You have created a custom key manager configuration that references a JAR file in the installation directory of WebSphere Application Server and associates the custom configuration with an SSL configuration during the connection handshake.

Example

Developing a custom key manager for custom Secure Sockets Layer key selection. The following example is of a sample custom key manager. This simple key manager returns the configured alias if it is set using the alias properties com.ibm.ssl.keyStoreClientAlias or com.ibm.ssl.keyStoreServerAlias, depending on which side of the connection the key manager is used. The key manager defers to the JSSE default IbmX509 key manager to select an alias if these properties are not set.

After you build and package a custom key manager, you can configure it from either the `ssl.client.props` file for a pure client or by using the SSLConfiguration KeyManager link in the administrative console. See “Key manager control of X.509 certificate identities” on page 1711 for more information about key managers.

Because only one key manager can be configured at a time for any given Secure Sockets Layer (SSL) configuration, the certificate selections on the server side might not work as they would when the default IbmX509 key manager is specified. When a custom key manager is configured, it is up to the owner of that key manager to ensure that the selection of the alias from the SSL configuration supplied is set properly when `chooseClientAlias` or `chooseServerAlias` are called. Look for the `com.ibm.ssl.keyStoreClientAlias` and `com.ibm.ssl.keyStoreServerAlias` SSL properties.

Note: This example should only be used as a sample, and is not supported.

```
package com.ibm.test;

import java.security.cert.X509Certificate;
import com.ibm.wsspi.ssl.KeyManagerExtendedInfo;

public final class CustomKeyManager
 implements javax.net.ssl.X509KeyManager, com.ibm.wsspi.ssl.KeyManagerExtendedInfo
{
    private java.util.Properties props = null;
    private java.security.KeyStore ks = null;
    private javax.net.ssl.X509KeyManager km = null;
    private java.util.Properties sslConfig = null;
    private String clientAlias = null;
    private String serverAlias = null;
    private int clientslotnum = 0;
    private int serverslotnum = 0;

    public CustomKeyManager()
    {
    }

    /**
     * Method called by WebSphere Application Server runtime to set the custom
     * properties.
     *
     * @param java.util.Properties - custom props
     */
    public void setCustomProperties(java.util.Properties customProps)
    {
        props = customProps;
    }

    }

}
```

What to do next

You can create a custom key manager for a pure client. For more information, see the keyManagerCommands command group for the AdminTask object.

Associating a Secure Sockets Layer configuration dynamically with an outbound protocol and remote secure endpoint

After you create a Secure Sockets Layer (SSL) configuration, you must associate a secure outbound management scope with the new configuration. In this release, you can associate one SSL configuration with one remote secure endpoint and a different SSL configuration to another remote secure endpoint. Both endpoints can use the same outbound protocol, if appropriate. This task describes how to create the association dynamically.

Before you begin

Dynamic outbound selection requires that you provide only the outbound protocol name, the target host, and the target port so that WebSphere Application Server can make a connection between the SSL configuration and the outbound protocol or remote secure endpoint. The dynamic outbound selection method takes precedence over other selection methods, such as central management and direct selection, but is second to the programmatic method, that is, setting an SSL configuration on the running thread. For more information about the selection types and precedence rules, see “Secure communications using Secure Sockets Layer (SSL)” on page 1700.

About this task

Complete the following steps in the administrative console:

Procedure

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > Outbound**.
2. Select the management scope that you want to associate with an SSL configuration on the topology tree.
3. Under Related Items, click **Dynamic outbound endpoint SSL configurations**. The default dynamic outbound configuration name, the target protocol, host, and port connection information, and the SSL configuration name display.
4. Click **New** to create a new dynamic outbound configuration.
5. Type a dynamic outbound configuration name. Use a name that is descriptive of the purpose of the dynamic selection configuration.
6. Optionally, type a dynamic selection configuration description.

7. Type the connection information that you want to associate with the configuration that is displayed in the SSL configuration drop-down list. The connection information must be in the format *protocol name*, *target host*, *target port*. You can substitute an asterisk (*) for any value, as in the following examples, where 443 is a port, www.mycompany.com is a host, HTTP is a protocol, and .hometown.mycompany.com is a target host. You can add multiple connections, but each additional connection can affect outbound performance.
   - ***,*,443**
   - ***,www.mycompany.com,443**
   - **HTTP,.hometown.mycompany.com,***
   - ***,*,***

     gotcha: Do not use this configuration because it matches all outbound specifications. Therefore, no other SSL configuration is used for outbound connections.

   gotcha:
   - Unless the intention is to set the protocol property through the JSSEHelper API, the protocol filter should be set to * (as in the first two examples). See "Dynamic Selection" in “Secure communications using Secure Sockets Layer (SSL)” on page 1700 for more information.
   - The connection protocols that are used for dynamic outboud SSL configuration selection, that are illustrated in the preceding examples, which are not corresponding the protocol name of the URL. To use one of these protocols from a user-written application, programmatic SSL configuration selection must be implemented.
8. Click **Add** to add the new connection to the set of SSL configuration connections. To remove a connection, select it and click **Remove**.
9. Select an SSL configuration from the list.
10. Click **Get certificate aliases** to refresh the certificate aliases that are contained in the associated key store.
11. Choose a certificate alias from the list.
12. Click **OK** and **Save**.

Results

WebSphere Application Server is ready to connect one or more SSL configurations to one or more remote secure endpoints.

What to do next

You can return to the outbound tree and select another management scope to associate with the same or a new outbound configuration.

Programmatically specifying an outbound SSL configuration using JSSEHelper API:

WebSphere Application Server provides a way to specify programmatically which Secure Sockets Layer (SSL) configurations to use prior to making an outbound connection. The com.ibm.websphere.ssl.JSSEHelper interface provides a complete set of application programming interfaces (APIs) for handling SSL configurations.

About this task

Perform the following steps for your application when using the JSSEHelper API to establish an SSL properties object on the thread for use by the runtime. Some of these APIs have Java 2 Security permission requirements. See the JSSEHelper API documentation for more information about the permissions required by your application.

Select the approach that best fits your connection situation when you specify programmatically which Secure Sockets Layer (SSL) configurations to use prior to making an outbound connection.

Procedure

1. Obtain an instance of the JSSEHelper API.

```
com.ibm.websphere.ssl.JSSEHelper jsseHelper  = com.ibm.websphere.ssl.JSSEHelper.getInstance();
```

2. Obtain SSL properties from the WebSphere Application Server configuration or use those provided by your application. Use one of the following options.
   - By direction selection of an alias name, within the same management scope or higher as in the following example:

```
try
{  String alias = "NodeAServer1SSLSettings";
  // As specified in the WebSphere SSL configuration  Properties
 sslProps = jsseHelper.getProperties(alias); }
 catch (com.ibm.websphere.ssl.SSLException e)
 {  e.printStackTrace();   // handle exception }
```

   - By using the getProperties API for programmatic, direction, dynamic outbound, or management scope selection (based on precedence rules and inheritance). The SSL runtime uses the getProperties API to determine which SSL configuration to use for a particular protocol. This decision is based on both the input (sslAlias and connectionInfo) and the management scope from which the property is called. The getProperties API makes decisions in the following order:
     a. The API checks the thread to see if properties already exist.
     b. The API checks for a dynamic outbound configuration that matches the ENDPOINT_NAME, REMOTE_HOST, and or REMOTE_PORT.
     c. The API checks to see if the optional sslAlias property is specified. You can configure any protocol as direct or centrally managed. When a protocol is configured as direct, the sslAlias parameter is `null`. When a protocol is configured as centrally managed, the sslAlias parameter is also `null`.
     d. If no selection has been made, the API chooses the dynamic outbound configuration based on the management scope it was called from. If the dynamic outbound configuration is not defined in the same scope, it then searches the hierarchy to locate one.

     The last choice is the cell-scoped SSL configuration (in WebSphere Application Server, Network Deployment) or the node-scoped SSL configuration (in Base Application Server). The com.ibm.websphere.ssl.SSLConfigChangeListener parameter is notified when the SSL configuration that is chosen by a call to the getProperties API changes. The protocol can then call the API again to obtain the new properties as in the following example:

```
try {  String sslAlias = null;
 // The sslAlias is not specified directly at this time.  String host = "myhost.austin.ibm.com";
 // the target host  String port = "443";
 // the target port   HashMap connectionInfo = new HashMap();
 connectionInfo.put(JSSEHelper.CONNECTION_INFO_DIRECTION,    JSSEHelper.DIRECTION_OUTBOUND);
 connectionInfo.put(JSSEHelper.CONNECTION_INFO_REMOTE_HOST, host);
 connectionInfo.put(JSSEHelper.CONNECTION_INFO_REMOTE_PORT,    Integer.toString(port));
 connectionInfo.put(JSSEHelper.CONNECTION_INFO_ENDPOINT_NAME,    JSSEHelper.ENDPOINT_IIOP);
             java.util.Properties props = jsseHelper.getProperties(sslAlias,    connectionInfo, null); }
 catch (com.ibm.websphere.ssl.SSLException e)
 {  e.printStackTrace();   // handle exception }
```

   - By creating your own SSL properties and then passing them to the runtime, as in the following example:

```
try {
 // This is the recommended "minimum" set of SSL properties. The trustStore can
  // be the same as the keyStore.  Properties sslProps = new Properties();
 sslProps.setProperty("com.ibm.ssl.trustStore", "some value");
 sslProps.setProperty("com.ibm.ssl.trustStorePassword", "some value");
```

```
 sslProps.setProperty("com.ibm.ssl.trustStoreType", "some value");
 sslProps.setProperty("com.ibm.ssl.keyStore", "some value");
 sslProps.setProperty("com.ibm.ssl.keyStorePassword", "some value");
 sslProps.setProperty("com.ibm.ssl.keyStoreType", "some value");
  jsseHelper.setSSLPropertiesOnThread(sslProps); }
 catch (com.ibm.websphere.ssl.SSLException e)
{  e.printStackTrace();   // handle exception }
```

3. Use the JSSEHelper.setSSLPropertiesOnThread(props) API to set the Properties object on the thread so that the runtime picks it up and uses the same JSSEHelper.getProperties API. You can also obtain properties from the thread after they are set with the jsseHelper.getSSLPropertiesOnThread() API, as in the following example:

```
try
{  Properties sslProps = jsseHelper.getProperties(null,    connectionInfo, null);
jsseHelper.setSSLPropertiesOnThread(sslProps); }
 catch (com.ibm.websphere.ssl.SSLException e)
{  e.printStackTrace();   // handle exception }
```

4. When the connection is completed, you must clear the SSL properties from the thread by passing the `null` value to the setPropertiesOnThread API.

```
try
 {  jsseHelper.setSSLPropertiesOnThread(null); }
 catch (com.ibm.websphere.ssl.SSLException e)
 {  e.printStackTrace();   // handle exception }
```

Associating Secure Sockets Layer configurations centrally with inbound and outbound scopes:

After you create a Secure Sockets Layer (SSL) configuration, you must associate a secure inbound or outbound management scope with the new configuration. You can manage the association centrally so that you can easily make changes that affect all the scopes that are lower on the topology and that are associated with the configuration. Beginning with WebSphere Application Server version 6.1, the recommended and the default configuration method is centrally managed SSL configurations.

Before you begin

You can simplify the number of associations that you need to make for an SSL configuration by associating the configuration with the highest level management scope requiring a unique configuration. SSL configuration associations manifest inheritance behaviors. Because of the inheritance behaviors, all of the scopes that are lower on the topology inherit this SSL configuration. For example, an association you make at the cell level affects nodes, servers, clusters, and endpoints. For more information, see “Central management of SSL configurations” on page 1718.

A precedence rule determines which SSL configuration association is used at a particular scope. The highest precedence is given to endpoints on the topology. If you establish an association at the endpoint, this association overrides any prior association that you made higher up on the management scope topology.

About this task

Complete the following steps in the administrative console:

Procedure

1. Click **Security > SSL certificate and key management**.
2. Select the **Dynamically update the runtime when SSL configuration changes** check box if you want changes that you make to an existing SSL configuration to occur dynamically. All outbound SSL communications honor the dynamic SSL changes. Protocols that do not use the channel frameworks SSL channel for inbound communications, including Object Request Broker (ORB) and administrative SOAP protocols, do not honor dynamic updates. For more information, see “Dynamic configuration updates in SSL” on page 1735.
3. Click **Manage endpoint security configurations**.
4. Select either the inbound or the outbound tree. After finishing the selected tree, you can return to this step to repeat the following steps for the other tree.

5. Click the link for the selected cell, node, node group, server, cluster, or endpoint on the topology tree. If the scope already has an associated SSL configuration and alias, these objects display in parentheses immediately following the scope name, for example: Node01(NodeDefaultSSLSettings,default). If the deployment manager has federated a node, the node scope SSL configuration overrides the cell scope configuration above it in the topology.
6. Decide whether to override the inherited values that display in the read-only fields. Read-only fields include the management scope name, the direction, and the inherited SSL configuration name and certificate alias.
   - If you are satisfied with these values, do not override them.
   - If you want to override the inherited values, select the **Override inherited values** check box.
7. Select an SSL configuration from the list.
8. Click **Update certificate alias list**. The certificate alias list comes from the key store that is referenced by the new SSL configuration.
9. Click **Manage certificates** if you want to manage the personal certificates that are contained in the key store that is referenced in the SSL configuration.
10. Click **Update certificate alias list** to refresh the list of aliases.
11. Select a certificate alias in the key store to represent the identity of the endpoint.
12. Click **OK** to save your changes.
13. Click **Manage endpoint security configurations and trust zones** to return to the topology tree.
14. Configure the opposite direction on the topology tree using the steps in this task. You can also select additional scopes to associate with the SSL configuration, as needed.

Results

Each SSL configuration at the selected scope and at scopes beneath it on the topology tree have the same SSL configuration properties. The following SSL configuration methods override the centrally managed configurations that you associate in the tree view:

- Direct selection at the endpoint
- Dynamic outbound SSL configuration associations
- Programmatic specifications

What to do next

At any management scope, you can configure the following objects: dynamic outbound endpoint SSL configurations, key stores, key sets, key set groups, key managers, and trust managers. Like SSL configurations, these objects are scoped automatically so that they are not visible higher up in the tree nor are they loaded during runtime by processes that are higher up in the tree.

Selecting an SSL configuration alias directly from an endpoint configuration:

You can associate a secure outbound endpoint with a new Secure Sockets Layer (SSL) configuration directly. If you are migrating from a release prior to version 6.1, WebSphere Application Server still supports configurations that were selected directly at an endpoint. Direct selection always overrides centrally managed configurations and preserves migrated configurations.

About this task

Select an SSL configuration alias directly at the following endpoints:

- **Security > Global security > RMI/IIOP security > CSIv2 outbound transport**
- **Security > Global security > RMI/IIOP security > CSIv2 inbound transport**
- **System administration > Deployment manager > Transport Chain > WCInboundAdminSecure > SSL inbound channel (SSL_1)**

- **System administration > Deployment manager > Administration Services > JMX connectors > SOAPConnector > Custom Properties > sslConfig**
- **System administration > Node agents > nodeagent > Administration Services > JMX connectors > SOAPConnector > Custom Properties > sslConfig**
- **Servers > Application servers > server1 > Messaging engine inbound transports > InboundSecureMessaging > SSL inbound channel (SIB_SSL_JFAP)**
- **Servers > Application servers > server1 > WebSphere MQ link inbound transports > InboundSecureMQLink > SSL inbound channel (SIB_SSL_MQFAP)**
- **Servers > Application servers > server1 > SIP Container Settings > SIP container transport chains > SIPCInboundDefaultSecure > SSL inbound channel (SSL_5)**
- **Servers > Application servers > server1 > Web Container Settings > Web container transport chains > WCInboundAdminSecure > SSL inbound channel (SSL_1)**
- **Servers > Application servers > server1 > Web Container Settings > Web container transport chains > WCInboundDefaultSecure > SSL inbound channel (SSL_2)**

Attention: The central management of SSL configurations can be a more efficient strategy because multiple configurations can be contained within a single SSLConfigGroup. If you need to convert configuration references that are already directly managed to centrally managed configurations, modify each endpoint individually. Use the **AdminConfig.modify** command to set the `sslConfigAlias` value to an empty string (""). Below is an example of doing this:

- Using Jacl:

```
set s1 [$AdminConfig getid /Cell:mycell/Node:mynode/Server:server1/]
set sslChannel [lindex [$AdminConfig list SSLInboundChannel $s1] 0]
$AdminConfig modify $sslChannel [list[list sslConfigAlias ""]]
```

For more information on using this command, see the information about configuring processes using scripting.

For more information on specific wsadmin commands that affect a repertoire as opposed to individual endpoints, see the SSLConfigGroupCommands group for the AdminTask topic.

Complete the following steps in the administrative console:

Note: These steps provide an example to follow when you directly select any of the endpoints listed above.

Procedure

1. Click **Security > Global security > RMI/IIOP security > CSIv2 outbound transport**.
2. Click **Use specific SSL alias**. When you identify a specific SSL alias, you override the centrally managed scope associations.
3. Select an SSL configuration alias from the drop-down list.
4. Click **OK**.
5. Repeat these steps for additional protocols or endpoints, if desired.

Results

By associating the endpoint directly, you have overridden a centrally managed SSL configuration.

What to do next

If you decide to use management scopes instead of endpoints to associate an SSL configuration, follow the steps above, but click **Centrally managed** instead of **Use specific SSL alias**, then click **Manage endpoint security configurations**. The console is redirected to **Security > SSL certificate and key management > Manage endpoint security configurations**.

Enabling Secure Sockets Layer client authentication for a specific inbound endpoint:

When you establish a Secure Sockets Layer (SSL) configuration, you can enable client authentication for a specific inbound endpoint.

Before you begin

The endpoint configuration must already exist in the SSL topology.

About this task

Complete the following steps in the administrative console:

Procedure

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > Inbound >** *SSL_configuration*. If you want to enable SSL client authentication for all processes, define an SSL configuration for the new endpoint at the node or cell level so that it is visible to all processes on the same node or on the entire cell. For more information, see "Creating a Secure Sockets Layer configuration" on page 1741.
2. Select **Override inherited values**. The SSL configuration is used for the current scope and any lower scopes that have not already designated an SSL configuration. This field displays for server and node groups within the object hierarchy and does not display for the top-level node or cell.
3. Select an SSL configuration from the drop-down list.
4. Click **Update certificate alias list**.
5. Select a **Certificate alias** from the drop-down list.
6. Click **OK** to save the configuration.

Results

You can repeat the previous steps for each endpoint that uses the same SSL configuration to enable client authentication for the inbound endpoints.

What to do next

CSIv2 Protocol Exception:

The Common Secure Interoperability Version 2 (CSIv2) secure endpoints, used for Remote Method Invocation over the Internet Inter-ORB Protocol (RMI/IIOP) security, cannot override inherited values. While the rest of the SSL properties are effective for CSIv2 when they are selected at the centrally-managed Secure Communications panel, the client authentication selection is controlled by the CSIv2 protocol configuration.

To enable SSL client certificate authentication for the CSIv2 protocol, you must use the CSIv2 inbound and outbound authentication panels. For SSL client authentication to occur between two servers, you must enable (support or require) SSL client certificate authentication for both the inbound and the outbound policies.

WebSphere Application Server can either request (support) clients to provide signer certificates for the SSL handshake, or the server can require clients to provide a valid signer certificate for the SSL handshake, which is a more secure method. However, when the server requires certificates, the server must obtain a signer for each client that connects to the server, which involves more server-side management.

The client certificate should not be used for the identity when it is used from server-to-server. However, when a pure client sends the client certificate it is used for the identity unless a message level identity is specified, such as a user ID or a password.

Do the following to enable client certificate authentication for the CSIv2 protocol for server-to-server:

1. **Click Security > Global security**.
2. Expand the **RMI/IIOP** security section.
3. Click **CSIv2 inbound authentication**.
4. Under Client authentication, select either **supported** or **required**. When you select required, only one SSL port is opened (CSV2_SSL_MUTUALAUTH_LISTENER_ADDRESS). When you select supported, two SSL ports are opened (both CSIV2_SSL_MUTUALAUTH_LISTENER_ADDRESS and CSIV2_SSL_SERVERAUTH_LISTENER_ADDRESS).

   If there are two ports, the client can select either based on the security configuration policy of the port.
5. Click **OK** to save.
6. If you want server-to-server SSL client authentication, then complete the remaining steps. If you don't complete the remaining steps, only pure clients are enabled to send client certificates.
7. Expand the **RMI/IIOP** security section.
8. Click **CSIv2 outbound authentication**.
9. Under Client authentication, select either **supported** or **required**.

The SSL configuration for the inbound secure endpoints for which you enable SSL client certificate authentication must have the signer certificate from any client that attempts to open a connection to that inbound secure endpoint. You must collect those signers and then add them to the trust store associated with the inbound secure endpoints SSL configuration.

Manage endpoint security configurations:

Use this page to select a Secure Socket Layer (SSL) configuration from the Local Topology hierarchy, which includes cells, nodes, node groups, servers, and clusters.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations**.

Local topology:

The Local topology represents the hierarchy of nodes, node groups, clusters, servers, and end points within the cell that comprise a centralized SSL configuration.

The topology acts as a hierarchical tree in terms of inheritance. For example, if an SSL configuration has been associated with a specific node, then all servers within that node will inherit that SSL configuration selection, provided the servers are not associated with an SSL configuration at the server scope. Centralized management of SSL is the default configuration; however, it can be overridden at various locations to directly select a specific SSL alias as in previous releases for backwards compatibility.

Scope	Description
Inbound/Outbound	Specifies the topology tree in terms of connection direction. For example, the inbound tree represents all server endpoints that receive connections at the various servers within the cell. The outbound tree represents the client side of connections from the various servers within the cell.

Scope	Description
Nodes	Specifies the nodes that are part of the cell. The list of nodes is updated anytime a node gets federated into the cell.
Servers	Specifies the servers that are part of a specific node. You can enable a specific server to have an SSL configuration associated with it so that resources within the same server can use the associated SSL configuration.
Clusters	Specifies the clusters that are part of the cell. When an SSL configuration is associated with a cluster, all servers within the cluster will use the same SSL configuration unless specified at a lower level in the topology.
Nodegroups	Specifies the node groups that are part of the cell. When an SSL configuration is associated with a node group, all nodes within that node group may use the same SSL configuration unless one is specified at a lower scope in the topology or the specific end point has chosen a direct alias reference.
Secure port and transport	Specifies an endpoint name to associate with an SSL configuration when more specific SSL settings are needed at this level. You could select an alias directly at the endpoint panel; however, when you use **Secure port and transport**, you can maintain more centralized control of the SSL configuration and make changes more easily.

Dynamic inbound and outbound endpoint SSL configurations collection:

Use this page to manage dynamic endpoint Secure Sockets Layer (SSL) configurations, which represent associations between Secure Socket Layer (SSL) configurations and their target protocol, host, and port.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***. Under Related items, click **Dynamic outbound endpoint SSL configurations**.

When an outbound connection is attempted, this association is checked ahead of the SSL configuration scope association. Based on the target protocol,host,port, the outbound SSL configuration used can be different from the default specified in the SSL scope configuration.

Table 151. Dynamic inbound and outbound endpoint SSL configurations buttons. This table lists the dynamic inbound and outbound endpoint SSL configuration buttons.

Button	Resulting action
New	Adds a new dynamic outbound selection criteria. The outbound connection selects an SSL configuration based upon connection information, including DNS host name and domain, port, and protocol type. When an outbound connection is being made, the dynamic outbound selection criteria are queried for a match, and if found the SSL configuration associated is used.
Delete	Deletes an existing dynamic outbound endpoint SSL configuration.

Name:

Specifies the unique name of the dynamic endpoint configuration.

Connection information:

Specifies the set of target protocol, host, port for the outbound request in the form *protocol*,*host*,*port*.

SSL Configuration:

Specifies the SSL configuration that is used by requests at this scope when a match occurs for the given selection criteria.

Dynamic outbound endpoint SSL configuration settings:

Use this page to set properties for dynamic outbound endpoint SSL configurations, which represent associations between SSL configurations and their target protocol, host, and port.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***. Under Related items, click **Dynamic [inbound | outbound] endpoint SSL configurations**. Then click the **New** button.

When an outbound connection is attempted, this association is checked ahead of the Secure Sockets Layer (SSL) configuration scope association. This means based on the target protocol,host,port, the outbound SSL configuration used can be different than the default specified in the SSL scope configuration.

Name:

Specifies the unique name of the dynamic endpoint configuration.

Data type: Text

Description:

Specifies text that describes the purpose of this dynamic selection criteria.

Data type: Text

Add connection information:

Specifies select information in the form protocol,host,port for the outbound connection. Multiple selection criteria can be entered. All of the connection information for dynamic outbound selection might not be available, and you may have to adjust the dynamic outbound selection connection filter and fill in an asterisk (*) for the missing part of the connection information. An asterisk (*) can be used to mean all protocols, hosts, or ports. You can use an asterisk(*) for any field.

Data type: Text

An example of selection criteria is `*,www.ibm.com,*`, which means that any time the target host is www.ibm.com, you must use the SSL configuration specified here. Another example selection criteria is `IIOP,*,*`, which means that any outbound IIOP request uses the SSL configuration that is specified in the SSL configuration field. When there is a conflict between two selection criteria, the application server uses the first match. The list of valid protocols you can use include: IIOP, HTTP, JMS, LDAP, SIP, ADMIN_SOAP, ADMIN_IIOP, or WEBSERVICES_HTTP.

When user written applications are expecting to take advantage of dynamic outbound selections, know that not all connection information may be available. For example, the openConnection() call on an URL object ultimately calls `createSocket(java.net.Socket socket, String host, int port, boolean autoClose)`. The connection information can be built with the host and port provided, but there is no protocol provided. In this case, a wild card, an asterisk (*), should be used for the protocol part of the dynamic selection connection information.

Add:

Specifies to add the selected information from the **Add select information** menu to the right-hand list.

Remove:

Specifies to remove the selection from the right-hand list.

SSL Configuration:

Specifies the SSL configuration to be used by requests at this scope when a match occurs for the given selection criteria.

Data type: Text

Get certificate alias:

When selected, the keystore within the selected SSL configuration is queried for a list of personal certificates from which to choose.

Certificate alias:

Specifies the certificate alias that is used as the identity for the connection.

If you select **None**, the Java Secure Sockets Extension (JSSE) key manager determines which certificate is used. If multiple certificates exist in the keystore, the key manager might not consistently select the same certificate.

Data type: Text
Default: (none)

Quality of protection (QoP) settings

Use this page to specify security level, ciphers, and mutual authentication settings for the Secure Socket Layer (SSL) configuration.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***. Under Related items, click **SSL configurations >** . Click on {*SSL_configuration_name* }. Under **Additional Properties**, click **Quality of protection (QoP) settings**.

Client authentication:

Specifies the whether SSL client authentication should be requested if the SSL connection is used for the server side of the connection.

If `None` is selected, the server does not request that a client certificate be sent during the handshake. If `Supported` is selected, the server requests that a client certificate be sent. If the client does not have a certificate, the handshake might still succeed. If `Required` is selected, the server requests that a client certificate be sent. If the client does not have a certificate, the handshake fails.

Data type: Text
Default: None

Protocol:

Specifies the Secure Sockets Layer (SSL) handshake protocol. This protocol is typically SSL_TLS, which supports all handshake protocols except for SSLv2 on the server side. When United States Federal Information Processing standard (FIPS) option is enabled, Transport Layer Security (TLS) is automatically used regardless of this setting.

Data type: text
Default: SSL_TLS

Predefined JSSE provider:

Specifies one of the predefined Java Secure Sockets Extension (JSSE) providers. The IBMJSSE2 provider is recommended for use on all platforms which support it. It is required for use by the channel framework SSL channel. When Federal Information Processing Standard (FIPS) is enabled, IBMJSSE2 is used in combination with the IBMJCEFIPS crypto provider.

Default: Enabled

Select provider:

Specifies a package that implements a subset of the cryptography aspects for the Java security application programming interface (API). This value is a JSSE provider name that is listed in the java.security file. Note that cipher suites and protocol values depend upon the provider.

Data type: Text
Default: IBMJSSE2

Custom JSSE provider:

Specifies that a custom JSSE provider should be used.

Default: Disabled

Custom provider:

Specifies a package that implements a subset of the cryptography aspects for the Java security application programming interface (API). This value is a Java Secure Sockets Extension (JSSE) provider name that is listed in the java.security file. Note that cipher suites and protocol values depend upon the provider.

Data type: Text

Cipher suite groups:

Specifies the various cipher suite groups that can be chosen depending upon your security needs. The stronger the cipher suite strength, the better the security; however, this can result in performance consequences.

Data type: Text
Default: Strong

Update selected ciphers:

When selected, the cipher suites that are contained within the selected Cipher suite group are added to the list of **Selected ciphers**. Any change to this list changes the Cipher suite group to `custom`.

Selected ciphers:

Specifies the ciphers that are effective when the configuration is saved. These ciphers are used to negotiate with the remote side of the connection during the handshake. A common cipher needs to be selected or the handshake fails.

Data type: Text

Add:

Specifies to add the selected cipher to the **Selected ciphers** list.

Remove:

Specifies to remove the selected cipher from the **Selected ciphers** list.

ssl.client.props client configuration file

Use the `ssl.client.props` file to configure Secure Sockets Layer (SSL) for clients. In previous releases of WebSphere Application Server, SSL properties were specified in the `sas.client.props` or `soap.client.props` files or as system properties. By consolidating the configurations, WebSphere Application Server enables you to manage security in a manner that is comparable to server-side configuration management. You can configure the `ssl.client.props` file with multiple SSL configurations.

Setting up the SSL configuration for clients

Client runtimes are dependent on the WebSphere Application Server `ssl.client.props` configurations.

Use the `setupCmdLine` script on the command line to specify the com.ibm.SSL.ConfigURL system property. The setupclient script also sets the CLIENTSSL variable.The com.ibm.SSL.ConfigURL property references a file URL that points to the `ssl.client.props` file. You can reference the CLIENTSSL variable on the command line of any script that uses the `setupCmdLine` file.

When you specify the com.ibm.SSL.ConfigURL system property, the SSL configuration is available to all protocols that use SSL. SSL configurations, which are referenced in the `ssl.client.props` file, also have aliases that you can reference. In the following sample code from the `sas.client.props` file, all of the SSL properties are replaced with a property that points to an SSL configuration in the `ssl.client.props` file:

```
com.ibm.ssl.alias=DefaultSSLSettings
```

The following sample code shows a property in the `soap.client.props` file that is similar to the com.ibm.SSL.ConfigURL property. This property references a different SSL configuration on the client side:

```
com.ibm.ssl.alias=DefaultSSLSettings
```

In the `ssl.client.props` file, you can change the administrative SSL configuration to avoid modifying the `soap.client.props` file.

Tip: Support for SSL properties is still specified in the `sas.client.props` and `soap.client.props` files. However, consider moving the SSL configurations to the `ssl.client.props` file, because this file is the new configuration model for client SSL.

When you are configuring a client which does not call setupCmdLine.sh to connect to an application server using security, you must ensure that the following system property is defined on the client configuration:

```
-Djava.security.properties=profile_root/properties/java.security
```

Properties of the ssl.client.props file

This section describes the default `ssl.client.props` file properties in detail, by sections within the file. Be aware that if you specify javax.net.ssl system properties, these will override the settings in `ssl.client.props` file.

Global properties

Global SSL properties are process-specific properties that include Federal Information Processing Standard (FIPS) enablement, the default SSL alias, the profile_root of the profile for specifying the root location of the key and truststore paths, and so on.

Table 152. Properties of the ssl.client.props file. This table describes the properties of the `ssl.client.props` file.

Property	Default	Description
com.ibm.ssl.defaultAlias	DefaultSSLSettings	Specifies the default alias that is used whenever an alias is not specified by the protocol that calls the JSSEHelper API to retrieve an SSL configuration. This property is the final arbiter on the client side for determining which SSL configuration to use.
com.ibm.ssl.validationEnabled	false	When set to `true`, this property validates each SSL configuration as it is loaded. Use this property for debug purposes only, to avoid unnecessary performance overhead during production.
com.ibm.ssl.performURLHostNameVerification	false	When set to `true`, this property enforces URL host name verification. When HTTP URL connections are made to target servers, the common name (CN) from the server certificate must match the target host name. Without a match, the host name verifier rejects the connection. The default value of `false` omits this check. As a global property, it sets the default host name verifier. Any javax.net.ssl.HttpsURLConnection object can choose to enable host name verification for that specific instance by calling the setHostnameVerifier method with its own HostnameVerifier instance. **gotcha:** This property does not apply to SSL channels.
com.ibm.security.useFIPS	false	When set to `true`, FIPS-compliant algorithms are used for SSL and other Java Cryptography Extension (JCE)-specific applications. This property is typically not enabled unless the property is required by the operating environment.

Certificate creation properties

Use certificate creation properties to specify the default self-signed certificate values for the major attributes of a certificate. You can define the distinguished name (DN), expiration date, key size, and alias that are stored in the keystore.

Table 153. Certificate creation properties. This table describes the certificate creation properties.

Property	Default	Description
com.ibm.ssl.defaultCertReqAlias	default_alias	This property specifies the default alias to use to reference the self-signed certificate that is created in the keystore. If the alias already exists with that name, the default alias is appended with `_#`, where the number sign (#) is an integer that starts with 1 and increments until it finds a unique alias.
com.ibm.ssl.defaultCertReqSubjectDN	cn=${*hostname*}, o=IBM,c=US	This property uses the property distinguished name (DN) that you set for the certificate when it is created. The ${*hostname*} variable is expanded to the host name on which it resides. You can use correctly formed DNs as specified by the X.509 certificate.

Table 153. Certificate creation properties (continued). This table describes the certificate creation properties.

Property	Default	Description
com.ibm.ssl.defaultCertReqDays	365	This property specifies the validity period for the certificate and can be as small as 1 day and as large as the maximum number of days that a certificate can be set, which is approximately 15 years.
com.ibm.ssl.defaultCertReqKeySize	1024	This property is the default key size. The valid values depend upon the Java Virtual Machine (JVM) security policy files that are installed. By default, the product JVMs ship with the export policy file that limits the key size to 1024. To get a large key size such as 2048, you can download the restricted policy files from the website.

Certificate revocation checking

To enable certificate revocation checking, you can set a combination of Online Certificate Status Protocol (OCSP) properties. These properties are not used unless you set the com.ibm.ssl.trustManager property to `IbmPKIX`. In addition, to successfully process revocation checking on the client, you must turn off the signer exchange prompt. To turn off the signer exchange prompt, change the com.ibm.ssl.enableSignerExchangePrompt property to `false`. For more information, see the related link to the "Enabling certificate revocation checking with the default IbmPKIX trust manager" topic.

SSL configuration properties

Use the SSL configuration properties section to set multiple SSL configurations. For a new SSL configuration specification, set the com.ibm.ssl.alias property because the parser starts a new SSL configuration with this alias name. The SSL configuration is referenced by using the alias property from another file, such as `sas.client.props` or `soap.client.props`, through the default alias property. The properties that are specified in the following table enable you to create a javax.net.ssl.SSLContext, among other SSL objects.

Table 154. SSL configuration properties. This table lists the SSL configuration properties.

Property	Default	Description
com.ibm.ssl.alias	DefaultSSLSettings	This property is the name of this SSL configuration and must be the first property for an SSL configuration because it references the SSL configuration. If you change the name of this property after it is referenced elsewhere in the configuration, the runtime defaults to the com.ibm.ssl.defaultAlias property whenever the reference is not found. The error `trust file is null` or `key file is null` might display when you start an application using an SSL reference that is no longer valid.
com.ibm.ssl.protocol	SSL_TLS	This property is the SSL handshake protocol that is used for this SSL configuration. This property attempts Transport Layer Security (TLS) first, but accepts any remote handshake protocol, including SSLv3 and TLS. Valid values for this property include SSLv2 (client side only), SSLv3, SSL, TLS, TLSv1, and SSL_TLS.
com.ibm.ssl.securityLevel	STRONG	This property specifies the cipher group that is used for the SSL handshake. The typical selection is STRONG, which specifies 128-bit or higher ciphers. The MEDIUM selection provides 40-bit ciphers. The WEAK selection provides ciphers that do not perform encryption, but do perform signing for data integrity. If you specify your own cipher list selection, uncomment the property com.ibm.ssl.enabledCipherSuites. **Note:** The use of javax.net.ssl system properties causes this value to always be HIGH.

Table 154. SSL configuration properties (continued). This table lists the SSL configuration properties.

Property	Default	Description
com.ibm.ssl.trustManager	IbmX509	This property specifies the default trust manager that you must use to validate the certificate sent by the target server. This trust manager does not perform certificate revocation list (CRL) checking. You can choose to change this value to IbmPKIX for CRL checking using CRL distribution lists in the certificate, which is a standard way to perform CRL checking. When you want to perform custom CRL checking, you must implement a custom trust manager and specify the trust manager in the com.ibm.ssl.customTrustManagers property. The IbmPKIX option might affect performance because this option requires IBMCertPath for trust validation. Use IbmX509 unless CRL checking is necessary. If you are using the Online Certificate Status Protocol (OCSP) properties, set this property value to `IbmPKIX`.
com.ibm.ssl.keyManager	IbmX509	This property specifies the default key manager to use for choosing the client alias from the specified keystore. This key manager uses the com.ibm.ssl.keyStoreClientAlias property to specify the keystore alias. If this property is not specified, the choice is delegated to Java Secure Socket Extension (JSSE). JSSE typically chooses the first alias that it finds.
com.ibm.ssl.contextProvider	IBMJSSE2	This property is used to choose the JSSE provider for the SSL context creation. It is recommended that you default to IBMJSSE2 when you use a Java virtual machine (JVM). The client plug-in can use the SunJSSE provider when using a Sun JVM.
com.ibm.ssl.enableSignerExchangePrompt	true	This property determines whether to display the signer exchange prompt when a signer is not present in the client truststore. The prompt displays information about the remote certificate so that WebSphere Application Server can decide whether or not to trust the signer. It is very important to validate the certificate signature. This signature is the only reliable information that can guarantee that the certificate has not been modified from the original server certificate. For automated scenarios, disable this property to avoid SSL handshake exceptions. Run the `retrieveSigners` script, which sets up the SSL signer exchange, to download the signers from the server prior to running the client. If you are using the Online Certificate Status Protocol (OCSP) properties, set this property value to `false`.
com.ibm.ssl.keyStoreClientAlias	default	This property is used to reference an alias from the specified keystore when the target does not request client authentication. When WebSphere Application Server creates a self-signed certificate for the SSL configuration, this property determines the alias and overrides the global com.ibm.ssl.defaultCertReqAlias property.
com.ibm.ssl.customTrustManagers	Commented out by default	This property enables you to specify one or more custom trust managers, which are separated by commas. These trust managers can be in the form of *algorithm*|*provider* or *classname*. For example, IbmX509IIBMJSSE2 is in the *algorithm*|*provider* format, and the com.acme.myCustomTrustManager interface is in the *classname* format. The class must implement the javax.net.ssl.X509TrustManager interface. Optionally, the class can implement the com.ibm.wsspi.ssl.TrustManagerExtendedInfo interface. These trust managers run in addition to the default trust manager that is specified by the com.ibm.ssl.trustManager interface. These trust managers do not replace the default trust manager.

Table 154. SSL configuration properties (continued). This table lists the SSL configuration properties.

Property	Default	Description
com.ibm.ssl.customKeyManager	Commented out by default	This property enables you to have one, and only one, custom key manager. The key manager replaces the default key manager that is specified in the com.ibm.ssl.keyManager property. The form of the key manager is *algorithm*|*provider* or *classname*. See the format examples for the com.ibm.ssl.customTrustManagers property. The class must implement the javax.net.ssl.X509KeyManager interface. Optionally, the class can implement the com.ibm.wsspi.ssl.KeyManagerExtendedInfo interface. This key manager is responsible for alias selection.
com.ibm.ssl.dynamicSelectionInfo	Commented out by default	This property enables dynamic association with the SSL configuration. The syntax for a dynamic association is *outbound_protocol*, *target_host*, or *target_port*. For multiple specifications, use the vertical bar (|) as the delimiter. You can replace any of these values with an asterisk (*) to indicate a wildcard value. Valid *outbound_protocol* values include: IIOP, HTTP, LDAP, SIP, BUS_CLIENT, BUS_TO_WEBSPHERE_MQ, BUS_TO_BUS, and ADMIN_SOAP. When you want the dynamic selection criteria to choose the SSL configuration, uncomment the default property, and add the connection information. For example, add the following on one line `com.ibm.ssl.dynamicSelectionInfo=HTTP, .ibm.com,443|HTTP,.ibm.com,9443`
com.ibm.ssl.enabledCipherSuites	Commented out by default	This property enables you to specify a custom cipher suite list and override the group selection in the com.ibm.ssl.securityLevel property. The valid list of ciphers varies according to the provider and JVM policy files that are applied. For cipher suites, use a space as the delimiter.
com.ibm.ssl.keyStoreName	ClientDefaultKeyStore	This property references a keystore configuration name. If you have not already defined the keystore, the rest of the keystore properties must follow this property. After you define the keystore, you can specify this property to reference the previously specified keystore configuration. New keystore configurations in the `ssl.client.props` file have a unique name.
com.ibm.ssl.trustStoreName	ClientDefaultTrustStore	This property references a truststore configuration name. If you have not already defined the truststore, the rest of the truststore properties must follow this property. After you define the truststore, you can specify this property to reference the previously specified truststore configuration. New truststore configurations in the `ssl.client.props` file should have a unique name.

Keystore configurations

SSL configurations reference keystore configurations whose purpose is to identify the location of certificates. Certificates represent the identity of clients that use the SSL configuration. You can specify keystore configurations with other SSL configuration properties. However, it is recommended that you specify the keystore configurations in this section of the `ssl.client.props` file after the com.ibm.ssl.keyStoreName property identifies the start of a new keystore configuration. After you fully define the keystore configuration, the com.ibm.ssl.keyStoreName property can reference the keystore configuration at any other point in the file.

Table 155. Keystore configuration properties. This table lists the keystore configuration properties.

Property	Default	Description
com.ibm.ssl.keyStoreName	ClientDefaultKeyStore	This property specifies the name of the keystore as it is referenced by the runtime. Other SSL configurations can reference this name further down in the `ssl.client.props` file to avoid duplication.

Table 155. Keystore configuration properties (continued). This table lists the keystore configuration properties.

Property	Default	Description
com.ibm.ssl.keyStore	${user.root}/etc/key.p12	This property specifies the location of the keystore in the required format of the com.ibm.ssl.keyStoreType property. Typically, this property references a keystore file name. However, for cryptographic token types, this property references a Dynamic Link Library (DLL) file. **gotcha:** If you are using a 4764 cryptography card, then the keystore file name for the client configuration should be specified as the file `4764.cfg` in a directory structure of your choice, and the corresponding com.ibm.ssl.keyStoreType should be set to PKCS11. The 4764.cfg file is NOT supplied with WebSphere Application Server.
com.ibm.ssl.keyStorePassword	WebAS	This property is the default password, which is the cell name for the profile when it is created. The password is typically encoded using an {xor} algorithm. You can use iKeyman to change the password in the keystore, then change this reference. If you do not know the password and if the certificate is created for you, change the password in this property, then delete the keystore from the location where it resides. Restart the client to recreate the keystore by using the new password, but only if the keystore name ends with DefaultKeyStore and if the fileBased property is `true`. Delete both the keystore and truststore at the same time so that a proper signer exchange can occur when both are recreated together.
com.ibm.ssl.keyStoreType	PKCS12	This property is the keystore type. Use the default, PKCS12, because of its interoperability with other applications. You can specify this property as any valid keystore type that is supported by the JVM on the provider list.
com.ibm.ssl.keyStoreProvider	IBMJCE	The IBM Java Cryptography Extension property is the keystore provider for the keystore type. The provider is typically IBMJCE or IBMPKCS11Impl for cryptographic devices.
com.ibm.ssl.keyStoreFileBased	true	This property indicates to the runtime that the keystore is file-based, meaning it is located on the file system.
com.ibm.ssl.keyStoreReadOnly	false	This property indicates to the run time for WebSphere Application Server whether the key store can be modified during the run time.

Truststore Configurations

SSL configurations reference truststore configurations, whose purpose is to contain the signer certificates for servers that are trusted by this client. You can specify these properties with other SSL configuration properties. However, it is recommended that you specify truststore configurations in this section of the `ssl.client.props` file after the com.ibm.ssl.trustStoreName property has identified the start of a new truststore configuration. After you fully define the truststore configuration, the com.ibm.ssl.trustStoreName property can reference the configuration at any other point in the file.

A truststore is a keystore that JSSE uses for trust evaluation. A truststore contains the signers that WebSphere Application Server requires before it can trust the remote connection during the handshake. If you configure the com.ibm.ssl.trustStoreName=ClientDefaultKeyStore property, you can reference the

keystore as the truststore. Further configuration is not required for the truststore because all of the signers that are generated through signer exchanges are imported into the keystore where they are called by the runtime.

Table 156. Truststore Configuration properties. This table lists the truststore configuration properties.

Property	Default	Description
com.ibm.ssl.trustStoreName	ClientDefaultTrustStore	This property specifies the name of the truststore as it is referenced by the runtime. Other SSL configurations can reference further down in the `ssl.client.props` file to avoid duplication.
com.ibm.ssl.trustStore	${user.root}/etc/trust.p12	This property specifies the location of the truststore in the format that is required by the truststore type that is referenced by the com.ibm.ssl.trustStoreType property. Typically, this property references a truststore file name. However, for cryptographic token types, this property references a DLL file. **gotcha:** If you are using a 4764 cryptography card, then the keystore file name for the client configuration should be specified as the file `4764.cfg` in a directory structure of your choice, and the corresponding com.ibm.ssl.keyStoreType should be set to PKCS11. The 4764.cfg file is NOT supplied with WebSphere Application Server.
com.ibm.ssl.trustStorePassword	WebAS	This property specifies the default password, which is the cell name for the profile when it is created. The password is typically encoded using an {xor} algorithm. You can use iKeyman to change the password in the keystore, then change the reference in this property. If you do not know the password and if the certificate was created for you, change the password in this property, then delete the truststore from the location where it resides. Restart the client to recreate the truststore by using the new password, but only if the keystore name ends with DefaultTrustStore and the fileBased property is `true`. It is recommended that you delete the keystore and the truststore at the same time so that a proper signer exchange can occur when both are recreated together.

Table 156. Truststore Configuration properties (continued). This table lists the truststore configuration properties.

Property	Default	Description
com.ibm.ssl.trustStoreType	PKCS12	This property is the truststore type. Use the default PKCS12 type because of its interoperability with other applications. You can specify this property as any valid truststore type that is supported by the JVM functionality on the provider list.
com.ibm.ssl.trustStoreProvider	IBMJCE	This property is the truststore provider for the truststore type. The provider is typically IBMJCE or IBMPKCS11Impl for cryptographic devices.
com.ibm.ssl.trustStoreFileBased	true	This property indicates to the runtime that the truststore is file-based, meaning it is located on the file system.
com.ibm.ssl.trustStoreReadOnly	false	This property indicates to the run time for WebSphere Application Server whether the truststore can be modified during the run time.

Creating a CA client in SSL

A plug point is provided to allow users to connect to a certificate authority (CA) to request, query, and revoke certificates. A security configuration object, called a CAClient, must be created for WebSphere to communicate with the CA. The CAClient object must contain a WSPKIClient() implementation, and it will handle the connection and communicate with the CA server. Users can also create there own implementation.

Before you begin

The WSPKIClient interface must be implemented and the class name provided as part of the CAClient when it is created.

You use the administrative console to create a new CA client.

Procedure

1. Click **Security > SSL certificate and key management**.
2. Click **Certificate Authority (CA) client configurations**. A panel of existing CA clients appears.
3. Click **New** to create a new CA client in the configuration.

   Note: You can also create a CA client by using the **createCAClient** AdminTask .
4. Fill in the following information for the CA client
   - Name of the CA client.
   - The management scope (selected from the drop-down list).
   - WSPKIClient implementation class.
   - CA server host name.
   - User name.
   - Password.
   - Confirm of password.
   - Number of times to poll.

- Polling interval (in minutes) when requestin certificates.
- Custom properties.

5. Click **Apply** then **OK**.

Results

The information in the object can then be used by the runtime to connect to a CA to create, revoke, or replace a certificate.

Deleting a CA client in SSL

You can delete the CAClient object from the security configuration if a connection to a certificate authority (CA) is no longer needed.

Before you begin

You use the administrative console to delete a CA client.

Procedure

1. Click **Security > SSL certificate and key management**.
2. Click **Certificate Authority (CA) client configurations**. A panel displaying the existing CA clients appears.
3. Click the CA client name you want to delete.
4. Click the **Delete** button.

Note: You can also use the **deleteAClient** AdminTask to delete the CA client.

Results

The CA client is deleted from the configuration.

Note: When you use the deleteCAClient AdminTask to delete the CA client, the CA client cannot be deleted if a CA certificate that exists in the keystore was obtained from the certificate authority and is still referenced by the CA client. For example, when such CA certificate still exists, the user receives the following message:

```
wsadmin>$AdminTask deleteCAClient {-caClientName myca}
WASX7015E: Exception running command:
 "$AdminTask deleteCAClient {-caClientName myca}"; exception information:
 com.ibm.websphere.management.cmdframework.CommandValidationException:
 CWPKI0687E: The Certificate Authority (CA) client myca is still referenced by:
 [Certificate alias myca21 in key store CellDefaultKeyStore].
wsadmin>
```

Viewing or modifying a CA client in SSL

You can view or modify the CAClient object settings in the security configuration. The CAClient object contains all the information needed to connect and communicate with a certificate authority (CA). A connection to a Certificate Authority is used to request a certificate, query a certificate, or revoke a certificate.

Before you begin

You use the administrative console to view or modify a CA client.

Procedure

1. Click **Security > SSL certificate and key management**.

2. Click **Certificate Authority (CA) client configurations**. A panel displaying the existing CA clients appears.
3. Click the CA client name you want to examine and modify.

   Note: You can also use the **getCAClient** AdminTask to get information about the existing CA client and the **modifyCAClieint** AdminTask to make changes to the CA client.
4. Make the changes to the CA client information as required. Modify the following information as required.
   - Name of the CA client.
   - The management scope (selected from the drop-down list.
   - Implementation class.
   - CA server host name.
   - User name.
   - Password.
   - Confirm of password.
   - Number of times to poll.
   - Polling interval (in minutes) when requestin certificates.
   - Custom properties.
5. Click **Apply** then **OK**.

Results

The information in the object can then be used by the runtime to connect to a CA to create, revoke, or replace a certificate

What to do next

Creating a keystore configuration for a preexisting keystore file

A Secure Sockets Layer (SSL) configuration references keystore configurations during WebSphere Application Server runtime. Whether a keystore file was created by another keystore tool or saved from a previous configuration, the file must be referenced by a keystore configuration object to be used by the server. A keystore configuration object can be created to reference a pre-existing keystore object.

Before you begin

A keystore must already exist.

Alternative Method: To create a keystore by using the wsadmin tool, use the **createKeyStore** command of the AdminTask object. For more information, see the KeyStoreCommands command group for the AdminTask object article.

About this task

Complete the following steps in the administrative console:

Procedure

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound}**.
2. Under Related Items, click **Key stores and certificates**, then click **New**.
3. Type a name in the **Name** field. This name uniquely identifies the keystore in the configuration.

4. Type the location of the keystore file in the **Path** field. The location can be a file name or a file URL to an existing keystore file.
5. Type the keystore password in the **Password** field. This password is for the keystore file that you specified in the **Path** field.
6. Type the keystore password again in the **Confirm Password** field to confirm the password.
7. Select a keystore type from the list. The type that you select is for the keystore file that you specified in the **Path** field.
8. Select any of the following optional selections:
   - The **Read only selection** creates a keystore configuration object but does not create a keystore file. If this option is selected, the keystore file that you specified in the **Path** field must already exist.
   - The **Initialize at startup selection** initializes the keystore during runtime.
   - The **Enable cryptographic operations on a hardware device** specifies whether a hardware cryptographic device is used for cryptographic operations only.

     Note: Operations that require login are not supported when using this option.
9. Click **Apply** and **Save**.

Results

You have created a keystore configuration object for the keystore file that you specified. This keystore can now be used in an SSL configuration.

What to do next

You can create additional keystore configurations, as needed.

Recreating the .kdb keystore internal password record

The IBM i keystore type `IBMi5OSKeyStore` does not recognize or generate `.sth` password stash files. Instead it keeps an internal record of the password for the `.kdb` keystore file where it is created. If the `.kdb` file is moved, the password is no longer associated with the keystore. In that case, you must use the Digital Certificate Manager (DCM) to recreate the internal record of the password for the `.kdb` keystore file.

Before you begin

Refer to the topic “Keystore configurations for SSL” on page 1715 before attempting this task.

About this task

To recreate the internal record of the password for the `.kdb` keystore file, start the DCM. For more information, see the Digital Certificate Manager information.

Procedure

1. Click **Select a Certificate Store**.
2. Select **Other System Certificate Store**.
3. Enter the certificate store path and filename.
4. Enter the certificate store password.
5. Click **Continue**.
6. In the left hand panel, select **Manage Certificate Store**.
7. Click **Change password**.
8. Enter the new password and confirm it. Note that DCM requires a different password than the one you specified in step 4.
9. Select **Automatic login**.

10. Click **Continue**.
11. Click **OK** when a message displays that confirms that the password is changed.
12. Repeat steps 1 through 5 to create the internal record of the new password for the `.kdb` keystore file.
13. Repeat steps 1 through 12 to change the password back to the original password and to create the internal record of the original password for the `.kdb` keystore file.

Results

You have recreated the internal record of the password for the `.kdb` keystore file.

Configuring a hardware cryptographic keystore

You can create a hardware cryptographic keystore that WebSphere Application Server can use to provide cryptographic token support in the server configuration.

About this task

Note: The hardware accelerator is not supported except for the following situations:

- If you are using WebSphere Application Server for z/OS and are using the IBMJCECCA crypto provider.
- If you are using WebSphere Application Server Version 7.0 and above running on zLinux and are using the IBMPKCS11 provider.

Complete the following steps in the administrative console:

Procedure

1. Click **Security > SSL certificate and key management > Key stores and certificates**.
2. Click **New**.
3. Type a name to identify the keystore. This name is used to enable hardware cryptography in the Web Services Security configuration.
4. Optionally, you can type a description for the keystore in the **Description** field.
5. You can specify a **Management scope** for the key store. This is not required. The management scope specifies the scope where this Secure Sockets Layer (SSL) configuration is visible. For example, if you choose a specific node, then the configuration is only visible on that node and any servers that are part of that node.
6. Type the path for the hardware device-specific configuration file. The configuration file is a text file that contains entries in the following format: *attribute* = *value*. The valid values for attribute and value are described in detail in the Software Developer Kit, Java Technology Edition documentation. The two mandatory attributes are name and library, as shown in the following sample code:

   ```
   name = FooAccelerator
   library = /opt/foo/lib/libpkcs11.so
   slotListIndex = 0
   ```

   The configuration file should also include device-specific configuration data. Navigate to the PKCS11ImplConfigSamples.jar file, which contains sample configuration files, under the heading "PKCS 11 Implementation Provider" on the Java technology site http://www.ibm.com/developerworks/java/jdk/security/60/.

   Note: JSSE2 is unable to use the IBMPKCS11Impl provider for acceleration.

   a. You can use this link http://www.ibm.com/developerworks/java/jdk/security/50/secguides/pkcs11implDocs/IBMJavaPKCS11ImplementationProvider.html to initialize the IBMPKCS11 provider in a thread safe way

b. Specify a unique .cfg file that contains information about the supported hardware device. A list of supported hardware devices are available at http://www.ibm.com/developerworks/java/jdk/security/50/secguides/pkcs11implDocs/IBMPKCS11SupportList.html

c. You specify the Signature.getInstance method with the properly initialized IBMPKCS11Impl provider instance as shown.

```
Signature.getInstance("SHA1withRSA", ibmpkcs11implinstance);
```

7. Type a password if the token login is required. Operations that use keys on the token require a secure login. This field is optional if the keystore is used as a cryptographic accelerator. In this case, you need to select **Enable cryptographic operations on hardware device**.
8. Select the **PKCS11** type.
9. Select **Read only**.
10. Click **OK** and **Save**.

Results

WebSphere Application Server can now provide cryptographic token support in the server configuration.

Managing keystore configurations remotely

You can manage keystores remotely in a WebSphere Application Server, Network Deployment environment on separate machines. A node server can hold the configuration for a keystore, while the actual keystore resides on another system. After you set up a remotely managed configuration, you can perform all of the certificate and keystore operations for the keystore on the remote machine from the server that contains the keystore remote configuration.

Before you begin

Key stores can be remotely managed only in network deployed environments.

Alternative Method: To manage a self-signed certificates by using the wsadmin tool, use the **PersonalCertificateCommands** group commands of the AdminTask object. For more information, see the PersonalCertificateCommands command group for the AdminTask object article.

About this task

Complete the following steps in the administrative console:

Procedure

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration* > Key stores and certificates**.
2. Click **New**.
3. Type a name in the **Name** field. This name uniquely identifies the keystore in the configuration.
4. Type the location of the keystore file in the **Path** field. The location can be a file name or a file Uniform Resource Locator (URL) to an existing keystore file.
5. Type the keystore password in the **Password** field. This password is for the keystore file that you specified in the **Path** field.
6. Type the keystore password again in the **Confirm Password** field to confirm the password.
7. Select a keystore type from the list. The type you select is for the keystore file that you specified in the **Path** field.
8. Select the **Remotely managed** check box, and then fill in one or more hosts names of the systems where the keystore file is to be located. If you provide multiple host names, separate the host names with a pipe (**|**).
9. Select any of the following optional selections:

- The **Read only selection** creates a keystore configuration object but does not create a keystore file. If this option is selected, the keystore file that you specified in the **Path** field must already exist.
- The **Initialize at startup selection** initializes the keystore during run time.

10. Select **Apply** and **Save**.

Results

A keystore configuration object is created on the server from where the command was run. The keystore file for the configuration will be created on each system that you specified in the host list.

What to do next

Now, you can perform all certificate management operations on the keystore from the system where the keystore configuration resides. For example, you can perform certificate management operations, such as: creating a self-signed certificate, extracting a certificate, or extracting a signer certificate.

Keystores and certificates collection

Use this page to manage keystore types, including cryptography, Resource Access Control Facility (RACF), Certificate Management Services (CMS), Java, and all trust store types.

gotcha: In most cases, having unused and expired signer certificates in a trust store does not cause problems. However, if you experience a problem because the trust store includes an unused or expired signer certificate, you can safely delete the following expired signer certificates from the dummy keystores files:

- DummyClientKeyFile.jks
- DummyClientTrustFile.jks
- DummyServerKeyFile.jks
- DummyServerTrustFile.jks

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***. Under Related items, click **Keystores and certificates**.

Table 157. Keystores and certificates buttons. This table describes the keystores and certificates buttons.

Button	Resulting action
New	Adds a new keystore object that can be referenced by Secure Sockets Layer (SSL) configurations or KeySets. The Keystore management scope is based on the part of the topology tree from which it was created.
Delete	Deletes an existing keystore. The keystore should not be referenced by any other parts of the configuration before you delete it.
Change password	Allows for changing a keystore password.
Exchange signers	Refers to exchanging signers in a keystore. You can select two keystores, along with personal certificates or signer certificates from a selected keystore, then add them as a signer to another selected keystore.

Keystore usages: Filters the keystore usage types in the keystore collection.

The default value for the keystore usage filter depends on the navigation path that you followed to get to the Keystores and certificates panel. You can change the value of the keystore usage filter by clicking on the drop-down list and selecting a different filter value.

Navigation path	Keystore usage default value
Security > SSL certificate and key management > Keystores and certificates	SSL keystores

Navigation path	Keystore usage default value
Security > SSL certificate and key management > Key sets > CellLTPAKeyPair > Keystores and certificates	Key set keystores
Security > SSL certificate and key management > SSL configurations > CellDefaultSSLSettings > Keystores and certificates	SSL keystores
Security > SSL certificate and key management > Manage endpoint security configurations > *node name* > Keystores and certificates	SSL keystores

Name:

Specifies the unique name that is used to identify the keystore. This name is typically scoped by the ManagementScope scopeName and based upon the location of the keystore. The name must be unique within the existing keystore collection.

This is a user-defined name.

Description:

Specifies the description of the keystore.

This is a user-defined description.

Path:

Specifies the location of the keystore file in the format needed by the keystore type. This file can be a card-specific configuration file for cryptographic devices or a filename or file URL for file-based keystores. It can be a safkeyring URL for RACF keyrings.

Key store settings

Use this page to create all keystore types, including cryptographic, Resource Access Control Facility (RACF), Certificate Management Services (CMS), Java, and all truststore types.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound}**. Under Related Items, click **Key stores and certificates**. Click either **New** or an existing keystore.

Links to Personal certificates, Signer certificates, and Personal certificate requests enable you to manage certificates in a manner similar to iKeyman capabilities. A keystore can be file-based, such as CMS or Java keystore types, or it can be remotely managed.

Note: Any changes made to this panel are permanent.

Name:

Specifies the unique name to identify the keystore. The keystore is typically scoped by the ManagementScope scopeName based on the location of the keystore. The name must be unique within the existing keystore collection.

Data type: Text

Description:

Specifies the description of the keystore.

Data type: Text

Management scope:

Specifies the scope where this Secure Sockets Layer (SSL) configuration is visible. For example, if you choose a specific node, then the configuration is only visible on that node and any servers that are part of that node.

Data type: Text

Path:

Specifies the location of the keystore file in the format needed by the keystore type. This file can be a dynamic link library (DLL) for cryptographic devices or a filename or file URL for file-based keystores. It can be a safkeyring URL for RACF keyrings.

Data type: Text

Control region user:

Specifies the Control region Started Task user ID in which the Control region System Authorization Facility (SAF) keyring is created. The user ID must match the exact ID being used by the Control region. Note: This option only applies when creating writable SAF keyrings on z/OS.

Data type: Text

Servant region user:

Specifies the Servant region Started Task user ID in which the Servant region System Authorization Facility (SAF) keyring is created. The user ID must match the exact ID being used by the Servant region. Note: This option only applies when creating writable SAF keyrings on z/OS.

Data type: Text

Password [new keystore] / Password [existing keystore]:

Specifies the password used to protect the physical keystore in the operating system. For the default keystore (names ending in DefaultKeyStore or DefaultTrustStore), the password is `WebAS`. This default password must be changed.

This field can be edited.

Data type: Text

Note: If you want to push the key store to all nodes, the path should be: `${CONFIG_ROOT}/cells/CELLNAME/yourkeystore.kdb`.

Confirm password:

Specifies confirmation of the password to open the keystore file or device.

Data type: Text

Type:

Specifies the implementation for keystore management. This value defines the tool that operates on this keystore type.

The list of options is returned by java.security.Security.getAlgorithms("KeyStore"). Some options might be filtered and some might be added based on the java.security configuration.

Data type: Text
Default: PKCS12

Read only:

Specifies whether the keystore can be written to or not. If the keystore cannot be written to, certain operations cannot be performed, such as creating or importing certificates.

Default: Disabled

Remotely managed:

Specifies whether the key store is remotely managed, which means that a remote MBean call is needed to update the key store based on the host name specified in the host list field. Most hardware cryptographic token devices are remotely managed. If a key store is marked remotely managed, list the host name of the server where the device is installed in the Host list field.

Default:

Initialize at startup:

Specifies whether the keystore needs to be initialized before it can be used for cryptographic operations. If enabled, the keystore is initialized at server startup.

Default: Disabled

Enable cryptographic operations on hardware device:

Specifies whether a hardware cryptographic device is used for cryptographic operations only. Operations that require a login are not supported when using this option.

Default: Disabled

Key managers collection

Use this page to define the implementation settings for key managers. A key manager is invoked during a Secure Sockets Layer (SSL) handshake to determine which certificate alias is used. The default key manager (WSX509KeyManager) performs alias selection. If more advanced function is desired, define a custom key manager on the **Manage endpoint security configurations** panel.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***. Under Related items, click **Key managers**.

Table 158. Key managers buttons. This table describes the key managers buttons.

Button	Resulting action
New	Adds a new key manager that can be selected by an SSL configuration. A key manager is invoked during an SSL handshake to select a specific certificate alias to use from a key store.
Delete	Deletes an existing key manager. The key manager should not be referenced by any SSL configuration before you can delete it.

Name:

Specifies the name of the key manager, which you can select on the SSL configuration panel.

Class name:

Specifies the name of the key manager implementation class. This class implements javax.net.ssl.X509KeyManager interface and, optionally, the com.ibm.wsspi.ssl.KeyManagerExtendedInfo interface.

Algorithm:

Specifies the algorithm name of the key manager that is implemented by the selected provider.

Key managers settings

Use this page to define key managers implementation settings. A key manager gets invoked during an Secure Sockets Layer (SSL) handshake to determine the certificate alias to be used. The default key manager (WSX509KeyManager) performs alias selection. If more advanced function is desired, a custom key manager can be specified here and selected in the SSL configuration.

To view this administrative console page, click **Security** > **SSL certificate and key management**. Under Configuration settings, click**Manage endpoint security configurations** > **{Inbound | Outbound}** > ***ssl_configuration***. Under Related items, click **Key managers**. On the next panel, click **New**.

Name:

Specifies the name of the key manager, which you can select on the SSL configuration panel.

Data type: Text

Management scope:

Specifies the scope where this Secure Sockets Layer (SSL) configuration is visible. For example, if you choose a specific node, then the configuration is only visible on that node and any servers that are part of that node.

Data type List
Range: Applicable scopes

Standard:

Specifies the key manager selection that is available from a Java provider that is installed in the java.security file. This provider might be shipped by Java Secure Sockets Extension (JSSE) or be a custom provider that implements an X509KeyManager interface.

Default: Enabled

Provider:

Specifies the provider name that has an implementation of an X509KeyManager interface. This provider is typically set to IBMJSSE2.

Data type: Text
Default: IBMJCE

Algorithm:

Specifies the algorithm name of the trust manager implemented by the selected provider.

Data type: Text
Default: IbmX509

Custom:

Specifies that the key manager selection is based on a custom implementation class that implements the javax.net.ssl.X509KeyManager interface and optionally the com.ibm.wsspi.ssl.KeyManagerExtendedInfo interface to obtain additional connection information not otherwise available.

Default: Disabled

Class name:

Specifies the name of the key manager implementation class.

Data type: Text

Creating a self-signed certificate

You can create a self-signed certificate. WebSphere Application Server uses the certificate at runtime during the handshake protocol. Self-signed certificates are located in the default keystore.

Before you begin

You must create a keystore before you can create a self-signed certificate.

Alternative Method: To create a self-signed certificate by using the wsadmin tool, use the **createSelfSignedCertificate** command of the AdminTask object. For more information, see the PersonalCertificateCommands command group for the AdminTask object article.

About this task

Complete the following steps in the administrative console:

Procedure

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration* > Key stores and certificates > [*keystore*]**.
2. From Additional Properties, click **Personal certificates**.
3. Click **Create a self-signed certificate**.
4. Type a certificate alias name. The alias identifies the certificate request in the keystore.

5. Type a common name (CN) value. This value is the CN value in the certificate distinguished name (DN).
6. Type the validity period The default validity period value is 365 days.
7. You can configure one or more of the following optional values:
   a. Optional: Select a key size value. The default key size value is 2048 bits.
   b. Optional: Type an organization value. This value is the O value in the certificate DN.
   c. Optional: Type an organizational unit value. This organizational unit value is the OU value in the certificate DN.
   d. Optional: Type a locality value. This locality value is the L value in the certificate DN.
   e. Optional: Type a state or providence value. This value is the ST value in the certificate DN.
   f. Optional: Type a zip code value. This zip code value is the POSTALCODE value in the certificate DN.
   g. Optional: Select a country value from the list. This country value is the C= value in the certificate request DN.
8. Click **Apply**.

Results

You have created a self-signed certificate that resides in the keystore. The SSL configuration for the WebSphere Application Server runtime uses this certificate for SSL communication. Extract the signer of the self-signed certificate to add the signer to another keystore.

Replacing an existing personal certificate

Occasionally, you need to replace an existing personal certificate with a new certificate. This task discusses how to replace the existing personal certificate in the keystore. It searches all keystores for a signer certificate extracted from the original personal certificate, and places the signer of the new personal certificate in it's place. It also updates all of the certificate alias references in the security configuration with the new one.

Before you begin

The current certificate and the certificate replacement must exist in the same keystore before you can replace a certificate.

Alternative Method: To replace a self-signed certificate by using the wsadmin tool, use the **replaceCertificate** command of the AdminTask object. For more information, see the PersonalCertificateCommands command group for the AdminTask object article

About this task

Complete the following steps in the administrative console:

Procedure

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration* > Key stores and certificates > [*keystore*]**.
2. Under Additional Properties, click **Personal certificates**.
3. Select the certificate to be replaced. The alias list must include the certificate to be replaced and the certificate to replace it with.
4. Click **Replace**.
5. Select a replacement certificate alias from the list.
6. You can delete one of the following types of certificates:
   - Select **Delete old certificate** to delete the existing or expired certificate.

- Select **Delete old signers** to delete the existing signer certificates.

7. Click **Apply**.

Results

Your results depend on what you selected:

- If you selected **Delete old certificate**, the new certificate alias replaces all of the references to the certificate alias in the configuration.
- If you selected **Delete old signers**, the new signer certificate replaces all of the occurrences of the old signer certificates.
- If the new certificate alias replaces the existing alias, the WebSphere Application Server runtime checks to make sure that:
  - All of the SSL Configurations objects reference the certificate
  - The Dynamic SSL Configuration Selections objects and the SSL Configuration group objects reference the certificate.
- If you selected **Delete old signers**, the existing signer certificates are replaced.
- If you selected **Delete old certificate**, the existing certificate is deleted.

Creating a new SSL certificate to replace an existing one in a node

When using the -asExistingNode option on the addNode command, you might be adding an existing node to a different machine. The default Secure Sockets Layer (SSL) certificate of the node does not contain the name of the machine the node is located on. In most scenarios, the subject DN of the default certificate does not make a difference. However, you might want to change the default certificate of the node to contain the hostname of the node.

Before you begin

To replace the default certificate of a node, you must create a new NodeDefaultKeyStore for the certificate and then replace the old certificate with the new one.

The certificate created by default on the WebSphere Application Server subjectDN is of the form cn=<hostname>, ou=<cell name>, ou=<node name>, o=ibm, c=us. When creating a new certificate you can also customize the subjectDN.

About this task

To create a new SSL certificate in the administrative console:

Procedure

1. Click **Security > SSL certificate and key management > Key stores and certificates**.
2. Select the NodeDefaultKeyStore of the node you want to change.
3. Under Additional Properties, select **Personal certificates**.
4. Under the Create pull-down, select **Chained Certificate**.
5. Enter a certificate and alias name. This can be any name you choose as long as the alias does not already exist. It is just a label to identify the certificate in the keystore.
6. Enter a common name. This is typically the hostname the node is running on.
7. Optional: Fill in any of the other Subject DN related fields. If you want the subject DN to look like the default subjectDN on WebSphere Application Server, then enter:
   - `IBM` in the Organization field.
   - `<cell name>,ou=<node name>` in the Organization unit field.
   - Under the Country or region pull-down, select **US**.

8. You can use the defaults for Root certificate used to sign the certificate, Key Size, and Validity Period or supply your own values.
9. Click **Apply**.

   Note: You can also create a new chained certificate using the createChainedCertificate command. Read PersonalCertificateCommands command group for the AdminTask object for more information.

   You must now replace the old certificate with the one you just created. The replace certificate option not only replaces the old default certificate with a new one but also replaces any occurrences of the signer of the old certificate with the signer of the new certificate. The configuration is also checked for references to the alias name of the old certificate and replaces it with the alias name of the new certificate. To replace the old certificate with the new one, complete the remaining steps.
10. Click **Security > SSL certificate and key management > Key stores and certificates**.
11. Select the NodeDefaultKeyStore of the node you want to change.
12. Under Additional Properties, select **Personal certificates**.
13. Select the default certificate of the node, usually called `default`.
14. Click **Replace**.
15. Select the certificate alias name for the certificate you just created from the **Replace with** pull-down.
16. Click **Delete old Certificate after replacement**.
17. Click **Apply**.

    Note: You can also create a new chained certificate using the replaceCertificate command. Read PersonalCertificateCommands command group for the AdminTask object for more information.

What to do next

You can also replace default certificates in an entire cell. Read Creating new SSL certificates to replace existing ones in a cell for more information.

Creating new SSL certificates to replace existing ones in a cell

To replace default Secure Socket Layer (SSL) certificates in an entire cell, you must create a new self-signed root certificate in the root keystore, DmgrDefaultRootStore, and replace the old root certificate with the new one.

About this task

For the default certificate of the cell in CellDefaultKeyStore and the default certificate of each node in NodeDefaultKeyStore, create a new chained certificate and replace the old default certificate with the new certificate.

The root certificate is created by default on WebSphere Application Server, and has a subjectDN in the form cn=<hostname>, ou=Root Certificate, ou=<cell name>, ou=<node name>, o=ibm, c=us. When you create a new root certificate you can also customize the subject DN.

To create a new SSL root certificate in the administrative console:

Procedure

1. Click **Security > SSL certificate and key management > Key stores and certificates**.
2. Under the Keystore usages pull-down, select **Root certificate keystore**.
3. Select the DmgrDefaultRootStore in the keystore collection.
4. Under Additional Properties, select **Personal certificates**.
5. Under the Create pull-down, select **Self-signed Certificate**.

6. Enter a certificate and alias name. This can be any name you choose as long as the alias does not already exist. It is just a label to identify the certificate in the keystore.
7. Enter a common name. This is typically the hostname the node is running on.
8. Optional: Fill in any of the other Subject DN related fields. If you want the subject DN to look like the default subjectDN on WebSphere Application Server, then enter:
   - `IBM` in the Organization field.
   - `<cell name>,ou=<node name>` in the Organization unit field.
   - Under the Country or region pull-down, select **US**.
9. You can use the defaults for Root certificate used to sign the certificate, Key Size, and Validity Period or supply your own values.
10. Click **Apply**.

    Note: You can also create a self-signed certificate using the createSelfSignedCertificate command. Read PersonalCertificateCommands command group for the AdminTask object for more information.

    You must now replace the old root certificate with the one you just created. The replace certificate option not only replaces the old default certificate with a new one but also replaces any occurrences of the signer of the old certificate with the signer of the new certificate. The configuration is also checked for references to the alias name of the old certificate and replaces it with the alias name of the new certificate. To replace the old certificate with the new one, complete the remaining steps.
11. Click **Security > SSL certificate and key management > Key stores and certificates**.
12. Select the CellDefaultKeyStore of the node you want to change.
13. Under Additional Properties, select **Personal certificates**.
14. Select the default certificate of the node, usually called `default`.
15. Click **Replace**.
16. Select the certificate alias name for the new certificate you just created from the **Replace with** pull-down.
17. Click **Delete old Certificate after replacement**.
18. Click **Apply**.

What to do next

You can also replace default certificates in a node. Read Creating a new SSL certificate to replace an existing one in a node for more information

Creating a certificate authority request

To ensure Secure Sockets Layer (SSL) communication, servers require a personal certificate that is either self-signed, chained or signed by an external certificate authority (CA). You must first create a personal certificate request to obtain a certificate that is signed by a CA.

Before you begin

The keystore that contains a personal certificate request must already exist.

Alternative Method: To create a certificate request by using the wsadmin tool, use the **createCertificateRequest** command of the AdminTask object. For more information, see the CertificateRequestCommands command group of the AdminTask object article.

About this task

Complete the following steps in the administrative console:

Procedure

1. Click **Security > SSL certificate and key management > Key stores and certificates > *keystore***.
2. Click **Personal certificate requests > New**.
3. Type the full path of the certificate request file. The certificate request is created in this location.
4. Type an alias name in the **Key label** field. The alias identifies the certificate request in the keystore.
5. Type a common name (CN) value. This value is the CN value in the certificate distinguished name (DN).
6. You can configure one or more of the following optional values:
   a. Optional: Select a key size value. The valid key size values are 512, 1024, 2048, 4096, and 8192. The default key size value is 2048 bits.
   b. Optional: Type an organization value. This value is the O value in the certificate DN.
   c. Optional: Type an organizational unit value. This organizational unit value is the OU value in the certificate DN.
   d. Optional: Type a locality value. This locality value is the L value in the certificate DN.
   e. Optional: Type a state or providence value. This value is the ST value in the certificate DN.
   f. Optional: Type a zip code value. The zip code value is the POSTALCODE value in the certificate DN.
   g. Optional: Select a country value from the list. This country value is the C= value in the certificate request DN.
7. Click **Apply**.

Results

The certificate request is created in the specified file location in the keystore. The request functions as a temporary placeholder for the signed certificate until you manually receive the certificate in the keystore.

Note: Key store tools (such as iKeyman and keyTool) cannot receive signed certificates that are generated by certificate requests from WebSphere Application Server. Similarly, WebSphere Application Server cannot accept certificates that are generated by certificate requests from other keystore utilities.

What to do next

Now you can receive the CA-signed certificate into the keystore to complete the process of generating a signed certificate for your server.

Certificate request settings

Use this page to verify the properties of a personal certificate request.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***. Under Related items, click **Key stores and certificates > *key store***. Under Additional Properties, click **Personal certificate requests > *certificate request*** .

File for certificate request:

Specifies the fully qualified name of the file that contains the certificate request that can be sent to a certificate authority (CA) server.

Key label:

Specifies the certificate alias name for the signer in the key store.

Key size:

Specifies the size of the keys that are generated.

Requested by:

Specifies the Subject distinguished name (DN) that represents the identity of the certificate request.

Fingerprint (SHA Digest):

Specifies the SHA hash of the personal certificate, which can be used to verify that the certificate has not been altered when it is used in a remote connection.

Signature algorithm:

Specifies the algorithm used to sign the certificate.

Personal certificates collection

Use this page to manage personal certificates.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***. Under Related items, click **Key stores and certificates > *key store*** . Under Additional Properties, click **Personal certificates**.

The **Personal certificates** page lists all personal certificates in the selected key store. You can do most certificate management operations in this panel, including creating a new self-signed certificate, deleting a certificate, receiving one generated from a CA, replacing a certificate (simultaneous delete and create, replacing references across all key stores), extracting the signer, and importing or exporting a personal certificate.

Personal certificate requests are temporary place holders for certificates that will be signed by a certificate authority (CA).

The Key store collection must contain at least two key store files. You must select one file in order to replace, extract, or export a key store,

Table 159. Personal certificates buttons. This table lists the personal certificates buttons.

Button	Resulting action
Create (drop-down list)	Enables the application server to create the following certificates: • Self-signed Certificate • CA-signed Certificate • Chained Certificate
Delete	Specifies to delete a certificate from the key store. Be careful that the certificate alias is not referenced elsewhere in the Secure Sockets Layer configuration.
Receive a certificate from a certificate authority	Enables the application server to receive a certificate authority (CA)-generated certificate from a file to complete a certificate request.
Replace	Replaces a personal certificate with another personal certificate. All key stores in the configuration looking for signer certificate form the original personal certificate and replaces them with the new personal certificates signer. Any place in the security configuration where the certificate alias is referenced will be replaced with the new certificate alias.
Extract	Extracts the signer part of personal certificate from the key store and stores it to a file. The file can then be used to add the signer to another key store.
Import	Imports a certificate, including the private key, from a key store file or managed key store.

Table 159. Personal certificates buttons (continued). This table lists the personal certificates buttons.

Button	Resulting action
Export	Exports a certificate, including the private key, to a specified key store file or manage key store.
Revoke	Revokes a CA-signed certificate.
Renew	Renews a self signed or chained certificate.

Alias:

Specifies the alias by which the personal certificate is referenced in the key store.

When you select an alias, the View Certificate panel opens.

Issued by:

Specifies the distinguished name of the entity by which the certificate was issued. This name is the same as the issued-to distinguished name when the personal certificate is self-signed.

Issued to:

Specifies the distinguished name of the entity to which the certificate was issued.

Serial number:

Specifies the certificate serial number that is generated by the issuer of the certificate.

Expiration:

Specifies the expiration date of the signer certificate for validation purposes.

Self-signed certificates settings

Use this page to create self-signed certificates.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***. Under Related items, click **Key stores and certificates >** *keystore*. Under Additional Properties, click **Personal certificates > Create (drop-down list) > Self-signed certificate**.

This same help file is available when you create a new certificate or view an existing certificate. The fields in this help file are described according to how they appear and are used on the administrative console.

Alias:

Specifies the alias for the personal certificate in the keystore.

You enter the alias name for the personal certificate in the keystore when you are creating a certificate. *The alias name is read-only when you view an existing certificate.*

Data type: Text

Version:

Specifies the version of the personal certificate. Valid versions include X509 V3, X509 V2, or X509 V1. It is recommended to use X509 V3 certificates.

This field is read-only when you create or view a certificate.

Data type: Text
Default: X509 V3
Range:

Key size:

Specifies the key size of the private key that is used by the personal certificate.

When you are creating a certificate you can select the key size from the drop-down list. *This field is read-only when you view a certificate.*

Data type: Integer
Default: 1024
Other valid key sizes: 512, 2048, 4096

Common name:

Specifies the common name portion of the distinguished name (DN). It is recommended that this name be the host name of the machine on which the certificate resides. In some cases, the common name is used to login during Secure Socket Layer (SSL) certificate authentication; therefore, in some cases, this name might be used as a user ID for a local operating system registry.

When you create a new certificate you can enter the common name in this field. *This field does not display when you view an existing certificate.*

Data type: Text

Serial number:

Identifies the certificate serial number that is generated by the issuer of the certificate. When creating a certificate this field does not appear.

This field is read-only when you view an existing certificate.

Validity period:

Specifies the length in days during which the certificate is valid. The default is 365 days. You can enter any number of days you wish.

This field is read-only when you view an existing certificate. This field displays a validity period as a range of days between two dates. For example, Valid from March 16, 2008 to March 16, 2009.

Data type: Text

Organization:

You enter the organization portion of the distinguished name. This field is optional.

This field displays only when you create a new certificate.

Data type: Text

Organization unit:

Specifies the organization unit portion of the distinguished name. This field is optional.

This field displays only when you create a new certificate.

Data type: Text

Locality:

Specifies the locality portion of the distinguished name. This field is optional.

This field displays only when you create a new certificate.

Data type: Text

State/Province:

Specifies the state portion of the distinguished name. This field is optional.

This field displays only when you create a new certificate.

Data type: Text

Zip code:

Specifies the zip code portion of the distinguished name. This field is optional.

This field displays only when you create a new certificate.

Data type: Integer

Country or region:

Select the country portion of the distinguished name from the drop-down list. This field is optional.

This field displays only when you create a new certificate.

Data type: Text
Default: (none)

Refer to http://www.iso.org/iso/en/prods-services/iso3166ma/02iso-3166-code-lists/list-en1.html for a list of ISO 3166 country codes.

Validity period:

Identifies the length, in days, when the certificate is valid. The default is 365 days.

This field is read-only when you view an existing certificate and shows the start and end dates.

Issued to:

Identifies the distinguished name of the entity to which the certificate was issued.

This field is read-only when you view an existing certificate.

Issued by:

Identifies the distinguished name of the entity that issued the certificate. When the personal certificate is self-signed, this name is identical to the **Issued to** distinguished name.

This field is read-only when you view an existing certificate.

Fingerprint (SHA Digest):

Identifies the Secure Hash Algorithm (SHA hash) of the certificate, which can be used to verify the certificate's hash at another location, such as the client side of a connection.

This field is read-only when you view an existing certificate.

Signature algorithm:

Identifies the algorithm used to sign the certificate.

This field is read-only when you view an existing certificate.

Personal certificate requests collection

Use this page to manage personal certificate requests. Personal certificate requests are temporary place holders for certificates that will be signed by a certificate authority (CA).

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***. Under Related items, click **Key stores and certificates > *key store*** . Under Additional Properties, click **Personal certificate requests**.

A private key is generated during the certificate request generation, but only the certificate is sent to the CA. The CA generates a new certificate, signed by the CA. This can be added in the Personal Certificates panel.

Table 160. Personal certificate requests buttons. This table lists the personal certificate requests buttons.

Button	Resulting action
New	Creates a personal certificate request that can be given to a certificate authority to complete.
Delete	Deletes a personal certificate request.
Extract	Extracts a personal certificate request. Only one certificate request can be selected at a time.
Query	Queries a personal certificate request. Only one certificate request can be selected at a time.

Note: Any changes made to this panel are permanent.

Key label:

Specifies the alias that represents the personal certificate request in the key store.

Requested by:

Specifies the Subject distinguished name (DN) that represents the identity of the certificate request.

Personal certificate requests settings

Use this page to create a new certificate request that can be extracted and sent to a certificate authority (CA).

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} >**

ssl_configuration. Under Related items, click **Key stores and certificates** > ***key store*** . Under Additional Properties, click **Personal certificates requests**. Then click the **New** button.

Personal certificate requests are temporary place holders for certificates that will be signed by a certificate authority (CA). The private key is generated during the certificate request generation, but only the certificate is sent to the CA. The CA generates a new certificate, signed by the CA.

Note: Any changes made to this panel are permanent.

File for certificate request:

Specifies the fully qualified file name from which the certificate request is exported. This portion of the certificate request can be given to the certificate authority to generate the real certificate. After the real certificate is generated, you can perform a "Receive a certificate from a certificate authority" from the personal certificate collection view.

Data type: String

Key label:

Specifies the alias that represents the personal certificate request in the key store.

Data type: String

Key size:

Specifies the size of the keys that are generated.

Data type: Integer
Default: 2048

Common name:

Specifies the name of the entity that the certificate represents. This common name can represent a person, company, or machine. For websites, the common name is frequently the DNS host name where the server resides.

Data type: String

Organization:

Specifies the organization portion of the distinguished name.

Data type: String

Organizational unit:

Specifies the organization unit portion of the distinguished name. This field is optional.

Data type: String

Locality:

Specifies the locality portion of the distinguished name. This field is optional.

Data type: String

State or province:

Specifies the state portion of the distinguished name. This field is optional.

Data type: String

Zip code:

Specifies the zip code portion of the distinguished name. This field is optional.

Data type: Integer

Country or region:

Specifies the country portion of the distinguished name.

Data type: String

Refer to http://www.iso.org/iso/en/prods-services/iso3166ma/02iso-3166-code-lists/list-en1.html for a list of ISO 3166 country codes.

Extract certificate request

Use this page to extract a certificate request to a file so it can be sent to a certificate authority (CA).

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***. Under Related items, click **Key stores and certificates > *key store*** . Under Additional Properties, click **Personal certificate requests > Extract**.

Key label:

Specifies the alias that represents the personal certificate request in the key store.

File for certificate request:

Specifies the filename where the extracted certificate request is placed.

Data type: Text

Receiving a certificate issued by a certificate authority

When a certificate authority (CA) receives a certificate request, it issues a new certificate that functions as a temporary placeholder for a CA-issued certificate. A keystore receives the certificate from the CA and generates a CA-signed personal certificate that WebSphere Application Server can use for Secure Sockets Layer (SSL) security.

Before you begin

The keystore must contain the certificate request that was created and sent to the CA. Also, the keystore must be able to access the certificate that is returned by the CA.

Note: To receive a certificate by using the wsadmin tool, use the **receiveCertificate** command of the AdminTask object. For more information, see the PersonalCertificateCommands command group for the AdminTask object article.

About this task

WebSphere Application Server can receive only those certificates that are generated by a WebSphere Application Server certificate request. It cannot receive certificates that are created with certificate requests from other keystore tools, such as **iKeyman** and **keyTool**.

Complete the following steps in the administrative console:

Procedure

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration* > Key stores and certificates >** [*keystore*].
2. Under Additional Properties, click **Personal certificates**.
3. Select a personal certificate.
4. Click **Receive a certificate from a certificate authority**.
5. Type the full path and name of the certificate file.
6. Select a data type from the list.
7. Click **Apply** and **Save**.

Results

The keystore contains a new personal certificate that is issued by a CA. The original certificate request is changed to a personal certificate.

What to do next

The SSL configuration is ready to use the new CA-signed personal certificate.

Export certificate to a keystore file or a managed keystore:

Use this page to specify a personal certificate to export to a keystore file or a managed keystore.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***. Under Related items, click **Key stores and certificates > *keystore*** . Under Additional Properties, click **Personal certificates**. Select a personal certificate using the check box. Then click the **Export** button.

Certificate alias to export:

Displays the name of the certificate that you selected to export on the previous panel.

Data type: Text

Keystore Password:

Type in the password of the keystore to use for the export.

Data type: Text

Alias:

Specifies the alias that the personal certificate is referenced by in the destination keystore.

Data type: Text

Managed key store:

Select this option with the radio button. Then select a keystore from the pull-down list, which is managed by the security configuration, to export the certificate to.

Data type: Drop-down list

Key file name:

Select this option with the radio button. Then type the keystore file name into which the exported certificate is added. If the keystore file name already exists, the exported certificate is added. If the keystore file name does not already exist, a keystore file name is created, and the exported certificate is added.

Data type: Text

Type:

Specifies the type of keystore file. The valid types are listed in the drop-down list.

Data type: Text
Default: PKCS12

Key file password:

Specifies the password that is used to access the keystore file.

Data type: Text

Import certificate from a key file or managed keystore:

Use this page to specify a personal certificate to import from a keystore or key file.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***. Under Related items, click **Key stores and certificates > *keystore*** . Under Additional Properties, click **Personal certificates**. Select a personal certificate using the check box. Then click the **Import** button.

Managed key store:

Select this option with the radio button. This selection indicates that the keystore that contains the certificate to import is a managed keystore.

Data type: radio button

Get key store aliases:

Clicking this button queries the configuration for the list of keystore aliases for which the certificate will be imported to.

Key store:

Select an alias of the keystore from the pull-down list of managed keystores that are managed by the security configuration. The alias you select identifies the keystore that contains the certificate to import.

Data type: drop-down list

Key store password:

Specifies the password for the keystore to use for import.

Data type: Text

Key store file:

Select this option with the radio button. This selection indicates a keystore file that contains the certificate to import.

Data type: radio button

Key file name:

Specifies the fully qualified path to keystore file that contains the certificate to import.

Data type: Text

Get key file aliases:

Clicking this button, queries the key file for the aliases of all the personal certificates in the keystore from which to choose.

Type:

Specify the type of keystore file. Select a valid type from the drop-down list.

Data type: Text

Key file password:

Type the password that is used to access the keystore file.

Data type: Text

Certificate alias to import:

Specifies the certificate alias identified as the **Key file name** that you want to import into the current keystore.

Data type: Text
Default: (none)

Imported certificate alias:

Specifies the new alias that you want the certificate to be named in the current keystore.

Data type: Text

Receive certificate from CA:

Use this page to import your personal certificate from the certificate authority (CA). The imported certificate replaces the temporary certificate associated with the public/private keys in the certificate request that is stored in the key store.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***. Under Related items click **Key stores and certificates** > ***key store*** . Under Additional Properties, click **Personal certificates > Receive certificate from certificate authority**.

Certificate file name:

Specifies the filename that contains the certificate generated by the certificate authority (CA).

Data type: Text

Data type:

Specifies the format of the file that is either Base64 encoded ASCII data or Binary DER data.

Data type: Text
Default: Base64-encoded ASCII data

Replace a certificate

Use this page to specify two certificates: the first selected certificate is replaced by the second selected certificate. The replace function replaces all the old signer certificates in key stores that are managed throughout the cell with the new signer from the new certificate. The same level of trust that was established with the old certificate is maintained. All places the certificate's alias is referenced in the security configuration will be replaced with the certificate's alias. The alias could be referenced on a security object like the SSL configuration, the dynamic outbound endpoint SSL configuration and key set groups.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***. Under Related items, click **Key stores and certificates** > ***key store*** . Under Additional Properties click **Personal certificates**. Select a personal certificate, then click the **Replace** button.

Old certificate:

Specifies the certificate that you want to replace.

Data type: Text

Replace with:

Specifies the certificate that you want to replace the old certificate.

Data type: Text
Default: (none)

Delete old certificate after replacement:

Specifies that you want to delete the old certificate and all associated signer certificates after the new certificate replaces it. If you do not replace the old personal certificate, it might be assigned a new alias name.

Default: Disabled

Delete old signers:

Specifies that you want to delete the old signer certificates that are associated with the old certificate after the new signer certificates replace them. If you do not delete the old signer certificates, they might be assigned new alias names.

Default: Disabled

Extracting a signer certificate from a personal certificate

Personal certificates contain a private key and a public key. You can extract the public key, called the *signer certificate*, to a file, then import the certificate into another keystore. The client requires the signer portion of a personal certificate for Security Socket Layer (SSL) communication.

Before you begin

The keystore that contains a personal certificate must already exist.

Alternative Method: To extract a signer certificate from a personal certificate using the wsadmin tool, use the **extractCertificate** command of the AdminTask object. For more information, see the PersonalCertificateCommands command group for the AdminTask object article.

About this task

Complete the following steps in the administrative console:

Procedure

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration* > Key stores and certificates > *keystore*** .
2. Under Additional Properties, click **Personal certificates**.
3. Select a personal certificate.
4. Click **Extract**.
5. Type the full path for the certificate file name. The signer certificate is written to this certificate file.
6. Select a data type from the list.
7. Click **Apply**.

Results

The signer portion of the personal certificate is stored in the file that is provided.

What to do next

This signer can now be imported into other keystores.

Extract certificate

Use this page to extract the signer from the personal certificate and store it in a file. The certificate can be added to a trust store for trust verification. When extracting the signer from a chained personal certificate, the signer at the top level of the chain is extracted.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***. Under Related items, click **Key stores and certificates > *key store*** . Under Additional Properties, click **Personal certificates > Extract**.

Certificate alias to extract:

Displays the name of the certificate that you selected for extraction on the previous panel.

Data type: Text

Certificate file name:

Specifies the fully qualified path where the certificate file will reside.

Data type: Text

Data type:

Specifies the format of the file, which is either Base64-encoded ASCII data or Binary DER data.

Data type: Text
Default: Base64-encoded ASCII data

Extract signer certificate

Use this page to extract a signer certificate from the keystore to a file so that it can be added elsewhere.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***. Under Related items, click **Key stores and certificates > *key store***. Under Additional Properties, click **Signer certificates** . Select a signer certificate, then click the **Extract** button

File name:

Specifies the fully qualified file name where the extracted signer certificate is placed.

Data type: Text

Data type:

Specifies the format of the file, which is either Base64 encoded ASCII data or Binary DER data.

Data type: Text

Retrieving signers using the retrieveSigners utility at the client

The client requires the signer certificates from the server to be able to communicate with WebSphere Application Server. Use the **retrieveSigners** command to get the signer certificate from a server.

Before you begin

The retrieveSigners utility is located in one of the following directories, depending on your operating system:

- *profile_root*/bin

In this release, a Java client that does not have access to a stdin console prompt should use the retrieveSigners utility to download the signers from the remote server key store when signers are needed for a Secure Sockets Layer (SSL) handshake. For example, you might interpret the client as failing to respond if an applet client or Java Web Start Client application cannot access the stdin signer exchange prompt. Thus, you must add the WebSphere Java method call **com.ibm.wsspi.ssl.RetrieveSignersHelper.callRetrieveSigners** to your client application to retrieve the signers and to avoid running the retrieveSigners utility manually.

Use the retrieveSigners utility for situations where you cannot verify whether or not the com.ibm.ssl.enableSignerExchangePrompt= property is enabled or disabled when the application makes a request. Set the com.ibm.ssl.enableSignerExchangePrompt= property to `false` in the ssl.client.props file if you cannot see the console.

Alternatively, you can manually create the server key in the client truststore.

About this task

Complete the following steps, as required:

Procedure

1. Use the **retrieveSigners** command to get the signer certificate from a server. You can find details about the **retrieveSigners** parameters in “Secure installation for client signer retrieval in SSL” on page 1727.
2. If the client and server are on the same machine, you will need only the *remoteKeyStoreName* and *localKeyStoreName* parameters. The most typical key store to reference on a remote system is `CellDefaultTrustStore` on a network deployed environment and `NodeDefaultTrustStore` on an application server.
3. When retrieving signers from a remote server, add these required connection-related parameters: **–host** *host*, **–port** *port*, **–conntype** {*RMI* | *SOAP*}.
4. Use the **–autoAcceptBootstrapSigner** parameter if you want to enable automation of the signer retrieval. This parameter automatically adds to the server all the signers that are needed to make the connection.

Results

After running, the command displays the SHI-1 digest of the signers added. The output looks similar to the following output:

```
/QIBM/UserData/WebSphere/AppServer/V67/Express/profiles/AppSrv01/bin/retrieveSigners
CellDefaultTrustStore ClientDefaultTrustStore

CWPKI0308I: Adding signer alias "default_signer" to local keystore
          "ClientDefaultTrustStore" with the following SHA digest:
```

Example

The following examples illustrate how to call the `retrieveSigners.bat` file.

To retrieve signers on the same system, enter:

```
profile_root/bin/retrieveSigners CellDefaultTrustStore ClientDefaultTrustStore
```

To retrieve signers on a remote system with a SOAP connection, enter:

```
profile_root/bin/retrieveSigners CellDefaultTrustStore ClientDefaultTrustStore
-host myRemoteHost -port 8879 -conntype SOAP -autoAcceptBootstrapSigner
```

To retrieve signers on a remote system that has security enabled, enter:

```
profile_root/bin/retrieveSigners CellDefaultTrustStore ClientDefaultTrustStore
-host myRemoteHost -port 8879 -conntype SOAP -user testuser -password testuserpwd
-autoAcceptBootstrapSigner
```

Changing the signer auto-exchange prompt at the client

For clients to communicate with WebSphere Application Server, clients must obtain a signer certificate from the server. Clients can use the **retrieveSigners** command to connect to a server to obtain the appropriate signer. A prompt displays that asks whether or not you want to add a signer to the truststore. If the Secure Sockets Layer (SSL) configuration uses an automated script that might hang, use the prompt to obtain the certificate.

Before you begin

The com.ibm.ssl.enableSignerExchangePrompt property in the *profile_home*/properties/ssl.client.props file controls the signer certificate prompt. By default, this property is set to `true`, meaning the prompt is enabled.

About this task

Complete the following steps to disable or enable the signer-exchange prompt at the client:

Procedure

1. Open the *profile_home*/properties/ssl.client.props file using an editor.
2. Locate the section containing the SSL configuration information for the client that you are working with.
3. Change the value of the com.ibm.ssl.enableSignerExchangePrompt property to `false` if you do not want the signer-exchange prompt, or set it to `true` if you want to be prompted.
4. Save and close the file.

Results

When the com.ibm.ssl.enableSignerExchangePrompt property is set to `false`, no prompt displays if a signer is not trusted. In this case the SSL handshake fails. Once the proper signer for the connection being made is manually installed in the trust store, the SSL handshake can succeed.

When the com.ibm.ssl.enableSignerExchangePrompt property is set to `gui` or `true`, a signer-exchange window is displayed, and you are asked to accept or reject the certificate. If you accept the certificate, it is installed in the trust store automatically and the handshake succeeds. If you reject the certificate, it does not get installed in the trust store and the handshake fails since the certificate is not trusted.

When the com.ibm.ssl.enableSignerExchangePrompt property is set to `stdin`, a signer-exchange ASCII prompt is displayed, and you are asked to accept or reject the certificate. If you accept the certificate, it is installed in the trust store automatically and the handshake succeeds. If you reject the certificate, it does not get installed in the trust store and the handshake fails since the certificate is not trusted.

The prompt looks like the following example:

Example

```
/QIBM/UserData/WebSphere/AppServer/V8/Express/profiles/default/bin/serverStatus -all
ADMU0116I: Tool information is being logged in file
/QIBM/UserData/WebSphere/AppServer/V8/Express/profiles/default/logs/serverStatus.log
ADMU0128I: Starting tool with the default profile
ADMU0503I: Retrieving server status for all servers
ADMU0505I: Servers found in configuration:
ADMU0506I: Server name: server1

*** SSL SIGNER EXCHANGE PROMPT ***
SSL signer from target host 192.174.1.5 is not found in truststore
/QIBM/UserData/WebSphere/AppServer/V8/Express/profiles/default/etc/trust.p12.
```

Verify that the digest value matches what is displayed at the server in the following signer information:

```
Subject DN:    CN=hostname.austin.ibm.com, O=IBM, C=US
Issuer DN:     CN=hostname.austin.ibm.com, O=IBM, C=US
Serial number: 1128544457
Expires:       Thu Oct 20 15:34:17 CDT 2006
SHA-1 Digest:  91:A1:A9:2D:F2:7D:70:0F:04:06:73:A3:B4:A4:9C:56:9D:A8:A3:BA
MD5 Digest:    88:72:C5:88:00:1C:A7:FA:D6:EB:04:88:AC:A1:C9:13

Add signer to the truststore now? (y/n) y
A retry of the request might need to occur.
ADMU0508I: The Application Server "server1" is STARTED.
```

What to do next

Clients can instigate communications for various processes using signer certificates obtained from WebSphere Application Server.

Retrieving signers from a remote SSL port

To perform Secure Sockets Layer (SSL) communication with a server, WebSphere Application Server must retrieve a signer certificate from a secure remote SSL port during the handshake. After the signer certificate is retrieved, you can add the signer certificate to a keystore.

Before you begin

The keystore that is to contain the signer certificate must already exist.

Alternative Method: To retrieve a signer certificate from a port using the wsadmin tool, use the **retrieveSignerFromPort** command of the AdminTask object. For more information, see the SignerCertificateCommands command group for the AdminTask object article.

About this task

Complete the following steps in the administrative console:

Procedure

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > Key stores and certificates > *keystore* > Signer certificates > Retrieve from port**.
2. Click **Retrieve from port**.
3. Type the host name of the machine on which the signer resides.

4. Type the port location on the host machine on which the signer resides. The port location is not limited to ports on WebSphere Application Server. The ports can include Lightweight Directory Access Protocol (LDAP) ports or ports on any server on which an SSL port is already configured, such as `SIB_ENDPOINT_SECURE_ADDRESS`.
5. Select an SSL configuration for the outbound connection from the list.
6. Type an alias name for the certificate.
7. Click **Retrieve signer information**. A message window displays information about the retrieved signer certificate, such as: the serial number, issued-to and issued-by identities, SHA hash, and expiration date. If a chained certificate is on the port, information about the root is displayed.
8. Click **Apply**. This action indicates that you accept the credentials of the signer.

Results

The signer certificate that is retrieved from the remote port is stored in the keystore.

What to do next

An SSL configuration or client process that requires an SSL connection to the server can use the retrieved and approved signer certificate.

Retrieve from port

Use this page to retrieve a signer certificate from a remote SSL port. The system connects to the specified remote SSL host and port and receives the signer during the handshake using an SSL configuration.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***. Under Related items, click **Key stores and certificates > *key store***. Under Additional Properties, click **Signer certificates**. Then click the **Retrieve from port** button.

To retrieve a signer certificate from a specific port, you enter the host and port, select an SSL configuration from the pull-down list, and enter an alias to identify the signer certificate. Click **Retrieve Signer Information** and information about the signer certificate is displayed, such as the serial number of the certificate, who the certificate is issued to and by, the certificate finger print, and the expiration information for the certificate. If you want the certificate to be stored in the keystore, click **Apply** or **Save**.

Host:

Specifies the host name to which you connect when attempting to retrieve the signer certificate from the Secure Sockets Layer (SSL) port.

Data type: Text

Port:

Specifies the SSL port to which you connect when attempting to retrieve the signer certificate.

Data type: Text

SSL configuration for outbound connection:

Specifies the SSL configuration that is used to connect to the previously specified SSL port. This configuration is also the SSL configuration that contains the signer after retrieval. This SSL configuration does not need to have the trusted certificate for the SSL port as it is retrieved during validation and presented here.

Data type: Text

Alias:

Specifies the certificate alias name that you want to reference the signer in the key store, which is specified in the SSL configuration.

Data type: Text

Retrieved signer information:

Specifies the signer certificate information if it is retrieved from the remote host and port.

Adding a signer certificate to a keystore

Signer certificates establish the trust relationship in SSL communication. You can extract the signer part of a personal certificate from a keystore, and then you can add the signer certificate to other keystores.

Before you begin

The keystore that you want to add the signer certificate to must already exist.

Alternative Method: To add a signer certificate to a keystore by using the wsadmin tool, use the **addSignerCertificate** command of the AdminTask object. For more information, see the SignerCertificateCommands command group for the AdminTask object article.

Note: If the security custom property com.ibm.websphere.security.OverwriteAndReplaceOnImport is set to `true` then import certificate imports a certificate and overwrites an existing certificate. It then perform the certificate replace operation on that certificate. Typically, an existing certificate cannot be overwritten by a certificate that is being imported. The task also replaces all signer certificates from the original certificate and replaces them with the signer certificate from the new certificate that is being imported

About this task

Complete the following steps in the administrative console:

Procedure

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > Inbound | Outbound > *ssl_configuration* > Key stores and certificates**.
2. Select a ***keystore*** from the list of keystores.
3. Click **Signer certificates**.
4. Click **Add**.
5. Enter an alias for the signer certificate in the **Alias** field
6. Enter the full path to the signer certificate file in the **File name** field.
7. Select a data type from the list in the **Data type** field.
8. Click **Apply**.

Results

When these steps are completed, the signer from the certificate file is stored in the keystore. You can see the signer in the keystore files list of signer certificates. Use the keystore to establish trust relationships for the SSL configurations.

Add signer certificate settings

Use this page to add a signer certificate in a certificate file to the keystore in the security configuration.

To view this administrative console page, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration* > Key stores and certificates > *keystore* > Signer certificates > Add**.

Alias:

Specifies the alias that is used to identify the signer certificate in the keystore.

Data type: String

File name:

Specifies the path to the filename where the signer certificate is located.

Data type: String

Data type:

Specifies the format of the file, which is either Base64 encoded ASCII data or Binary DER data.

Data type: String

Signer certificates collection

Use this page to manage signer certificates in key stores. Signer certificates are used by Java Secure Socket Extensions (JSSE) to validate certificates sent by the remote side of the connection during a Secure Sockets Layer (SSL) handshake. If a signer does not exist in the trust store that can validate the certificate sent, the handshake fails and generates an "unknown certificate" error.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***. Under Related items, click **Key stores and certificates > *key store***. Under Additional Properties, click **Signer certificates**.

Table 161. Signer certificates buttons. This table lists the signer certificates buttons.

Button	Resulting action
Add	Adds a new trusted (signer) certificate.
Delete	Deletes an existing signer certificate.
Extract	Extracts a signer certificate from a personal certificate to a file.
Retrieve from port	Makes a test connection to an SSL port and retrieves the signer from the server during the handshake. The information from the certificate will be displayed so you can decide whether to trust it based upon the MD5 and/or SHA hash.

Alias:

Specifies the alias for this signer certificate in the key store.

Issued to:

Specifies the distinguished name of the entity that requested the certificate.

Fingerprint (SHA digest):

Specifies the Secure Hash Algorithm (SHA hash) of the certificate. This can be used to verify the hash for the certificate at another location, such as the client side of a connection.

Expiration:

Specifies the expiration date of the signer certificate for validation purposes.

Signer certificate settings

Use this page to verify the general properties of the selected signer certificate.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***. Under Related items, click **Key stores and certificates > *key store***. Under Additional Properties, click **Signer certificates**. Then click on a signer certificate.

Alias:

Specifies the alias for this signer certificate in the key store.

Version:

Specifies the version of the personal certificate. Valid versions include X509 V3, X509 V2, or X509 V1.

Key size:

Specifies the key size of the public key used by the signer certificate.

Serial number:

Specifies the certificate serial number that is generated by the issuer of the certificate.

Validity period:

Specifies the begin and end dates of the certificate.

Issued to:

Specifies the distinguished name of the entity that requested the certificate.

Issued by:

Specifies the distinguished name of the entity that issued the certificate. This name is the same as the issued-to distinguished name when the signer certificate is self-signed.

Fingerprint (SHA Digest):

Specifies the Secure Hash Algorithm (SHA) hash of the certificate, which can be used to verify the hash for the certificate at another location such as the client side of a connection.

Signature algorithm:

Specifies the algorithm that is used to sign the certificate.

Adding a signer certificate to the default signers keystore

Signer certificates are added to a keystore on the client side of an SSL communication to establish trust with the server. There is common practice for keystores to have trust established when they are created.

The **DmgrDefaultSignersStore** on a deployment manager and the **NodeDefaultSignersStore** on a stand alone application server are created to hold signer certificates used to establish trust by default in newly create keystores.

Before you begin

The default signers key store is created during profile creation and contains the signer certificate of the server default root certificate. Additional signer certificates can be added to the default signers key store at any time. Anytime a keystore is created using the admin console or by using the **createKeyStore** AdminTask object in scripting, all signer certificates from the default signer store are added to the newly created keystore.

Alternative Method:

- To add a signer certificate to a default signer keystore by using the wsadmin tool, use the **addSignerCertificate** command of the AdminTask object.
- To create a new keystore by using the wsadmin tool, use the **createKeyStore** command of the AdminTask object.
- To extract the signer from a personal certificate using the wsadmin tool, use the **extractCertificate** of the AdminTask object.
- To exchange a signer certificate using the wsadmin tool, use the **KeyStoreCommands** command group for the AdminTask object.

For more information, see the SignerCertificateCommands command group for the AdminTask object article and the KeyStoreCommands command group for the AdminTask object article.

Procedure

1. If the certificate is in a certificate file, it can be added to the default signer keystore using the administrative console.
   a. Click **Security > SSL certificate and key management**.
   b. Under Related Items, click **Key stores and certificates**.
   c. c. Select Default signers keystore under KeyStore Usages. A panel displaying a list of keystores appears.
   d. Click on **DmgrDefaultSignersStore**.
   e. Under Additional Properties, click **Signer certificates**.
   f. Click **Add** .
   g. Enter an alias in the alias box, a path to the certificate file in the filename box, and an asterisk (•). Select the format of the certificate file from the pull down list in the “Data type” box.
   h. Click **Apply** then **Save**.

   Note: You can also perform this addition using the AdminTask, **addSignerCertificate**.
2. If the signer certificate form of a personal certificate needs to be added to default signers keystore, you can extract the signer from the personal certificate to a certificate file or the signer can be extracted directly to the default signers keystore. To extract a signer certificate from a personal certificate to a certificate file,
   a. Click **Security > SSL certificate and key management**.
   b. Under Related Items, click **Key stores and certificates**.
   c. c. Select All under Keystore Usages. A panel displaying a list of keystores appears.
   d. Click on the keystore name
   e. Under Additional Properties, click **Personal certificates**.
   f. Select a personal certificate.

g. Click **Extract**.
h. Enter the path to the certificate file in “Certificate file name” box and select a format type from the pull down list in “Data type” box
i. Click **Apply** then **Save**.
j. The signer can be added to the default signers keystore by following step 1.

Note: You can also extract the signer from a personal certificate using scripting and the AdminTask **extractCertificate**.

3. To extract a signer certificate to the default signers keystore, an exchange of the signer certificate can be performed from the administrative console.
   a. Click **Security > SSL certificate and key management**
   b. Under Related Items, click **Key stores and certificates**.
   c. c. Select All under Keystore Usages. A panel displaying a list of keystores appears.
   d. Click on the default signers keystore and the keystore that contains the personal certificate whose signer certificate is needed.
   e. Click **Exchange Signers**.
   f. Select the personal certificate whose signer is needed.
   g. Click **Add**.
   h. Click **Apply** then **Save**.

   Note: You can also perform the exchange using the AdminTask, **exchangeSigner**.

   Note: A DataPower certificate can be removed from the default signers keystore if it is present. If you are not using the DataPower appliance manager you should remove the DataPower certificate from the default trust store to avoid unintentional trust relationships. However, if you start to use DataPower appliance manager at a later date you must add the DataPower certificate back to the default trust store.

Results

When these steps are completed, the signer from the certificate file is stored in the default signers keystore. You can see the signer in the keystore files list of signer certificates.

What to do next

The new keystore will contain the default signers that were added to the default signers keystore.

Exchanging signer certificates

To establish trust relationships, you can exchange signer certificates between keystores. When you exchange signer certificates, you are extracting a personal certificate from one keystore and adding it to another keystore as a *signer certificate*.

Before you begin

To exchange signer certificates, there must be two keystores.

About this task

Complete the following steps in the administrative console:

Procedure

1. Click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration* > Key stores and certificates**.
2. Select two keystores from the list of keystores.
3. Click **Exchange signers**.
4. Select any of the certificates in the first personal certificates list, and click **Add**. After adding, the signer part of the selected personal certificate appears in the other (second) keystore signers list.
5. Select any of the certificates in the second personal certificates list, and click **Add**. After adding, the signer part of the selected personal certificate appears in the other (first) keystore signers list.
6. Optional: If you need to remove any of the certificates from either of the signers lists, highlight one or more of the certificates, and click **Remove**.
7. Click **Apply** and **Save**.

Results

The signer certificate appears in the list for each keystore.

What to do next

The extracted signer certificate is available to both keystores during the connection handshake.

Keystores and certificates exchange signers

Use this page to extract the signer part of a personal certificate from one keystore and add it to another keystore as a signer certificate. Signer certificates can also be listed, and they will be added to the other keystore as well.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***. Under Related items, click **Key stores and certificates** then select two key stores to exchange and click the **Exchange signers**.

Note: Any changes made to this panel are permanent.

[keystore] personal certificates:

Specifies the personal certificates and signer certificates that are currently stored in the specified keystore.

Press and hold the **Ctrl** key to select more than one item from the list.

Data type: Text

[keystore] signers:

Specifies the trusted signer certificates that are currently stored in the specified keystore and selected for the exchange.

Press and hold the **Ctrl** key to select more than one item from the list.

Data type: Text

Add:

Specifies to extract the signer from the selected personal certificate in the keystore list on the left and add it to the signers list of the keystore on the right.

After the certificate is added, it no longer displays in the left-hand list. The personal certificate is still in the keystore, but it is no longer selectable

Remove:

Specifies to remove a selected signer from the signers list of the keystore on the right. The removed certificate displays in the keystore list on the left.

Configuring certificate expiration monitoring

When certificates expire, they can no longer be used by the system. WebSphere Application Server provides a utility to monitor certificates that are close to expiration or have already expired. You can schedule certificate monitoring, or you can request certificate monitoring on demand. You can also configure options for deleting expired certificates and for recreating certificates.

Before you begin

Important: The Certificate Expiration Monitor does not handle replacing client self-signed certificates and is not capable of sending the new signer certificate needed for trust. If the client is a web server plug-in, it will not be able to securely communicate with the application server after self-signed certificate replacement.

WebSphere Application Server notifies you when a certificate is about to expire. Complete the information required for notification messaging in “Notifications” on page 1833.

About this task

Complete the following configuration steps in the administrative console:

Procedure

1. Click **Security > SSL certificate and key management > Manage certificate expiration**.
2. Type a number for the number of days threshold in the **Expiration notification threshold** field. WebSphere Application Server issues an expiration warning *n* number of days before expiration.
3. Select or check one or more of the following options:
   - **Expiration check notification**. Select the method from the list that you want to use to receive your notification.
   - **Automatically replace expiring self-signed certificates**. If you do not want to recreate the self-signed certificate, clear the check box.

     Attention: When using writable System Authorization Facility (SAF) keyrings in your configuration, the certificate expiration monitor does not replace expired certificates in the writable SAF keyrings, but only provides a notification of the expiration.
   - **Delete expiring certificates and signers after replacement**. If you do not want to delete the expired certificates and signers, clear the check box.
   - **Enable checking**. If you do not want to have certificate monitoring enabled, clear the check box.
4. Enter the time of day when you want certificate monitoring to take place to schedule the running of the certificate expiration monitor.
5. Select one of the following options:
   - **Check by calendar**. For **Weekday**, enter the day of week that you want to run the certificate expiration monitor. For **Repeat Interval**, specify the frequency to run the certificate monitor.
   - **Check by number of days**. Enter a number for how frequently the monitor runs, in number of days.

6. Type the number of days before the threshold date in which the certificate monitor warns that a certificate is about to be replaced. When a certificate is within the expiration threshold, and automatic replacement is enabled, certificates are replaced. This value specifies the time period before the threshold when warnings are issued by the certificate monitor concerning upcoming replacement dates.
7. Click **Apply**.

Results

After completing the settings, a certificate expiration monitor object and a schedule are set up in the configuration. The certificate expiration monitor runs according to the configurations options that you configured.

What to do next

You can generate reports that state which certificates have expired. The reports identify the notifications of certificate replacements and deletions. The report is sent according to the notification option that you specified.

Manage certificate expiration settings

Use this page to configure the certificate expiration monitor.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage certificate expiration**.

Attention: To see the changes to the Expiration checking fields, you must click **Apply**.

Start now:

Specifies to start certificate monitoring. When the monitor runs, it visits all the key stores and checks to see if they are within certificate expiration range. If you set the option to delete or replace expired certificates, you can run these operations immediately by pressing **Start now**.

Expiration notification threshold:

Specifies the period of time that occurs chronologically just before the expiration day of the certificate, within which, if the ExpirationMonitor thread runs, and **Automatically replace expiring self-signed and chained certificates** is enabled, a new self-signed or chained certificate is generated. By default, the replacement period for the certificate is 60 days in length or less as defined in the daysBeforeNotification property.

There is a pre-notification period where the certificate is added to the notification list but not touched for 90 days prior to the 60 days. By default, this pre-notification period is 90 days in length as defined in the com.ibm.ws.security.expirationMonitorNotificationPeriod property.

Data type:	Integer
Default:	60 days or less

Enable checking:

Specifies the certificate monitor is active and will run as scheduled.

Scheduled time of day to check for expired certificates:

Specifies the scheduled time that the system checks for expired certificates.

You can type the scheduled time in hours and minutes, specify either A.M. or P.M., or 24-hour.

Data type Integer
Default: 0, 0
Range: 1–12, 0–59

Check by calendar:

Indicates that you want to schedule a specific day of the week on which the expiration monitor runs. For example, it might run on Sunday.

Default: Enabled

Weekday:

Specifies the day of the week on which the expiration monitor runs if **Check on a specific day** is selected.

Default: Sunday
Range: Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday

Repeat interval:

Specifies the period of time between each schedule time to check for expired certificates or the interval between schedule checks.

Default: Daily
Range: Daily, Weekly

Check by number of days:

Specifies that you want to schedule a specific number of days between each run of the expiration monitor. The day of the week on which this occurs is not counted. For example, if you set the interval to check for expired certificates every seven days, the expiration monitor runs on day eight.

Default: Disabled

Next start date:

Specifies the date for the next scheduled check. This allows the deployment manager to be stopped and restarted without resetting the date.

Expiration check notification:

Specifies the notification type (either email, or an entry in the system log) when an expiration monitor runs.

Default:

Automatically replace expiring self-signed certificates and chained certificates:

Specifies a new self-signed certificate or chained certificate be generated using the same certificate information if the expiration notification threshold is reached. The old certificate is replaced and uses the same alias. All old signers are managed by the key store configuration are also replaced. The system only replaces self-signed certificates.

Note: This checkbox is only applicable when using file based keystores.

Default: Enabled

Delete expiring certificates and signers after replacement:

Specifies whether to completely remove old, self-signed certificates from the key store during a replace operation or leave them there under a renamed alias. If an old certificate is not deleted, the system renames the alias so that the new certificate can use the old alias, which might be referenced elsewhere in the configuration.

Note: This checkbox is only applicable when using file based keystores.

Default: Enabled

Notifications

Use this page to specify the generic notification definitions that are used in certificate expiration monitors.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click**Manage certificate expiration**. Under Related items, click **Notifications**.

Table 162. Notifications buttons. This table lists the notifications buttons.

Button	Resulting action
New	Adds a notification. The notification configures how the expiration monitor notifies the administrator of certificates that will expire within the specified threshold.
Delete	Deletes an existing notification.

Notification name:

Specifies the notification name.

Message log:

Specifies that this configuration intends to log certificate expiration information to the message log file.

Send Email:

Specifies that this configuration intends to send certificate expiration information to the list of users in the email list.

List of email addresses:

Specifies the email addresses that are sent notifications when certificates fall within the expiration threshold. You must specify the SMTP server for each email address. If an email address is not specified, by default the application server assumes that the SMTP server is "smtp-server." For example, if you type *name*@domain, the SMTP server will be smtp-server.domain.

Notifications settings

Use this page to set properties for new notifications used in certificate expiration monitors or for security audit subsystem failures.

To view this administrative console page perform one of the following:

- Click **Security > SSL certificate and key management** > **Manage certificate expiration** >**Notifications > New**.
- Click **Security** > **Security auditing** > **Audit monitor** > **New**

.

Notification name:

Specifies the name of the notification configuration.

Data type: Text

Message log:

Specifies that this configuration will log the notification to a message log file.

Default: Disabled

Email sent to notification list:

Specifies that this configuration send a notification as an email to the email list.

Default: Disabled

Email address to add:

Specifies the email addresses that are sent notifications. You must specify the SMTP server for each email address. If an email address is not specified, by default the application server assumes that the SMTP server is "smtp-server." For example, if you type *name*@domain, the SMTP server will be smtp-server.domain.

Data type: Text (format as valid Internet mail address)

Add:

Adds the email address to the right-hand list.

Remove:

Removes the email address from the right-hand list.

Outgoing mail (SMTP) server:

Specifies the SMTP server to be used with the email address. If none is specified, the email realm will be used.

Key management for cryptographic uses

WebSphere Application Server provides a framework for managing keys (secret keys or key pairs) that applications use to perform cryptographic operations on data. The key management framework provides an application programming interface (API) for retrieving these keys. Keys are managed in keystores so the keystore type can be supported by WebSphere Application Server, provided that the keystores can store the referenced key type. You can configure keys and scope keystores so that they are visible only to particular processes, nodes, clusters, and so on.

The key management infrastructure is based on two key configuration object types: key sets and key set groups. WebSphere Application Server uses a key set to manage instances of keys of the same type. You can configure a key set to generate a single key or a key pair, depending on the key or key pair generator class. A key set group manages one or more key sets and enables you to configure and generate different

key types at the same time. For example, if your application needs both a secret key and key pair for cryptographic operations, you can configure two key sets, one for the key pair and one for the secret key that the key set group manages. The key set group controls the auto-generation characteristics of the keys, including the schedule. The framework can automatically generate keys on a scheduled basis, such as on a particular day of the week and time of day, so that key generation is done during off-peak hours.

Figure 1 shows an example of a key set group that is configured to manage two key sets: key set 1 and key set 2.

Figure 35.

Key set 1 generates key pairs. Key set 2 generates secret keys. The application needs both types of keys for its cryptographic operations, signing and encryption, on data. The keys for each key set need to be generated in tandem. The application stores the key set group name with the encrypted data. The key set group generates a new set of keys every Sunday night at 11 P.M.. The application maintains key generation data for two weeks.

Creating a key set configuration

You can use key sets to manage multiple instances of cryptographic keys. WebSphere Application Server uses keys to encrypt or sign outbound data, and decrypt or verify inbound data during cryptographic operations.

Before you begin

You must have write-access to the keystore that will contain the keys after you generate them from a key set. However, if you want to generate keys outside of WebSphere Application Server, you can reference the keys from a read-only keystore that contains a secret key that you can access when you generate the keys. If you are creating a key pair using an X509Certificate and a PrivateKey object , see “Example: Developing a key or key pair generation class for automated key generation” on page 1842.

About this task

Complete the following steps in the administrative console:

Procedure

1. Decide whether you want to create the key set at the cell scope or below the cell scope at the node, server, or cluster, for example:
   - To create a key set at the cell scope, click **Security > SSL certificate and key management > Key sets**.
   - To create a key set at a scope below the cell level, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration* > Key sets**.
2. Click **New** to create a new key set.
3. Type a key set name. For example, `CellmyKey`.
4. Type a key alias prefix name. For example, `myKey`. This field specifies the prefix for the key alias when the new key is generated and stored in the keystore. Following the prefix is the key reference version number, for example, 2, so that the full key alias name would be `myKey_2`. If the key reference already has a specified alias for a key that exists in the keystore, then WebSphere Application Server ignores this field.
5. Type a key password. The key password protects the key in the keystore. This password is ignored by WebSphere Application Server if you already specified a password for the key alias reference. To

check for a key reference password, click **Active key history** under Additional Properties. The key reference password protects keys that are generated by a key generator class.

6. Type the password again to confirm it.
7. Optional: Type the key generator class name. For example, `com.ibm.ws.security.ltpa.LTPAKeyGenerator`. The class name generates keys. If the class implements com.ibm.websphere.crypto.KeyGenerator, then a getKey method returns a java.security.Key object that is set in the keystore using the setKey method without a certificate chain. If the class implements com.ibm.websphere.crypto.KeyPairGenerator, then a getKeyPair method returns a com.ibm.websphere.crypto.KeyPair object that contains either a java.security.PublicKey and java.security.PrivateKey or a java.security.cert.Certificate and a java.security.PrivateKey object. The key generator class and the KeySetHelper API specify the details of the keys that are generated.
8. Optional: Select **Delete key references that are beyond the maximum number of keys** if you do not want old keys saved in the keystore after WebSphere Application Server removes their references from the Active key history listing. The Active key history lists the keys that the KeySetHelper API is currently tracking. The number of keys in the list is equal to the number of keys that you specify in **Maximum number of keys referenced**.
9. Type a numeric value for the maximum number of keys referenced. For example, if you type `3` and select **Delete key references that are beyond the maximum number of keys**, the fourth key version generation automatically triggers WebSphere Application Server to delete the first key version from the keystore. If you choose not to delete the old keys, they do not display in the Active key history list but instead remain in the keystore where you can remove them manually.
10. Select a keystore from the drop-down list.
    - Select a JCEKS keystore if you are storing a secret key.
    - Select any keystore if you are storing a key pair with an X509Certificate and PrivateKey object.
11. Optional: Select **Generates key pair** if your key generator class name implements the com.ibm.websphere.crypto.KeyPairGenerator interface instead of the com.ibm.websphere.crypto.KeyGenerator interface. This option designates that the key references a key pair instead of a single key. A key pair contains both a public key and a private key. The WebSphere Application Server run time determines whether or not key pairs are stored and loaded differently than single keys.
12. Optional: Click **Apply** if you want to select **Active key history** under Additional Properties to add alias references or generate more keys.
    a. Click **Active key history**.
    b. Click **Add key alias reference** if you are not using the key generator class name to add key alias references to the keys that already exist in the keystore. Use this option to retrieve the keys from a read-only keystore without the key set generating them.
    c. Type an alias reference.
    d. Click **Generate key** if you want to generate a key using the class name that you defined in the key sets panel. Each new key increments numerically, for example, `myAlias_2`.
    e. Click **Apply**.
13. Click the key set name in the navigation path at the top of the panel.
14. Click **OK** and **Save**.

Results

You have created a key set that you can manage using the **Active key history** link. You can generate keys manually to associate them with specified key sets.

What to do next

After you generate new keys from a key set, you can access them programmatically using the com.ibm.websphere.crypto.KeySetHelper API. You must have Java 2 Security permissions, if enabled, to

access keys in key sets. Specify the key set name within the fine-grained permissions, as in the following code sample: `WebSphereRuntimePermission "getKeySets.keySetName"`. For more information, see "Example: Retrieving the generated keys from a key set group" on page 1841. To generate multiple key types at the same time or to schedule the key generation on a specific schedule, see "Creating a key set group configuration" on page 1840.

Active key history collection

Use this page to manage key alias references.

To view this administrative console page, click **Security** > **SSL certificate and key management** > **Manage endpoint security configurations > {Inbound | Outbound}** > ***ssl_configuration*** > **Key Sets** > ***key set*** > **Active key history**.

Table 163. Active key history buttons. This table lists the active key history buttons.

Button	Resulting action
Add key alias reference	Adds a reference to a key that already exists in a key store. If a key generation class is configured, the references are added automatically during generation and do not need to be added manually.
Delete	Deletes an existing key reference. This action does not delete the key in the keystore.
Generate key	Generates a key. The button is displayed only if a generator class name is specified for the key set, and the selected key store is editable.

Alias reference:

Specifies the name of the alias as it appears in the keystore.

Add key alias reference settings

Use this page to access key alias reference information.

To view this administrative console page, Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***. Under Related items, click **Key Sets > *key set***. Under Additional Properties, click **Active key history** then click the **Add key alias reference** button.

Alias reference:

Specifies the name of the alias as it appears in the key store.

Data type: Text

Password:

Specifies the key password to get access to the key. This password is enforced by the keystore for that specific key. If the key does not have a password, this field can be left blank.

Data type: Text

Confirm password:

Confirms the password entered in the previous field.

Data type: Text

Key sets collection

Use this page to manage key sets, which control a set of key instances of the same type for use in cryptographic operations. The keys can either be generated using a custom class or reference keys that already exist in a keystore.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***. Under Related items, click **Key sets**.

Table 164. Key set buttons. This table lists the key set buttons.

Button	Resulting action
New	Adds a new key set.
Delete	Deletes an existing key set. Make sure the key set is not referenced by a key set group before deleting it.

Key set name:

Specifies the key set name that is used to select the key set from a key set group and from runtime application programming interfaces (API).

Key store:

Specifies the key store that contains the keys for storage, retrieval, or both.

Key alias prefix name:

Specifies the prefix for the key alias when a new key is generated and stored in a key store. The rest of the key alias comes from the key reference version number.

For example, if the alias prefix is `mykey` and the key reference version is 2, the keystore references the key using alias `mykey_2`. If the key reference already has a specified alias for a key already existing in the keystore, this field is ignored.

Key sets settings

Use this page to set the properties for a new key set.

To view this administrative console page, click **Security** > **SSL certificate and key management**. Under Configuration settings, click**Manage endpoint security configurations** > **{Inbound | Outbound}** > ***ssl_configuration***. Under Related items, click **Key sets** > **New**.

Key set name:

Specifies the key set name that is used to select the key set from a key set group and from runtime application programming interfaces (API).

Data type: Text

Management scope:

Specifies the scope where this Secure Sockets Layer (SSL) configuration is visible. For example, if you choose a specific node, then the configuration is only visible on that node and any servers that are part of that node.

Data type List
Range: Applicable scopes

Key alias prefix name:

Specifies the prefix for the key alias when a new key is generated and stored in a keystore. The rest of the key alias comes from the key reference version number. For example, if the alias prefix is `mykey` and the key reference version is 2, the keystore references the key using alias `mykey_2`. If the key reference already has a specified alias for a key already existing in the keystore, this field is ignored.

Data type: Text

Key password:

Specifies the password used to protect the key in the keystore. If a password is specified in the key reference as well, this password is ignored. This password is used for keys that get generated by a key generator class.

Data type: Text

Confirm password:

Specifies the same password again to confirm it was entered correctly the first time.

Data type: Text

Key generator class name:

Specifies the class name that generates keys. If the class implements com.ibm.websphere.crypto.KeyGenerator, then a getKey() method should return a java.security.Key object that is set in the key store using the setKey method without a certificate chain. The key store type associated with the key set must support storing keys without certificates, such as JCEKS.

Data type: Text

If the class implements com.ibm.websphere.crypto.KeyPairGenerator, then a getKeyPair() method should return a com.ibm.websphere.crypto.KeyPair object containing either a java.security.PublicKey and java.security.PrivateKey, or a java.security.cert.Certificate[] and a java.security.PrivateKey. The key generator class and the caller of the KeySetHelper API should know the details of the keys that are generated. This framework does not need to understand the key algorithms and lengths.

Delete key references that are beyond the maximum number of keys:

Specifies that the keys are deleted from the keystore at the same time that the key reference is deleted. The server deletes the older key references as the Maximum number of keys referenced value is exceeded.

Maximum number of keys referenced:

Specifies the maximum number of key instances that are returned when keys from this key set are requested. The oldest key reference gets removed whenever a new key reference gets generated after the maximum has been reached.

Data type: Integer
Default: 3

Key store:

Specifies the key store that contains the keys for storage, retrieval, or both.

Data type: Text

Generates key pair:

Specifies that a key references a key pair instead of a key. The key pair contains both a public key and a private key.

Creating a key set group configuration

A key set group manages one or more key sets. WebSphere Application Server uses key set groups to automatically generate cryptographic keys or multiple synchronized key sets.

About this task

Complete the following steps in the administrative console:

Procedure

1. Decide whether you want to create the key set group at the cell scope or below the cell scope at the node, server, or cluster, for example.
   - To create a key set group at the cell scope, click **Security > SSL certificate and key management > Key set groups**.
   - To create a key set group at a scope below the cell level, click **Security > SSL certificate and key management > Manage endpoint security configurations > {Inbound | Outbound} > *SSL_configuration* > Key set groups**.
2. You can choose to generate a key for an existing key set group, delete an existing key set group, or create a new key set group.
   - To generate a key for an existing key set group, select a key set group from the list of existing key set groups, and click **Generate keys**. You have generated a new key for each key set in the selected group.
   - To delete an existing key set group, select a key set group from the list of existing key set groups, and click **Delete**. You have deleted the key set group.
   - To create a new key set group, go to step 3.

   CAUTION:
   Do not delete the cell or node LTPAKeySetGroup, which is used by the Lightweight Third Party Authentication (LPTA) mechanism.
3. Click **New** to create a new key set group.
4. Type a key set group name. You can reference this name by using the com.ibm.websphere.crypto.KeySetHelper API to retrieve the managed keys from an application.
5. Select one or more key sets from the Key sets list.

   Note: If the key set(s) you want is not listed, make sure that it was created at the same scope or a higher scope than where you are creating the new key set group.
6. Click **Add** to add the selected key set(s) to the new key set group.
7. Select **Automatically generate keys** to generate the new keys on a schedule. If you decide to generate keys automatically, then you must specify a scheduled time of day.
8. Specify the scheduled time to generate keys automatically in hours and minutes, A.M. or P.M., or every 24 hours.
9. You can choose to generate new keys on a specific day or at an interval.

- Select **Generate on a specific day**. Select a day of the week from the drop-down list, and type a repeat interval number for the number of days between each key generation. This choice enables you to schedule key generation when your systems are least busy.
- Select **Generate at an interval**. Type a repeat interval number for the number of days between each key generation. This choice enables you to schedule key generation more frequently than once a week.

Note: The **Next start date** is a read-only field that specifies the date for the next scheduled generation. You can stop and restart the deployment manager or base application server without resetting this date. If you do not see the next start date appear after changing the configuration, click **OK** to save it, then check that the next start date displays.

10. Click **Save**.

Results

You have created a new key set group to manage key sets and key generation on a schedule.

What to do next

After you generate new keys from a key set, you can access them programmatically using the com.ibm.websphere.crypto.KeySetHelper API. You must have Java 2 Security permissions, if enabled, to access keys in key sets. Specify the key set name within the fine-grained permissions, as in the following code sample: `WebSphereRuntimePermission "getKeySets.`*`keySetName`*`"`. For more information, see "Example: Retrieving the generated keys from a key set group."

Example: Retrieving the generated keys from a key set group

This example shows how applications can use the com.ibm.websphere.crypto.KeySetHelper API to retrieve managed keys from the KeySet or KeySetGroup configurations. Use the com.ibm.websphere.crypto.KeySetHelper API to get either the latest set of keys or all the keys in the KeySet or KeySetGroup object.

Use the latest keys when performing any new cryptographic operations. All of the other keys that are defined in the KeySet or KeySetGroup object are for the validation of previously performed cryptographic operations.

The following example uses a method that an application might use to initialize the keys in the associated KeySetGroup object. The application might want to store the keys in two separate maps, one for generation and one for validation. Refer to the API documentation for KeySetHelper API to determine which Java 2 Security requirements are required.

```
/**
     * Initializes the primary and secondary Maps used for initializing the keys.
     */

    public void initializeKeySetGroupKeys() throws com.ibm.websphere.crypto.KeyException
    {
        java.util.Map generationKeys = null;
        java.util.Map validationKeys = null;

        PublicKey tempPublicKey = null;
        PrivateKey tempPrivateKey = null;
        byte[] tempSharedKey = null;

        keySetGroupName = "ApplicationKeySetGroup";
        com.ibm.websphere.crypto.KeySetHelper ksh = com.ibm.websphere.crypto.KeySetHelper.getInstance();
        generationKeys = ksh.getLatestKeysForKeySetGroup(keySetGroupName);

        /***
        *  Latest keys: {
        *  KeyPair_3=com.ibm.websphere.crypto.KeyPair@64ec64ec,
        *  Secret_3=javax.crypto.spec.SecretKeySpec@fffe8aa7
        *  }
        ***/

        if (generationKeys != null)
        {
```

```
            Iterator iKeySet = generationKeys.keySet().iterator();

            while (iKeySet.hasNext())
            {
                String keyAlias = (String)iKeySet.next();

                Object key = generationKeys.get(keyAlias);

                if (key instanceof java.security.Key)
                {
                    tempSharedKey = ((java.security.Key)key).getEncoded();
                }
                else if (key instanceof com.ibm.websphere.crypto.KeyPair)
                {
                    java.security.Key publicKeyAsSecret =
    ((com.ibm.websphere.crypto.KeyPair)key).getPublicKey();
                    tempPublicKey = new PublicKey(publicKeyAsSecret.getEncoded());
                    java.security.Key privateKeyAsSecret =
    ((com.ibm.websphere.crypto.KeyPair)key).getPrivateKey();
                    tempPrivateKey = new PrivateKey(privateKeyAsSecret.getEncoded());
                }
            }

            // save these for use later, if necessary
            validationKeys = ksh.getAllKeysForKeySetGroup(keySetGroupName);

            /***
            *  All keys: {
            *  version_1=
            *      {Secret_1=javax.crypto.spec.SecretKeySpec@178cf,
            *       KeyPair_1=com.ibm.websphere.crypto.KeyPair@1c121c12},
            *  version_2=
            *      {Secret_2=javax.crypto.spec.SecretKeySpec@17a77,
            *       KeyPair_2=com.ibm.websphere.crypto.KeyPair@182e182e},
            *  version_3=
            *      {Secret_3=javax.crypto.spec.SecretKeySpec@fffe8aa7,
            *       KeyPair_3=com.ibm.websphere.crypto.KeyPair@4da04da0}
            *  }
            ***/
        }
        else
        {
            throw new com.ibm.websphere.crypto.KeyException("Could not generateKeys.");
        }
    }
```

Example: Developing a key or key pair generation class for automated key generation

A class that generates keys for cryptographic operations can be created automatically. With this capability, the key management infrastructure can maintain a list of keys for a predefined key set, and applications can access these keys.

You can schedule new key generation at predefined frequencies. Remember that key generation frequency affects the security of your data. For example, for persistent data, you might schedule key generation less frequently than for real time communications, which require that the keys be generated more often as old keys expire.

When you develop a key generation class, decide if you are creating a shared key or a key pair because this decision determines the interface you must use.

If you are developing shared keys, refer to the following example, which uses the KeyGenerator class to implement the com.ibm.websphere.crypto.KeyGenerator interface. The interface returns a java.security.Key key, which is stored as a SecretKey in a JCEKS keystore type. You can use any other keystore type that supports storing secret keys.

```
package com.ibm.test;

import java.util.*;
import com.ibm.ws.ssl.core.*;
import com.ibm.ws.ssl.config.*;
import com.ibm.websphere.crypto.KeyException;

public class KeyGenerator implements com.ibm.websphere.crypto.KeyGenerator
{
    private java.util.Properties customProperties = null;
    private java.security.Key secretKey = null;

    public KeyGenerator()
    {
```

```
    }

     /**
      * This method is called to pass any custom properties configured with
      * the KeySet to the implementation of this interface.
      *
      * @param java.util.Properties
      **/
    public void init (java.util.Properties customProps)
    {
        customProperties = customProps;
    }

     /**
      * This method is called whenever a key needs to be generated either
      * from the schedule or manually requested. The key is stored in the
      * KeyStore referenced by the configured KeySet that contains the
      * keyGenerationClass implementing this interface. The implementation of
      * this interface manages the key type. The user of the KeySet
      * must know the type that is returned by this keyGenerationClass.
      *
      * @return java.security.Key
      * @throws com.ibm.websphere.crypto.KeyException
      **/
    public java.security.Key generateKey () throws KeyException
    {
        try
        {
            // Assume generate3DESKey is there to create the key.
            byte[] tripleDESKey = generate3DESKey();
            secretKey = new javax.crypto.spec.SecretKeySpec(tripleDESKey, 0, 24, "3DES");

            if (secretKey != null)
            {
                return secretKey;
            }
            else
            {
                throw new com.ibm.websphere.crypto.KeyException ("Key could not be generated.");
            }
        }
        catch (Exception e)
        {
            e.printStackTrace();  // handle exception
        }
    }
}
```

If you are developing a key pair, refer to the following example, which uses the KeyPairGenerator class to implement the com.ibm.websphere.crypto.KeyPairGenerator interface.

```
package com.ibm.test;

import java.util.*;
import javax.crypto.spec.SecretKeySpec;
import com.ibm.websphere.crypto.KeyException;

/**
 * This implementation defines the method to generate a java.security.KeyPair.
 * When a keyGeneration class implements this method, the generateKeyPair method
 * is called and a KeyPair is stored in the keystore. The isKeyPair
 * attribute is ignored since the KeyGenerationClass is an
 * implementation of KeyPairGenerator. The isKeyPair attributes is for when
 * the keys already exist in a KeyStore, and are just read (not
 * generating them).
 *
 * @author IBM Corporation
 * @version WebSphere Application Server 6.1
 * @since WebSphere Application Server 6.1
 **/
public class KeyPairGenerator implements com.ibm.websphere.crypto.KeyPairGenerator
{
    private java.util.Properties customProperties = null;

    public KeyPairGenerator()
    {
    }

     /**
      * This method is called to pass any custom properties configured with
      * the KeySet to the implementation of this interface.
     *
      * @param java.util.Properties
      **/
    public void init (java.util.Properties customProps)
    {
        customProperties = customProps;
    }
```

```
     /**
     * This method is called whenever a key needs to be generated either
      * from the schedule or manually requested and isKeyPair=true in the KeySet
      * configuration. The key is stored in the KeyStore referenced by
      * the configured KeySet which contains the keyGenerationClass implementing
      * this interface. The implementation of this interface manages the
      * type of the key. The user of the KeySet must know the type that
      * is returned by this keyGenerationClass.
      *
      * @return com.ibm.websphere.crypto.KeyPair
      * @throws com.ibm.websphere.crypto.KeyException
      **/
    public com.ibm.websphere.crypto.KeyPair generateKeyPair () throws KeyException
    {
        try
        {
            java.security.KeyPair keyPair = generateKeyPair();

            // Store as SecretKeySpec
            if (keyPair != null)
            {
                java.security.PrivateKey privKey = keyPair.getPrivate();
                java.security.PublicKey pubKey = keyPair.getPublic();

                SecretKeySpec publicKeyAsSecretKey = new SecretKeySpec
                    (pubKey.getEncoded(), "RSA_PUBLIC");
                SecretKeySpec privateKeyAsSecretKey = new SecretKeySpec
                    (privKey.getEncoded(), "RSA_PRIVATE");

                com.ibm.websphere.crypto.KeyPair pair = new
    com.ibm.websphere.crypto.KeyPair(publicKeyAsSecretKey, privateKeyAsSecretKey);
                return pair;
            }
            else
            {
                throw new com.ibm.websphere.crypto.KeyException ("Key pair could
                not be generated.");
            }
        }
        catch (Exception e)
        {
            e.printStackTrace();  // handle exception
        }
    }
}
```

This interface returns a com.ibm.websphere.crypto.KeyPair key pair, which can contain either a X509Certificate and PrivateKey object or PublicKey and PrivateKey objects. If the com.ibm.websphere.crypto.KeyPair interface contains aX509Certificate and PrivateKey object, the certificate and private key are stored in the keystore. Consequently, they can use any KeyStore type.

If the com.ibm.websphere.crypto.KeyPair interface contains PublicKey and PrivateKey objects, you must convert the encoded values to the SecretKeySpec object in order to store them. The WebSphere Application Server runtime stores and retrieves the key pair as secret keys. The runtime converts the key pair back to PublicKey and PrivateKey objects when the server retrieves the pair during the handshake.

Use the following constructors to develop the com.ibm.websphere.crypto.KeyPair interface:

- Public and private constructor

```
public KeyPair(java.security.Key publicKey, java.security.Key privateKey)
```

- Certificate and private constructor.

```
public KeyPair(java.security.cert.Certificate[] certChain,
java.security.Key privateKey)
```

The previous example code shows the KeyPairGenerator class using the public and private constructor. Each call to this class generates a new and unique key pair, and this class is invoked by a KeySet to create a new key pair when `isKeyPair=true`. The version number in the key set increments each time it is called.

Key set groups collection

Use this page to manage groups of public, private, and shared keys. These key groups enable the application server to control multiple sets of Lightweight Third Party Authentication (LTPA) keys.

To view this administrative console page, click **Security > SSL certificate and key management**. Under Configuration settings, click **Manage endpoint security configurations > {Inbound | Outbound} > *ssl_configuration***. Under Related items, click **Key set groups**.

Table 165. Key set groups buttons. This table lists the key set groups buttons.

Button	Resulting action
New	Adds a key set group. A key set group combines one or more key sets together as a single key set group. It allows the generation of multiple different types of keys to occur at the same time. A single key set represents one type of key, so a key set group allows you to group the different types.
Delete	Deletes an existing key set group. You must be sure that there are no other references to this key set group before you delete it.
Generate keys	Generates keys for key set group. The system generates keys for each key set within the key set group so that the keys remain synchronized with each other in terms of version. You must configure a valid key generation class and a key store that is writable. See the com.ibm.websphere.crypto.KeySetHelper application programming interfaces (APIs) to enable the use of keys that are managed by a KeySetGroup or KeySet.

Key set group name:

Specifies the name of the key set group used to reference it.

Automatically generate keys:

Specifies that the keys are to be generated automatically on a schedule.

Key set groups settings

Use this page to create new key set groups.

To view this administrative console page, click **Security** > **SSL certificate and key management**. Under Configuration settings, click**Manage endpoint security configurations** > **{Inbound | Outbound}** > ***ssl_configuration***. Under Related items, click **Key set groups** > **New**.

Key set group name:

Specifies the name of key set group used. This name can be referenced using the com.ibm.websphere.crypto.KeySetHelper API to retrieve the managed keys from an application.

Data type: Text

Management scope:

Specifies the scope where this Secure Sockets Layer (SSL) configuration is visible. For example, if you choose a specific node, then the configuration is only visible on that node and any servers that are part of that node.

Data type List
Range: Applicable scopes

Key sets:

Specifies a set of key instances of the same type for use in cryptographic operations.

This setting has the following options:

Add Specifies to add the selected key set part of this key set group.

Remove
Specifies to remove the selection from the **Key sets** list.

Automatically generate keys:

Specifies that the keys are generated automatically on a schedule. When a new key is generated, the `security.xml` is updated and saved by the runtime to track the key reference version. This can cause save conflicts when updating the same file from admin applications.

gotcha: Starting with Versions 6.1.0.23 and 7.0.0.3, the default value for this property is Disabled.

If you try to enable this property, and automatic synchronization is off in any node, the following administrative console message displays:

```
Warning: At least one node in the cell was unreachable or is not configured to automatically synchronize.
It is strongly recommended that you verify your node settings, and do not enable automatic
generation of LTPA keys while automatic synchronization is disabled on any node.
```

Default for Versions 7.0, and 7.0.0.1:	Enabled
Default for Versions 7.0.0.3 and higher:	Disabled

Scheduled time for generation:

Specifies the scheduled time when the system generates selected key set group or groups. You can specify the scheduled time in hours and minutes; specify either A.M. or P.M., or specify 24-hour. You can also specify the day of the week you want the scheduled event to occur. It is recommended that you set this event to occur during a low peak time, especially for keys that are used by runtime for token validation.

Data type	Integer
Default:	8, 0 A.M.
Range:	1–12, with a A.M. or P.M. setting 0–59, with a 24-hour setting

Generate on a specific day:

Specifies whether to have the generation occur on a specific day of the week. It is best to auto-generate keys during a low peak day.

This setting has the following options:

Weekday

Specifies the day of the week on which the expiration monitor will run if the Check on a specific day option is selected.

Default:	Sunday
Range:	Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, Saturday

Repeat interval

Specifies the period of time, in weeks, between each schedule time to check for expired certificates or the interval between schedule checks.

Default:	4 weeks

Generate at an interval:

Specifies to generate keys at the specified frequency regardless of the day of the week on which generation occurs.

Default: Disabled

This setting has the following options:

Repeat interval
Specifies the period of time, in days, between each schedule time to check for expired certificates or the interval between schedule checks.

Default: 7 days

Next start date:

Specifies the date for the next scheduled check. This allows the deployment manager to be stopped and restarted without resetting the date.

Auditing the security infrastructure

You can use the Auditing Facility to report and track auditable events to ensure the integrity of your system.

Before you begin

Before enabling the security auditing subsystem, you must enable global security in your environment.

About this task

Note: The security auditing subsystem has been introduced as part of the security infrastructure. The primary responsibility of the security infrastructure is to prevent unauthorized access and usage of resources. Utilizing security auditing has two primary goals:

- Confirming the effectiveness and integrity of the existing security configuration.
- Identifying areas where improvement to the security configuration might be needed.

Security auditing achieves these goals by providing the infrastructure that allows you to implement your code to capture and store supported auditable security events. During run time, all code other than the Java EE 5 application code is considered to be trusted. Each time a Java EE 5 application accesses a secured resource, any internal application server process with an audit point included can be recorded as an auditable event.

The security auditing subsystem has the ability to capture the following types of auditable events:

- Authentication
- Authorization
- Principal/Credential Mapping
- Audit policy management
- Delegation

Restriction: Audit instrumentation has not been included in the web services client run time.

These types of events can be recorded into audit log files. Each audit log has the option to be signed and encrypted to ensure data integrity. These audit log files can be analyzed to discover breaches over the existing security mechanisms and to discover potential weaknesses in the current security infrastructure. Security event audit records are also useful for providing evidence of accountability and nonrepudiation as well as vulnerability analysis. The security auditing configuration provides four default filters, a default audit service provider, and a default event factory. The default implementation write to a binary text-file based log. Use this topic to customize your security auditing subsystem.

Procedure

1. “Enabling the security auditing subsystem”

   Security auditing will not be performed unless the audit security subsystem has been enabled. Global security must be enabled for the security audit subsystem to function, as no security auditing occurs if global security is not also enabled.

2. Assign the auditor role to a user

   A user with the auditor role is required to enable and configure the security auditing subsystem. It is important to require strict access control for security policy management. The auditor role has been created providing granularity to allow for separation of the auditing role from the authority of the administrator. When Security Auditing is initially enabled, the cell administrator has auditor privileges. If the environment requires separation of privileges, then changes will need to be made to the default role assignments.

3. “Creating security auditing event type filters” on page 1853

   You can configure event type filters to only record a specific subset of auditable event types in your audit logs. Filtering the event types that are recorded makes for easier analysis of your audit records by ensuring only those records important to your environment are archived.

4. Configuring the audit service provider.

   The audit service provider is used to format the audit data object that was passed to it before outputting the data to a repository. A default audit service provider implementation is in included. See “Configuring the default audit service providers for security auditing” on page 1864 for more details on the default implementation. A third party implementation can also be coded and used. See “Configuring a third party audit service providers for security auditing” on page 1868 for more details on this implementation.

5. “Configuring audit event factories for security auditing” on page 1869

   The audit event factory gathers the data associated with the auditable events and creates an audit data object. The audit data object is then sent to the audit service provider to be formatted and recorded to the repository.

6. “Protecting your security audit data” on page 1872

   It is important to secure and ensure the data integrity of the recorded audit data. To ensure that access to the data is restricted and tamper proof, you can encrypt and sign your audit data.

7. “Configuring security audit subsystem failure notifications” on page 1861

   Notifications can be enabled to generate alerts when the security auditing subsystem experiences a failure. Notifications can be configured to record an alert in the System logs or can be configured to send an alert through email to a specified list of recipients.

Results

After successfully completing this task, you audit data will be recorded for the selected auditable events that were specified in the configuration.

What to do next

After configuring security auditing, you can analyze your audit data for potential weaknesses in the current security infrastructure and to discover security breaches that may have occurred over the existing security mechanisms. You can also use the security auditing subsystem to provide data for problem determination. If the default audit service provider was selected, the resulting binary audit log file can be read using the Audit Reader.

Enabling the security auditing subsystem

Security auditing will not be performed unless the audit security subsystem has been enabled. Global security must be enabled for the security audit subsystem to function, as no security auditing occurs if global security is not also enabled.

Before you begin

Before enabling security auditing subsystem, enable global security in your environment.

About this task

The recording of auditable security events is achieved by enabled the security auditing subsystem. Follow these steps to enable the security auditing subsystem.

Procedure

1. Click **Security > Security auditing**.
2. Select Enable security auditing. The Enable security auditing check box is not selected by default. This check box must be selected to allow security auditing to be performed with the configurations that have been specified in the `audit.xml` file.

   Note: The `audit.xml` file is used to store the audit subsystem configurations. Changes to the security auditing subsystem should be made with the user interface or the wsadmin utility. This file should not be edited manually.
3. Select the action from the Audit subsystem failure action dropdown menu to be perform when an audit subsystem failure occurs. Notifications configured to warn of a security auditing subsystem failure will not be posted if the No Warning option is selected for this field. If you select either the Log warning or the Terminate server option, then you must also configure a notification for the action to be performed.
4. Select the Auditor ID from the dropdown menu. The auditor role is needed to make changed to the security auditing configurations. By default, when auditing is first enabled, the primary administrator is also given the auditor role. The primary administrator can then add the auditor role to other users. After the auditor role is added to other users, the auditor role can be removed from the administrator to create a separation of authority between the auditor and the administrator. The Auditor ID is the user considered to be the primary auditor.
5. Optional: Select Enable verbose auditing. When an auditable event is recorded, a default set of audit data is included in the audit data object and recorded to the repository. An additional set of audit data is made available by enabling verbose auditing.
6. Click **Apply**.
7. Restart the application server. The application server must be restarted before the changes go into effect.

Results

The successful competition of these steps results in the security auditing subsystem being enabled.

What to do next

After enabling the security auditing subsystem, refinements can be made to the configuration. You might want to modify the access control of the audit subsystem to separate the authority of the administrator from the authority of the auditor. If no changes to your access control are needed, then you can configure the types of auditable security events should be recorded. To configure the types of events that are recorded, click **Event type filters**.

Security Auditing detail

The Security auditing subsystem can be enabled and configured from this panel, by users assigned the auditor role.

To view this administrative console page, click **Security > Security Auditing**. If Enable security auditing is not selected, then all of the other fields on this panel will be disabled.

Enable security auditing:

The Enable security auditing check box allows users to enable or disable Security Auditing. By default, Security Auditing will not be enabled. This field corresponds with the auditEnabled field in the `audit.xml` file.

Audit subsystem failure action:

The Audit subsystem failure action setting describes the behavior of the application server in the event of a failure in the auditing subsystem. Audit Notifications must be configured in order for notifications of a failure in the audit subsystem to be logged. If security auditing is not enabled, then these actions will not be performed. Failures can include an error in the interface or in the event processing. By default, the audit subsystem failure action setting is set to No warning.

The Audit subsystem failure action dropdown menu has the following options:

- No warning

  The No warning action specifies that the auditor will not be notified of a failure in the audit subsystem. The product will continue processing but audit reporting will be disabled.
- Log warning

  The Log warning action specifies that the auditor will be notified of a failure in the audit subsystem. The product will continue processing but audit reporting will be disabled.
- Terminate server

  The Terminate server action specifies the application server to gracefully quiesce when an unrecoverable error occurs in the auditing subsystem. If email notifications are configured, the auditor will be sent a notification that an error has occurred. If logging to the system log is configured, the notification of the failure will be logged to the system file.

Primary auditor user name:

The Primary auditor user name dropdown menu defines a valid user which exists in the current user registry and for whom the auditor role has been given. By default, this field is blank and is a required field.

Enable verbose auditing:

The Enable verbose auditing option determines the amount of audit data that is reported in an audit record. Verbose mode captures all the auditable data points, whereas not enabling verbose mode captures only a subset of the available data. This option is disabled by default.

Context object fields

Each auditable event has an associated set of information that is available for logging. This information is grouped into specific context objects. The context objects that are available for logging a specific event are specified by the event type. This topic details the information that exists for each context object and specifies whether the information is logged by default or is only logged when the verbose logging option is enabled.

The SessionContextObj object

Table 166. SessionContextObj fields. This table lists the SessionContextObj fields.

Field	Type	Description	Default or Verbose logging
sessionId	String	An identifier for the user session	Default
remoteAddr	String	The IP address for the remote host	Default
remotePort	String	The port of the remote host	Default
remoteHost	String	The host name of the remote host	Default

The PropagationContextObj object

Table 167. PropagationContextObj fields. This table lists the PropagationContextObj fields.

Field	Type	Description	Default or Verbose logging
firstCaller	String	The identity of the first user in the caller list	Default
callerList	String array	A list of names representing the identities of the users	Verbose

The RegistryContextObj object

Table 168. RegistryContextObj fields. This table lists the RegistryContextObj fields.

Field	Type	Description	Default or Verbose logging
type	String	The type of user registry being used, such as LDAP or AIX	Default

The ProcessContextObj object

Table 169. ProcessContextObj fields. This table lists the ProcessContextObj fields.

Field	Type	Description	Default or Verbose logging
domain	String	The domain to which the user belongs	Verbose
realm	String	The registry partition to which the user belongs	Default

The EventContextObj object

Table 170. EventContextObj fields. This table lists the EventContextObj fields.

Field	Type	Description	Default or Verbose logging
lastEventTrailId	String	The last ID associated with a given transaction	Verbose
eventTrailId	String array	An array of IDs that allow events that belong to a given transaction to be correlated	Default
creationTime	Date	The date an event was created	Default
globalInstanceId	Long	The unique identifier of this event	Default

The DelegationContextObj object

Table 171. DelegationContextObj fields. This table lists the DelegationContextObj fields.

Field	Type	Description	Default or Verbose logging
delegationType	String	no delegation, simple delegation, method delegation or switch user delegation	Default
roleName	String	The Run as role being used: runAsClient, runAsSpecified, runAsSystem, own ID	Default
identityName	String	Information about the mapped user	Default

The AuthnContextObj object

Table 172. AuthnContextObj fields. This table lists the AuthnContextObj fields.

Field	Type	Description	Default or Verbose logging
authnType	String	The type of authentication used	Default

The ProviderContextObj object

Table 173. ProviderContextObj fields. This table lists the ProviderContextObj fields.

Field	Type	Description	Default or Verbose logging
provider	String	The provider of the authentication or authorization service	Default
providerStatus	String	Status of whether the authentication or authorization event processed successfully by the provider	Default

The AuthnMappingContextObj object

Table 174. AuthnMappingContextObj fields. This table lists the AuthnMappingContextObj fields.

Field	Type	Description	Default or Verbose logging
mappedSecurityDomain	String	The security domain after mapping has occurred	Default
mappedRealm	String	The realm after mapping has occurred	Default
mappedUserName	String	The user name after mapping has occurred	Default

The AuthnTermContextObj object

Table 175. AuthnTermContextObj fields. This table lists the AuthnTermContextObj fields.

Field	Type	Description	Default or Verbose logging
terminateReason	String	The reason authentication ended	Default

The AccessContextObj object

Table 176. AccessContextObj fields. This table lists the AccessContextObj fields.

Field	Type	Description	Default or Verbose logging
progName	String	The name of the program that was involved in the event	Default
action	String	The action being performed.	Default
registryUserName	String	The name of the user in the registry	Default
appUserName	String	The name of the user within an application	Default
accessDecision	String	The decision of the authorization call	Default
resourceName	String	The name of the resource in the context of the application	Default
resourceType	String	The type of resource	Default
resourceUniqueId	Long	The unique identifier of the resource	Default
permissionsChecked	String array	The permissions that were checked during the authorization call	Default
permissionsGranted	String array	The permissions that were granted during the authorization call	Default
rolesChecked	String array	The roles that were checked during the authorization call	Default
rolesGranted	String array	The roles that were granted during the authorization call	Default

The PolicyContextObj object

Table 177. PolicyContextObj fields. This table lists the PolicyContextObj fields.

Field	Type	Description	Default or Verbose logging
policyName	String	The name of the policy	Default

Table 177. PolicyContextObj fields (continued). This table lists the PolicyContextObj fields.

Field	Type	Description	Default or Verbose logging
policyType	String	The type of policy	Default

The KeyContextObj object

Table 178. KeyContextObj fields. This table lists the KeyContextObj fields.

Field	Type	Description	Default or Verbose logging
keyLabel	String	The key or certificate label	Default
keyLocation	String	The physical location of the key database	Default
certLifetime	Date	The date when a certificate expires	Default

The CipherContextObj object

Table 179. CipherContextObj fields. This table lists the CipherContextObj fields.

Field	Type	Description	Default or Verbose logging
cipherData	Byte array	The cipher data that is captured	Verbose

The MgmtContextObj object

Table 180. MgmtContextObj fields. This table lists the MgmtContextObj fields.

Field	Type	Description	Default or Verbose logging
mgmtType	String	The type of management operation	Default
mgmtCommand	String	The application-specific command that was performed	Default
targetInfoAttributes	Target Atrribute array	Information about one or more secondary objects involved in this operation	Verbose

The ResponseContextObj object

Table 181. ResponseContextObj fields. This table lists the ResponseContextObj fields.

Field	Type	Description	Default or Verbose logging
url	String	The URL of the HTTP request	Default
httpRequestHeaders	Attributes array	The HTTP request headers provided by the client	Verbose
httpResponseHeaders	Attributes array	The HTTP response headers returned by the server	Verbose

The CustomPropertyContextObj object

Table 182. CustomPropertyContextObj fields. This table lists the CustomPropertyContextObj fields.

Field	Type	Description	Default or Verbose logging
key	String	The label representing the custom property key name	Verbose
value	Object	The object value of the custom property	Verbose

Creating security auditing event type filters

Event type filters are used to specify the types of auditable security events that are audited. Default event type filters are included with the product, but you can also configure new event type filters to specify a subset of auditable event types to be recorded by the security auditing subsystem.

Before you begin

Before configuring security auditing filters and the rest of the security auditing subsystem, enable global security in your environment. You must be assigned the auditor role to complete this task. Event type filters are used to specify what events are audited. The amount of data that is recorded for each event is specified with the **Enable verbose auditing** check box on the same panel used to enable the auditing subsystem. Navigate to **Security** > **Security auditing** to enable security auditing and determine the data recorded for each event.

About this task

Table 183. Commonly used event type filters by default in the audit.xml template file. The application server provides the following commonly used event type filters by default in the `audit.xml` template file:

Name	Event name	Outcome of event
DefaultAuditSpecification_1	SECURITY_AUTHN	SUCCESS
DefaultAuditSpecification_2	SECURITY_AUTHN	DENIED
DefaultAuditSpecification_3	SECURITY_RESOURCE_ACCESS	SUCCESS
DefaultAuditSpecification_4	SECURITY_AUTHN	REDIRECT

New event type filters can be created, or the existing default filters can be extended, to capture more event types and outcomes. Use this task to create new event type filters.

.

Procedure

1. Click **Security > Security Auditing > Event type filters> New**.
2. Enter the unique name that should be associated with this event type filter configuration in the Name field.
3. Specify the events that should be recorded when this filter is applied:
   a. Select the events that you want to be audited from the Selectable events list.
   b. Click **Add >>** to add the selected events to the Enabled events list.
   c. Select the outcomes that you want to be audited from the Selectable event outcomes list.
   d. Click **Add >>** to add the selected outcomes to the Enabled event outcomes lists.
4. Click **OK**.

Results

The successful completion of this task results in the creation of an event type filter than can be selected by the audit service providers and audit event factories to gather and record a specific set of auditable security events.

What to do next

After creating an event type filter, the filter must be specified in the audit service provider and the audit event factory to be used to gather or report audit data. The next step in configuring the security auditing subsystem is you should configure an audit service provider to define where the audit data will be archived.

Auditable security events

Auditable security events are security events that have audit instrumentation added to the security run time code to enable them to be recorded. Event filters are configured to specify which auditable security events are recorded to the audit log files.

The following list describes each valid auditable event that you can specify as an enabled event type when creating an event filter:

Table 184. Event types. Valid auditable events can be specified as an enabled event type when creating an event filter:

Event name	Description
SECURITY_AUTHN	Audits all authentication events
SECURITY_AUTHN_MAPPING	Audits events that record mapping of credentials where two user identities are involved
SECURITY_AUTHN_TERMINATE	Audits authentication termination events such as a timeout, terminated session, or user-initiated logging out
SECURITY_AUTHZ	Audits events related to authorization checks when the system enforces access control policies
SECURITY_RUNTIME	Audits runtime events such as the starting and the stopping of security servers. This event type is not meant for administrative operations performed by a system administrator as such operations need to use the other SECURITY_MGMT_* event types.
SECURITY_MGMT_AUDIT	Audits events that record operations related to the audit subsystem such as starting audit, stopping audit, turning audit on or off, changing configuration of audit filters or level, archiving audit data, purging audit data, and so on.
SECURITY_RESOURCE_ACCESS	Audits events that record all accesses to a resource. Examples are all accesses to a file, all HTTP requests and responses to a given web page, and all accesses to a critical database table
SECURITY_SIGNING	Audits events that record signing such as signing operations used to validate parts of a SOAP Message for web services
SECURITY_ENCRYPTION	Audits events that record encryption information such as encryption for web services
SECURITY_AUTHN_DELEGATION	Audits events that record delegation, including identity assertion, RunAs, and low assertion. Used when the client identity is propagated or when delegation involves the use of a special identity. This event type is also used when switching user identities within a given session.
SECURITY_AUTHN_CREDS_MODIFY	Audits events to modify credentials for a given user identity

For each audit event type, you must specify an outcome. Valid outcomes include SUCCESS, FAILURE, REDIRECT, ERROR, DENIED, WARNING, and INFO. Not all outcomes are applicable with all event types.

Note: Support for the SECURITY_RUNTIME auditing event type has been fully implemented for this release of WebSphere Application Server. It audits runtime events such as the starting and the stopping of security servers.

Event type filter settings

The Event type filter settings panel is used by an auditor to manage and create event type filters. Default event type filters have been included, this panel allows additional event type filters to be added. Existing event type filters are also managed using this panel.

To view this administrative console page, click one of the following paths:

- **Security > Security Auditing > Event type filters >** *event_type_filter_name*.
- **Security > Security Auditing > Event type filters > New** .

Name:

The Name field specifies the unique name of the event type filter.

Enabled:

The state of enablement of the filter is defined by the Enable check box. This field is represented as a boolean value. A value of true specifies that the enable field associated with the audit specification in the `audit.xml` is set to true. It does not imply that all configured event factories and service providers will be using this filter.

Filters still need to be configured for each event factory and service provider. Filters are enabled by default during configuration. However, if a filter has the enabled checkbox set to false, the filter will not gather or report data for the events and outcomes defined in that filter.

Events to associate with an audit filter:

The Events to associate with an audit filter field specifies the auditable security events to be associated with this filter.

- Selectable events:

  The Selectable events list displays the available auditable security events. To enable an event for this filter, select the event from the Selectable event outcomes list and then click **Add**.

- Enabled events:

  The Enabled events list displays the audit security events that are currently enabled for this filter. To disable an event for this filter, select the event from the Enabled events list and then click **Remove**.

Event outcomes to associate with an audit filter:

The Event outcomes to associate with an audit filter field specifies the auditable security event outcomes to be associated with this filter.

- Selectable event outcomes:

  The Selectable event outcomes list displays the available auditable security event outcomes. To enable an event outcome for this filter, select the event outcome from the Selectable event outcomes list and then click **Add**.

- Enabled event outcomes:

  The Enabled event outcomes list displays the audit security event outcomes that are currently enabled for this filter. To disable an event outcome for this filter, select the event outcome from the Enabled event outcomes list and then click **Remove**.

Event type filters collection

The Event type filters panel displays a listing of all configured audit specifications with their unique names, the state of their enablement, and the event types and event outcomes that are specified for each configuration.

To view this administrative console page, click **Security > Security Auditing > Event type filters**.

Name:

The Name field displays the unique name of the event type filter that is being represented.

Enable:

The Enable check box species the state of enablement for the filter. This field is represented as a boolean value. A value of true specifies that the enable field associated with the audit specification in the `audit.xml` is set to true. It does not imply that all configured event factories and service providers will be using this filter. Filters are enabled by default when they are created. Even though it is enabled by default when it is created, the event type filter must be specified for the event factory and the audit service provider before it is actually used,

Filters still need to be configured for each event factory and service provider. A filter that is configured for an event factory or a service provider that has Enabled set to false, will not gather or report data for the events and outcomes defined in that filter.

Events and outcomes:

The event types and the event outcomes that are specified by this filter. The specifications are listed in the form event_type:event_outcome and separated by commas if multiple combinations are specified by the event type filter.

Example: Generic Event Interface

This interface is used for processing generic audit events. Other interfaces can be defined which extend this interface to process specific audit event groupings, such as security events, transaction events, or other custom groupings. For WebSphere Application Server version 7.0, only security types of events are supported.

Generic Event Interface

Specific implementations might be developed to handle the data in a particular internal format. When the buildEvent() method is called, the implementation must then build the specified base event type using the internal information it has stored. After the information has been stored into a GenericEvent instance, the GenericEvent interface provides a generic way of handling the event.

```
public interface GenericEvent {

  /** * Property name used to specify the base event type to the
 * {@link GenericEvent#buildEvent} method.
 */
public static final String BASE_EVENT_TYPE = GenericEvent.class.getName() + ".baseEventType";

/**
* Returns the eventType of the event. The eventType distinguishes between these
* related events.
* The eventType depends on the particular implementation
* of the GenericEvent. For example, the Security Event implmentation has
* eventTypes such as SECURITY_AUTHN and SECURITY_AUTHZ.
* @return eventType - the eventType of the event
*/

public String getEventType();
/**
* Returns the creationTime, the creation time of the event.
* @return creationTime - the creation time of the event
*/ public Date getCreationTime(); /** * Returns the version, the version of the event.
* @return version - the version of the event
*/

public String getVersion (Properties props) throws GenericEventConfigurationException;
/**
* Returns the globalInstanceId, which is a globally unique instance
* identifier for the event.
* @return globalInstanceId - a globally unique instance identifier for the event
*/

public Long getGlobalInstanceId();
/**
* Verifies whether the event is valid; which depends on the particular
* implementation of the GenericEvent. If the event is not valid, an
* GenericEventValidationException error occurs.
*/

public void validate() throws GenericEventValidationException;
 /**
* Returns the internally wrapped base event instance after
* completing and validating the current instance of the GenericEvent.
* An GenericEvent implementation can maintain its information
* in any undisclosed internal format. The buildEvent()
* method that specifies that a specific base event type be built
* using the internal information. This allows GenericEvent implementations
* to support multiple base event formats. Thus the GenericEvent implmentation
* provides a layer of abstraction higher than the base event type.
* @param properties The value of the property BASE_EVENT_TYPE
* defines the type of the base event * @return the internally wrapped base event instance
* @throws GenericEventConfigurationException if the base event type is invalid
* or the JAR files to support that event type are not available.
* @throws GenericEventCompletionException if event completion has failed.
* @throws GenericEventValidationException if the validation has failed. This is
* validation as is performed by the validate() method.
*/

public Object buildEvent(Properties properties)
  throws GenericEventConfigurationException,
      GenericEventValidationException,
       GenericEventCompletionException;
/**
* Returns the wrapped base event instance as a string after
* completing and validating the current instance of the GenericEvent.
* An GenericEvent implementation can maintain its information
* in any undisclosed internal format. It is the buildEventString()
* method that specifies that a specific base event type be built
* using the internal information. This allows GenericEvent implementations
* to support multiple base event formats. Thus the GenericEvent implmentation
* provides a layer of abstraction higher than the base event type.
```

```
* @param properties The value of the property BASE_EVENT_TYPE
* defines the type of the base event
* @return the wrapped base event instance as a String
* @throws GenericEventConfigurationException if the base event type is invalid
* or the JAR files to support that event type are not available.
* @throws GenericEventCompletionException if event completion has failed.
* @throws GenericEventValidationException if the validation has failed. This is
* validation as is performed by the validate() method.
*/

public String buildEventString(Properties properties)
  throws GenericEventConfigurationException,
      GenericEventValidationException,
      GenericEventCompletionException;
}
```

Context objects for security auditing

Each event has an associated set of information that is available for logging. This information is grouped into specific context objects. The context objects that are available for logging a specific event are specified by the event type. All event types have the sessionContextObj, eventContextObj, accessContextObj, propogationContextObj, processContextObj and registryContextObj objects. This topic specifies which additional context objects are available for each event type.

Table 185. Context objects associated with event types. The following table describes the context objects associated with event types.

Event Type	Additional Context Objects
SECURITY_AUTHN	authnContextObj, providerContextObj
SECURITY_AUTHN_DELEGATION	delegationContextObj
SECURITY_AUTHN_MAPPING	authnMappingContextObj, providerContextObj
SECURITY_AUTHZ	providerContextObj, policyContextObj
SECURITY_ENCRYPTION	keyContextObj
SECURITY_MGMT_AUDIT	mgmtContextObj
SECURITY_RESOURCE_ACCESS	responseContextObj

For more details on the auditable data that is gather for each of these context objects, see the information for context object fields.

Context object fields

Each auditable event has an associated set of information that is available for logging. This information is grouped into specific context objects. The context objects that are available for logging a specific event are specified by the event type. This topic details the information that exists for each context object and specifies whether the information is logged by default or is only logged when the verbose logging option is enabled.

The SessionContextObj object

Table 186. SessionContextObj fields. This table lists the SessionContextObj fields.

Field	Type	Description	Default or Verbose logging
sessionId	String	An identifier for the user session	Default
remoteAddr	String	The IP address for the remote host	Default
remotePort	String	The port of the remote host	Default
remoteHost	String	The host name of the remote host	Default

The PropagationContextObj object

Table 187. PropagationContextObj fields. This table lists the PropagationContextObj fields.

Field	Type	Description	Default or Verbose logging
firstCaller	String	The identity of the first user in the caller list	Default
callerList	String array	A list of names representing the identities of the users	Verbose

The RegistryContextObj object

Table 188. RegistryContextObj fields. This table lists the RegistryContextObj fields.

Field	Type	Description	Default or Verbose logging
type	String	The type of user registry being used, such as LDAP or AIX	Default

The ProcessContextObj object

Table 189. ProcessContextObj fields. This table lists the ProcessContextObj fields.

Field	Type	Description	Default or Verbose logging
domain	String	The domain to which the user belongs	Verbose
realm	String	The registry partition to which the user belongs	Default

The EventContextObj object

Table 190. EventContextObj fields. This table lists the EventContextObj fields.

Field	Type	Description	Default or Verbose logging
lastEventTrailId	String	The last ID associated with a given transaction	Verbose
eventTrailId	String array	An array of IDs that allow events that belong to a given transaction to be correlated	Default
creationTime	Date	The date an event was created	Default
globalInstanceId	Long	The unique identifier of this event	Default

The DelegationContextObj object

Table 191. DelegationContextObj fields. This table lists the DelegationContextObj fields.

Field	Type	Description	Default or Verbose logging
delegationType	String	no delegation, simple delegation, method delegation or switch user delegation	Default
roleName	String	The Run as role being used: runAsClient, runAsSpecified, runAsSystem, own ID	Default
identityName	String	Information about the mapped user	Default

The AuthnContextObj object

Table 192. AuthnContextObj fields. This table lists the AuthnContextObj fields.

Field	Type	Description	Default or Verbose logging
authnType	String	The type of authentication used	Default

The ProviderContextObj object

Table 193. ProviderContextObj fields. This table lists the ProviderContextObj fields.

Field	Type	Description	Default or Verbose logging
provider	String	The provider of the authentication or authorization service	Default
providerStatus	String	Status of whether the authentication or authorization event processed successfully by the provider	Default

The AuthnMappingContextObj object

Table 194. AuthnMappingContextObj fields. This table lists the AuthnMappingContextObj fields.

Field	Type	Description	Default or Verbose logging
mappedSecurityDomain	String	The security domain after mapping has occurred	Default
mappedRealm	String	The realm after mapping has occurred	Default
mappedUserName	String	The user name after mapping has occurred	Default

The AuthnTermContextObj object

Table 195. AuthnTermContextObj fields. This table lists the AuthnTermContextObj fields.

Field	Type	Description	Default or Verbose logging
terminateReason	String	The reason authentication ended	Default

The AccessContextObj object

Table 196. AccessContextObj fields. This table lists the AccessContextObj fields.

Field	Type	Description	Default or Verbose logging
progName	String	The name of the program that was involved in the event	Default
action	String	The action being performed.	Default
registryUserName	String	The name of the user in the registry	Default
appUserName	String	The name of the user within an application	Default
accessDecision	String	The decision of the authorization call	Default
resourceName	String	The name of the resource in the context of the application	Default
resourceType	String	The type of resource	Default
resourceUniqueId	Long	The unique identifier of the resource	Default
permissionsChecked	String array	The permissions that were checked during the authorization call	Default
permissionsGranted	String array	The permissions that were granted during the authorization call	Default
rolesChecked	String array	The roles that were checked during the authorization call	Default
rolesGranted	String array	The roles that were granted during the authorization call	Default

The PolicyContextObj object

Table 197. PolicyContextObj fields. This table lists the PolicyContextObj fields.

Field	Type	Description	Default or Verbose logging
policyName	String	The name of the policy	Default
policyType	String	The type of policy	Default

The KeyContextObj object

Table 198. KeyContextObj fields. This table lists the KeyContextObj fields.

Field	Type	Description	Default or Verbose logging
keyLabel	String	The key or certificate label	Default
keyLocation	String	The physical location of the key database	Default
certLifetime	Date	The date when a certificate expires	Default

The CipherContextObj object

Table 199. CipherContextObj fields. This table lists the CipherContextObj fields.

Field	Type	Description	Default or Verbose logging
cipherData	Byte array	The cipher data that is captured	Verbose

The MgmtContextObj object

Table 200. MgmtContextObj fields. This table lists the MgmtContextObj fields.

Field	Type	Description	Default or Verbose logging
mgmtType	String	The type of management operation	Default
mgmtCommand	String	The application-specific command that was performed	Default
targetInfoAttributes	Target Atrribute array	Information about one or more secondary objects involved in this operation	Verbose

The ResponseContextObj object

Table 201. ResponseContextObj fields. This table lists the ResponseContextObj fields.

Field	Type	Description	Default or Verbose logging
url	String	The URL of the HTTP request	Default
httpRequestHeaders	Attributes array	The HTTP request headers provided by the client	Verbose
httpResponseHeaders	Attributes array	The HTTP response headers returned by the server	Verbose

The CustomPropertyContextObj object

Table 202. CustomPropertyContextObj fields. This table lists the CustomPropertyContextObj fields.

Field	Type	Description	Default or Verbose logging
key	String	The label representing the custom property key name	Verbose
value	Object	The object value of the custom property	Verbose

Configuring security audit subsystem failure notifications

Notifications can be generated by a failure of the security audit subsystem. The security audit subsystem notifications can alert auditors that the security audit system is no longer recording auditable security events. Notifications are generated by a failure of the auditing subsystem, they are not related to any auditable security events or event outcome that has occurred. Notifications triggered by an event or an event outcome are not supported.

Before you begin

Before configuring notifications, enable global security and the security audit subsystem in your environment. You must be assigned the auditor role to complete this task.

About this task

If a problem is experienced with the security audit subsystem, then a notification can be generated. This is an alert that security events are no longer being audited. Notification can be written to the system log file or can be sent to a specified group of users as an email. You are able to configure notifications to alert the auditor of a problem using both of these methods simultaneously. Notifications are only generated when

the Audit subsystem failure action field is set to Log warning or Terminate server.

Procedure

1. Optional: Click **Security** > **Security Auditing**.
2. Optional: Confirm the Audit subsystem failure action field is set to Log warning or Terminate server. If the Audit subsystem failure action field is set to No warning, then notifications will not be generated.
3. Click **Security** > **Security Auditing** > **Audit monitor** .
4. Under Notifications, Click **New**
5. Enter the name that should be associated with this notification configuration in the Notification name field.
6. Select the Message log check box to specify the failure notifications are recorded in the audit log.
7. Select the email sent to notification list check box to specify that failure notification email should be sent to the addresses listed in the notification list.
8. Enter an email address in the email address to add field This step is not needed if email notifications are not going to be sent.
9. Enter the mail server address in the Outgoing mail (STMP) server address. This step is not needed if email notifications are not going to be sent.
10. Click **Add >>** to add the email address and associated mail server to the email notification list.
11. Repeat steps 5 through 7 for each email address you want to specify in the email notification list.
12. Click **OK**.
13. Select the Enable monitoring check box to turn on audit failure notifications.
14. Select the notification configuration to be used from the Monitor notification dropdown menu.
15. Click **OK**.

Results

After completing this task, a notification will be generated if the security auditing subsystem experiences an unrecoverable error resulting in security events no longer being audited.

What to do next

After configuring notifications, you can analyze your audit data for potential weaknesses in the current security infrastructure and to discover possible security breaches that might have occurred.

Audit notifications cannot be removed using the administrative console. To remove an audit notification you first must run the deleteAuditNotificationMonitorByRef or the deleteAuditNotificationMonitorByName command. After running one of those commands, remove the audit notification by running the deleteAuditNotification command.

Audit monitor collection

Use this page to configure audit subsystem failure notifications. The Auditor monitor panel lists the existing notification configurations and is the gateway for creating new notification configurations and for managing the existing notification configurations.

To view this administrative console page, click **Security > Security Auditing > Audit monitor**.

Enable monitoring:

Specifies whether to enable or disable notifications. If the check box is selected, then monitoring is enabled. If the check box is not selected, then monitoring is disabled. This check box is disabled by default.

Monitor notification:

Specifies the notification configuration that will be used for reporting audit subsystem failures.

Notification name:

Specifies a string that uniquely identifies a notification configuration.

Message log:

Specifies if the configuration will send failure notifications to the message log file. If the value is true, then failure notifications will be sent to the message log file. If the value is false, then failure notifications will be not be sent to the message log file. When creating a notification, this field is in the form of a check box and is not selected by default.

Send Email:

Specifies whether an email notification is sent to the addresses listed in the List of email addresses column.

List of email addresses:

Specifies the email addresses listed as recipients for email notification in the event of an audit subsystem failure. No email addresses are listed by default. Email addresses will appear in this column if they are listed in the notification list in the notification, this applies even when the Email sent to notification list check box is not selected in the notification.

Audit notification settings

Use this page to create and manage notification configurations that define how auditors are made aware of audit subsystem failures.

To view this administrative console page, click **Security > Security Auditing > Audit monitor > New**.

Notification name:

Specifies a string that uniquely identifies a notification configuration.

Message log:

Specifies if the configuration will send failure notifications to the message log file. If the check box is selected, then failure notifications will be sent to the message log file. If the check box is not selected, then failure notifications will be not be sent to the message log file. This check box is not selected by default.

Send secure emails:

Email sent to the notification list:

Specifies whether the configuration will send a failure notification to the recipients listed in the notification list. If the check box is selected, then failure notifications will be sent to the recipients in the notification list. If the check box is not selected, then failure notifications will not be sent to the recipients in the notification list. This check box is not selected by default.

Email address to add:

Specifies the email address to be added to the notification list to received failure notification emails. To add a recipient to the notification list, this field and the Outgoing mail (SMTP) server field must both be completed before you click the **Add**.

Outgoing mail (SMTP) server:

Specifies the SMTP server to be used with this email address. If no server is specified, then the email realm will be used.

Configuring the default audit service providers for security auditing

The audit service provider is used to format the audit data object that was sent by the audit event factory. After being formatted, the audit data is recorded to the repository defined in the audit service provider configuration.

Before you begin

Before configuring the audit service provider, enable global security in your environment.

About this task

This task configures the audit service provider used to record generated audit records.

Procedure

1. Click **Security** > **Security Auditing** > **Audit service provider**.
2. Click **New** and then select **Binary file based emitter**.
3. Enter the unique name that should be associated with this audit service provider in the Name field.
4. Enter the file location of the binary log file in the Audit log file location field.
5. Optional: Enter the maximum size allowed for a single binary log file in the Audit log file size field.

   This field is specified in megabytes. After the maximum audit file size is reached, a new audit file will be created or an existing audit file will be overwritten. If the maximum number of audit log files has not been set, the default maximum file value used is 10 megabytes. There is no audit archiving utility included with the product. You are responsible for the archiving of your audit data.
6. Optional: In the Maximum number of audit log files field, enter the maximum number of audit logs to be stored before the oldest is overwritten.

   The default value for this field is 100. The value of 100 is also used if the field is empty.

   Note: The maximum number of logs does not include the current binary log that is being written to. It is a reference to the maximum number of archived (timestamped) logs. The total number of binary logs that can exist for a server process is the maximum number of archived logs plus the current log.

   Also under this field, there are additional options to select the behavior when the maximum number of logs is reached. The choices are:

   oldest If you select this option, when the maximum audit logs are reached, the oldest audit log is rewritten; notification is not sent to the auditor.

   stop server
   This option does not rewrite over the oldest audit log. It stops the audit service, sends a notification to the SystemOut.log, and quiesces the application server.

   stop logging
   This option does not rewrite over the oldest audit log. It also stops the audit service, but does allow the WebSphere process to continue. Notifications are not posted in the SystemOut.log.
7. Select the filters to be used by this audit service provider. The Selectable filter list consists of a list of the configured filters that have been configured and are currently enabled.

a. Select the filters that should be audited from the Selectable filter list.
b. Click **Add >>** to add the selected filters to the Enabled filter list.

8. Click **Apply**.

Results

After completing these steps, your audit data will be sent to the specified repository in the format required by that repository.

What to do next

After creating an audit service provider, the audit service provider must be associated with an audit event factory provide the audit data objects to the audit service provider. Next you should configure an audit event factory.

Audit service provider collection

The Audit service provider panel displays a listing of all configured audit service provider implementations. Using this panel, a user can define a new audit service provider implementation, delete an existing implementation, and display or modify the fields associated with an existing implementation.

To view this administrative console page, click **Security > Security Auditing > Audit service provider**.

By default, the `audit.xml` will contain the IBM audit service provider implementation which emits audit records to a binary filed-based text file. This implementation is used for Binary file- based audit service provider configurations. For each existing audit service provider in the list on this panel, the unique name, type and event formatting class associated with the audit service provider will be displayed.

Name:

The Name field is the unique name associated with the audit service provider implementation.

Type:

The Type field specifies if the implementation is a binary file-based implementation, SMF implementation or a third party implementation.

Event formatting module class name:

The event formatting class is a class used to format the generic event data object into a format that is specific to the audit service provider implementation. For example, a third party audit service provider implementation might have an event formatting class that takes the generic event and translates it into XML data. There is no Event formatting module class for binary file-based implementations nor for SMF implementations.

Audit service provider settings

Use this page to define the implementation details of the audit service provider. There are three types of audit service providers: binary file-based, third party and SMF.

To view this administrative console page, click one of the following paths:

- **Security** > **Security auditing** > **Audit service provider** > ***audit_service_provider_name***.
- **Security** > **Security auditing** > **Audit service provider** > **New** > **Binary File-based emitter**.
- **Security** > **Security auditing** > **Audit service provider** > **New** > **Third party emitter**.

Name:

Specifies the unique name associated with the audit service provider.

Third party emitter class name:

Specifies the name of the class for this implementation. This field is only present for Third party emitter implementations.

Audit file location:

Specifies the path to the binary log file.

Audit file size:

Specifies the maximum size of a single binary log file. This value is defined in megabytes.

Maximum number of audit log files:

Specifies the maximum number of binary log files to create before the oldest is replaced.

Note: The maximum number of logs does not include the current binary log that is being written to. It is a reference to the maximum number of archived (timestamped) logs. The total number of binary logs that can exist for a server process is the maximum number of archived logs plus the current log.

Audit log wrapping:

Specifies the wrapping behavior of the binary audit log when the maximum number of binary audit log files is reached.

Note: In this release of WebSphere Application Server, there are new customizable options available when specifying the default audit log wrapping behavior. This is only applicable to the Binary Audit Log implementation.

Choose from one of the following options:

WRAP
If you select this option, when the maximum audit logs are reached, the oldest audit log is rewritten; notification is not sent to the auditor. This is the default option, and mimics the default behavior in WebSphere Application Server Version 7.0.

NOWRAP
This option does not rewrite over the oldest audit log. It stops the audit service, sends a notification to the `SystemOut.log`, and quiesces the application server.

SILENT_FAIL
This option does not rewrite over the oldest audit log. It also stops the audit service, but does allow the WebSphere process to continue. Notifications are not posted in the `SystemOut.log`.

Note: If audit notification of failures in the audit subsystem is configured, and SILENT_FAIL is selected, the auditor is not notified of the audit subsystem failure. The SILENT_FAIL option takes precedence

Note: If you use the NOWRAP or SILENT_FAIL options, when the server is stopped as a result of the logs being maxed-out, a stopserver is performed, or because the server abends in some way, you must archive the binary audit logs before you restart the server.

Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

Event formatting module class name:

Specifies a class used to format the generic event into a format that is specific to the audit service provider implementation. For example, a third party audit service provider implementation might have an event formatting class that takes the generic event and translates it into XML data.

Selectable filters:

Specifies the available event filters. To enable a filter for an implementation, select the filter from the Selectable event filters list and then click **>**.

Enabled filters:

Specifies the event filters that are currently enabled for an implementation. To disable a filter for an implementation, select the filter from the Enabled filters list and then click **<**.

Custom properties:

Specifies any custom properties that might be used to add properties to a third party implementation. Custom properties are not available for binary file-based implementations or SMF implementations.

- Name
- Value

Example: Base Generic Emitter Interface

The Base Generic Emitter interface defines how audit events are emitted. Other interfaces can exist to extend this interface and to process specific audit events groupings, such as security events, transactional events, or some other custom grouping. Use this interface to create a custom implementation of the emitter.

Base Generic Emitter Interface

```
/**
* This is the interface for the event emitter. Event sources use this interface
* to send events to an event service.
*
*/
public interface BaseGenericEmitter {
/**
* Sends an event to the configured GenericEmitter implementation.
*
* @param event The event to be sent to the event service.
* This value cannot be null.
* @return The global instance ID of the event that was built.
* @exception GenericEmitterException If an error occurs during emitter processing.
* @exception IllegalArgumentException If the event parameter is null.
*/
public String sendEvent(GenericEvent event) throws
     GenericEventException;
/** * Sends an array of events to the configured GenericEmitter implementation.
* @param events The event array to be sent to the event service.
* This value cannot be null.
* @return The global instance IDs of the events that were built.
* @exception GenericEmitterException If an error occurs during emitter processing.
* @exception IllegalArgumentException If the events parameter is null.
*/
public String[] sendEvents(GenericEvent events[]) throws
     GenericEventException;
/**
* Causes the emitter to release all resources that are owned by this
```

```
* object and its dependents.
* Subsequent calls to this method have no effect.
*
* @throws GenericEmitterException If the emitter does release the
* held resources.
* resources.
* @throws GenericEventException If any other error occurs when releasing resources.
*/
public void close() throws
     GenericEventException;
}
```

Configuring a third party audit service providers for security auditing

The audit service provider is used to format the audit data object that was sent by the audit event factory. In addition to the default audit service provider, you may use a third party implementation as your audit service provider.

Before you begin

Before configuring the audit service provider, enable global security in your environment.

About this task

This task configures the audit service provider used to record generated audit records.

Procedure

1. Click **Security** > **Security Auditing** > **Audit service provider**.
2. Click **New** and then select **Third party emitter**.
3. Enter the unique name that should be associated with this audit service provider in the Name field.
4. Enter the Third party emitter class name.
5. Enter the Event formatting module class name. This field specifies the class used to format the generic event into a format that is specific to the audit service provider implementation. For example, your implementation might have an event formatting class that takes the generic event and translates it into XML data.
6. Select the filters to be used by this audit service provider. The Selectable filter list consists of a list of the configured filters that have been configured and are currently enabled.
   a. Select the filters that should be audited from the Selectable filter list.
   b. Click **Add >>** to add the selected filters to the Enabled filter list.
7. Optional: Enter any custom properties that you included in your third party emitter code.
8. Click **Apply**.

Results

After completing these steps, your audit data will be sent to the specified repository in the format required by that repository.

What to do next

After creating an audit service provider, the audit service provider must be associated with an audit event factory provide the audit data objects to the audit service provider. Next you should configure an audit event factory.

Example: Base Generic Emitter Interface

The Base Generic Emitter interface defines how audit events are emitted. Other interfaces can exist to extend this interface and to process specific audit events groupings, such as security events, transactional events, or some other custom grouping. Use this interface to create a custom implementation of the emitter.

Base Generic Emitter Interface

```
/**
* This is the interface for the event emitter. Event sources use this interface
* to send events to an event service.
*
*/
public interface BaseGenericEmitter {
/**
* Sends an event to the configured GenericEmitter implementation.
*
* @param event The event to be sent to the event service.
* This value cannot be null.
* @return The global instance ID of the event that was built.
* @exception GenericEmitterException If an error occurs during emitter processing.
* @exception IllegalArgumentException If the event parameter is null.
*/
public String sendEvent(GenericEvent event) throws
     GenericEventException;
/** * Sends an array of events to the configured GenericEmitter implementation.
* @param events The event array to be sent to the event service.
* This value cannot be null.
* @return The global instance IDs of the events that were built.
* @exception GenericEmitterException If an error occurs during emitter processing.
* @exception IllegalArgumentException If the events parameter is null.
*/
public String[] sendEvents(GenericEvent events[]) throws
     GenericEventException;
/**
* Causes the emitter to release all resources that are owned by this
* object and its dependents.
* Subsequent calls to this method have no effect.
*
* @throws GenericEmitterException If the emitter does release the
* held resources.
* resources.
* @throws GenericEventException If any other error occurs when releasing resources.
*/
public void close() throws
     GenericEventException;
}
```

Configuring audit event factories for security auditing

The audit event factory collects the data associated with the auditable security events and builds the audit data object. The object is then sent to the audit service provider to be formatted and recorded to a specified repository.

Before you begin

Before configuring an event factory, enable global security in your environment. An event type filter and an audit service provider need to be created before completing these steps

About this task

Procedure

1. Click **Security** > **Security Auditing** > **Audit event factory configurations** > **New**.
2. Enter the unique name that should be associated with this Audit event factory configuration in the Name field.
3. Select either **IBM audit event factory** or **Third party event factory**.
   a. Enter the Third party audit event factory class name. This step is only required if a Third party event factory is being created.
4. Select the appropriate audit service provider implementation from the Audit service provider dropdown menu,
5. Select the event type filter configuration to be used by this audit event factory. The Filters list consists of a list of the event type filter configurations that have been created and are currently enabled.
   a. Select the event type filters that should be used from the Selectable filter list.
   b. Click **Add >>** to add the selected event type filter configurations to the Enabled filter lists.
6. Enter any Custom properties that need to be included with this audit event factory configuration. Custom properties are only available for Third party event factory implementations.

7. Click **Apply**.

Results

After successful completion of these steps, you will have an event factory that can be used to gather auditable event data.

What to do next

After configuring an audit event factory, you can optionally protect your data by configuring the security auditing subsystem to sign and encrypt your audit logs.

Audit event factory configuration collection

The Audit event factory configuration panel displays a list of all currently configured audit event factory implementations. This panel allows a user with the auditor role to manage their configured audit event factories. This includes the ability to configure a new implementation, which is done using the **New** button on this panel.

To view this administrative console page, click **Security > Security Auditing > Audit event factory configuration**.

Name:

The Name field specifies the unique name associated with the audit event factory configuration.

Type:

The Type field specifies this audit event factory configuration as either an IBM audit event factory or a Third party audit event factory.

Class name:

The Class name field specifies the class that is being implemented in an audit event factory configuration.

The class name is `com.ibm.ws.security.audit.AuditEventFactoryImpl` for an IBM event factory. For a Third party audit event factory, the class name is the class specified in the Third party audit event factory class name field.

Audit event factory settings

The Audit event factory settings panel displays the details of a specific audit event factory. The auditor uses this panel to manage and create audit event factory configurations.

To view this administrative console page, click on of the following paths:

- **Security** > **Security Auditing** > **Audit event factory configuration** > ***audit_event_factory_configuration_name***.
- **Security** > **Security Auditing** > **Audit event factory configuration** > **New**.

Name:

Specifies the unique name associated with the audit event factory configuration.

Type:

Specifies this audit event factory configuration as either an IBM audit event factory or a Third party audit event factory. This field does not appear on the panel during the creation of a new audit event factory. It is included when viewing or modifying an existing audit event factory.

IBM audit event factory:

Specifies that the Type field of this audit event factory is IBM audit event factory. This check box only appears on the panel during the creation of a new audit event factory. This check box is selected by default when creating a new audit event factory.

Third party audit event factory:

Specifies that the Type field of this audit event factory is Third party audit event factory. This check box only appears on the panel during the creation of a new audit event factory. This check box is not selected by default when creating a new audit event factory.

- The Third party audit event factory class name field is active when the Third party audit event factory check box is selected. This field represents the class name of the third-party implementation of the Audit Event Factory interface

Class name:

Specifies the class that is being implemented in a audit event factory configuration.

Although not specified during creation, the class name is `com.ibm.ws.security.audit.AuditEventFactoryImp` for an IBM event factory.

Audit service provider:

Specifies where the audit data objects gathered by this audit event factory will be sent.

Selectable filters:

Specifies the filters that are currently available to be used for an implementation. To enable a filter for an implementation, select the filter from the Selectable filter list and then click **>**.

Enabled filters:

Specifies the filters that are currently enabled for an implementation. To disable a filter for an implementation, select the filter from the Enabled filter list and then click **<**.

Custom properties:

Specifies properties that the auditor can define to configure the Audit Event Factory implementation. This might be used by third party implementation of the audit event factory interface. Custom properties are not used for the IBM audit event factory implementation.

Each custom property has the following fields:

- Name
- Value

Example: Generic Event Factory Interface

This interface is used for processing generic audit events. Other interfaces can be defined which extend this interface to process specific audit event groupings, such as security events, transaction events, or some other custom grouping.

Generic Event Factory Interface

```
/**
* GenericEventFactory is the interface that is used to generate audit events.
* This interface may be extended to generate application specific audit events.
*
* One or more GenericEventFactory implementations each with a unique name can be defined in the
* security configuration and be used by WebSphere Application Server security auditing service.
```

```
* @author IBM Corporation
* @version WAS 7.0
* @since WAS 7.0
*/
public interface GenericEventFactory {
/**
* The init method allows a GenericEventFactory implementation to
* initialize its internal auditing configuration using the properties and context object.
*
* The properties and context objects are treated as read-only and must not be modified by the
* GenericEventFactory implementation.
*
* @param A String object represents the name of this GenericEventFactory.
* @param A Map properties object that contains the custom properties that can be defined in the
* the admin console or by using wsadmin scripting tool.
* @param A Map object that contains the context that includes cell name, node name, and server name.
* @exception ProviderFailureException might occur if the audit factory does not initialize
*/
public void init(String name, Map properties, Map context) throws ProviderFailureException;
/**
*
* The terminate method gracefully quiesces the event factory implementation.
*/
public void terminate();
/**
*
* The refresh method allows a GenericEventFactory implementation to
* update its internal auditing configuration using the properties object.
*
* The properties object is treated as read-only and must not be modified by the
* GenericEventFactory implementation.
*
* @param A Map object that contains the custom properties
* @exception ProviderFailureException might occur if the factory does not refresh
*/
public void refresh(java.util.Map properties) throws ProviderFailureException;
/**
*
* The getName method returns the name of this GenericEventFactory.
*
* @param None
* @return a String object represents the name of the GenericEventFactory.
*/
public String getName();
/**
*
* The sendEvent method determines whether the specified audit event is generated by this
* GenericEventFactory.
*
* @param a String object represents an audit event
* @param a OutcomeType object represents the audit outcome value
* @exception ProviderFailureException might occur if the audit factory does not initialize
* @return a boolean success/failure
* @exception ProviderFailureException might occur if the audit factory does not send the event.
*/
public boolean sendEvent(String auditEventType, OutcomeType auditOutcome) throws
ProviderFailureException;
*
}
```

Protecting your security audit data

The security auditing subsystem allows for protection of your security audit data by increasing the assurance that the audit data has not been tampered or modified outside of the auditing facility. This option also protects the confidentiality of the data. The audit data is protected by encrypting and signing the recording data.

Before you begin

Restriction: Signing and encrypting your audit data is only available for data created using the default binary log audit service provider. If you are using the SMF emitter or a 3rd party emitter you will not be able to sign or encrypt your data.

Before configuring protection for your security audit data, enable global security and security auditing in your environment. You must be assigned the auditor role to complete the task of protecting your audit data. You will also need the administrator role to configure your audit data to be signed.

About this task

The practice of auditing requires assurances that your audit data is accurate and uncompromised. Your audit data has the option to be encrypted, signed, or encrypted and signed. You can protect your audit data using these options to provide assurances that you data is only viewed by authorized users and can not untraceably be modified . To protect the validity of your security auditing functionality, complete the following steps:

Procedure

1. “Encrypting your security audit records” Audit logs can be encrypted to ensure your audit data is protected. The audit logs will be encrypted using a certificate that is saved to a keystore in the `audit.xml` file. By encrypting your audit records, only users with the password to the keystore will be able to view or update the audit logs.
2. “Signing your security audit records” on page 1874 Audit logs can be signed to ensure the integrity of your audit data. By signing your audit records, you ensure any modifications of the audit logs can be traced.

Results

After completing these steps your data will be signed, encrypted or signed and encrypted to provide assurances that the data is accurate and confidential.

What to do next

After protecting your data, you can configure notifications to ensure you are notified if a problem with the security auditing subsystems occurs that prevents security events from being recorded.

Encrypting your security audit records

Audit logs can be encrypted to ensure your audit data is protected. By encrypting your audit records, only users with access to the encrypting certificate will be able to view the audit logs.

Before you begin

Restriction: Encrypting audit data is only available for data created using the default audit service provider. If you are using the SMF emitter or a 3rd party emitter you will not be able to encrypt your data.

Before configuring your security audit records to be encrypted, enable global security and security auditing in your environment. You must be assigned the auditor role to encrypt your security auditing records. If you are using a certificate stored in the `security.xml` file, you also require the administrator role to complete this task.

About this task

Procedure

1. Click **Security** > **Security Auditing** > **Audit record encryption configuration**.
2. Select the Enable encryption check box to specify that your audit records should be encrypted. All other fields on this panel will be unavailable until this check box has been selected.
3. Select the keystore that contains the encrypting certificate from the dropdown menu or click **New** to create a new certificate in an existing keystore. Use the following steps if you are creating a new certificate:
   a. Enter the name of the keystore in the Name field.
   b. Enter the path to the keystore file in the Path field.
   c. Enter the password to be associated with the keystore in the Password field.

d. Confirm the password associated with the keystore by retyping the password in the Confirm password field.
e. Select the keystore type from the Type dropdown list. The default value of the Type dropdown list is PKCS12.

4. If you are using an existing certificate to encrypt your audit records, ensure **Certificate in keystore** is selected and specify the intended certificate in the Certificate alias dropdown menu.
5. If you are generating a new certificate to encrypt your audit records, select **Create a new certificate in the selected keystore** and follow these steps:
   a. Enter the name of your new certificate in the Certificate alias field.
   b. Select either Automatically generate certificate or Import a certificate. The certificate used to encrypt the data in the audit log files can either be created or imported. If you selected to generate a certificate, then skip to the last step on this page. If you selected to import a certificate, then continue on with step c.
   c. Enter the name of the keystore file in the Key file name field.
   d. Enter the path to the keystore file in the Path field.
   e. Select the keystore type from the Type dropdown list. The default value of the Type dropdown list is PKCS12.
   f. Enter the password associated with the keystore in the Key File password field.
   g. Click **Get key file aliases** to populate the Certificate alias to import dropdown menu.
   h. Select the certificate to be imported from the Certificate alias to import dropdown menu.
6. Click **OK**.

Results

After completing these steps, your audit logs will be encrypted to ensure only authorized users can view the content of your audit log files.

What to do next

After you have finished configuring your audit logs to be encrypted, you can ensure the data integrity of your audit logs by configuring the audit subsystem to sign your audit records.

Signing your security audit records

Audit logs can be signed to ensure the integrity of your audit data. By signing your audit records, modifications of the audit logs can be traced.

Before you begin

Restriction: Signing audit data is only available for data created using the default audit service provider. If you are using the SMF emitter or a 3rd party emitter you will not be able to sign your data.

Before configuring your security audit records to be signed, enable global security and security auditing in your environment. You must be assigned the auditor role and the administrator role to configure audit record signing.

About this task

Procedure

1. Click **Security** > **Security Auditing** > **Audit record signing configuration**.
2. Select the Enable signing check box to specify that your audit records should be signed. All other fields on this panel will be unavailable until this check box has been selected.

3. Select the keystore that contains the signing certificate from the Managed keystore containing the signing certificate dropdown menu.
4. If you are using an existing certificate to sign your audit records, ensure Certificate in keystore is selected and specify the intended certificate in the Certificate alias dropdown menu.
5. If you are generating a new certificate to sign your audit records, select Create a new certificate in the selected keystore and follow these steps:
   a. Enter the name of your new certificate in the Certificate alias field.
   b. Select on of the following options: Import the encryption certificate, Automatically generate certificate or Import a certificate. The certificate used to encrypt the data in the audit log files can either be created or imported.
      - If you selected Import the encryption certificate, then you will use the encryption certificate to also sign your audit records. Skip to the last step on this page to complete this configuration.
      - If you selected to generate a certificate, then skip to the last step on this page to complete this configuration.
      - If you selected to import a certificate from an existing keystore, then continue on with step c.
   c. Enter the name of the keystore file in the Key file name field.
   d. Enter the path to the keystore file in the Path field.
   e. Select the keystore type from the Type dropdown list. The default value of the Type dropdown list is PKCS12.
   f. Enter the password associated with the keystore in the Key File password field.
   g. Click **Get key file aliases** to populate the Certificate alias to import dropdown menu.
   h. Select the certificate to be imported from the Certificate alias to import dropdown menu.
6. Click **OK**.

Results

After you have completed these steps, your audit logs will be digitally signed to ensure the integrity of the data.

What to do next

After you have finished configuring your audit logs to be signed, you can ensure the confidentiality of your audit logs by configuring the audit subsystem to encrypt your audit records.

Audit encryption keystores and certificates collection

The Audit encryption keystores and certificates panel allows the auditor to manage the keystores and certificates used for audit encryption.

To view this administrative console page, click **Security > Security Auditing > Audit encryption keystores and certificates**.

Name:

Specifies the unique name of the keystores used for storing the encryption certificate.

Path:

Specifies the path to the listed keystore file.

The path to the keystore file can be listed using environment variables, ${PROFILE_ROOT}, or with a fully qualified path.

Audit record encryption configuration settings

Use this page to enable encryption for your audit records. Encrypting your audit records ensures only a user given access to the certificate used for encryption is allowed to view the audit records.

To view this administrative console page, click **Security > Security auditing > Audit record encryption configuration**. If **Enable encryption** is not selected, then all of the other fields on this panel will be disabled. Encryption is not enabled by default.

Enable encryption:

Specifies whether your audit records will be encrypted. This check box is not selected by default.

Audit keystore containing the encryption certificate:

Specifies the audit keystore specified to store the encryption certificate.

A new keystore can be created by clicking on the **New...** button.

Certificate in keystore:

Specifies an existing certificate will be used from the keystore specified in the Audit keystore containing the encryption certificate field. This field is selected by default. If a keystore in the `security.xml` file is used, the administrator role is required.

- Certificate alias

  When the **Certificate in keystore** field is selected, the certificate alias dropdown menu displays a list of certificate aliases contained in the keystore defined by the **Audit keystore containing the encryption certificate** field. Select the certificate from the dropdown menu to be used to encrypt your audit records.

Create a new certificate in the selected keystore:

Specifies that a new certificate will be created in the keystore defined by the **Audit keystore containing the encryption certificate** field.

- Certificate alias

  When the **Create a new certificate in the selected keystore** is selected, the **Certificate alias** field is used to define the name of the certificate to be created in the keystore defined by the **Audit keystore containing the encryption certificate** field.
- Automatically generate certificate

  When selected, the **Automatically generate certificate** field specifies that the application server will automatically generate the certificate. This field is selected by default when the **Create a new certificate in the selected keystore** field is selected.
- Import a certificate

  When selected, the **Import a certificate** field specifies that an existing self-signed certificate will be imported by the auditor into the keystore and used to encrypt your audit records. This field is not selected by default when the **Create a new certificate in the selected keystore** field is selected. The following fields need to be defined to import an existing certificate.
  - The **Key file name** field specifies the keystore filename that contains the certificate to be imported.
  - The **Path** field specifies the path to the keystore file that contains the certificate to be imported.
  - The **Type** field specifies the type of the keystore file that contains the certificate to be imported.
  - The **Key file password** field specifies the password used to access the keystore file that contains the certificate to be imported.
  - **Certificate alias to import** field specifies the alias of the certificate to be imported.

Audit record signing configuration settings

Use this page to enable signing for your audit records. Signing audit records ensures tamper-proof recording of the auditable events. Both the auditor and administrator roles are required to configure the signing of your audit data.

To view this administrative console page, click **Security** > **Security auditing** > **Audit record signing configuration**. If **Enable signing** is not selected, then all of the other fields on this panel will be disabled.

Enable signing:

Specifies whether your audit records will be encrypted. This check box is not selected by default.

Managed keystore containing the signing certificate:

Specifies the keystore used to store the signing certificate.

Certificate in keystore:

Specifies an existing certificate will be used from the keystore specified in the **Managed keystore containing the signing certificate** field. This field is selected by default.

- Certificate alias

  When the **Certificate in keystore** field is selected, the **Certificate alias** dropdown menu displays a list of certificate aliases contained in the keystore defined by the **Managed keystore containing the signing certificate** field. Select the certificate from the dropdown menu to be used to sign your audit records.

Create a new certificate in the selected keystore:

Specifies that a new certificate will be created in the keystore defined by the **Managed keystore containing the signing certificate** field.

- Certificate alias

  When the **Create a new certificate in the selected keystore** is selected, the **Certificate alias** field is used to define the name of the certificate to be created in the keystore defined by the **Audit keystore containing the encryption certificate** field.
- Import the encryption certificate

  Specifies the certificate used for encryption will be imported into the signing keystore file and used for signing.
- Automatically generate certificate

  Specifies the application server will automatically generate the certificate. This field is selected by default when the **Create a new certificate in the selected keystore** field is selected.
- Import a certificate

  Specifies an existing self-signed certificate will be imported by the auditor into the keystore and used to encrypt your audit records. This field is not selected by default when the **Create a new certificate in the selected keystore** field is selected. The following fields need to be defined to import an existing certificate.
  - The **Key file name** field specifies the keystore filename that contains the certificate to be imported.
  - The **Path** field specifies the path to the keystore file that contains the certificate to be imported.
  - The **Type** field specifies the type of the keystore file that contains the certificate to be imported.
  - The **Key file password** field specifies the password used to access the keystore file that contains the certificate to be imported.
  - **Certificate alias to import** field specifies the alias of the certificate to be imported.

Audit record keystore settings

The Audit record keystore panel is used by an auditor to define the keystores used for storing the encryption certificate used to encrypt the audit records. Keystores used for auditing are managed outside of other keystores being used on the system to facilitate separation of the authority of the auditor for the authority of the administrator.

To view this administrative console page, click one of the following paths:

- **Security > Security Auditing > Audit encryption keystores and certificates >** *keystore_name*.
- **Security > Security Auditing > Audit encryption keystores and certificates > New**.
- **Security > Security Auditing > Audit record encryption configuration > New**

Name:

The Name field specifies the unique name for the keystore. This is a required field.

Path:

Specifies the path where the keystore file is located. This is a required field.

Password:

Specifies the password to be used for this keystore. This is a required field.

Confirm Password:

Specifies confirmation of the value provided in the Password field. This is a required field.

Type:

The Type field specifies the type of the keystore. The Type dropdown menu has the following options for defining the keystore type:

- JCEKS
- CMSKS
- PKCS12 - The default value for the Type field is PKCS12.
- Cryptographic Token Device (PKCS11)
- JKS
- PKCS12JarSigner

Using the audit reader

The audit reader is a utility that can be used to read the binary audit logs generated by the default binary emitter implementation. The audit reader parses the audit log to generate an HTML report. The audit reader is invoked using wsadmin commands and is not accessible using the administrative console.

Before you begin

The audit reader can only be used to parse log files that are created by the default audit service provider. Logs created by a third-party emitter can not be parsed by the audit reader.

About this task

Your audit logs might be encrypted, signed, encrypted and signed or neither encrypted nor signed. The audit reader is able to parse any of these combinations to generate an HTML report. If the audit log file is

encrypted, the password of the keystore storing the certificate used to encrypt the log must be provided. The showAuditLogEncryptionInfo wsadmin command can be used to get information to determine which keystore was used to sign the audit log.

Depending on the selections you made in your audit service provider configuration, the size of the audit logs can become large enough to make them cumbersome to review. What data has been recorded into your log is dependant on the event type filers you are using and whether you specified to use verbose logging. Options are provided for you to further limit the data included in the HTML report that is generated by the audit reader to a subset that you specify. The audit reader can be used to parse the same data multiple times to generate separate reports for your different requirements.

By default, all event types, outcome types, timestamps, and sequence numbers will be gathered from the Binary Audit log and generated into a report. The ability to specify only specific event types, only specific sequence numbers, only records with specific timestamps, as well as specific outcome types is provided. A sequence number is a unique identifier assigned to each audit record. Options exist to limit which events, outcomes, and sequence numbers are included in the report.

The report type controls what data is reported for each audit record in the log file. The default report type includes the follow data for each audit record:

- creationTime
- action
- progName
- registryType
- domain
- realm
- remoteAddr
- remotePort
- remoteHost
- resourceName
- resourceType
- resourceUniqueId

The complete report type generates a report based on all the data that was logged for the selected audit records. The complete report type includes all the data that is included by the default report type and all the additional datapoints that were logged for these audit records. The additional available datapoints for an audit record varies depending on the event type it represents.

A custom report type is also included. Use the custom report type to specify only the datapoints that you want generated in the report. A report may be generated based on the following criteria:

- all or specific event types
- all or specific outcome types
- all or a specific sequence number range
- all or a specific timestamp range

Procedure

Run the binaryAuditLogReader wsadmin command to use the audit reader to generate a log report. See the AuditReaderCommands command group for the AdminTask object article for more information.

Results

After you complete these steps, you will generated an HTML report containing the data specific to your requirement.

Example

Audit Event Outcome Codes

In a binary audit log or the output of the audit reader tool, audit event outcomes are expressed with a numeric code. Use this table to associate the audit event outcome code in the binary audit logs to a generic error messages.

Table 203. Event Outcome Codes. This table lists the event outcome codes.

Outcome Reason Code	Description
0	An error occurred while parsing the certificate.
1	The security context does not exist for the thread.
2	There is conflicting session evidence.
3	The session has been rejected.
4	The token has expired.
5	Successful authentication has occurred.
6	Successful authentication for accessing a resource has occurred.
7	Successful authentication occurred while mapping a user.
8	Successful authorization has occurred.
9	Login termination was successful.
10	Invalid evidence exists.
11	There was a GSS formatting error.
12	Credentials were unauthenticated.
13	Authentication failed.
14	An invalid resource was accessed.
15	Authentication was denied.
16	Authorization was denied.
17	Access was denied because of an authentication failure.
18	Authorization was excluded.
19	Authorization was excluded because of access without proper security role.
20	An unsupported authentication mechanism was used.
21	An authentication redirect occurred.
22	The context does not exist.
23	A TAI challenge occurred.
24	A TAI validation was not successful.
25	A TAI mapping was not successful.
26	A provider failure occurred.
27	A SSO token validation was not successful.
28	An invalid user id or password was provided.
29	A send login form
30	An invalid configuration exists.
31	An user id or password is missing.
32	Failure occurred for an unknown reason.
33	The account was disabled because of retry violations.
34	The account was locked out because of retry violations.
35	The account was locked out because the maximum number of unsuccessful login attempts has occurred.
36	The account is disabled.
37	The account has expired.

Table 203. Event Outcome Codes (continued). This table lists the event outcome codes.

38	The account is unlocked.
39	The maximum inactive time permitted for the account has elapsed.
40	The password has expired.
41	The minimum interval for a password change has unexpired.
42	The maximum interval permitted before a password must be changes has elapsed.
43	An authentication failure has occurred.
44	An invalid user name was provided.
45	A pin is required.
46	This outcome code is not used in this release.
47	A user mapping did not occur successfully.
48	A certificate failure occurred.
49	A policy violation has occurred.
50	A policy violation has occurred because of the time of day.
51	The policy allows access.
52	A policy violation has occurred because the maximum number of unsuccessful login attempts has been reached.
53	A user name mismatch has occurred.
54	An invalid user password was provided.
55	A token signature violation has occurred.
56	The token is not yet valid.
57	The token is not supported.
58	The token is not in a valid format.
59	A credential mapping failure occurred.
60	The delegate is not authorized.
61	Access to a resource is unauthorized because of an authorization.
62	Access to a resource is unauthorized because of a time of day policy.
63	Access to a resource is unauthorized.
64	Access to a resource is unauthorized because of quality of protection.
65	Access to a resource is unauthorized because of an authorization level.
66	Access to a resource is unauthorized because reauthentication is required.
67	A password error has occurred because it does not meet password standards: minimum alphabetic characters required.
68	A password error has occurred because it does not meet password standards: minimum alphanumeric characters required.
69	A password error has occurred because it does not meet password standards: minimum numeric characters required.
70	A password error has occurred because it does not meet password standards: minimum alphabetic low case characters required.
71	A password error has occurred because it does not meet password standards: minimum alphabetic upper case characters required.
72	A password error has occurred because it does not meet password standards: minimum special characters required.
73	A password error has occurred because it does not meet password standards: maximum repeated characters exceeded.
74	A password error has occurred because it does not meet password standards: contains user name
75	A password error has occurred because it does not meet password standards: reused password.
76	A password error has occurred because it does not meet password standards: contains previous password.
77	A password error has occurred because it does not meet password standards: violations in number of characters.
78	A password error has occurred because it does not meet password standards: first or last characters are numeric.
79	An illegal form login configuration exists.
80	Access is denied because of a incorrect URI.

Table 203. Event Outcome Codes (continued). This table lists the event outcome codes.

81	Start was successful
82	Stop was successful.
83	The audit subsystem has been stopped.
84	The audit subsystem has successfully been enabled.
85	The audit subsystem has had a successful policy change.
86	Delegation was successful.
87	Delegation was not successful.
88	The audit subsystem has successfully been disabled.
89	An audit subsystem has occurred because a security header is missing.
90	An audit timestamp has been confirmed.
91	A bad audit timestamp has occurred.
92	Audit confidentially has been confirmed
93	Audit confidentially cannot be confirmed.
94	An audit decryption error has occurred.
103	A login attempt has been made by a user who has already logged in successfully.

Chapter 24. Administering Service integration

This page provides a starting point for finding information about service integration.

Service integration provides asynchronous messaging services. In asynchronous messaging, producing applications do not send messages directly to consuming applications. Instead, they send messages to destinations. Consuming applications receive messages from these destinations. A producing application can send a message and then continue processing without waiting until a consuming application receives the message. If necessary, the destination stores the message until the consuming application is ready to receive it.

Enabling or disabling service integration notification events

You can monitor your service integration environment by using notification events.

About this task

Service integration notification events allow you to monitor the activity of your service integration configuration by using your own system management application. For more details see Service integration notification events.

You can enable or disable service integration notification events at either the bus or the messaging engine level. The following table illustrates the effect of the two setting levels on the enablement of notifications:

Table 204. Notification settings. The first and second columns of the table list the combinations of the bus-level and messaging engine level notification settings. The third column indicates if the notification is enabled or not based on the combination of the two notification settings.

Bus-level notification setting	ME-level notification setting	Are notifications enabled
Not set	Not set	Disabled
Not set	Enabled	Enabled
Not set	Disabled	Disabled
Disabled	Not set	Disabled
Disabled	Enabled	Disabled
Disabled	Disabled	Disabled
Enabled	Not set	Enabled
Enabled	Enabled	Enabled
Enabled	Disabled	Disabled

Procedure

1. By using the administrative console, open the **Custom properties** page for either the bus or the messaging engine for which you want to set notification events:
   - Click **Service integration -> Buses -> *bus_name* -> [Additional Properties] Custom properties** to display the custom properties for a bus.
   - Click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional Properties] Custom properties** to display the custom properties for a messaging engine.
2. Click **New** to create a new custom property.
3. Enter sib.event.notification as the name of the custom property. Set the value of the custom property to either “enabled” or “disabled” as required.
4. Optional: Enter a description for the custom property.
5. Click **OK** and save your changes to the master configuration.

Administering service integration buses

Application servers or clusters of application servers in a WebSphere Application Server cell can cooperate to provide asynchronous messaging services. Service integration provides asynchronous messaging services, and a group of servers or clusters that cooperate in this way is called a service integration bus. Each of the cooperating servers or clusters is made a member of the bus. In the simplest case, a service integration bus consists of a single bus member, which is one application server.

Procedure

- Service integration technologies
- Bus configurations
- “Configuring buses”
- “Operating buses” on page 1941

Configuring buses

You can configure service integration buses in a variety of ways; for example you can create and apply security to a bus and you can then add servers or server clusters to that bus.

Creating a bus

When you create a service integration bus, you add a new bus in the administrative console, and then add one or more servers or server clusters as bus members. Thereafter, you administer the bus, and its constituent bus members, as a single unit.

Before you begin

- Plan your bus topology. For more information, see Bus configurations.
- Plan your security strategy. For more information, see Service integration security planning.

About this task

You can create a bus by using the administrative console. Wizards are provided to help you add a secured bus, and add a member to the bus. A messaging engine is created for most types of bus member, and you are prompted to specify a data store. The exception is WebSphere MQ server where, because a messaging engine is not created, a message store is not required.

Procedure

1. Add a secured bus or an unsecured bus. For the steps, see “Adding buses” on page 1885.
2. Add a member to the bus. See “Adding a server as a new bus member” on page 1889. This creates a messaging engine with default properties.
3. Optional: Configure the messaging engine, if required. See “Configuring messaging engine properties” on page 1897.
4. Optional: Configure the message store for the messaging engine, if required. For a messaging engine in an application server, you can change the data store configuration. You might do this, for example, if you want to use DB2 rather than Apache Derby as the database system. For more information about changing the data store configuration, see “Configuring a JDBC data source for a messaging engine” on page 1960. You can also change the file store configuration. Refer to “Modifying file store configuration” on page 1954.
5. Restart the server. The messaging engine starts when the server starts.

Results

A new bus is created.

What to do next

You can now change the configuration of the bus; for example, by adding additional members, by creating bus destinations, and by creating links to WebSphere MQ networks. You can create other buses and, if required, connect them together.

Adding buses

You can add a new service integration bus by using the administrative console. If messaging security is enabled, security settings are configured for the bus by default. You can add a unsecured bus if you disable messaging security.

Adding a secured bus:

In this task you add a new service integration bus that is secured by default. The security settings for the bus are stored in a security domain. When you add a new bus, you can assign it to the default global security domain, the cell-level domain, or specify a custom domain that contains a set of settings that are unique to the bus, or shared with another resource.

Before you begin

- Plan the security requirements for the bus. For more information about security planning, see Service integration security planning. For more information about security domains, see Messaging security and multiple security domains.
- Stop all servers that have the SIB Service enabled. This ensures that the bus security configuration is applied consistently when the servers are restarted. For more information, see Stopping an application server.

About this task

This task uses an administrative console security wizard to add a new bus. If the wizard detects that administrative security is disabled, it prompts you to configure a user repository, and enable administrative security.

By default, connecting clients are required to use SSL protected transports to ensure data confidentiality and integrity. If you do not want clients to use SSL protected transports, you can specify that you do not require this option.

The type of security domain you can specify for the bus depends on the versions of the bus members you intend to add to the bus:

- You must specify the global domain if you want to add one or more WebSphere Application Server Version 6 bus members.
- You can specify the global, cell-level, or custom domain if you want to add WebSphere Application Server Version 7.0 or later bus members only.

Procedure

1. In the navigation pane, click **Service integration -> Buses**. A list of buses is displayed.
2. Click **New**.
3. Type a name for the new bus. You must choose bus names that are compatible with the WebSphere MQ queue manager naming restrictions. You cannot change a bus name after the bus is created, which means that you can only interoperate with WebSphere MQ in the future if you use compatible names. See the topic about WebSphere MQ naming restrictions in the related links.
4. Ensure that the **Bus security** check box is selected.
5. Click **Next**. The Bus Security Configuration wizard is started.
6. Read the Introduction panel, and click **Next**.

7. If the wizard detects that administrative security is disabled, follow the prompts to select, and configure the appropriate user repository.
8. Click **Next**. A summary of the administrative security settings for the bus is displayed.
9. Review the summary, and click **Finish**. Administrative security for the cell is now enabled.
10. If you do not want clients to use SSL protected transports, clear the check box **Require clients use SSL protected transports** .
11. Select a security domain for the bus.
12. If you have selected to use a custom security domain, follow the prompts to specify a user realm.
13. Review the summary of your choices, and click **Finish**.
14. Save your changes to the master configuration.

Results

You have created a new bus secured with your chosen security settings.

What to do next

- You must restart the servers. Starting an application server provides more information.
- You can add bus members to the bus.
- Groups of users in the user repository require explicit authority to access the bus. For more information, see Administering authorization permissions.

Adding an unsecured bus:

By default, bus security is enabled and you add buses with security configured. However, you can add a new service integration bus without any security settings. If you want to secure the bus at a later date, you can do so by configuring the security settings for the bus.

About this task

To add a bus, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Service integration -> Buses**. A list of buses is displayed.
2. In the content pane, click **New**.
3. Type a name for the new bus. You must choose bus names that are compatible with the WebSphere MQ queue manager naming restrictions. You cannot change a bus name after the bus is created, which means that you can only interoperate with WebSphere MQ in the future if you use compatible names. See the topic about WebSphere MQ naming restrictions in the related links.
4. Clear the **Bus security** check box to disable bus security.
5. Click **Next**.
6. Review the summary of the settings for the new bus, then click **Finish**.
7. Save your changes to the master configuration.

Results

Bus security is disabled, and you have added a new unsecured service integration bus.

What to do next

You can now add servers to the bus.

Configuring bus properties

You can configure how many messages the bus can handle, when to discard messages, and which messaging engines the bus can communicate with. You can also specify changes that can be made to the bus that do not require a restart of the messaging engines.

About this task

You configure bus properties after you have created a bus. To configure the properties of a bus, use the administrative console to complete the following steps:

Procedure

1. Click **Service integration -> Buses -> *bus_name***.
2. Specify the following properties for the bus:

   Description
   A service integration bus supports applications using message-based and service-oriented architectures. A bus is a group of interconnected servers and clusters that have been added as members of the bus. Applications connect to a bus at one of the messaging engines associated with its bus members.

   Inter-engine transport chain
   The transport chain used for communication between messaging engines in this bus.

   The transport chain must correspond to one of the transport chains defined in the *Messaging engine inbound transports* settings for the server. All servers automatically have a number of transport chains defined to them, and it is also possible to create new transport chains.

   When you specify the name of a transport chain, that chain must be defined to all servers hosting messaging engines in the bus. Otherwise, some messaging engines might not be able to communicate with their peers in the bus.

   When the use of permitted chains is enforced and a protocol is not specified for intra-bus communications then InboundSecureMessaging is assumed instead of InboundBasicMessaging. This can be overridden by setting the protocol attribute in the bus configuration. If InboundSecureMessaging is not a permitted chain then an error occurs.

   Discard messages
   Whether messages on a deleted message point should be retained at a system exception destination or can be discarded. Select this option to indicate that after a queue has been deleted, any messages left in the data store for that queue should be discarded.

   Configuration reload enabled
   Select this option to enable automatic update of configuration information on all the messaging engines on the bus.

   Changes to bus destinations or mediations are applied when destinations or mediations are added to or removed from the bus.

   Changes to the modifiable configuration information for any foreign bus connections are also updated automatically. The time when these changes take effect varies:

   Foreign Bus Connection properties
   Immediately

   WebSphere MQ link properties
   On channel restart, except Description (immediately), and Initial State (on messaging engine restart)

   MQ sender channel properties
   On channel restart, except Initial State (on messaging engine restart or sender channel creation)

MQ receiver channel properties
On channel restart, except Initial State (on messaging engine restart or receiver channel creation)

Publish/subscribe broker profile (0 to n) properties
Immediately

Service integration bus link properties
On link restart, except Description (immediately), and Initial State (on messaging engine restart or link creation)

To ensure that dynamic configuration updates are made on an application server, click **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] SIB service** then select **Configuration reload enabled**.

To ensure that dynamic configuration updates are made to each node, click **System administration -> Console Preferences** to display the Console Preferences window then select **Synchronize changes with nodes**.

Default messaging engine high message threshold
A threshold above which the messaging system will take action to limit the addition of more messages to a message point. When a messaging engine is created on the bus, the value of this property is used to set the default high message threshold for the messaging engine.

3. Specify topology, destination resources, web services and additional properties for the bus, as required. To restrict the number of audit messages, add a custom property called `audit.bus.authentication` with one of the following values:
   - `all` (audit all attempts to authenticate to the bus)
   - `failure` (audit only failure to authenticate to the bus)
   - `none` (do not audit any attempts to authenticate to the bus)
4. Click **OK**.
5. Save your changes to the master configuration.

Listing the buses

You can view the list of the service integration buses that currently exist. You can decide which buses you want to change, for example, to add a server to a bus.

About this task

To list the buses, use the administrative console to complete the following step. After you list the service integration buses, you can add or delete a bus. Also, you can select a bus to view its details, add a member to the bus, create a foreign bus connection, or apply security to the bus.

Procedure

In the navigation pane, click **Service integration -> Buses**.

Results

A list of buses is displayed in the content pane.

What to do next

You can now add or delete buses, or click on a bus name to display or configure its properties.

Displaying the topology of a service integration bus

You can display a tree view of the members of a bus, and the messaging engines used by a selected bus, in the administrative console. You can also view the runtime status for each messaging engine.

About this task

Use this task to display a *local topology* view of the bus members and messaging engines in a service integration bus. You can use this view to add servers as members of the bus.

To display the local topology view of a service integration bus, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Service integration -> Buses**. A list of buses is displayed in the content pane.
2. In the content pane, click the name of the bus. For example, `SCA.SYSTEM.localhostCell01.Bus`
3. Click the tab **Local Topology**

Results

The topology of the bus is displayed as an expandable tree.

What to do next

You can expand nodes of the tree to display the bus members and their messaging engines.

You can add servers as members of the bus.

Deleting a bus

You can delete a service integration bus, for example if it is no longer in use.

Before you begin

Attention: When you delete a bus, each messaging engine on the bus is also deleted and any associated messages are discarded. If you subsequently create a new bus with the same name as the deleted bus, the new bus will not have the same universal unique identifier (UUID) as the deleted bus.

About this task

To delete a bus, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click **Service integration -> Buses**. A list of buses is displayed in the content pane.
2. In the content pane, select the bus that you want to delete.
3. Click **Delete**.
4. Click **OK**.
5. Save your changes to the master configuration.

What to do next

You must disable the SIB Service at server startup.

Configuring the members of a bus

Use the administrative console to add, remove, and list the members of a bus.

Adding a server as a new bus member:

The members of a service integration bus are the application servers and clusters within which messaging engines for that bus can run. When you add a new bus member, you configure its message store, which is either a file store or a data store.

About this task

If you add a server as a member of a bus, WebSphere Application Server creates a messaging engine for the server. By default, the messaging engine is configured to use a file store. If you choose a data store, you have the choice of using the default JDBC data source and Derby JDBC Provider for its data store. If you do not want to use the default data source configuration, you can choose to use a different data source or you can configure the data store to use a different JDBC provider.

If you subsequently delete a bus member and then recreate it, you should make sure that you understand the life cycle of the file store or a data store. Refer to Data store life cycle and "Removing a messaging engine from a bus" on page 1898 for details.

If you are working in a mixed-version cell, a service integration bus running in this version of the product can only include WebSphere Application Server Version 6 bus members that are running in the following versions of the product:

- 6.0.2 (Fix Pack 23 or later)
- 6.1.0 (Fix Pack 13 or later)

If security is enabled, and the bus has mixed-version bus members, the bus members establish trust by using an inter-engine authentication alias. If you add a server as a bus member at WebSphere Application Server Version 6, and it is the first bus member at this level, you must select or create an authentication alias during this task. This action sets the inter-engine authentication alias.

You can optionally tune the initial and maximum Java virtual machine (JVM) heap sizes. Tuning the heap sizes helps to ensure that application servers hosting one or more messaging engines are provided with an appropriate amount of memory for the message throughput you require.

Procedure

1. In the navigation pane, click **Service integration -> Buses -> *bus_name* -> [Topology] Bus members**. A list of members in the bus is displayed.
2. Click **Add**.
3. Select scope of the new bus member: this is one of *Server*, *Cluster* or *WebSphere MQ server*. **Server** is selected by default. Only select the **Cluster** scope in WebSphere Application Server environments that support server clusters.
4. Make your selection and click **Next**.
5. Select the type of message store: it is either a file store or a data store. For more information, see File stores and Data stores. **File store** is selected by default.
6. Click **Next**.

   Optional: If you use a file store and want to change the default values, you can change them here. For more information refer to "Modifying file store configuration" on page 1954.

   Optional: If you use a data store and want the messaging engine in the bus member to use a non-default data source, select **Use existing data source** and enter the JNDI name of an existing data source, and the name of the schema and authentication alias to be used. For more information, see "Configuring a messaging engine to use a data store" on page 1957. If there are multiple messaging engines, you must configure each messaging engine to use a unique schema, otherwise FFDC error messages stating that `Connection cannot be provided as Datasource has been disabled!` might appear. This applies to DB2 in particular.

7. Click **Next**.

   Optional: You can view the current settings of the initial and maximum Java Virtual Machine (JVM) heap sizes. If you want to tune performance by changing the current settings, select the **Change heap sizes** check box and enter the required changes in the **Proposed heap sizes** fields.
8. Click **Next**.
9. If security is enabled, and adding this server creates a mixed-version bus, the wizard prompts for an authentication alias. Do one of the following:
   - Select an existing authentication alias.
   - Create a new authentication alias. Specify a unique alias name and password.

   This action sets the inter-engine authentication alias.
10. Click **Finish** to confirm the creation of the bus member.
11. Save your changes to the master configuration. You must restart the server for the changes to take effect.

Results

The member is added to the bus and a messaging engine is created for that member.

What to do next

Next, you can configure the messaging engine. For more information about configuring messaging engines and their message stores, see the related tasks.

Adding a WebSphere MQ server as a member of a bus:

A WebSphere MQ server represents a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. A WebSphere MQ server bus member is used as a bus member for assigning queue points and mediation points to WebSphere MQ queues.

Before you begin

Get details of the client connection from your WebSphere MQ administrator.

Ensure that the WebSphere MQ server has been configured, that the bus has been defined and that the server is not already a member of the bus.

Decide which method to use to configure these resources. You can add the WebSphere MQ server as a bus member by using the administrative console as described in this task, or by using the “addSIBusMember command” on page 2268.

About this task

When you add a WebSphere MQ server to one or more buses, messaging engines on these buses can access queues on the target WebSphere MQ installation. When you make the server a bus member, you can override the server connection settings with settings that are specific to the new bus member. This can be useful in a multiple bus topology.

Procedure

1. Start the administrative console.
2. Navigate to the list of bus members for the bus to which you are adding the WebSphere MQ server. Click **Service integration -> Buses -> *bus_name* -> [Topology] Bus members**.

3. Click **Add**. The “Add a new bus member” wizard is displayed.
4. Select the WebSphere MQ server to add to the bus:
   a. Select **WebSphere MQ server**.
   b. From the drop-down list, select the server to add.
   c. Click **Next**.
5. Specify the virtual queue manager name.

   When sending messages to WebSphere MQ, the WebSphere MQ gateway queue manager sees the bus as a remote queue manager. The virtual queue manager name is the name that is passed to WebSphere MQ as the name of this remote queue manager. The default value is the name of the bus. If this value is not a valid name for a WebSphere MQ queue manager, or if another WebSphere MQ queue manager already exists that has the same name, then replace the default value with another value that is a valid and unique name for a WebSphere MQ queue manager. To be valid, the name must meet the following criteria:
   - It must contain between 1 and 48 characters.
   - It must conform to the WebSphere MQ queue naming rules (see the *Rules for naming WebSphere MQ objects* topic in the WebSphere MQ information center).
6. Optional: To override the server connection settings, select the **Override WebSphere MQ server connection properties** check box.

   When you select this option, the connection properties for the server are made available so that you can change them to settings that are specific to this bus member. For more information about these connection properties, see “WebSphere MQ server bus member [Settings]” on page 2250.
7. Optional: If you have changed the server connection settings, you can click **Test connection** to test the connection to the associated WebSphere MQ network.
8. Click **Next**.
9. Click **Finish** to confirm.
10. Save your changes to the master configuration.

What to do next

You are now ready to create a WebSphere MQ queue-type destination for the new bus member.

Listing the members of a bus:

You can display a list of servers that have been added as members of a bus.

About this task

You can list the members of a bus, then you can add, remove, or edit the bus members. To list the members of a bus, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click **Service integration -> Buses**. A list of buses is displayed in the content pane.
2. In the content pane, select the bus whose members you want to list.
3. In the content pane, under **Topology**, click **Bus members**. A list of members of the bus is displayed.

Removing a member from a bus:

You can remove an application server from a bus so that it is no longer used to process messages.

Before you begin

Attention:

- When you remove a member from a bus, all messaging engines on that bus member are also deleted and their associated messages are discarded. If you add the same bus member again, first you must manually delete the old data source for the messaging engines to ensure that once the new messaging engines are created, they can restart.
- If you remove a member from a bus, and it is the only member for that server, you must also disable the SIB Service at server start up.

About this task

To remove a member from a bus, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Service integration -> Buses**. A list of buses is displayed in the content pane.
2. In the content pane, select the bus from which you want to remove the member.
3. In the content pane, under **Topology**, click **Bus members**. A list of members in the bus is displayed.
4. Select the bus member that you want to remove.
5. Click **Remove**.
6. Save your changes to the master configuration.

Results

The member is removed from the bus. All the messaging engines on that bus member and the core group policies that are associated with those messaging engines are deleted.

What to do next

If you have removed the only bus member for a server, you must now disable the SIB Service at server start up.

Disabling the service integration service:

The SIB Service, which provides messaging capability, is enabled automatically when you add a server to a service integration bus. If required, you can disable service integration bus functions when the application server starts.

About this task

You can choose to disable the SIB Service, for example if you have removed the only bus member for a server.

You can use the administrative console to disable the SIB Service, or wsadmin scripting. The following example shows a Jython script for disabling the SIB Service:

```
server = AdminConfig.getid('/Server:server1/')
sibService = AdminConfig.list('SIBService', server)
AdminConfig.modify(sibService, [["enable", "false"]])
```

To use the administrative console to disable the SIB Service, complete the following steps.

Procedure

1. Click **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] SIB service** to display the SIB service settings pane.
2. Click the Configuration tab to display configuration properties for the service integration service.
3. Clear the Enable service at server startup check box.
4. Save your changes to the master configuration.

Results

You have disabled the SIB Service. Service integration bus functions are not available when the application server starts up.

Administering bootstrap members for a bus

A service integration bus can have bootstrap members. These are bus members, cell members for which the Service Integration Bus Service is enabled, or nominated cell members that can service requests to bootstrap into the bus, depending on the bootstrap policy configured for the bus.

Before you begin

Note: If the bus is in a mixed-version cell, the deployment manager must be at a Version 7.0 or later level.

About this task

You can configure the bootstrap member policy for a bus, nominate, list and delete bootstrap members for a selected bus as follows:

Configuring a bootstrap member policy for a bus:

By configuring a bootstrap member policy for a selected service integration bus, you control which servers respond to bootstrap requests from client applications.

Before you begin

Note: If the bus is in a mixed-version cell, the deployment manager must be at a Version 7.0 or later level.

About this task

A bus can use bootstrap members to service connection requests from client applications. In this task, you define a bootstrap member policy for a selected bus that defines which servers can bootstrap into the bus. The default bootstrap member policy is all cell members that have the Service Integration Bus Service enabled. You can restrict bootstrap membership to bus members only, or to bus members, and nominated bootstrap members. These are servers that are not bus members, but have been nominated as bootstrap members.

Procedure

1. Log onto the administrative console.
2. Click **Service integration -> Buses -> *bus_name***. The configuration panel for the selected bus is displayed.
3. Choose one of the following bootstrap members policies for the bus:

   All members of the cell with the Service Integration Bus Service enabled
   This is the default option. All the servers in the cell that have the Service Integration Bus Service enabled are bootstrap members.

Bus members and nominated bootstrap members
Bootstrap membership is restricted to servers that are bus members, or have been nominated as bootstrap members.

Bus members only
Bootstrap membership is restricted to servers that are bus members.

4. Click **Apply**.
5. Save your changes to the master configuration.

Results

Requests from client applications to connect to the bus are serviced by the servers in the cell that meet the criteria set by the bootstrap member policy you have configured for the bus.

What to do next

Use the administrative console to list, nominate or delete bootstrap members for the selected bus.

Listing the bootstrap members for a bus:

Use this task to find out which servers in the cell are available to service requests from clients to connect to a particular service integration bus. The list of available servers is restricted by the bootstrap member policy configured for the bus.

Before you begin

You must ensure that the appropriate bootstrap member policy has been configured for the bus. For more information, see “Configuring a bootstrap member policy for a bus” on page 1894.

About this task

In this task, you use the administrative console to list the bootstrap members for a selected bus. The list of bootstrap members depends on which of the following bootstrap member policies is configured for the bus:

All members of the cell with the Service Integration Bus Service enabled
This is the default policy. The list includes all the WebSphere Application ServerVersion 7.0 or later servers in the cell that have the Service Integration Bus Service enabled.

Bus members and nominated bootstrap members
The list includes all the servers that are bus members, or have been nominated as bootstrap members.

Bus members only
The list includes only servers that are members of the bus.

Procedure

1. Log into the administrative console.
2. Click **Service integration -> Buses -> *bus_name* -> [Topology] Bootstrap members**.

Results

A list of the bootstrap members for the selected bus is displayed.

What to do next

You can use the administrative console to nominate or remove bootstrap members, or configure a different bootstrap member policy for the bus.

Nominating bootstrap members for a bus:

You can nominate one or more servers on cell nodes as bootstrap members for a selected bus. When the Bus members and nominated bootstrap members policy is configured for the bus, the nominated bootstrap members can service requests from client applications to connect to the bus.

Before you begin

Note: You must ensure that the following requirements are met:

- If the bus is in a mixed-version cell, the deployment manager must be at a Version 7.0 or later level.
- The servers that you want to nominate as bootstrap members must be on Version 7.0 or later cell nodes.

About this task

In this task, you use an administrative console wizard to configure the **Bus members and nominated bootstrap members** policy, and nominate bootstrap members for a selected bus.

Procedure

1. Log onto the administrative console.
2. Click **Service integration -> Buses -> *bus_name* -> [Topology] Bootstrap members**. The Bootstrap members panel displays all the bus members, servers in the cell that have the Service Integration Bus Service enabled.
3. Select the policy **Bus members and nominated bootstrap members**.
4. Click **Apply**. A list of current bus members, and nominated bootstrap members is displayed.
5. Click **New**. The Nominate a bootstrap server wizard is started.
6. Type the name of the server that you want to add in the **Name** field. The first match in the list of available servers and clusters is highlighted. Click **Add** to add the named server to the list of servers to add.
7. When you have listed all the servers that you want to add, click **Next**.
8. Review the summary of the servers that you have chosen to add.
9. If you want to change your selections:
   a. Click **Previous** to return to the first step of the wizard.
   b. Make the changes you require, and click **Next**.
10. Click **Finish** to add the new bootstrap members to the local configuration.
11. Save your changes to the master configuration. An updated list of bus members and nominated bootstrap members is displayed.

Results

The nominated servers can service requests from client applications to bootstrap into the bus.

Deleting nominated bootstrap members from a bus:

Deleting a nominated bootstrap member from a selected service integration bus prevents the server from servicing requests from client applications to bootstrap into the bus.

Before you begin

You must configure the **Bus members and nominated bootstrap members** policy for the selected bus. For more information, refer to “Configuring a bootstrap member policy for a bus” on page 1894.

About this task

In this task, you use the administrative console to list all the bootstrap members for a selected bus, and then delete the nominated bootstrap members that you no longer want to use to bootstrap into the bus. Note that you can delete only nominated bootstrap members.

Procedure

1. Log onto the administrative console.
2. Click **Service integration -> Buses -> *bus_name* -> [Topology] Bootstrap members**. All the nominated bootstrap members for the bus are listed.
3. Select the nominated bootstrap members that you no longer want to use to bootstrap into the bus, and click **Delete**. The Bootstrap members panel displays an updated list of bootstrap members.
4. Save your changes to the master configuration.

Results

You cannot use the deleted nominated bootstrap members to bootstrap into the selected bus.

Configuring messaging engines

You can configure messaging engines in a variety of ways. For example, you can create and apply security to a messaging engine, then use this engine to send and receive messages. When you add a server cluster to a service integration bus, at least one messaging engine is created automatically. If you also use messaging engine policy assistance, some configuration properties are set automatically.

Configuring messaging engine properties:

You can configure the properties of a messaging engine in the administrative console. For example you can select whether the messaging engine is started automatically when its associated application server is started, how many messages it can process, and target groups that the engine can join.

About this task

In most cases, you can configure the properties of a messaging engine without interrupting the processing of messages by the messaging engine.

Procedure

1. Start the administrative console.
2. Navigate to **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name***.
3. Configure the messaging engine properties. For information about the properties that you can configure, see the property descriptions in “Messaging engines [Settings]” on page 2124
4. Click **OK**.
5. Save your changes to the master configuration.

Listing the messaging engines in a bus:

You can view the list of existing messaging engines in a bus by using the administrative console. You can decide which messaging engines you want to change, for example which buses they are associated with.

About this task

To list the messaging engines in a bus, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click **Service integration -> Buses**.
2. In the content pane, click the name of the bus that your messaging engine belongs to.
3. In the content pane, under **Topology**, click **Messaging engines**. The list of messaging engines in the bus is displayed.

Removing a messaging engine from a bus:

You can remove a messaging engine from a service integration bus if you no longer require it to send and receive messages on the bus.

Before you begin

You should be wary of deleting and recreating messaging engines on bus members for which WS-Notification-administered subscribers have been configured, because in some cases this can leave the remote web service subscription active (and passing notification messages to the local server) even though there is no longer any record of it. For more information, see the WS-Notification troubleshooting tip Problems can occur when deleting administered subscribers and messaging engines.

Procedure

1. Stop the messaging engine. You can stop either in **Immediate** or **Force** mode, as described in "Stopping a messaging engine" on page 1951.
2. Use the wsadmin command deleteSIBEngine to delete the messaging engine. All service integration bus links, MQ links, and custom properties that are owned by the engine are deleted.

   Note: When you remove a messaging engine, WebSphere Application Server does not delete the data store tables automatically. You must remove them manually, or delete all the rows in all the tables. If you do this, a new messaging engine might fail to start if it attempts to use an orphaned data store. Refer to the documentation for your chosen relational database management system for information about deleting tables.

   Alternatively, for Apache Derby, you can delete the database directory, which is located in *profile_root*/databases/com.ibm.ws.sib, where *profile_root* is the directory in which profile-specific information is stored. However, do this only if the messaging engine is the sole user of the database.

   For more information, see Data store life cycle.

   Similarly, the file store files are not automatically deleted when you delete the messaging engine. You might want to delete the file store files to reclaim disk space.

Listing the messaging engines defined for a server bus member:

You can display a list of messaging engines defined for a server bus member by using the administrative console. You can decide which messaging engines you want to change, for example, which buses they are associated with.

About this task

To display the list of messaging engines, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click either **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines** or **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] Messaging engines**. A list of messaging engines is displayed in the content pane.
2. Optional: Select one or more messaging engines to work with, for example to change the properties of the messaging engine.

Creating the database, schema and user ID for a messaging engine:

Before the data store for a messaging engine can be set up, you must first create the database, the schema and the database user ID that the messaging engine needs to access the data store tables.

Before you begin

Before you start this task, review the information in Configuration planning for a messaging engine to use a data store, and ensure that you have taken any appropriate action.

About this task

To create the database, schema and user ID for a messaging engine, complete the following steps.

Procedure

1. Create the database for the data store.
2. Create users and schemas in the database. Ensure that the user ID has sufficient privilege to allow the messaging engine to access the data store tables. For more information about the privileges that are required for the selected database, see “Database privileges” on page 1967.
3. If required, create the data store tables by using the data definition language (DDL) statements generated by using the sibDDLGenerator command.

Configuring a messaging engine data store to use a data source:

After configuring a JDBC data source, you can configure a messaging engine data store to use the data source.

Before you begin

To complete this task, you must have chosen or created a bus and a messaging engine, and the messaging engine must specify data store as its message store type.

You must also have configured a data source, as described in “Creating the database, schema and user ID for a messaging engine.”

About this task

A messaging engine uses an instance of a JDBC data source to interact with the database that contains the data store for that messaging engine.

Use the WebSphere Application Server administrative console to set the data store configuration parameters.

Procedure

1. In the navigation pane, click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name***.

2. Check that the **Message store type** is *Data store*.
3. Click **[Additional Properties] Message store**. The data store configuration detail panel is displayed.
4. Specify the following data store configuration details:

Data source JNDI name
Type the JNDI name of the data source that provides access to database that holds the data store.

Schema name
Type the name of the database schema that contains the tables used by the data store.

General tip: The schema name is usually the same as the user ID that is declared in the authentication alias. With some databases, for example DB2, you can provide an alternative schema name. For more information about the relationship between users and schema, refer to the documentation for your chosen RDBMS.

Informix tip: When you configure your messaging engine to use an Informix database, you must specify the schema name in lowercase letters.

When it is starting, a messaging engine that uses a data store checks to see if its data store exists. If the **Create tables** option is selected for the configuration, the messaging engine creates the tables in its chosen schema.

The **Schema name** field is optional. If you require a schema name, consider the following:

- The default schema name is `IBMWSSIB`.
- If you delete the text so that field is blank, the messaging engine takes the user id defined in the authentication alias to be the schema name.
- If you define a schema name explicitly, that schema name is used by the messaging engine.
- If there are multiple messaging engines, you must configure each messaging engine to use a unique schema, otherwise FFDC error messages stating that `Connection cannot be provided as Datasource has been disabled!` might appear. This applies to DB2 in particular.

Authentication alias
Select the authentication alias that enables access to the data source.

Apache Derby Tip: When you create a new Network Attached Apache Derby data store, by default you get a blank authentication alias.

Create tables
Select the check box if you want WebSphere Application Server to create the database tables automatically.

Note: The user ID that the messaging engine uses to connect to the data source must have sufficient authority to create the database tables and indexes.

DB2 for z/OS restriction: Do not select **Create tables** if you are using DB2 for z/OS, otherwise an exception will be thrown when WebSphere Application Server attempts to create the tables.

Number of tables for permanent objects
Permanent tables contain persistent objects for the data store.

Note: You can only increase the number of permanent tables, not decrease them.

Number of tables for temporary objects
Temporary tables contain nonpersistent objects that have been saved to the data store to reduce the messaging engine memory requirement.

Note: You can only increase the number of temporary tables, not decrease them.

Configuring service integration bus links:

You can configure service integration bus links on messaging engines in a variety of ways. For example, you can start, stop, or remove links.

About this task

When you create a foreign bus connection to connect two service integration buses, a service integration bus link is created automatically. The foreign bus connection contains a routing definition, which is a virtual link, and the service integration bus link is the corresponding physical link on the messaging engine.

Configuring foreign bus connections:

You can configure a bus to connect to, and exchange messages with, other messaging networks. To do this, you must configure a foreign bus connection. A foreign bus connection encapsulates information related to the remote messaging network, such as the type of the foreign bus and whether messaging applications are allowed to send messages to the foreign bus.

About this task

A foreign bus connection is associated with a service integration bus. The bus with which the foreign bus connection is associated is known as the local bus. The foreign bus connection represents another service integration bus, either in the same cell as the local bus or in a different cell, or it represents a WebSphere MQ queue manager. From the local bus, every other bus is regarded as a foreign bus, even if it is a bus in the same cell.

Messages route to a foreign bus either directly through a link between the local bus and the foreign bus, or indirectly through one or more intermediate buses.

If, when you configure the local bus, you select **Configuration reload enabled**, future changes to the configuration information for any foreign bus connections are updated automatically. The time when these changes take effect varies:

Foreign Bus Connection properties
: Immediately

WebSphere MQ link properties
: On channel restart, except Description (immediately), and Initial State (on messaging engine restart)

MQ sender channel properties
: On channel restart, except Initial State (on messaging engine restart or sender channel creation)

MQ receiver channel properties
: On channel restart, except Initial State (on messaging engine restart or receiver channel creation)

Publish/subscribe broker profile (0 to n) properties
: Immediately

Service integration bus link properties
: On link restart, except Description (immediately), and Initial State (on messaging engine restart or link creation)

To ensure that dynamic configuration updates are made to each node, click **System administration -> Console Preferences** to display the Console Preferences window, then select **Synchronize changes with nodes**.

Configuring the properties of a service integration bus link:

After establishing a service integration bus link you might want to configure the properties of a service integration bus link such as the name of the service integration bus link, or authentication alias used by foreign bus that the link connects to.

About this task

To configure the properties of a service integration bus link, use the administrative console to complete the following steps:

Procedure

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine for which you want to configure the service integration bus link.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you want to configure.
5. Specify the following properties for the service integration bus link:

   Name The name of the service integration bus link. In order to work, the name must be the same as the name of the corresponding service integration bus link configured on the target foreign bus.

   Description
   An optional description for the service integration bus link, for administrative purposes.

   UUID The universal unique identifier assigned by the system to the service integration bus link for administrative purposes.

   Foreign messaging engine
   The messaging engine on the foreign bus to which this link connects.

   Note: This foreign bus name must not be altered after it has been configured. If you alter it, any messaging engines that already hold state information on the link will not be able to use the link unless the foreign bus name is reset to its original value.

   Target inbound transport chain
   The type of transport chain used for communication with the foreign bus. The transport chain name must be the name of the transport chain as defined on the server on which the target messaging engine is hosted.

   Bootstrap endpoints
   The comma-separated list of endpoints used to connect to a bootstrap server. This property is set in the same way as the **Provider endpoint** property in the JMS connection factory settings. For more information, see the steps relating to setting bootstrap endpoints in “Configuring a connection to a non-default bootstrap server” on page 531.

   Note: Service integration bus links over BootstrapTunneledMessaging and BootstrapTunneledSecureMessaging transport chains only work directly between application server instances. Bus links over TunneledMessaging transport chains do not work if an HTTP server is placed in front of either application server instance.

   Authentication alias
   The name of the authentication alias, used to authenticate access to the foreign bus. The alias must be known to the foreign bus.

   Initial state
   Whether the link is started automatically when the messaging engine is started. Until started,

the gateway link is unavailable. If this property is set to **Started** the service integration bus link is started when the messaging engine is started.

6. Click **OK**.
7. Save your changes to the master configuration.

Listing the service integration bus links:

You can list all the service integration bus links that are linked to a messaging engine.

About this task

To list the service integration bus links for a messaging engine, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Service integration -> Buses**.
2. In the content pane, click the name of the bus that your messaging engine belongs to.
3. In the content pane, under **Additional properties**, click **Messaging engines**. The list of messaging engines in the bus is displayed.
4. In the content pane, select the messaging engine for which you want to list the service integration bus links.
5. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.

Example

The following combinations of **Status** and **Activity** values are possible:

Table 205. Results of possible status and activity values. The first and second columns of the table provide the possible combinations of status and activity values, and the third column explains the possible connection status of the local and foreign buses.

Status	Activity	Meaning
started	inactive	The service integration bus link is started on the local messaging engine but has no connection to the foreign bus. The service integration bus link is attempting to activate a connection to the foreign bus. The service integration bus link on the foreign bus must also be started to successfully activate of a connection between the buses.
started	active	The service integration bus link is started on the local messaging engine and has an active connection to the foreign bus.
stopped	inactive	The service integration bus link is stopped on the local messaging engine and there is no connection to the foreign bus.
unknown	inactive	An error might have occurred in setting up the link, such that the object that is used to report the current state is not available.

What to do next

You can now add or remove a service integration bus link or select a service integration bus link to start, stop, or configure.

Starting a service integration bus link:

When a service integration bus link has been started, it can be used for communicating with its associated messaging engines.

About this task

To start a service integration bus link, use the administrative console to complete the following steps:

Procedure

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine for which you want to start the service integration bus link.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you want to start.
5. Click **Start**.

Stopping a service integration bus link:

When a service integration bus link has been stopped, it cannot be used for communication until it is restarted.

About this task

To stop a service integration bus link, use the administrative console to complete the following steps:

Procedure

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine to which the service integration bus link that you want to stop belongs.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you want to stop.
5. Click **Stop**.

Removing a service integration bus link:

When a service integration bus link to a messaging engine has been removed, it cannot be used for communication until it is recreated.

Before you begin

Before you remove the service integration bus link you must stop the link.

When you remove a service integration bus link, all traffic that uses the link needs to be dealt with in a similar way to when you remove a destination. For further details, see “Deleting a non-topic space bus destination” on page 1997. Note that express Quality of Service (QoS) messages are discarded.

About this task

To remove a service integration bus link from a messaging engine, use the administrative console to complete the following steps:

Procedure

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine that is associated with the service integration bus link that you want to remove.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you want to remove.
5. Click **Delete**.
6. Save your changes to the master configuration.

What to do next

When you remove a service integration bus link, all traffic that uses the link must be diverted by alternative routes or held pending further administrative action. Express QoS messages are discarded.

Configuring bus destinations

Use the following tasks to configure permanent bus destinations on service integration buses.

About this task

The steps involved in configuring a bus destination depend on the intended usage of the destination.

For example, the following figure shows a basic scenario based on an application using a JMS queue for point-to-point messaging. A producing application sends messages to a JMS queue from which a consuming application retrieves the messages. The JMS queue is assigned to a queue destination and its associated queue point, where messages are stored.

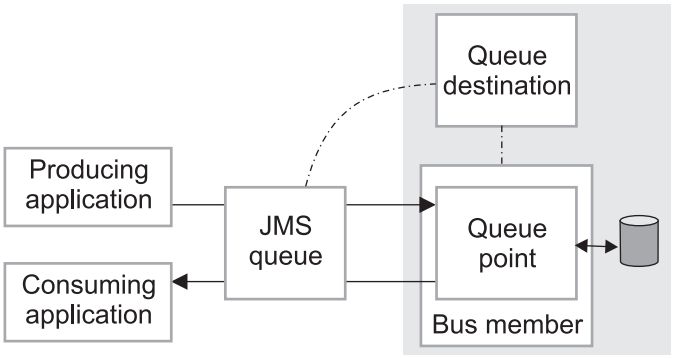

Figure 36. Application use of destinations - basic case

To enable the JMS applications to use a queue destination, you configure the following administrative destination objects:

1. A queue destination on a service integration bus. This configures the properties of the queue, such as the name, and associates the queue with one bus member (an application server). This also automatically configures, on the bus member, a queue point where messages for the queue are held and processed.
2. A JMS queue, which configures the name that applications can use to look up the queue in JNDI. The JMS queue encapsulates the name of the queue destination, as defined in the queue destination above, together with other properties to be used by applications.

After you have created a queue destination, you can optionally configure the queue point to override some properties configured on the queue destination. You can also undertake other configuration tasks on the destination and its queue point, and can act on the runtime view.

Each messaging engine has a default exception destination, named `_SYSTEM.Exception.Destinaton.`*`messaging_engine_name`*. This exception destination can be used to handle messages that cannot be delivered for all bus destinations that are localized to the messaging engine. Each bus destination can be configured with a non-default exception destination.

For more information about configuring bus destinations, see the following topics:
- Listing bus destinations
- Creating a bus destination
- Configuring qualities of service for a destination
- Deleting a non-topic space bus destination
- Deleting a topic space

Connecting buses

You can connect several service integration buses in a network directly, or indirectly, by creating and configuring foreign bus connections. You can connect a service integration bus and a WebSphere MQ queue manager or queue-sharing group in a similar way. You can enable point-to-point or publish/subscribe messaging across multiple buses.

About this task

For a conceptual overview of connecting different service integration buses, including security issues, see Interconnected buses. You can configure a bus to connect to, and exchange messages with, other messaging networks. To do this, you must configure a foreign bus connection. A foreign bus connection encapsulates information related to the remote messaging network, such as the type of the foreign bus and whether messaging applications are allowed to send messages to the foreign bus. Messages route to a foreign bus either directly through a link between the local bus and the foreign bus, or indirectly through one or more intermediate buses.

Configuring foreign bus connections:

You can configure a bus to connect to, and exchange messages with, other messaging networks. To do this, you must configure a foreign bus connection. A foreign bus connection encapsulates information related to the remote messaging network, such as the type of the foreign bus and whether messaging applications are allowed to send messages to the foreign bus.

About this task

A foreign bus connection is associated with a service integration bus. The bus with which the foreign bus connection is associated is known as the local bus. The foreign bus connection represents another service integration bus, either in the same cell as the local bus or in a different cell, or it represents a WebSphere MQ queue manager. From the local bus, every other bus is regarded as a foreign bus, even if it is a bus in the same cell.

Messages route to a foreign bus either directly through a link between the local bus and the foreign bus, or indirectly through one or more intermediate buses.

If, when you configure the local bus, you select **Configuration reload enabled**, future changes to the configuration information for any foreign bus connections are updated automatically. The time when these changes take effect varies:

Foreign Bus Connection properties
: Immediately

WebSphere MQ link properties
On channel restart, except Description (immediately), and Initial State (on messaging engine restart)

MQ sender channel properties
On channel restart, except Initial State (on messaging engine restart or sender channel creation)

MQ receiver channel properties
On channel restart, except Initial State (on messaging engine restart or receiver channel creation)

Publish/subscribe broker profile (0 to n) properties
Immediately

Service integration bus link properties
On link restart, except Description (immediately), and Initial State (on messaging engine restart or link creation)

To ensure that dynamic configuration updates are made to each node, click **System administration -> Console Preferences** to display the Console Preferences window, then select **Synchronize changes with nodes**.

Connecting a bus and a WebSphere MQ gateway queue manager to use point-to-point messaging:

You can connect a service integration bus to a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue sharing group to send or receive messages by using point-to-point messaging. One way to do this is to create a foreign bus connection, where the WebSphere MQ queue manager or queue-sharing group is configured as a foreign bus.

Before you begin

To connect a service integration bus and a WebSphere MQ queue manager or queue-sharing group to use point-to-point messaging, the following resources must be defined in WebSphere Application Server:

- A service integration bus that you want to connect from, known as the local bus. The bus must have at least one bus member.

The following resources must be defined in WebSphere MQ:

- A queue manager or queue-sharing group, which acts as the gateway to the WebSphere MQ network.
- A listener that is configured and running.
- A sender channel (to receive messages on the local bus), a receiver channel (to send messages from the local bus), or both.

About this task

In point-to-point messaging, the sending application specifies the target destination for the message. To receive the message, the receiving application specifies the same destination when it communicates with the messaging provider. Therefore, there is a one-to-one mapping between the sender and receiver of a message.

This task describes one way to achieve point-to-point messaging between WebSphere MQ queue manager or queue-sharing group. For further information about interoperation with a WebSphere MQ network, see the related tasks.

Procedure

1. In the navigation pane, click **Service integration -> Buses**. A list of service integration buses is displayed.
2. In the Buses pane, click the service integration bus that you want to connect from, that is, the local bus.

3. In the configuration tab, under **Topology**, click **Foreign bus connections**.
4. In the Foreign bus connections pane, click **New** to start the Foreign bus connection wizard.
5. In the Bus connection type pane, ensure that **Direct connection** is selected.
6. In the Foreign bus type pane, select **WebSphere MQ**.
7. In the Local bus details pane, select the messaging engine that you want to use and enter the name of the virtual queue manager, that is, the name by which the virtual queue manager of the service integration bus is known to the WebSphere MQ network.
8. In the WebSphere MQ details pane, enter a name for the foreign bus, that is, the bus that represents the WebSphere MQ queue manager. Enter a name for the WebSphere MQ link that connects to the foreign bus. Ensure that these two names are not the same.
9. Ensure that the **Configure publish-subscribe messaging for this connection** check box is clear.
10. To send messages from the local bus to the WebSphere MQ queue manager, complete the following details:
    a. Ensure that **Enable Service integration bus to WebSphere MQ message flow** is selected.
    b. Enter the WebSphere MQ receiver channel name, host name and communication port.
    c. If the WebSphere MQ queue manager requires a secure connection, select the **Is the WebSphere MQ receiver channel secure?** check box. When this option is selected, the WebSphere MQ receiver channel accepts only connections that have secure sockets layer (SSL) based encryption. The connection is successful only if a set of suitably compatible SSL credentials are associated with the service integration bus outbound channel and the WebSphere MQ receiver channel that it connects to.
11. To receive messages on the local bus from the WebSphere MQ queue manager, complete the following details:
    a. Ensure that **Enable WebSphere MQ to Service integration bus message flow** is selected.
    b. Enter the WebSphere MQ sender channel name.
    c. Optionally, enter the service integration bus inbound user ID. When the local bus is secure, the inbound user ID replaces the user ID in messages from the foreign bus that arrive at the local bus and is used to authorize whether those messages can access their destinations. Specify an inbound user ID for the local service integration bus under the following circumstances:
       - The foreign bus is in a different security domain, so user IDs in the foreign bus are not recognized in the local bus.
       - You want local control of access to inbound messages to the local bus.

       If the local bus is not secure, the inbound user ID has no effect on messages. If the local bus is secure, the foreign bus is not secure, and an inbound user ID is not set, an inbound message from the foreign bus is only authorized to destinations that allow unauthenticated users access.
12. When the Foreign bus connection wizard is finished, save your changes to the master configuration.

Results

You have created a connection between a service integration bus and a WebSphere MQ queue manager to use point-to-point messaging. You have created a direct foreign bus connection, which contains a routing definition, or virtual link. The physical link, a WebSphere MQ link on the messaging engine for the local bus, is created automatically.

What to do next

You can test the connection.

Connecting a bus and a WebSphere MQ network to use publish/subscribe messaging:

You can connect a service integration bus and a WebSphere MQ network to send and receive messages by using publish/subscribe messaging. To do this, you create a foreign bus connection, where the WebSphere MQ network is viewed as a foreign bus.

Before you begin

To connect a service integration bus and a WebSphere MQ network to use publish/subscribe messaging, the following resources must be defined in WebSphere Application Server:

- A service integration bus that you want to connect from, known as the local bus. The bus must have at least one bus member.

The following resources must be defined in WebSphere MQ:

- A queue manager or (for WebSphere MQ for z/OS) queue-sharing group, which acts as the gateway to the WebSphere MQ network.
- A listener that is configured and running.
- A topic and input queue for broker publish/subscribe flow configured in WebSphere MQ.
- A sender channel (to receive messages on the local bus), a receiver channel (to send messages from the local bus), or both.

About this task

In publish/subscribe messaging, the sending application publishes messages to an intermediate broker destination. Multiple receiving applications can subscribe to this destination to receive a copy of any messages that are published. When a message arrives at a destination, the messaging provider distributes a copy of the message to all the receiving applications that subscribe to the destination. There can be a one-to-many relationship between the sender and receiver of a message, depending on how many receiving applications are subscribed to a destination when a message arrives.

Procedure

1. In the navigation pane, click **Service integration -> Buses**. A list of service integration buses is displayed.
2. In the Buses pane, click the service integration bus that you want to connect from, that is, the local bus.
3. In the configuration tab, under **Topology**, click **Foreign bus connections**.
4. In the Foreign bus connections pane, click **New** to start the Foreign bus connection wizard.
5. In the Bus connection type pane, ensure that **Direct connection** is selected.
6. In the Foreign bus type pane, select **WebSphere MQ**.
7. In the Local bus details pane, select the messaging engine that you want to use and enter the name of the virtual queue manager, that is, the name by which the virtual queue manager of the service integration bus is known to the WebSphere MQ network.
8. In the WebSphere MQ details pane, complete the following details:
   a. Enter a name for the foreign bus, that is, the bus that represents the WebSphere MQ network.
   b. Enter a name for the WebSphere MQ link that connects to the foreign bus. Ensure that the Foreign bus name and MQ link name are different.
   c. Select the **Configure publish-subscribe messaging for this connection** check box.
9. To send messages from the local bus to the WebSphere MQ network, complete the following details:
   a. Ensure that **Enable Service integration bus to WebSphere MQ message flow** is selected.
   b. Enter the WebSphere MQ receiver channel name, host name and communication port.
   c. If the WebSphere MQ gateway queue manager or queue-sharing group requires a secure connection, select the **Is the WebSphere MQ receiver channel secure?** check box. When this option is selected, the WebSphere MQ receiver channel accepts only connections that have

secure sockets layer (SSL) based encryption. The connection is successful only if a set of suitably compatible SSL credentials are associated with the service integration bus outbound channel and the WebSphere MQ receiver channel that it connects to.

10. To receive messages on the local bus from the WebSphere MQ network, complete the following details:
    a. Ensure that **Enable WebSphere MQ to Service integration bus message flow** is selected.
    b. Enter the WebSphere MQ sender channel name.
    c. Optionally, enter the service integration bus inbound user ID. When the local bus is secure, the inbound user ID replaces the user ID in messages from the foreign bus that arrive at the local bus and is used to authorize whether those messages can access their destinations. Specify an inbound user ID for the local service integration bus under the following circumstances:
       - The foreign bus is in a different security domain, so user IDs in the foreign bus are not recognized in the local bus.
       - You want local control of access to inbound messages to the local bus.

       If the local bus is not secure, the inbound user ID has no effect on messages. If the local bus is secure, the foreign bus is not secure, and an inbound user ID is not set, an inbound message from the foreign bus is only authorized to destinations that allow unauthenticated users access.
11. From the Publish-subscribe details pane, repeat the following steps for each topic mapping you want to create:
    a. Enter the name of the topic on the local bus.
    b. Select the name of the topic space on the local bus that will map to the topic space on the foreign bus.
    c. Enter the name of the gateway queue manager or queue sharing group for the WebSphere MQ broker configured for broker publish/subscribe flow.
    d. To send messages from the local bus to the WebSphere MQ gateway queue manager or queue-sharing group, enter the name of the queue for the WebSphere MQ broker destination.
    e. To receive messages on the local bus from the WebSphere MQ gateway queue manager or queue-sharing group, enter the name of the subscription point that will receive messages.
    f. Select the direction of message flow for the publish/subscribe topic mapping. The options available depend on whether you completed details on the WebSphere MQ details pane to send messages, receive messages, or both, on the local bus.
    g. Click **Add**.
12. When the Foreign bus connection wizard is finished, save your changes to the master configuration.

Results

You have created a connection between a service integration bus and a WebSphere MQ network to use publish/subscribe messaging. You have created a direct foreign bus connection, which contains a routing definition, or virtual link. The physical link, a WebSphere MQ link on the messaging engine for the local bus, is created automatically.

What to do next

You can test the connection.

Connecting service integration buses to use point-to-point messaging:

You can connect a service integration bus to another service integration bus to send and receive messages by using point-to-point messaging. To do this, you create a foreign bus connection.

Before you begin

To connect a service integration bus to another service integration bus to use point-to-point messaging, the following resources must be defined:

- A service integration bus that you want to connect from, known as the local bus. The bus must have at least one bus member.
- A service integration bus that you want to connect to, known as the foreign bus. The bus must have at least one bus member.
- Optionally, to configure a secure connection, an authentication alias.

The buses that you connect must have unique names, because the connection will fail if the buses have the same name.

About this task

In point-to-point messaging, the sending application specifies the target destination for the message. To receive the message, the receiving application specifies the same destination when it communicates with the messaging provider. Therefore, there is a one-to-one mapping between the sender and receiver of a message.

Procedure

1. In the navigation pane, click **Service integration -> Buses**. A list of service integration buses is displayed.
2. In the Buses pane, click the service integration bus that you want to connect from, that is, the local bus.
3. In the configuration tab, under **Topology**, click **Foreign bus connections**.
4. In the Foreign bus connections pane, click **New** to start the Foreign bus connection wizard.
5. In the Bus connection type pane, ensure that **Direct connection** is selected.
6. In the Foreign bus type pane, ensure that **Service integration bus** is selected.
7. In the Local bus details pane, select from the drop-down list the messaging engine that you want to use.
8. Optionally, enter a name for the inbound user ID. When the local bus is secure, the inbound user ID replaces the user ID in messages from the foreign bus that arrive at the local bus and is used to authorize whether those messages can access their destinations. Specify an inbound user ID for the local service integration bus under the following circumstances:
   - The foreign bus is in a different security domain, so user IDs in the foreign bus are not recognized in the local bus.
   - You want local control of access to inbound messages to the local bus.

   If the local bus is not secure, the inbound user ID has no effect on messages. If the local bus is secure, the foreign bus is not secure, and an inbound user ID is not set, an inbound message from the foreign bus is only authorized to destinations that allow unauthenticated users access.
9. In the Foreign bus details pane, complete the details as appropriate:
   - If the service integration bus you want to connect to is in a different cell from the local bus, complete the following details:
     a. Ensure that **Configure a foreign bus in a remote cell** is selected.
     b. Enter the name of the service integration bus to connect to, that is, the foreign bus. Enter the exact name of the existing service integration bus.
     c. Enter the name of the gateway messaging engine in the foreign bus, that is, the messaging engine to connect to in the foreign bus.
     d. Ensure that the **Configure publish-subscribe messaging for this connection** check box is clear.

e. Enter the name of the service integration bus link.

f. Enter one or more bootstrap endpoints, that is, the host, port location, and transport chain for the messaging engine on the foreign bus that the local service integration bus connects to. The port is the SIB_ENDPOINT_ADDRESS (or SIB_ENDPOINT_SECURE_ADDRESS if security is enabled) of the messaging engine. Use the format *hostName*:*portNumber*:*chainName*, separating each bootstrap endpoint by a comma. For more information, see the steps relating to setting bootstrap endpoints in "Configuring a connection to a non-default bootstrap server" on page 531.

- If the service integration bus you want to connect to is in the same cell as the local bus, complete the following details:

  a. Ensure that **Configure a foreign bus in a local cell** is selected.

  b. Select the name of the service integration bus to connect to, that is, the foreign bus.

  c. Select the name of the gateway messaging engine in the foreign bus, that is, the messaging engine to connect to in the foreign bus.

  d. Ensure that the **Configure publish-subscribe messaging for this connection** check box is clear.

  e. Enter the name of the service integration bus link.

10. Optionally, to secure the connection, in the Foreign bus details pane, complete the following details:

    a. Select the **Secure connection** check box.

    b. Select the type of transport chain to use to communicate with the messaging engine in the foreign bus. Select one of the following:

       - InboundBasicMessaging. InboundBasicMessaging is a predefined transport chain where communication uses the TCP protocol.
       - InboundSecureMessaging. InboundSecureMessaging is a predefined transport chain where communication is secured by using the secure sockets layer (SSL) based encryption protocol over a TCP network. For successful connection, a set of suitably compatible SSL credentials must be associated with the local bus inbound channel and the foreign bus outbound channel.
       - Other, please specify. Select this option to specify your own transport chain and enter the details in the field that appears.

    c. Select the name of the authentication alias to use to authenticate access to the foreign bus. The alias must be known to the foreign bus.

11. When the Foreign bus connection wizard is finished, save your changes to the master configuration.

Results

You have created a connection from a local service integration bus to a foreign service integration bus to use point-to-point messaging. You have created a direct foreign bus connection, which contains a routing definition, or virtual link. The physical link, a service integration bus link on the messaging engine for the local bus, is created automatically.

What to do next

You must create a connection in the opposite direction between the two buses. To do this, repeat the procedure, using the bus you have just connected to as the local bus, and the bus you have just connected from as the foreign bus. Ensure that you use exactly the same name for the service integration bus link. After you create a foreign bus connection for each service integration bus, you can test the connection.

Connecting service integration buses to use publish/subscribe messaging:

You can connect a service integration bus to another service integration bus to send and receive messages by using publish/subscribe messaging. To do this, you create a foreign bus connection.

Before you begin

To connect a service integration bus to another service integration bus to use publish/subscribe messaging, the following resources must exist:

- A service integration bus that you want to connect from, known as the local bus. The bus must have at least one bus member.
- A service integration bus that you want to connect to, known as the foreign bus. The bus must have at least one bus member.
- A topic space on both service integration buses. If the foreign bus is in a remote cell, you must know the topic space name.
- Optionally, to configure a secure connection, an authentication alias.

The buses that you connect must have unique names, because the connection will fail if the buses have the same name.

About this task

In publish/subscribe messaging, the sending application publishes messages to an intermediate broker destination. Multiple receiving applications can subscribe to this destination to receive a copy of any messages that are published. When a message arrives at a destination, the messaging provider distributes a copy of the message to all the receiving applications that subscribe to the destination. There can be a one-to-many relationship between the sender and receiver of a message, depending on how many receiving applications are subscribed to a destination when a message arrives.

Procedure

1. In the navigation pane, click **Service integration -> Buses**. A list of service integration buses is displayed.
2. In the Buses pane, click the service integration bus that you want to connect from, that is, the local bus.
3. In the configuration tab, under **Topology**, click **Foreign bus connections**.
4. In the Foreign bus connections pane, click **New** to start the Foreign bus connection wizard.
5. In the Bus connection type pane, ensure that **Direct connection** is selected.
6. In the Foreign bus type pane, ensure that **Service integration bus** is selected.
7. In the Local bus details pane, select from the drop-down list the messaging engine that you want to use.
8. Optionally, enter a name for the inbound user ID. When the local bus is secure, the inbound user ID replaces the user ID in messages from the foreign bus that arrive at the local bus and is used to authorize whether those messages can access their destinations. Specify an inbound user ID for the local service integration bus under the following circumstances:
   - The foreign bus is in a different security domain, so user IDs in the foreign bus are not recognized in the local bus.
   - You want local control of access to inbound messages to the local bus.

   If the local bus is not secure, the inbound user ID has no effect on messages. If the local bus is secure, the foreign bus is not secure, and an inbound user ID is not set, an inbound message from the foreign bus is only authorized to destinations that allow unauthenticated users access.
9. In the Foreign bus details pane, complete the details as appropriate:
   - If the service integration bus you want to connect to is in a different cell from the local bus, complete the following details:
     a. Ensure that **Configure a foreign bus in a remote cell** is selected.
     b. Enter the name of the service integration bus to connect to, that is, the foreign bus. Enter the exact name of the existing service integration bus.

c. Enter the name of the gateway messaging engine in the foreign bus, that is, the messaging engine to connect to in the foreign bus.
d. Select the **Configure publish-subscribe messaging for this connection** check box.
e. Enter the name of the service integration bus link.
f. Enter one or more bootstrap endpoints, that is, the host, port location, and transport chain for the messaging engine on the foreign bus that the local service integration bus connects to. The port is the SIB_ENDPOINT_ADDRESS (or SIB_ENDPOINT_SECURE_ADDRESS if security is enabled) of the messaging engine. Use the format *hostName*:*portNumber*:*chainName*, separating each bootstrap endpoint by a comma. For more information, see the steps relating to setting bootstrap endpoints in "Configuring a connection to a non-default bootstrap server" on page 531.

- If the service integration bus you want to connect to is in the same cell as the local bus, complete the following details:
  a. Ensure that **Configure a foreign bus in a local cell** is selected.
  b. Select the name of the service integration bus to connect to, that is, the foreign bus.
  c. Select the name of the gateway messaging engine in the foreign bus, that is, the messaging engine to connect to in the foreign bus.
  d. Select the **Configure publish-subscribe messaging for this connection** check box.
  e. Enter the name of the service integration bus link.

10. Optionally, to secure the connection, in the Foreign bus details pane, complete the following details:
    a. Select the **Secure connection** check box.
    b. Select the type of transport chain to use to communicate with the messaging engine in the foreign bus. Select one of the following:
       - InboundBasicMessaging. InboundBasicMessaging is a predefined transport chain where communication uses the TCP protocol.
       - InboundSecureMessaging. InboundSecureMessaging is a predefined transport chain where communication is secured by using the secure sockets layer (SSL) based encryption protocol over a TCP network. For successful connection, a set of suitably compatible SSL credentials must be associated with the local bus inbound channel and the foreign bus outbound channel.
       - Other, please specify. Select this option to specify your own transport chain and enter the details in the field that appears.
    c. Select the name of the authentication alias to use to authenticate access to the foreign bus. The alias must be known to the foreign bus.
11. In the Publish-subscribe details pane, repeat the following steps for each topic mapping you want to create:
    a. Select the name of the topic space on the local bus that will map to the topic space on the foreign bus.
    b. Enter the name of the topic space on the foreign bus. If the foreign bus is in the same cell as the local bus, you can select this name from a drop-down list.
    c. Click **Add**.
12. When the Foreign bus connection wizard is finished, save your changes to the master configuration.

Results

You have created a connection from a local service integration bus to a foreign service integration bus to use publish/subscribe messaging. You have created a direct foreign bus connection, which contains a routing definition, or virtual link. The physical link, a service integration bus link on the messaging engine for the local bus, is created automatically.

What to do next

You must create a connection in the opposite direction between the two buses. To do this, repeat the procedure, using the bus you have just connected to as the local bus, and the bus you have just connected from as the foreign bus. Ensure that you use exactly the same name for the service integration bus link. After you create a foreign bus connection for each service integration bus, you can test the connection.

Connecting buses by using an indirect connection:

You can connect a service integration bus to another service integration bus or a WebSphere MQ queue manager or queue-sharing group (known as the “gateway queue manager”) through one or more intermediate foreign buses. To do this, you create an indirect foreign bus connection.

Before you begin

To create an indirect foreign bus connection, the following resources must be defined:

- A service integration bus that you want to connect from, known as the local bus.
- A direct foreign bus connection from the local bus to the bus you want to use as the intermediate bus.
- A service integration bus or a gateway queue manager that you want to connect to indirectly, known as the target foreign bus.

About this task

To connect two buses indirectly, you create a indirect foreign bus connection on the local bus that specifies a suitable intermediate bus and the required target bus. There must be a connection, either direct or indirect, between the intermediate bus and the target foreign bus, that is, the service integration bus or a gateway queue manager that you want to connect to.

To connect one bus to another bus through an intermediate bus, or a chain of buses, if the connection between the intermediate bus or the chain of buses and the target bus already exists, you do not require any new physical links. Instead, each foreign bus connection identifies a neighboring bus on the route to the final target bus as the "next hop" in the chain. Each bus in the chain must know about the next hop in the chain to reach the target bus. The local bus uses a foreign bus connection to identify the next bus in the chain to the target bus, and uses its direct physical link to flow messages to that bus. Then, each intermediate bus uses its locally defined foreign bus connection to identify the next bus in the chain until the target bus is reached.

Procedure

1. In the navigation pane, click **Service integration -> Buses**. A list of service integration buses is displayed.
2. In the Buses pane, click the service integration bus that you want to connect from, that is, the local bus.
3. In the configuration tab, under **Topology**, click **Foreign bus connections**.
4. In the Foreign bus connections pane, click **New** to start the Foreign bus connection wizard.
5. In the Bus connection type pane, select **Indirect, using another bus**.
6. In the Indirect connection details pane, complete the following details:
   a. Enter the name of the target foreign bus that you want to connect to indirectly.
   b. Select the name of the existing, directly connected foreign bus that will be the intermediate bus to the target bus.
7. When the Foreign bus connection wizard is finished, save your changes to the master configuration.

Results

You have created a connection from the local bus to the target bus by way of the intermediate bus. You have created an indirect foreign bus connection, which contains a routing definition, or virtual link.

What to do next

Check whether there are connections between the intermediate bus you specified and the target bus. If necessary, repeat the procedure to create the "next hop" in the chain.

Testing foreign bus connections:

After you define a direct foreign bus connection between a service integration bus and either another service integration bus or a WebSphere MQ queue manager, you can test the connection to check that it can be used to exchange messages.

Before you begin

To test a foreign bus connection, a service integration bus, known as the local bus, with a direct foreign bus connection to a service integration bus, or a WebSphere MQ queue manager must be defined.

About this task

You might want to test a foreign bus connection before you send messages that use that connection, or if you have difficulty sending and receiving messages that use that connection. You can test only direct foreign bus connections. You cannot test indirect foreign bus connections, because it might not be possible to reach the target destination bus.

If a connection name list is provided in the WebSphere MQ link sender channel properties, the connections are tried in the order in which they are specified in the connection list until a connection is successful. If no connection is successful an error message is logged.

Procedure

1. In the navigation pane, click **Service integration -> Buses**.
2. In the Buses pane, click the bus that has the connection you want to test.
3. In the configuration tab, under **Topology**, click **Foreign bus connections**. A list of foreign bus connections is displayed.
4. Select the check box for the connection you want to test.
5. Click **Test Connection**. A message is displayed at the top of the pane that shows the result of the test.

Results

You have tested a bus connection.

Listing the foreign bus connections:

You can list the foreign bus connections that are associated with a local bus to see which foreign buses are currently configured.

Before you begin

To list foreign bus connections, the following resources must be defined:

- A service integration bus with one or more foreign bus connections between it and another service integration bus or a WebSphere MQ queue manager.

About this task

You can list foreign bus connections by using the administrative console, as described in this topic, or by using the wsadmin tool and the listSIBForeignBuses command.

To list the foreign bus connections that are associated with the local bus, complete the following steps.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Buses**.
3. In the service integration buses pane, select the bus for which you want to list the connections.
4. In the configuration tab, under **Topology**, click **Foreign bus connections**. A list of buses that have a foreign bus connection from the local bus is displayed.

Results

You have listed the foreign bus connections that are associated with the local bus.

Removing a foreign bus connection from a bus:

You can remove a foreign bus connection from a bus so that the connection can no longer be used for sending and receiving messages.

Before you begin

When a foreign bus connection is deleted from the configuration, the next time the hosting messaging engine for a link transmitter is started, the messaging engine moves the messages to the exception destination. To avoid this situation, drain the messages from the link transmitter queue as far as is possible and then, before deleting the link configuration, either move any remaining messages from the transmission queues to an exception destination, or delete them. For more details, refer to the subtopics that follow.

About this task

Removing a foreign bus connection from a bus removes the resources associated with the connection. The bus will no longer service the deleted link.

Procedure

1. In the navigation pane, click **Service integration -> Buses**.
2. In the Buses pane, select the bus from which you want to remove the foreign connection.
3. In the configuration tab, under **Topology**, click **Foreign bus connections** to display a list of connections for this bus.
4. Select the check box that corresponds to the connection that you want to remove.
5. Click **Delete**.
6. Save your changes to the master configuration.

Results

You have now deleted the foreign bus connection from a bus. This connection can no longer be used for communication.

Preparing to remove a foreign bus connection between two service integration buses:

Before you remove a foreign bus connection between two service integration buses, drain as many messages as you can from the link transmitter queue, then manually move or delete any remaining messages.

Before you begin

You must know which foreign bus connection is being prepared for deletion.

About this task

When a foreign bus connection and its service integration bus link is deleted from the configuration, the next time the hosting messaging engine for a link transmitter is started, the messaging engine deletes all its messages or moves them to the exception destination. To avoid messages being unintentionally deleted or moved to the exception destination, drain the messages from the link transmitter queue as much as possible and then, before deleting the link configuration, either move any remaining messages to an exception destination or delete them.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Buses** to display a list of buses.
3. Select the bus from which you want to remove the foreign bus connection.
4. In the **Configuration** tab, under **Topology**, click **Foreign bus connections**. A list of connections for this bus is displayed.
5. From the list of foreign bus connections, click the name of the foreign bus connection to display its details.
6. Under **General properties**, clear the **Send Allowed** check box to prevent new messages from being produced for this service integration bus link.
7. Click **Apply** to save the configuration.
8. To determine when there are no more messages queued on this link, under **Related Items** click **Service integration bus links** to display the details of the service integration bus links.
9. Click the **Refresh** icon of **Status** to refresh the view of the current outbound messages.
10. When there are no current outbound messages, select the check box next to the appropriate link and then click **Stop** to stop the link to the foreign bus. When the status of the link turns to red, the link to the foreign bus has no remaining messages and is stopped.
11. Repeat steps 2 to 10 for the foreign bus, because the foreign bus can continue to produce messages after the foreign bus connection on the local bus has been deleted.
12. Save your changes to the master configuration.

Results

You have drained the messages from the link transmitter queue as much as possible, and either moved any remaining messages from the transmission queues to an exception destination or deleted them. You are now ready to remove the foreign bus connection.

Preparing to remove a foreign bus connection between a service integration bus and a WebSphere MQ network:

Before you remove a foreign bus connection between a service integration bus and a WebSphere MQ network, drain as many messages as you can from the link transmitter queue, then manually move or delete any remaining messages.

Before you begin

You must know which foreign bus connection is being prepared for deletion. You should also inform the WebSphere MQ administrator that the foreign bus connection is about to be deleted and therefore no longer paired with its WebSphere MQ gateway queue manager or message broker in the WebSphere MQ network.

About this task

When a foreign bus connection is deleted from the configuration, the next time the hosting messaging engine for a link transmitter is started, it deletes all its messages or moves them to the exception destination. To avoid messages being unintentionally deleted or moved to the exception destination, drain as many messages as possible from the link transmitter queue. Then, before you delete the link configuration, either move any remaining messages to an exception destination or delete them.

If there are publish/subscribe broker profiles defined, you should remove the subscriptions.

Procedure

1. Start the administrative console.
2. Optional: If there are publish/subscribe broker profiles defined on any of the links for this foreign bus connection, remove the subscriptions.

   Complete the following substeps for each broker profile:

   a. Navigate to **Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Related Items] WebSphere MQ links -> *link_name* -> [Additional Properties] Publish/subscribe broker profiles -> *profile_name***
   b. Click the **Runtime** tab.
   c. Click **Subscriptions**.
   d. Click **Unsubscribe** to remove all the subscriptions listed.

   When an unsubscribe command is sent to the message broker in the WebSphere MQ network, the relevant topic mapping is put into an indoubt state until the unsubscribe is confirmed when the topic mapping is deleted. After the unsubscribe is confirmed, the topic mapping is no longer shown in the runtime view. You might have to refresh the runtime view for all subscriptions to be shown as removed.
3. Prevent new messages from being produced for this foreign bus connection.
   a. Navigate to **Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name***
   b. Under **General properties**, clear the **Send Allowed** check box.
   c. Click **Apply** to save the configuration.
4. Determine when there are no more messages queued, then stop the link to the foreign bus in a controlled manner.
   a. Under **Related Items**, click **WebSphere MQ links** to display the list of links for this bus.
   b. Click the **Refresh** icon of **Status** to refresh the view of the current outbound messages.
   c. When there are no current outbound messages, select the check box next to the appropriate link and then select a **Stop mode** of "Quiesce".
   d. Select a **Target state** of "Stopped" so that the link can only be started again by administrator action.
   e. When the status of the link turns to red, the link to the foreign bus has no remaining messages and is stopped.
5. The foreign bus can continue to produce messages after the foreign bus connection on the local bus has been deleted. Because the foreign bus is a WebSphere MQ network, refer to the WebSphere MQ Intercommunication guide for details about the safe deletion of channels at Managing WebSphere MQ channels.

6. Save your changes to the master configuration.

Results

You have removed the subscriptions from any publish/subscribe brokers on the link. You have drained as many messages as possible from the link transmitter queue, and either moved any remaining messages from the transmission queues to an exception destination or deleted them.

What to do next

You are now ready to remove the foreign bus connection.

Configuring destination defaults for a foreign bus connection:

You can configure default values to apply when applications use destinations on a foreign bus and these properties are not explicitly defined elsewhere. You configure the destination defaults for the foreign bus connection, which represents either a service integration bus or a WebSphere MQ queue manager or queue-sharing group (known as a “gateway queue manager”).

Before you begin

To configure destination defaults for a foreign bus, at least one foreign bus connection that represents that foreign bus must be defined.

About this task

Destination defaults are default values for the destination attributes, such as the default priority. They are used when an application produces messages that are destined for a destination on a foreign bus, but the properties are not defined elsewhere:

- The application has not explicitly set certain attributes on the message.
- A foreign destination is not defined on the local bus, so cannot be a source of destination defaults.
- An alias destination is not defined on the local bus, so cannot be a source of destination defaults.

You configure destination defaults for a foreign bus connection to apply to all applicable destinations on the corresponding foreign bus. In contrast, the destination defaults of an alias destination or foreign destination apply to an individual destination on a foreign bus.

Procedure

1. In the navigation pane, click **Service integration -> Buses**.
2. In the service integration buses pane, select the bus that you want to configure.
3. In the configuration tab, under **Topology**, click **Foreign bus connections**. A list of foreign bus connections is displayed.
4. Select the foreign bus connection that you want to configure.
5. In the content pane, under **Additional properties**, click **Destination defaults**.
6. Specify the following properties for the destination defaults:

   Default priority
   The default priority assigned to messages sent to this destination when a priority has not been set by the producer.

   Default reliability
   The reliability assigned to a message produced to this destination when an explicit reliability has not been set by the producer.

Maximum reliability
The maximum reliability of messages accepted by this destination.

Send allowed
Clear this option (setting it to false) to stop producers from being able to send messages to destinations on this foreign bus.

Enable producers to override default reliability
Select this option to enable producers to override the default reliability that is set on the destination.

Include an RFH2 message header when sending messages to WebSphere MQ.
If selected, messages sent to WebSphere MQ include an RFH2 header. The RFH2 header stores additional information to that which is stored in theWebSphere MQ message header.

7. Click **OK**.
8. Save your changes to the master configuration.

Results

You have configured destination defaults for a foreign bus connection.

Managing messages that use foreign bus connections:

You can manage messages that use a foreign bus connection.

Before you begin

You must know whether the foreign bus connection represents a connection from a service integration bus to another service integration bus, or to a WebSphere MQ network, because this determines the points where you can manage messages.

About this task

For a foreign bus connection from a service integration bus to another service integration bus, you can manage messages that are queued for link transmitters and link receivers.

For a foreign bus connection from a service integration bus to a WebSphere MQ network, you can manage messages that are queued for link transmitters, known link transmitters, and the sender channel transmitter.

A link can have multiple link transmitters; one for each messaging engine that sends messages on the link to the foreign bus, and one for each topic space destination that is mapped to a topic space in the foreign bus.

For a foreign bus connection to a WebSphere MQ network, there is one known link transmitter for each link transmitter, and one sender channel transmitter for the WebSphere MQ link that sends messages to a gateway queue manager on the WebSphere MQ network.

Complete this task when you want to view, delete, or move messages on a transmitter.

Procedure

Select the appropriate task from the following topics.

Configuring exception destination processing for a link to a foreign bus:

You can configure the exception destination processing for a link from a service integration bus to another service integration bus or to a WebSphere MQ network. You can configure whether any undeliverable messages that the link handles are rerouted to an exception destination, and whether to use a system default exception destination or configure a specific exception destination.

Before you begin

To configure the exception destination processing for a service integration bus link or WebSphere MQ link, you must know the name of the foreign bus connection that is associated with that link. A foreign bus connection represents either a connection between two service integration buses or a connection between a service integration bus and a WebSphere MQ network.

To configure a specific exception destination for the link, the exception destination must exist. An exception destination must be a queue destination, and can be on the local bus or a foreign bus. See “Creating a queue for point-to-point messaging” on page 1972.

About this task

An exception destination for a link is the destination for an inbound message when the service integration bus link or WebSphere MQ link cannot deliver the message to its target bus destination, or to the exception destination that is configured for that target destination, or when the target destination does not exist.

You can configure an exception destination for a link as one of the following:

- None. The link does not use an exception destination and undeliverable messages are not rerouted to an exception destination. For a service integration bus link, such messages can block the processing of other messages waiting for delivery to the same destination. For a WebSphere MQ link, such messages can block the processing of other messages waiting for delivery through that link to the same bus.
- System. The link uses the default exception destination. Messages that cannot be delivered to the bus destination are rerouted to the system default exception destination for the messaging engine that this link is assigned to: _SYSTEM.Exception.Destination.*messaging_engine_name*. This is the default option.
- Specify. The link uses the specified exception destination. If the link cannot use this exception destination, it uses the system exception destination.

Note that best-effort messages are always discarded if they cannot be delivered to their target destination, that is, they never use an exception destination.

Any report options that are set in the properties of a message also affect exception destination processing. Depending on the report options, a message might be discarded if it is not delivered.

Procedure

1. In the navigation pane of the administrative console, click **Service integration -> Buses** to display a list of buses.
2. Select the bus that has the link for which you want to configure exception destination processing.
3. In the **Configuration** tab, under **Topology**, click **Foreign bus connections** to display a list of connections for this bus.
4. Select the name of the foreign bus connection that is associated with the link for which you want to configure exception destination processing.
5. For a link to another service integration bus, under **Related Items**, click **Service integration bus links**. For a link to a WebSphere MQ network, under **Related Items**, click **WebSphere MQ links**.
6. Select the name of the link you require from the list. The details of that link are displayed.

7. In the **Configuration** tab, under **General properties**, in the Exception destination section, use the radio buttons to configure the exception destination processing that this link uses:
   - Select **None** to specify that the link does not use an exception destination.
   - Select **System** to use the default exception destination.
   - Select **Specify** and enter an exception destination to configure the exception destination you require.
8. Save your changes to the master configuration.

Results

You have configured the exception destination processing for undeliverable messages that are handled by the link.

What to do next

You can also configure exception destination processing for a bus destination.

Managing messages in a link transmission queue for a connection between two buses:

You can manage messages in a link transmission queue that is associated with a foreign bus connection from one service integration bus to another service integration bus.

Before you begin

You must know the link transmitter on which messages are to be managed.

About this task

A service integration bus link can have multiple link transmitters. For applications that use point-to-point messaging, there is one link transmitter for each messaging engine in the sending bus. For applications that use publish/subscribe messaging, there is one link transmitter for each topic space destination that is mapped to a topic space in the foreign bus.

Complete this task when you want to view, delete, or move messages that are queued for a link transmitter.

Procedure

1. From the navigation pane of the administrative console, click **Service integration -> Buses** to display a list of buses.
2. Select the bus whose link transmission queue you want to manage.
3. In the **Configuration** tab, under **Topology**, click **Foreign bus connections** to display a list of connections for this bus.
4. From the list of foreign bus connections, select the name of a foreign bus connection to display its details.
5. Under **Related Items**, click **Service integration bus links**, then select the check box for a link.
6. In the **Runtime** tab, click **Link transmitters** to display the list of link transmitters for messaging engines that are sending messages to the foreign bus.
7. Optional: To manage all messages that are queued for a link transmitter, select the link transmitter and complete your required task:
   - Click **Delete all messages** to delete all the available messages that are queued for a selected link transmitter.
   - Click **Move all messages** to move all the available messages that are queued for a selected link transmitter to the configured exception destination. If the exception destination is configured as

None, or if the link transmitter is a publish/subscribe link transmitter, the messages are discarded. If it is configured as **System**, the messages are sent to the system default exception destination. If a specified destination is configured, the messages are sent to the exception destination specified for this link.

8. Optional: To manage selected messages that are queued for a link transmitter, click the name of the messaging engine from the list of link transmitters, and then click **View messages** to view the messages on an outbound stream from this link transmitter to the foreign bus.
9. Select one or more messages and complete your required task:
   - Click **Delete** to delete the selected messages.
   - Click **Move** to move the selected messages to the local exception destination. If the exception destination is configured as **None**, or if the link transmitter is a publish/subscribe link transmitter, the messages are discarded.
   - Click **Refresh** to view the current messages that are queued for a selected link transmitter.

     Note: Only messages up to the specified maximum displayed messages are displayed.

Results

You have managed the messages that are queued for a specified link transmitter for a specified foreign bus connection.

Viewing messages in a link receiver queue for a connection between two buses:

You can view messages in a link receiver queue that is associated with a foreign bus connection from one service integration bus to another service integration bus.

Before you begin

You must know the link receiver on which messages are to be viewed.

About this task

A service integration bus link can have multiple link receivers. For applications that use point-to-point messaging, there is one link receiver for each messaging engine in the foreign bus, that is, the bus that sends messages through the link. For applications that use publish/subscribe messaging, there is one link receiver for each topic space in the foreign bus.

In this situation, the bus with the link receiver is the local bus. The bus that the applications that produce messages are connected to is the foreign bus.

Complete this task when you want to view messages on a link receiver.

Procedure

1. From the navigation pane of the administrative console, click **Service integration -> Buses** to display a list of buses.
2. Select the bus that has the link receiver queue you want to view.
3. In the **Configuration** tab, under **Topology**, click **Foreign bus connections** to display a list of connections for this bus.
4. From the list of foreign bus connections, select the name of the foreign bus connection to display its details.
5. Under **Related links** click **Service integration bus links**, then select the check box for a link.
6. In the **Runtime** tab, click **Link receivers** to display the list of link receivers for messaging engines on the foreign bus that are sending messages to this bus.

7. To view the messages on the link receiver, select the name of the messaging engine from the list of link receivers, then click **View messages** to view the messages on an inbound stream from the messaging engine on the foreign bus. Click **Refresh** to view the current messages on the selected link receiver.

Results

You have viewed the messages on a specified link receiver queue for a specified foreign bus connection.

Managing messages in a link transmission queue for a connection to a WebSphere MQ network:

You can manage messages in a link transmission queue that is associated with a foreign bus connection from a service integration bus to a WebSphere MQ network.

Before you begin

You must know the foreign bus connection and the link transmitter for which you want to manage messages.

About this task

A link can have multiple link transmitters; one for each messaging engine that sends messages on the link to the foreign bus, and one for each topic space destination that is mapped to a topic space in the foreign bus.

Complete this task when you want to view, delete, or move messages that are queued for a link transmitter.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Buses** to display a list of buses.
3. Select the bus whose link transmission queue you want to manage.
4. In the **Configuration** tab, under **Topology**, click **Foreign bus connections** to display a list of connections for this bus.
5. Select the name of the foreign bus connection to display its details.
6. Under **Related Items**, click **WebSphere MQ links**, then select the name of the link.
7. In the **Runtime** tab, click **Sender channel** to display the sender channels that are sending messages to the foreign bus.
8. Optional: To manage all messages that are queued for a link transmitter, select the link transmitter and complete your required task:
   - Click **Delete all messages** to delete all the available messages that are queued for the selected link transmitter.
   - Click **Move all messages** to move all the available messages that are queued for the selected link transmitter to the configured exception destination. If the exception destination is configured as **None**, or if the link transmitter is a publish/subscribe link transmitter, the messages are discarded. If it is configured as **System**, the messages are sent to the system default exception destination. If a specified destination is configured, the messages are sent to the exception destination specified for this link.
9. Optional: To manage selected messages that are queued for a link transmitter, click the name of the messaging engine from the list of link transmitters and then click **View messages** to view the messages on an outbound stream from this link transmitter to the foreign bus.
10. Select one or more messages and complete one of the following tasks:
    - Click **Delete** to delete the selected messages.

- Click **Move** to move the selected messages to the local exception destination.If the exception destination is configured as **None**, or if the link transmitter is a publish/subscribe link transmitter, the messages are discarded.
- Click **Refresh** to view the current messages that are queued for the selected link transmitter.

  Note: Only messages up to the specified **Maximum displayed messages** are displayed.

Results

You have managed the messages that are queued for a specified link transmitter for a specified foreign bus connectoin.

Managing messages in a known link transmission queue for connection to a WebSphere MQ network:

You can manage messages in a known link transmission queue that is associated with a foreign bus connection from a service integration bus to a WebSphere MQ network.

Before you begin

You must know the foreign bus connection and the known link transmitter for which for which you want to manage messages.

About this task

A link can have multiple known link transmitters; one for each messaging engine in the bus that has sent messages through the link to the foreign bus, and one for each topic space destination that is mapped to a topic space in the foreign bus.

Complete this task when you want to view, delete, or move messages that are queued for a known link transmitter.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Buses** to display a list of buses.
3. Select the bus whose known link transmission queue you want to manage.
4. In the **Configuration** tab, under **Topology**, click **Foreign bus connections** to display a list of connections for this bus.
5. Select the name of the foreign bus connection to display its details.
6. Under **Related Items** click **WebSphere MQ links**, then select the name of the link.
7. In the **Configuration** tab, under **Additional Properties**, click **Sender channel** to display the sender channels for all messaging engines that are sending messages to this bus. The sender channel sends messages to the gateway queue manager.
8. From the list of sender channels, select the check box of a **Sender MQ channel name** and click **View known link transmitters** to display a list the remote messaging engines producing messages for this WebSphere MQ link.
9. Click **Refresh** to view the current messages on the message engines.
10. Optional: To manage all messages that are queued for a known link transmitter, select a known link transmitter and complete your required task:
    - Click **Delete all messages** to remove the messages from the known link transmission queue.
    - Click **Move all messages** to move all the available messages that are queued for a selected known link transmitter to the configured exception destination. If the exception destination is configured as **None**, or if the known link transmitter is a publish/subscribe known link transmitter, the messages are discarded. If it is configured as **System default** the messages are sent to the

system default exception destination. If a **Specified destination** is configured, the messages are sent to the exception destination specified for this link.

11. Optional: To manage selected messages that are queued for a known link transmitter, select a known link transmitter then click **View messages** to view the messages.
12. Select one or more messages and complete your required task:
    - Click **Delete** to remove the selected messages from the known link transmission queue.
    - Click **Move** to move the selected messages to the configured exception destination. If the exception destination is configured as **None**, or if the known link transmitter is a publish/subscribe known link transmitter, the messages are discarded. If the exception destination is configured as **System default**, the messages are sent to the system default exception destination. If a **Specified destination** is configured, the messages are sent to the exception destination specified for this link.

Results

You have managed the messages in a known link transmission queue for a specified foreign bus connection between a service integration bus and a WebSphere MQ network.

Managing messages in a sender channel transmission queue for a connection to a WebSphere MQ network:

You can manage messages in a sender channel transmission queue that is associated with a foreign bus connection between a service integration bus and a WebSphere MQ network.

Before you begin

You must know the foreign bus connection and the sender channel transmitter for which you want to manage messages.

About this task

There is one sender channel transmitter on the WebSphere MQ link that sends messages to a gateway queue manager on the WebSphere MQ network (the foreign bus).

Complete this task when you want to view, delete, or move messages that are queued for the sender channel transmitter.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Buses** to display a list of buses.
3. Select the bus whose sender channel transmission queue you want to manage.
4. In the **Configuration** tab, under **Topology**, click **Foreign bus connections** to display a list of connections for this bus.
5. Select the name of the foreign bus connection to display its details.
6. In the **Configuration** tab, under **Related Items** click **WebSphere MQ links**, then select the check box for a link.
7. Click **Sender channel transmitter** under **Current outbound messages**, or click **Sender channel transmitter** under **Messages sent**, to see the relevant message details for this sender channel transmitter.
8. Select the check box of the sender channel transmitter and complete your required task:
    - Click **Delete all messages** to remove the messages from the sender channel transmission queue.
    - Click **Move all messages** to move all the available messages on the sender channel transmitter to the configured exception destination. If the exception destination is configured as **None**, the

messages are discarded. If it is configured as **System**, the messages are sent to the system default exception destination. If a specified destination is configured, the messages are sent to the exception destination specified for this link.

Results

You have managed the messages on a sender channel transmitter that sends messages to a gateway queue manager on the WebSphere MQ network.

Managing pending acknowledgement messages on a deleted WebSphere MQ link:

If a foreign bus link to a WebSphere MQ network is deleted from the WebSphere Application Server configuration before being drained of messages, a batch of messages pending acknowledgement remains stored in the WebSphere MQ link sender channel transmitter. You can use the administrative console to resolve these messages.

Before you begin

You must know the name of the WebSphere MQ link that has been deleted.

About this task

To resolve pending acknowledgement messages on a deleted WebSphere MQ link, use the administrative console to complete the following steps.

Procedure

1. Start the administrative console.
2. In the navigation pane, click **Service integration -> Buses** to display a list of buses.
3. Select the bus whose link transmission queue you want to manage.
4. In the **Configuration** tab, under **Topology**, click **Foreign Bus Connections** to display a list of connections for this bus.
5. From the list of foreign bus connections, select the name of a foreign bus connection to display its details.
6. Under **Related Items** click **Service integration bus links** to display the details of the service integration bus links.
7. Select the MQ network foreign bus that has a connection that is active, but a configuration status that is **Deleted**. If clicking **Link transmitters** displays an empty list, no messaging engines are producing messages to this link and all the link transmitters have been deleted because they were drained of messages. The **Sender channel transmitter** link displays the status of the sender channel as stopped but **Current outbound messages** shows remaining messages on the sender channel transmitter.
8. Click a WebSphere MQ link **Sender channel** link to display the messages that are queued on the WebSphere MQ link sender channel transmitter for transmission to the WebSphere MQ network.
9. If the Status of a batch of messages is "Commit pending batch", the batch has arrived safely at the MQ network. Select the batch and click **Commit pending batch** to remove the messages from the transmission queue.
10. If the Status of a batch of messages is "Pending batch acknowledgement", the batch did not arrive at the MQ network. Select the batch and click **Rollback pending acknowledge batch** to roll back the transaction and restore the messages to the channel in an available state. These messages are either automatically deleted or moved to the exception destination. When the channel transmitter is empty, the link is automatically deleted from the runtime environment.

Results

You have resolved any pending acknowledgement messages on a WebSphere MQ link that has been deleted from a foreign bus connecting to a service integration bus.

Modifying a routing definition:

You can view or change the routing definition of an existing foreign bus connection between a local bus and a foreign bus. The routing definition defines the virtual link between two buses that enables them to exchange messages. The routing definition can define properties for a virtual service integration bus link, a virtual WebSphere MQ link, or an indirect foreign bus connection.

About this task

You create a routing definition when you create a foreign bus connection. For a direct foreign bus connection, the routing definition, or virtual link, has a corresponding physical link on a messaging engine.

To change the properties of the routing definition, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Service integration -> Buses**. A list of service integration buses is displayed.
2. In the Buses pane, click the service integration bus that is connected to another bus, that is, the local bus you require.
3. In the content pane, under **Topology**, click **Foreign bus connections**. A list of buses that have a foreign bus connection from the local bus is displayed.
4. Select the required foreign bus.
5. In the content pane, under **Additional properties**, click the routing properties option. The routing properties option depends on the type of routing definition and is one of the following:
   - **Service integration bus link routing properties**
   - **WebSphere MQ link routing properties**
   - **Indirect routing properties**
6. Specify the new routing properties:
   - For a virtual service integration bus link or a virtual WebSphere MQ link, specify properties as follows:

     Inbound user ID
     The user name used to authenticate inbound message flows from the foreign bus.

     When the local bus is secure, the inbound user ID replaces the user ID in messages from the foreign bus that arrive at the local bus and is used to authorize whether those messages can access their destinations. Specify an inbound user ID for the local service integration bus under the following circumstances:

     – The foreign bus is in a different security domain, so user IDs in the foreign bus are not recognized in the local bus.
     – You want local control of access to inbound messages to the local bus.

     If the local bus is not secure, the inbound user ID has no effect on messages. If the local bus is secure, the foreign bus is not secure, and an inbound user ID is not set, an inbound message from the foreign bus is only authorized to destinations that allow unauthenticated users access.

     Outbound user ID
     The user name used to authenticate outbound message flows to the foreign bus.

The outbound user ID replaces the user ID that identifies the message source in every message sent to the foreign bus. Where it is defined, the outbound user ID replaces the user ID in messages sent by the local bus to the foreign bus. If the local bus and the foreign bus are both secure, and the foreign bus has not overridden the user ID with its own inbound user ID, the foreign bus also uses the outbound user ID to authorize the message to its destination.

- For an indirect foreign bus connection, select the name of the next foreign bus you require in the chain of intermediate buses. For a bus to be available for selection, it must already have a direct foreign bus connection from the local bus.

7. Click **OK**.
8. Save your changes to the master configuration.

Configuring service integration bus links:

You can configure service integration bus links on messaging engines in a variety of ways. For example, you can start, stop, or remove links.

About this task

When you create a foreign bus connection to connect two service integration buses, a service integration bus link is created automatically. The foreign bus connection contains a routing definition, which is a virtual link, and the service integration bus link is the corresponding physical link on the messaging engine.

Configuring the properties of a service integration bus link:

After establishing a service integration bus link you might want to configure the properties of a service integration bus link such as the name of the service integration bus link, or authentication alias used by foreign bus that the link connects to.

About this task

To configure the properties of a service integration bus link, use the administrative console to complete the following steps:

Procedure

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine for which you want to configure the service integration bus link.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you want to configure.
5. Specify the following properties for the service integration bus link:

   Name The name of the service integration bus link. In order to work, the name must be the same as the name of the corresponding service integration bus link configured on the target foreign bus.

   Description
   An optional description for the service integration bus link, for administrative purposes.

   UUID The universal unique identifier assigned by the system to the service integration bus link for administrative purposes.

   Foreign messaging engine
   The messaging engine on the foreign bus to which this link connects.

Note: This foreign bus name must not be altered after it has been configured. If you alter it, any messaging engines that already hold state information on the link will not be able to use the link unless the foreign bus name is reset to its original value.

Target inbound transport chain
The type of transport chain used for communication with the foreign bus. The transport chain name must be the name of the transport chain as defined on the server on which the target messaging engine is hosted.

Bootstrap endpoints
The comma-separated list of endpoints used to connect to a bootstrap server. This property is set in the same way as the **Provider endpoint** property in the JMS connection factory settings. For more information, see the steps relating to setting bootstrap endpoints in "Configuring a connection to a non-default bootstrap server" on page 531.

Note: Service integration bus links over BootstrapTunneledMessaging and BootstrapTunneledSecureMessaging transport chains only work directly between application server instances. Bus links over TunneledMessaging transport chains do not work if an HTTP server is placed in front of either application server instance.

Authentication alias
The name of the authentication alias, used to authenticate access to the foreign bus. The alias must be known to the foreign bus.

Initial state
Whether the link is started automatically when the messaging engine is started. Until started, the gateway link is unavailable. If this property is set to **Started** the service integration bus link is started when the messaging engine is started.

6. Click **OK**.
7. Save your changes to the master configuration.

Listing the service integration bus links:

You can list all the service integration bus links that are linked to a messaging engine.

About this task

To list the service integration bus links for a messaging engine, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Service integration -> Buses**.
2. In the content pane, click the name of the bus that your messaging engine belongs to.
3. In the content pane, under **Additional properties**, click **Messaging engines**. The list of messaging engines in the bus is displayed.
4. In the content pane, select the messaging engine for which you want to list the service integration bus links.
5. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.

Example

The following combinations of **Status** and **Activity** values are possible:

Table 206. Results of possible status and activity values. The first and second columns of the table provide the possible combinations of status and activity values, and the third column explains the possible connection status of the local and foreign buses.

Status	Activity	Meaning
started	inactive	The service integration bus link is started on the local messaging engine but has no connection to the foreign bus. The service integration bus link is attempting to activate a connection to the foreign bus. The service integration bus link on the foreign bus must also be started to successfully activate of a connection between the buses.
started	active	The service integration bus link is started on the local messaging engine and has an active connection to the foreign bus.
stopped	inactive	The service integration bus link is stopped on the local messaging engine and there is no connection to the foreign bus.
unknown	inactive	An error might have occurred in setting up the link, such that the object that is used to report the current state is not available.

What to do next

You can now add or remove a service integration bus link or select a service integration bus link to start, stop, or configure.

Starting a service integration bus link:

When a service integration bus link has been started, it can be used for communicating with its associated messaging engines.

About this task

To start a service integration bus link, use the administrative console to complete the following steps:

Procedure

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine for which you want to start the service integration bus link.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you want to start.
5. Click **Start**.

Stopping a service integration bus link:

When a service integration bus link has been stopped, it cannot be used for communication until it is restarted.

About this task

To stop a service integration bus link, use the administrative console to complete the following steps:

Procedure

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine to which the service integration bus link that you want to stop belongs.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you want to stop.
5. Click **Stop**.

Removing a service integration bus link:

When a service integration bus link to a messaging engine has been removed, it cannot be used for communication until it is recreated.

Before you begin

Before you remove the service integration bus link you must stop the link.

When you remove a service integration bus link, all traffic that uses the link needs to be dealt with in a similar way to when you remove a destination. For further details, see “Deleting a non-topic space bus destination” on page 1997. Note that express Quality of Service (QoS) messages are discarded.

About this task

To remove a service integration bus link from a messaging engine, use the administrative console to complete the following steps:

Procedure

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine that is associated with the service integration bus link that you want to remove.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you want to remove.
5. Click **Delete**.
6. Save your changes to the master configuration.

What to do next

When you remove a service integration bus link, all traffic that uses the link must be diverted by alternative routes or held pending further administrative action. Express QoS messages are discarded.

Configuring topic space mappings between service integration buses:

A topic space mapping allows subscribers on the local topic space to receive messages published in the foreign topic space. You can configure topic space mappings between a local service integration bus and a foreign service integration bus.

About this task

A topic space mapping allows subscribers on the local topic space to receive messages published in the foreign topic space. For publications to flow from the local topic space into the foreign bus, an equivalent topic space mapping is required by the foreign bus.

If you want to publish messages from a local bus to a foreign bus that is linked indirectly through a third bus, you must configure topic space mappings between the local bus and the intermediate bus, and between the intermediate bus and the foreign bus. The messages can be for publication to the foreign bus only, or to all three buses. If you want to publish messages only to the local and foreign buses, these two buses must be connected directly.

If you want to publish messages from a local service integration bus to a foreign bus that represents a WebSphere MQ network, you must define topic mappings on the broker profile associated with the WebSphere MQ link.

For more details about the foreign bus and publish/subscribe messaging between buses, see Foreign buses.

Creating topic space mappings:

A topic space mapping allows subscribers on the local topic space to receive messages published in the foreign topic space. You can create topic space mappings between two service integration buses.

About this task

You can create topic space mappings as part of the procedure to create a foreign bus connection, or you can create them separately, as described in this topic.

Note that for publishing and subscribing between a service integration bus and a foreign bus that represents a WebSphere MQ network, you must define topic mappings on the broker profile associated with the WebSphere MQ link.

To map a topic space on a local service integration bus to a topic space on a foreign service integration bus, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click **Service integration -> Buses**. A list of service integration buses is displayed.
2. In the Buses pane, click the service integration bus that is connected to another bus, that is, the local bus you require.
3. In the content pane, under **Topology**, click **Foreign bus connections**. A list of buses that have a foreign bus connection from the local bus is displayed.
4. Select the required foreign bus.
5. In the content pane, under **Additional properties**, click **Service integration bus link routing properties**.
6. In the content pane, under **Additional properties**, click **Topic space map entries**.
7. Click **New**.
8. Specify the mappings as follows:

   Local topic space
   The name of the topic space on this (local) bus that is mapped to the remote topic space on the foreign bus.

   Remote topic space
   The name of the topic space on the foreign bus that is mapped to the local topic space.

   Note: The names of the local and foreign topic space do not have to match, but the names of the topics must match in both local and foreign buses.
9. Click **OK**.
10. Save your changes to the master configuration.

Results

The remote topic space is mapped to the local topic space.

Deleting topic space mappings:

You can delete topic space mappings so that subscribers on the local topic space cannot receive messages that are published in the foreign topic space.

About this task

To delete topic space mappings, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Service integration -> Buses**. A list of service integration buses is displayed.
2. In the Buses pane, click the service integration bus that is connected to another bus, that is, the local bus you require.
3. In the content pane, under **Topology**, click **Foreign bus connections**. A list of buses that have a foreign bus connection from the local bus is displayed.
4. Select the required foreign bus.
5. In the content pane, under **Additional properties**, click **Service integration bus link routing properties**.
6. In the content pane, under **Additional properties**, click **Topic space map entries**. A list of topic space map entries is displayed.
7. Select the topic space map entry that you want to remove.
8. Click **Delete**.
9. Save your changes to the master configuration.

Listing topic space map entries:

A topic space mapping allows subscribers on the local topic space to receive messages published in the foreign topic space. You can list topic space map entries to view existing map entries.

Before you begin

There must be a service integration bus link between a local service integration bus and a foreign service integration bus.

About this task

To list the topic space map entries, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Service integration -> Buses**. A list of service integration buses is displayed.
2. In the Buses pane, click the service integration bus that is connected to another bus, that is, the local bus you require.
3. In the content pane, under **Topology**, click **Foreign bus connections**. A list of buses that have a foreign bus connection from the local bus is displayed.
4. Select the required foreign bus.
5. In the content pane, under **Additional properties**, click **Service integration bus link routing properties**.

6. In the content pane, under **Additional properties**, click **Topic space map entries**. The list of mappings between topic spaces in the local bus and topic spaces in the foreign bus is shown.

Topic names and use of wildcard characters in topic expressions:

Wildcard characters can be used in topic expressions to retrieve topics provided by the default messaging provider and service integration technologies.

Each subscribe request includes a topic expression that identifies one or more topics that the subscription is to be associated with, and that the request uses to match against incoming messages.

Subscription topic expressions for the default messaging provider and service integration technologies are based on a subset of the XPath location path syntax.

Identifying individual topics

Every topic in a topic space has a *topic name* consisting of one or more name parts, separated by / (forward slash) characters:

```
Topic name = name_part | (name_part '/' topic_name)
```

Using wildcards to identify multiple topics

To select one or more topics in a topic space, you can use a *topic path*, a location path that contains wildcard characters. Topic spaces are evaluated by using a subset of the XPath location path syntax with the <topicspace> element as the initial context node, so that non-wildcarded topic paths look exactly like topic names.

The syntax for topic paths can be summarized as follows:

- A topic path that contains no * (asterisk), // (double forward slash), or . (dot) symbols is asking for an exact match with the topic name specified.
- A * (asterisk) can be used as a wild card and matches one level (regardless of the value of the name part at that level)

  A * can be used anywhere in a topic path expression, but if it isn't at the start it must be preceded by a /, and if it is isn't at the end it must be followed by a /
- // can be used as a wild card and matches 0 or more levels

  A // can be used anywhere in the expression except at the end. To match 0 or more levels at the end of the expression you end the expression with the syntax //. (double-slash dot). To match one or more levels at the end use //* (double-slash asterisk)

  A topic path must not contain more than two consecutive / symbols.

The following table lists some example topic paths showing the XPath syntax and the equivalent WBI Message Broker selectors:

Table 207. XPath syntax and WBI Message Broker selectors. The first column of the table lists some topic path examples. The second column displays the topics selected in the path. The third column provides the equivalent WBI Message Broker selectors.

Topic path	Topics selected	WBI Message Broker equivalent
A/B	Selects the B child of A	A/B
A/*	Selects all children of A	A/+
A//*	Selects all descendents of A	A/#/+
A//.	Selects A and all descendents of A	A/#
//*	Selects everything	# (or #/+)

Table 207. XPath syntax and WBI Message Broker selectors (continued). The first column of the table lists some topic path examples. The second column displays the topics selected in the path. The third column provides the equivalent WBI Message Broker selectors.

A/./B	Equivalent to A/B	A/B
A/*/B	Selects all B grandchildren of A	A/+/B
A//B	Selects all B descendents of A	A/#/B
//A	Selects all A elements at any level	#/A
*	Selects all first level elements	+

Interoperation with Version 5.1 clients

Existing WebSphere Application Server Version 5.1 client applications using Version 5.1 connection factory and destination definitions use the WBI Message Broker wildcard convention. Such applications can connect to the default messaging provider and service integration bus, and automatically have their wildcard syntax mapped to the XPath convention when subscriptions are created. Any display of these subscriptions through an administrative interface to the bus shows the XPath syntax.

Defining outbound chains for bootstrapping

You can define new outbound chains by using the wsadmin utility. These chains can be used for bootstrapping connections to messaging engines.

About this task

To create outbound chains for bootstrapping, there are several main steps:

1. Locate the appropriate TransportChannelService configuration object. This object is the parent object of all the objects created.
2. Create the individual channels that comprise the transport channel service. Some of these channels might require references to other configuration objects.
3. Assemble the channels that you have created into an outbound channel chain.

The channels used to build an outbound bootstrap chain determine the protocol with which the outbound chain can be used to bootstrap. The following table shows all valid bootstrap chains with their bootstrap protocols.

Table 208. Valid bootstrap chains and protocols. The first column contains the bootstrap protocol used in building the outbound bootstrap chain. The second to fifth columns in the table contain the channels that are valid for the protocol specified on the first column. The order of the channels is important while building the chain. The order of the channels from left to right as given in the table is TCP, SSL, HTTP, HTTP tunneling, and JFAP channels.

Bootstrap protocol	TCP channel	SSL channel	HTTP channel	HTTP tunneling channel	JFAP channel
TCP	X				X
SSL	X	X			X
HTTP	X		X	X	X
HTTPS	X	X	X	X	X

For example, a chain for bootstrapping that uses the SSL protocol would consist of a TCP channel, SSL channel, and JFAP channel. When you create chains, the order of channels in the chain is important. You must specify channels in the order (left to right) in which they appear in the preceding table.

The example in this topic describes how to create a bootstrap chain that is capable of bootstrapping by using the HTTPS protocol. This requires a chain containing all the channel types described. Thus, it is easy to see how to create chains for other protocols by omitting channels during the chain creation step.

Note: You open a wsadmin command session from within Qshell. For more information, see the topic "Configure Qshell to run WebSphere Application Server scripts".

Procedure

1. Locate the TransportChannelService object for the server in which you want to create the new chain. For example, in a WebSphere Application Server Network Deployment configuration, you can list the available TransportChannelService objects and select the appropriate service as follows.

   Using Jython:

```
wsadmin>AdminConfig.list("TransportChannelService" )
(cells/BadgerCell01/nodes/BadgerCellManager01/servers/dmgr|server.xml
#TransportChannelService_1)
(cells/BadgerCell01/nodes/BadgerNode01/servers/nodeagent|server.xml
#TransportChannelService_1095
711814579)
(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml
#TransportChannelService_109571
2023139)
(cells/BadgerCell01/nodes/BadgerNode01/servers/server2|server.xml
#TransportChannelService_109571
2039302)
wsadmin>tcs = AdminConfig.list("TransportChannelService" ).split("\r\n")[2]
```

   Using Jacl:

```
wsadmin> $AdminConfig list TransportChannelService
(cells/BadgerCell01/nodes/BadgerCellManager01/servers/dmgr|server.xml
#TransportChannelService_1)
(cells/BadgerCell01/nodes/BadgerNode01/servers/nodeagent|server.xml
#TransportChannelService_1095
711814579)
(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml
#TransportChannelService_109571
2023139)
(cells/BadgerCell01/nodes/BadgerNode01/servers/server2|server.xml
#TransportChannelService_109571
2039302)
wsadmin> set tcs [lindex [$AdminConfig list TransportChannelService] 2]
(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml#
TransportChannelService_1095712023139)
```

2. Define an outbound TCP channel called testTCPChannel.

   Using Jython:

```
wsadmin>tcpChannel = AdminConfig.create("TCPOutboundChannel", tcs,
[["name", "testTCPChannel"]] )
```

   Using Jacl:

```
wsadmin>set tcpChannel [$AdminConfig create TCPOutboundChannel $tcs
"{name testTCPChannel}"]
testTCPChannel(cells/BadgerCell01/nodes/BadgerNode01/servers/
server1|server.xml#TCPOutboundChannel_1095969213949)
```

3. Define an outbound SSL channel called testSSLChannel. There are two steps required to define such a channel.

   a. Identify the SSL alias to be used by the channel.

      Using Jython:

```
wsadmin>for obj in AdminConfig.list("SSLConfig" ).split("\r\n"):
print obj+AdminConfig.show(obj, "alias")
(cells/BadgerCell01|security.xml#SSLConfig_1)
[alias BadgerCellManager01/DefaultSSLSettings]
(cells/BadgerCell01|security.xml#SSLConfig_1095711819776)
[alias BadgerNode01/DefaultSSLSettings]
```

      Using Jacl:

```
wsadmin>foreach obj [$AdminConfig list SSLConfig] { puts "$obj
[$AdminConfig show $obj alias]]" }
(cells/BadgerCell01|security.xml#SSLConfig_1) {alias BadgerCellManager01/
DefaultSSLSettings}]
(cells/BadgerCell01|security.xml#SSLConfig_1095711819776) {alias BadgerNode01/
DefaultSSLSettings}]
```

b. Create an SSL channel as in the following example, in which the BadgerNode01/DefaultSSLSettings alias is used.

Using Jython:

```
wsadmin>sslChannel =
AdminConfig.create("SSLOutboundChannel", tcs, [["name", "testSSLChannel"],
["sslConfigAlias", "BadgerNode01/DefaultSSLSettings"]] )
```

Using Jacl:

```
wsadmin>set sslChannel [$AdminConfig create SSLOutboundChannel $tcs
"{name testSSLChannel}
{sslConfigAlias BadgerNode01/DefaultSSLSettings}"]
testSSLChannel(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml#
SSLOutboundChannel_1095971760671)
```

4. Define an outbound HTTP channel called testHTTPChannel.

Using Jython:

```
wsadmin>httpChannel = AdminConfig.create("HTTPOutboundChannel", tcs,
[["name", "testHTTPChannel"]] )
```

Using Jacl:

```
wsadmin>set httpChannel [$AdminConfig create HTTPOutboundChannel $tcs
"{name testHTTPChannel}"]
testHTTPChannel(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml#
HTTPOutboundChannel_1095971896556)
```

5. Define an outbound HTTP tunneling channel called testHTCChannel.

Using Jython:

```
wsadmin>htcChannel = AdminConfig.create("HTTPTunnelOutboundChannel", tcs,
[["name", "testHTCChannel"]] )
```

Using Jacl:

```
wsadmin>set htcChannel [$AdminConfig create HTTPTunnelOutboundChannel $tcs
"{name testHTCChannel}"]
testHTCChannel(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml#
HTTPTunnelOutboundChannel_1095972164201)
```

6. Define an outbound JFAP channel called testJFAPChannel.

Using Jython:

```
wsadmin>jfapChannel = AdminConfig.create("JFAPOutboundChannel", tcs,
[["name", "testJFAPChannel"]] )
```

Using Jacl:

```
wsadmin>set jfapChannel [$AdminConfig create JFAPOutboundChannel $tcs
"{name testJFAPChannel}"]
testJFAPChannel(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml#
JFAPOutboundChannel_1095972226631)
```

7. Finally, create the channel chain by combining the channels defined so far. For example, to create a chain called testChain:

Using Jython:

```
wsadmin>AdminConfig.create("Chain", tcs, [["name", "testChain"], ["enable", "true"],
["transportChannels", [tcpChannel, httpChannel, htcChannel, jfapChannel]]] )
testChain(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml#
Chain_1095972662147)
```

Using Jacl:

```
wsadmin>$AdminConfig create Chain $tcs "{name testChain} {enable true}
{transportChannels {$tcpChannel $httpChannel $htcChannel $jfapChannel}}"
testChain(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml#
Chain_1095972662147)
```

Defining outbound chains for WebSphere MQ interoperation

You can define new outbound chains by using the wsadmin utility. These chains can be used for interoperating with WebSphere MQ.

About this task

The channels used to build an outbound chain determine with which configurations of the WebSphere MQ queue manager sender channel so a network connection can be successfully established. The following table shows all the valid chain configurations and describes the configuration of aWebSphere MQ queue manager sender channel with which they can be used to establish a connection.

Table 209. Valid chain and WebSphere MQ queue manager sender channel configurations. The first column of the table provides the WebSphere MQ channels. The second to fourth columns in the table indicate whether the TCP, SSL, and MQFAP channels in combination with the WebSphere MQ channel can establish a network connection successfully. It is important to follow a specific order of the channels while building the chain. The order of the channels from left to right as given in the table is TCP, SSL, and MQFAP channels.

WebSphere MQ channel	TCP channel	SSL channel	MQFAP channel
Unsecured WebSphere MQ channel	X		X
WebSphere MQ channel secured by using SSL	X	X	X

For example, an SSL-based chain would consist of a TCP channel, SSL channel and MQFAP channel. When creating chains, the order of channels in the chain is important. You must specify channels in the order (left to right) in which they appear in the above table.

The example in this topic describes how to create an outbound chain capable of being used to contact WebSphere MQ queue manager receiver channels by using SSL-based encryption.

Note: You open a wsadmin command session from within Qshell. For more information, see the topic "Configure Qshell to run WebSphere Application Server scripts".

Procedure

1. Locate the TransportChannelService object for the server in which you want to create the new chain. For example, in a WebSphere Application Server Network Deployment configuration, you can list the available TransportChannelService objects and select the appropriate service.

   Using Jython:

```
wsadmin>AdminConfig.list("TransportChannelService" )
(cells/BadgerCell01/nodes/BadgerCellManager01/servers/dmgr|server.xml
#TransportChannelService_1)
(cells/BadgerCell01/nodes/BadgerNode01/servers/nodeagent|server.xml
#TransportChannelService_1095
711814579)
(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml
#TransportChannelService_109571
2023139)
(cells/BadgerCell01/nodes/BadgerNode01/servers/server2|server.xml
#TransportChannelService_109571
2039302)
wsadmin>tcs = AdminConfig.list("TransportChannelService" ).split("\r\n")[2]
```

   Using Jacl:

```
wsadmin> $AdminConfig list TransportChannelService
(cells/BadgerCell01/nodes/BadgerCellManager01/servers/dmgr|server.xml
#TransportChannelService_1)
(cells/BadgerCell01/nodes/BadgerNode01/servers/nodeagent|server.xml
#TransportChannelService_1095711
814579)
(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml
#TransportChannelService_109571202
3139)
(cells/BadgerCell01/nodes/BadgerNode01/servers/server2|server.xml
#TransportChannelService_109571203
9302)
```

```
wsadmin> set tcs [lindex [$AdminConfig list TransportChannelService] 2]
(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml
#TransportChannelService_109571202
3139)
```

2. Define an outbound TCP channel called testTCPChannel.

   Using Jython:

```
wsadmin>tcpChannel = AdminConfig.create("TCPOutboundChannel", tcs,
[["name", "testTCPChannel"]] )
```

   Using Jacl:

```
wsadmin>set tcpChannel [$AdminConfig create TCPOutboundChannel $tcs
"{name testTCPChannel}"]
testTCPChannel(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml#
TCPOutboundChannel_1095969213949)
```

3. Define an outbound SSL channel called testSSLChannel. There are two steps required to define such a channel.

   a. Identify the SSL alias to be used by the channel.

      Using Jython:

```
wsadmin>for obj in AdminConfig.list("SSLConfig" ).split("\r\n"):
print obj+AdminConfig.show(obj, "alias")
```

      Using Jacl:

```
wsadmin>foreach obj [$AdminConfig list SSLConfig] { puts "$obj
[$AdminConfig show $obj alias]]" }
(cells/BadgerCell01|security.xml#SSLConfig_1) {alias BadgerCellManager01/
DefaultSSLSettings}]
(cells/BadgerCell01|security.xml#SSLConfig_1095711819776) {alias BadgerNode01/
DefaultSSLSettings}]
```

   b. Create an SSL channel as in the following example, in which the BadgerNode01/DefaultSSLSettings alias is used.

      Using Jython:

```
wsadmin>sslChannel = AdminConfig.create("SSLOutboundChannel", tcs, [["name",
"testSSLChannel"], ["sslConfigAlias","BadgerNode01/DefaultSSLSettings"]])
```

      Using Jacl:

```
wsadmin>set sslChannel [$AdminConfig create SSLOutboundChannel $tcs
"{name testSSLChannel}
{sslConfigAlias BadgerNode01/DefaultSSLSettings}"]
testSSLChannel(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml#
SSLOutboundChannel_1095971760671)
```

4. Define an outbound MQFAP channel called testMQFAPChannel.

   Using Jython:

```
wsadmin>mqfapChannel = AdminConfig.create("MQFAPOutboundChannel", tcs,
[["name", "testMQFAPChannel"]] )
```

   Using Jacl:

```
wsadmin>set mqfapChannel [$AdminConfig create MQFAPOutboundChannel $tcs
"{name testMQFAPChannel}"]
testMQFAPChannel(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml#
MQFAPOutboundChannel_1095977512682)
```

5. Finally, create the channel chain by combining the channels defined so far. For example, to create a chain called testChain:

   Using Jython:

```
wsadmin>AdminConfig.create("Chain", tcs, [["name", "testChain"], ["enable",
"true"], ["transportChannels", [tcpChannel, sslChannel, mqfapChannel]]] )
```

   Using Jacl:

```
wsadmin>$AdminConfig create Chain $tcs "{name testChain} {enable true}
{transportChannels {$tcpChannel $sslChannel $mqfapChannel}}"
testChain(cells/BadgerCell01/nodes/BadgerNode01/servers/server1|server.xml#Chain_109
5977640896)
```

Operating buses

Use these tasks to operate service integration buses.

About this task

The topics in this section describe how to display the runtime properties of messaging engines and their associated service integration bus links. The properties are influenced by the following operations:

- Starting and stopping messaging engines.
- Starting and stopping service integration bus links.

Displaying the runtime properties of a messaging engine

Display the runtime properties of a messaging engine by using the administrative console.

Before you begin

To be able to retrieve the status of messaging engines, you must be logged into the administrative console with at least monitor authority. If you do not have this authority, the messaging engine status is displayed as "Unavailable", even if the messaging engine has started. Also, if you are not logged in with the authority needed to retrieve the status of messaging engines, a SECJ0305I error message is logged in the server systemOut log file.

Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

About this task

To display the runtime properties of a messaging engine, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click **Service integration -> Buses**.
2. In the content pane, click the name of the bus to which your messaging engine belongs.
3. In the content pane, under **Topology**, click **Messaging engines**. A list of messaging engines is displayed.
4. Click the messaging engine name.
5. Click the **Runtime** tab. The status of the messaging engine, that is, whether it is currently started or stopped is displayed.

Displaying the runtime properties of a service integration bus link

Display the runtime properties of a service integration bus link by using the administrative console.

About this task

To display the runtime properties of a service integration bus link, use the administrative console to complete the following steps:

Procedure

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine that contains the service integration bus link.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.

4. Select the service integration bus link whose properties you want to display.
5. Click the **Runtime** tab. The following properties are displayed:

   Status
   The runtime status of the service integration bus link.

   Activity
   Whether the service integration bus link is currently inactive, active, or its activity is unknown.

Managing messages on message points

Use these tasks to list and act on runtime messages that exist on message points in a service integration bus.

About this task

You can list the message points for bus destinations and messaging engines, and list the messages on a selected message point. You can use the list of messages as part of a troubleshooting task to find messages that need to be deleted.

- "Listing messages on a message point" on page 595
- "Deleting messages on a message point" on page 596

Managing service integration buses with administrative commands

You can use these commands to manage service integration buses.

About this task

These commands provide an alternative to using the administrative console or using the more complex syntax of wsadmin and Jython.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Procedure

1. Open a wsadmin command session in local mode For example:

   ```
   wsadmin -conntype none -lang jython
   ```

2. Type `AdminTask.`*`command`*, where *command* is the command format as indicated in the related reference topics.

   For example:

```
wsadmin>AdminTask.listSIBusMembers('[-bus bus1 ]')
[cells/cell01/buses/bus1|sib-bus.xml#SIBusMember_1092155259869]
[cells/cell01/buses/bus1|sib-bus.xml#SIBusMember_1092159844593]
[cells/cell01/buses/bus1|sib-bus.xml#SIBusMember_1092160253751]

wsadmin>AdminTask.listSIBEngines('[-bus bus1 ]')
'node01.server1-bus1(cells/cell01/nodes/node01/servers/server1|sib-engines.xml#
SIBMessagingEngine_1212163145962)\r\n
node02.server2-bus2(cells/cell01/nodes/node02/servers/server2|sib-engines.xml#
SIBMessagingEngine_1212163146273)'
```

Administering messaging engines

These topics provide information about messaging engines, which provide the processing function on a service integration bus.

Procedure

- ../ae/cjk_learning.dita
- "Configuring messaging engines" on page 1897

- “Managing messaging engines with administrative commands” on page 1953
- “SIBAdminCommands: Messaging engine administrative commands for the AdminTask object” on page 2313
- ../ae/rjk_prob0.dita

Configuring messaging engines

You can configure messaging engines in a variety of ways. For example, you can create and apply security to a messaging engine, then use this engine to send and receive messages. When you add a server cluster to a service integration bus, at least one messaging engine is created automatically. If you also use messaging engine policy assistance, some configuration properties are set automatically.

Configuring messaging engine properties

You can configure the properties of a messaging engine in the administrative console. For example you can select whether the messaging engine is started automatically when its associated application server is started, how many messages it can process, and target groups that the engine can join.

About this task

In most cases, you can configure the properties of a messaging engine without interrupting the processing of messages by the messaging engine.

Procedure

1. Start the administrative console.
2. Navigate to **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name***.
3. Configure the messaging engine properties. For information about the properties that you can configure, see the property descriptions in “Messaging engines [Settings]” on page 2124
4. Click **OK**.
5. Save your changes to the master configuration.

Listing the messaging engines in a bus

You can view the list of existing messaging engines in a bus by using the administrative console. You can decide which messaging engines you want to change, for example which buses they are associated with.

About this task

To list the messaging engines in a bus, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click **Service integration -> Buses**.
2. In the content pane, click the name of the bus that your messaging engine belongs to.
3. In the content pane, under **Topology**, click **Messaging engines**. The list of messaging engines in the bus is displayed.

Removing a messaging engine from a bus

You can remove a messaging engine from a service integration bus if you no longer require it to send and receive messages on the bus.

Before you begin

You should be wary of deleting and recreating messaging engines on bus members for which WS-Notification-administered subscribers have been configured, because in some cases this can leave the remote web service subscription active (and passing notification messages to the local server) even

though there is no longer any record of it. For more information, see the WS-Notification troubleshooting tip Problems can occur when deleting administered subscribers and messaging engines.

Procedure

1. Stop the messaging engine. You can stop either in **Immediate** or **Force** mode, as described in “Stopping a messaging engine” on page 1951.
2. Use the wsadmin command deleteSIBEngine to delete the messaging engine. All service integration bus links, MQ links, and custom properties that are owned by the engine are deleted.

   Note: When you remove a messaging engine, WebSphere Application Server does not delete the data store tables automatically. You must remove them manually, or delete all the rows in all the tables. If you do this, a new messaging engine might fail to start if it attempts to use an orphaned data store. Refer to the documentation for your chosen relational database management system for information about deleting tables.

   Alternatively, for Apache Derby, you can delete the database directory, which is located in *profile_root*/databases/com.ibm.ws.sib, where *profile_root* is the directory in which profile-specific information is stored. However, do this only if the messaging engine is the sole user of the database.

   For more information, see Data store life cycle.

   Similarly, the file store files are not automatically deleted when you delete the messaging engine. You might want to delete the file store files to reclaim disk space.

Listing the messaging engines defined for a server bus member

You can display a list of messaging engines defined for a server bus member by using the administrative console. You can decide which messaging engines you want to change, for example, which buses they are associated with.

About this task

To display the list of messaging engines, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click either **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines** or **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] Messaging engines**. A list of messaging engines is displayed in the content pane.
2. Optional: Select one or more messaging engines to work with, for example to change the properties of the messaging engine.

Creating the database, schema and user ID for a messaging engine

Before the data store for a messaging engine can be set up, you must first create the database, the schema and the database user ID that the messaging engine needs to access the data store tables.

Before you begin

Before you start this task, review the information in Configuration planning for a messaging engine to use a data store, and ensure that you have taken any appropriate action.

About this task

To create the database, schema and user ID for a messaging engine, complete the following steps.

Procedure

1. Create the database for the data store.
2. Create users and schemas in the database. Ensure that the user ID has sufficient privilege to allow the messaging engine to access the data store tables. For more information about the privileges that are required for the selected database, see “Database privileges” on page 1967.
3. If required, create the data store tables by using the data definition language (DDL) statements generated by using the sibDDLGenerator command.

Configuring a messaging engine data store to use a data source:

After configuring a JDBC data source, you can configure a messaging engine data store to use the data source.

Before you begin

To complete this task, you must have chosen or created a bus and a messaging engine, and the messaging engine must specify data store as its message store type.

You must also have configured a data source, as described in “Creating the database, schema and user ID for a messaging engine” on page 1899.

About this task

A messaging engine uses an instance of a JDBC data source to interact with the database that contains the data store for that messaging engine.

Use the WebSphere Application Server administrative console to set the data store configuration parameters.

Procedure

1. In the navigation pane, click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name***.
2. Check that the **Message store type** is *Data store*.
3. Click **[Additional Properties] Message store**. The data store configuration detail panel is displayed.
4. Specify the following data store configuration details:

   Data source JNDI name
   Type the JNDI name of the data source that provides access to database that holds the data store.

   Schema name
   Type the name of the database schema that contains the tables used by the data store.

   General tip: The schema name is usually the same as the user ID that is declared in the authentication alias. With some databases, for example DB2, you can provide an alternative schema name. For more information about the relationship between users and schema, refer to the documentation for your chosen RDBMS.

   Informix tip: When you configure your messaging engine to use an Informix database, you must specify the schema name in lowercase letters.

   When it is starting, a messaging engine that uses a data store checks to see if its data store exists. If the **Create tables** option is selected for the configuration, the messaging engine creates the tables in its chosen schema.

   The **Schema name** field is optional. If you require a schema name, consider the following:

- The default schema name is `IBMWSSIB`.
- If you delete the text so that field is blank, the messaging engine takes the user id defined in the authentication alias to be the schema name.
- If you define a schema name explicitly, that schema name is used by the messaging engine.
- If there are multiple messaging engines, you must configure each messaging engine to use a unique schema, otherwise FFDC error messages stating that `Connection cannot be provided as Datasource has been disabled!` might appear. This applies to DB2 in particular.

Authentication alias
Select the authentication alias that enables access to the data source.

Apache Derby Tip: When you create a new Network Attached Apache Derby data store, by default you get a blank authentication alias.

Create tables
Select the check box if you want WebSphere Application Server to create the database tables automatically.

Note: The user ID that the messaging engine uses to connect to the data source must have sufficient authority to create the database tables and indexes.

DB2 for z/OS restriction: Do not select **Create tables** if you are using DB2 for z/OS, otherwise an exception will be thrown when WebSphere Application Server attempts to create the tables.

Number of tables for permanent objects
Permanent tables contain persistent objects for the data store.

Note: You can only increase the number of permanent tables, not decrease them.

Number of tables for temporary objects
Temporary tables contain nonpersistent objects that have been saved to the data store to reduce the messaging engine memory requirement.

Note: You can only increase the number of temporary tables, not decrease them.

Configuring service integration bus links

You can configure service integration bus links on messaging engines in a variety of ways. For example, you can start, stop, or remove links.

About this task

When you create a foreign bus connection to connect two service integration buses, a service integration bus link is created automatically. The foreign bus connection contains a routing definition, which is a virtual link, and the service integration bus link is the corresponding physical link on the messaging engine.

Configuring the properties of a service integration bus link:

After establishing a service integration bus link you might want to configure the properties of a service integration bus link such as the name of the service integration bus link, or authentication alias used by foreign bus that the link connects to.

About this task

To configure the properties of a service integration bus link, use the administrative console to complete the following steps:

Procedure

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine for which you want to configure the service integration bus link.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you want to configure.
5. Specify the following properties for the service integration bus link:

   Name The name of the service integration bus link. In order to work, the name must be the same as the name of the corresponding service integration bus link configured on the target foreign bus.

   Description
   An optional description for the service integration bus link, for administrative purposes.

   UUID The universal unique identifier assigned by the system to the service integration bus link for administrative purposes.

   Foreign messaging engine
   The messaging engine on the foreign bus to which this link connects.

   Note: This foreign bus name must not be altered after it has been configured. If you alter it, any messaging engines that already hold state information on the link will not be able to use the link unless the foreign bus name is reset to its original value.

   Target inbound transport chain
   The type of transport chain used for communication with the foreign bus. The transport chain name must be the name of the transport chain as defined on the server on which the target messaging engine is hosted.

   Bootstrap endpoints
   The comma-separated list of endpoints used to connect to a bootstrap server. This property is set in the same way as the **Provider endpoint** property in the JMS connection factory settings. For more information, see the steps relating to setting bootstrap endpoints in "Configuring a connection to a non-default bootstrap server" on page 531.

   Note: Service integration bus links over BootstrapTunneledMessaging and BootstrapTunneledSecureMessaging transport chains only work directly between application server instances. Bus links over TunneledMessaging transport chains do not work if an HTTP server is placed in front of either application server instance.

   Authentication alias
   The name of the authentication alias, used to authenticate access to the foreign bus. The alias must be known to the foreign bus.

   Initial state
   Whether the link is started automatically when the messaging engine is started. Until started, the gateway link is unavailable. If this property is set to **Started** the service integration bus link is started when the messaging engine is started.
6. Click **OK**.
7. Save your changes to the master configuration.

Listing the service integration bus links:

You can list all the service integration bus links that are linked to a messaging engine.

About this task

To list the service integration bus links for a messaging engine, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Service integration -> Buses**.
2. In the content pane, click the name of the bus that your messaging engine belongs to.
3. In the content pane, under **Additional properties**, click **Messaging engines**. The list of messaging engines in the bus is displayed.
4. In the content pane, select the messaging engine for which you want to list the service integration bus links.
5. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.

Example

The following combinations of **Status** and **Activity** values are possible:

Table 210. Results of possible status and activity values. The first and second columns of the table provide the possible combinations of status and activity values, and the third column explains the possible connection status of the local and foreign buses.

Status	Activity	Meaning
started	inactive	The service integration bus link is started on the local messaging engine but has no connection to the foreign bus. The service integration bus link is attempting to activate a connection to the foreign bus. The service integration bus link on the foreign bus must also be started to successfully activate of a connection between the buses.
started	active	The service integration bus link is started on the local messaging engine and has an active connection to the foreign bus.
stopped	inactive	The service integration bus link is stopped on the local messaging engine and there is no connection to the foreign bus.
unknown	inactive	An error might have occurred in setting up the link, such that the object that is used to report the current state is not available.

What to do next

You can now add or remove a service integration bus link or select a service integration bus link to start, stop, or configure.

Starting a service integration bus link:

When a service integration bus link has been started, it can be used for communicating with its associated messaging engines.

About this task

To start a service integration bus link, use the administrative console to complete the following steps:

Procedure

1. Display the list of messaging engines.

2. In the content pane, select the messaging engine for which you want to start the service integration bus link.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you want to start.
5. Click **Start**.

Stopping a service integration bus link:

When a service integration bus link has been stopped, it cannot be used for communication until it is restarted.

About this task

To stop a service integration bus link, use the administrative console to complete the following steps:

Procedure

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine to which the service integration bus link that you want to stop belongs.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you want to stop.
5. Click **Stop**.

Removing a service integration bus link:

When a service integration bus link to a messaging engine has been removed, it cannot be used for communication until it is recreated.

Before you begin

Before you remove the service integration bus link you must stop the link.

When you remove a service integration bus link, all traffic that uses the link needs to be dealt with in a similar way to when you remove a destination. For further details, see “Deleting a non-topic space bus destination” on page 1997. Note that express Quality of Service (QoS) messages are discarded.

About this task

To remove a service integration bus link from a messaging engine, use the administrative console to complete the following steps:

Procedure

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine that is associated with the service integration bus link that you want to remove.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link that you want to remove.
5. Click **Delete**.
6. Save your changes to the master configuration.

What to do next

When you remove a service integration bus link, all traffic that uses the link must be diverted by alternative routes or held pending further administrative action. Express QoS messages are discarded.

Starting a messaging engine

You can either start a messaging engine directly by using the administrative console or by starting the server that hosts the messaging engine.

About this task

To start a messaging engine, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click **Service integration -> Buses**.
2. In the content pane, click the name of the bus that your messaging engine belongs to.
3. Do one of the following to display a list of messaging engines:
   - For a list of messaging engines in the bus, in the content pane, under **Topology**, click **Messaging engines**.
   - For a list of messaging engines for a server, in the content pane, under **Topology**, click **Bus Members**. Click the name of the required server.
   - For a list of messaging engines for a cluster, in the content pane, under **Topology**, click **Bus Members**. Click the name of the required cluster.
4. Select the messaging engine that you want to start.
5. Click **Start**.

Stopping a messaging engine

You can either stop a messaging engine directly or stop it by stopping the server that hosts the messaging engine.

About this task

A messaging engine can stop in two ways:

Immediate
The messaging engine is stopped on completion of all messaging operations that are being carried out at the time of the stop request.

Force The messaging engine is stopped without allowing messaging operations to complete and applications are forcefully disconnected.

To stop a messaging engine, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click **Service integration -> Buses**.
2. In the content pane, click the name of the bus that the messaging engine belongs to.
3. Do one of the following to display a list of messaging engines:
   - For a list of messaging engines in the bus, in the content pane, under **Topology**, click **Messaging engines**.
   - For a list of messaging engines for a server, in the content pane, under **Topology**, click **Bus Members**. Click the name of the required server.

- For a list of messaging engines for a cluster, in the content pane, under **Topology**, click **Bus Members**. Click the name of the required cluster.

4. Select the messaging engine that you want to stop.
5. Select **Immediate** or **Force** from the **Stop mode** drop-down list.
6. Click **Stop**.

What to do next

Tip: If an immediate stop is taking too long, you can escalate it to a force stop by selecting the **Force** option. This overrides your previous selection of the **Immediate** option.

Displaying the runtime properties of a messaging engine

Display the runtime properties of a messaging engine by using the administrative console.

Before you begin

To be able to retrieve the status of messaging engines, you must be logged into the administrative console with at least monitor authority. If you do not have this authority, the messaging engine status is displayed as "Unavailable", even if the messaging engine has started. Also, if you are not logged in with the authority needed to retrieve the status of messaging engines, a SECJ0305I error message is logged in the server systemOut log file.

Note: This topic references one or more of the application server log files. Beginning in WebSphere Application Server Version 8.0 you can configure the server to use the High Performance Extensible Logging (HPEL) log and trace infrastructure instead of using `SystemOut.log` , `SystemErr.log`, `trace.log`, and `activity.log` files or native z/OS logging facilities. If you are using HPEL, you can access all of your log and trace information using the LogViewer command-line tool from your server profile bin directory. See the information about using HPEL to troubleshoot applications for more information on using HPEL.

About this task

To display the runtime properties of a messaging engine, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click **Service integration -> Buses**.
2. In the content pane, click the name of the bus to which your messaging engine belongs.
3. In the content pane, under **Topology**, click **Messaging engines**. A list of messaging engines is displayed.
4. Click the messaging engine name.
5. Click the **Runtime** tab. The status of the messaging engine, that is, whether it is currently started or stopped is displayed.

Displaying the runtime properties of a service integration bus link

Display the runtime properties of a service integration bus link by using the administrative console.

About this task

To display the runtime properties of a service integration bus link, use the administrative console to complete the following steps:

Procedure

1. Display the list of messaging engines.
2. In the content pane, select the messaging engine that contains the service integration bus link.
3. In the content pane, under **Additional properties**, click **Service integration bus links**. A list of service integration bus links is displayed.
4. Select the service integration bus link whose properties you want to display.
5. Click the **Runtime** tab. The following properties are displayed:

   Status
   The runtime status of the service integration bus link.

   Activity
   Whether the service integration bus link is currently inactive, active, or its activity is unknown.

Managing messaging engines with administrative commands

You can use these commands to manage messaging engines.

About this task

These commands provide an alternative to using the administrative console or using the more complex syntax of wsadmin and Jython.

Procedure

1. Open a wsadmin command session in local mode. For example:

```
wsadmin -conntype none -lang jython
```

   The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

2. Type `AdminTask.`*`command`*, where *command* is the command format as indicated in the related reference topics.

   For example:

```
wsadmin>AdminTask.listSIBusMembers('[-bus bus1 ]')
[cells/cell01/buses/bus1|sib-bus.xml#SIBusMember_1092155259869]
[cells/cell01/buses/bus1|sib-bus.xml#SIBusMember_1092159844593]
[cells/cell01/buses/bus1|sib-bus.xml#SIBusMember_1092160253751]

wsadmin>AdminTask.listSIBEngines('[-bus bus1 ]')
'node01.server1-bus1(cells/cell01/nodes/node01/servers/server1|sib-engines.xml#
SIBMessagingEngine_1212163145962)\r\n
node02.server2-bus2(cells/cell01/nodes/node02/servers/server2|sib-engines.xml#
SIBMessagingEngine_1212163146273)'
```

Administering message stores

A message store enables a messaging engine to preserve operating information and to retain those objects that messaging engines need for recovery in the event of a failure. The default message store for a typical messaging engine is file store. You can also configure a messaging engine to use a data store.

Procedure

- “Administering file stores”
- “Administering data stores” on page 1957

Administering file stores

A file store is a type of message store that directly uses files in the file system through the operating system. Each messaging engine has one and only one file store.

Configuring file store attributes for a messaging engine

When a messaging engine is created, it uses a file store by default. You can configure the file store attributes according to your requirements.

About this task

You set up a messaging engine to use a file store by accepting the default choice of message store when you are creating a bus and adding a new bus member. You can choose either to accept the default settings that the administrative console displays, or to make changes to these settings. After the file store has been created, you can, if required, then make changes to the file store settings.

Modifying file store configuration:

After a file store has been created, you can, if required, modify file store attributes.

About this task

When you add a new bus member that uses a file store, you can choose either to accept the default settings for the file store or make changes to these settings, depending on your requirements.

After the file store has been created, you can, if required, subsequently modify the log size, permanent store size, or temporary store size settings directly through the administrative console. The new values take effect the next time the messaging engine is started.

The directory paths for the file store are fixed when the file store is created, and cannot subsequently be modified. You can create a new file store in a new location. To do this you remove the server or cluster as a bus member and then add it again choosing a new location for the file store. Any messages remaining in the original file store would be lost during this process.

Note: The default configuration for a file store is intended to be sufficient when used in typical messaging workloads. To improve the performance or resilience of the log file, the permanent store file, or the temporary store file, you can modify the file store attributes to control where these files are placed. For example, you can achieve better performance if you place these three file store files on a faster disk. Similarly, you can control the sizes of the log file, the permanent store file, and the temporary store file so that they can handle workloads with a large number of active transactions, large messages, or a large volume of message data resident in the messaging engine.

Procedure

- To make changes to the log size, permanent store size or temporary store size, complete the following steps:
  1. Open the Administrative console.
  2. Click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional Properties] Message store**.
  3. Make the changes that you require to the existing log size, permanent store size, or temporary store settings, then click **OK**. For more information about configuring the properties, see “File store [Settings]” on page 2057
  4. Save your changes to the master configuration.
- To choose a new location for a file store, complete the following steps:
  1. To avoid losing messages on destinations that are localized on the file store, first ensure that no messages are left on the queues.
  2. Remove the server or cluster as a member of the bus.
  3. Add the server and cluster as a bus member again, choosing a new location for the file store.

Selecting messaging engine behavior when a file store is full:

You can specify what action a messaging engine takes when a file store is full and applications try to send further messages. You can make application threads wait for the checkpoint to complete, or throw an exception immediately.

About this task

When a file store is full, the messaging engine carries out a checkpoint of the log file to reconcile all message sends and receives since the last checkpoint. This process might take some time to complete. Between the time when the file store becomes full and the time when the checkpoint is complete, if applications try to send a message, the messaging engine throws the exception ObjectStoreFullException and issues message CWSOM1042E.

When an application thread that is sending a message finds that the file store is full, it requests a checkpoint. The default behavior is that the application thread then throws the exception ObjectStoreFullException to the application immediately. You can select an alternative behavior where the application thread does not throw the exception, but waits until the checkpoint has completed. If the checkpoint frees space in the file store, the application thread proceeds and sends the messages before returning. If the file store is still full after the checkpoint, the application thread throws the exception to the application.

Choose to make application threads wait if your applications delete all the messages in the file store, and so they logically know that the file store is no longer full. Although the applications must still wait until the checkpoint is complete, they do not receive exceptions while the checkpoint is being carried out, and they do not have to retry the send.

To change the behavior when the file store is full, use the administrative console to set the value of the property sib.msgstore.storeFullWaitForCheckPoint as follows:

Procedure

1. In the navigation pane, click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional Properties] Custom properties**.
2. Type the name of the property, `sib.msgstore.storeFullWaitForCheckPoint`.
3. Type the value `true` to make application threads wait for the checkpoint to complete before returning. The default value `false` makes application threads throw the exception ObjectStoreFullException immediately after requesting the checkpoint.
4. Click **OK**.
5. Save your changes to the master configuration.

What to do next

Remember: When you change this property, the new value does not take effect until you restart the messaging engine.

Deleting files following removal of a messaging engine:

Removing a messaging engine from the configuration does not automatically delete the file store files. You must also find and delete the log file, the permanent store file, and the temporary store file from the disk to reclaim disk space.

About this task

Files comprising a file store still remain when the messaging engine is deleted. If you are using the default values for the file store directory names, you can delete and then re-create a messaging engine with the same name without manually removing the files. This is due to the presence of the universal unique identifier (UUID) of the messaging engine in the default log and store directory names of a file store.

For example, if the deleted messaging engine is called messagingengine0, and the new one is called messagingengine1, then the log file in the old file store is:

```
C:\{USER_INSTALL_ROOT}\filestores\..\messagingengine0\..\logfile
```

The log file in the new files store is:

```
C:\{USER_INSTALL_ROOT}\filestores\..\messagingengine1\..\logfile
```

The two log files coexist in the same file stores directory. You do not have to delete the old files.

Procedure

1. Locate the directory in which your old file store log files and store files are stored.
2. Delete the redundant files by using the facilities of the operating systems.

Results

After deleting the files left by the redundant file store, free disk space becomes available to your file system.

Backing up and restoring a messaging engine file store

A file store is a type of message store that directly uses files in a file system through the operating system. Therefore, administration of the file store depends on the type of operating system.

About this task

- “Backing up a file store”
- “Restoring a file store”

Backing up a file store:

You can back up the files in a file store by using the facilities of your operating system, or by using a backup tool.

About this task

A file store is a type of message store that directly uses files in a file system through the operating system. Use the facilities of your operating system or a backup tool to back up the log file, the permanent store file, and the temporary store file, which comprise a file store. For more information about these files, see ../ae/cjm1450_.dita.

Important: If you start backing up files while the messaging engine is still running, data might be corrupted.

Note: You must treat the log file, the temporary store file, and the permanent store file as one unit; that is, any operations must be performed on all three files.

Restoring a file store:

You can restore the files in a file store by using the facilities of your operating system, or you can restore the backup copies of your files by using a backup tool.

Before you begin

Before you start this task, make sure that the messaging engine is not running.

Important: If you restore a file store while the messaging engine is still running, data might be corrupted.

About this task

When you complete this task, you must treat the log file, the temporary store file, and the permanent store file (which together comprise a file store) as one unit; that is, any operations must be performed on all three files. For more information about these files, see ../ae/cjm1450_.dita.

Procedure

Use the facilities of your operating system, or a backup tool, to restore the backup copy of the log file, the permanent store file, and the temporary store file.

Administering data stores

A data store is a type of message store that uses a relational database. A data store consists of a set of tables that are in the same database schema. It is used by a messaging engine to store operating information in the database, as well as to preserve essential objects that the messaging engine needs for recovery in the event of a failure.

About this task

A data store consists of the set of tables that a messaging engine uses to store persistent data in a database. See “Data store tables” on page 1967 for a list of the tables that comprise a data store. All the tables in a data store are held in the same database schema. You can create multiple data stores in the same database, provided that you use a different schema name for each data store.

Configuring a messaging engine to use a data store

Although the default message store for a typical messaging engine is file store, you can also configure a messaging engine to use a data store.

About this task

Each messaging engine has its own file store or data store. If the data store is chosen the messaging engine uses an instance of a JDBC data source to interact with the database that contains the data store for that messaging engine.

When a new messaging engine that uses a data store is created on a single server, it is configured to use an Apache Derby data source by default. This enables the messaging engine to run without needing any additional configuration.

If you want to configure a new messaging engine to use your chosen data source when you create that messaging engine on a single server, see “Adding a server as a new bus member” on page 1889.

If you do not want to use the default data source configuration, you can use the WebSphere Application Server administrative console to change the configuration parameters. For example, you can change the data source or you can configure the data store to use a different JDBC provider.

Note: WebSphere Application Server supports direct customer use of the Apache Derby database in *test* environments only. The product does not support direct customer use of Apache Derby database in *production* environments.

Creating the database, schema and user ID for a messaging engine:

Before the data store for a messaging engine can be set up, you must first create the database, the schema and the database user ID that the messaging engine needs to access the data store tables.

Before you begin

Before you start this task, review the information in Configuration planning for a messaging engine to use a data store, and ensure that you have taken any appropriate action.

About this task

To create the database, schema and user ID for a messaging engine, complete the following steps.

Procedure

1. Create the database for the data store.
2. Create users and schemas in the database. Ensure that the user ID has sufficient privilege to allow the messaging engine to access the data store tables. For more information about the privileges that are required for the selected database, see “Database privileges” on page 1967.
3. If required, create the data store tables by using the data definition language (DDL) statements generated by using the sibDDLGenerator command.

Creating the database for a data store:

When you are creating a database to use as the data store for your messaging engine, you must choose a relational database management system (RDBMS) and create the database in accordance with your selected RDBMS.

Before you begin

Choose which Relational Database Management System (RDBMS) you want to use for the data store. Unless you are using the embedded Apache Derby provider, create the database before you create a messaging engine. Make a note of the database parameters that you need for configuring the data source. For more information, see “Configuring a JDBC data source for a messaging engine” on page 1960.

Procedure

Refer to the documentation for your chosen RDBMS for information about how to create a database. The default database for a data store is an embedded Apache Derby database. If you have chosen to configure the bus member to use a data store with default settings, it can only be a server. Unless the data store database exists already, the messaging engine creates the database automatically when the messaging engine makes its initial connection.

Sybase tips:

- Ensure that you create the database server with a page size of at least 4 KB.
- Ensure that you set the **lock scheme** property on your server to the value `datarows`. This avoids the possibility of a deadlock on the data store tables.
- Ensure that you set the **enable housekeeper GC** property on your server to the value `5`. This improves the ability of the server to reclaim redundant space within your database when it is under heavy load.
- Ensure that you select the **allow nulls by default** option for your database instance. This is required for the correct operation of the messaging engine.

Informix tip: The one-to-one relationship between a messaging engine and a data store means that every messaging engine must have its own database tables. If you are using the Informix RDBMS, configure a separate database instance for each messaging engine. Problems have been observed in this environment when the data stores for multiple messaging engines were configured to use separate schemas in the same database.

Creating users and schemas in the database:

After you have created a database, you create the schema in which all tables in the data store are held. Depending on which database you are using, you create one or more database user IDs to enable the messaging engine to access the data store tables.

Before you begin

Before you begin this task, you must first create the database for your messaging engine.

About this task

All the tables in the data store must be stored in the same schema. You can create more than one data store in a database, provided that you use a different schema name for each data store. Although every messaging engine uses the same table names, its relationship with the schema gives each messaging engine exclusive use of its own tables.

To connect to WebSphere Application Server, you must create at least one messaging engine user ID. The number of user IDs you need depends on the database you use:

- If you are using Derby, DB2, or Oracle, the messaging engine can be configured to create any additional schemas that might be required for other data stores. That is, if you only create one user, it can have one to many relationships with the schemas in the database. See “Configuring a messaging engine data store to use a data source” on page 1899 for details.
- For all other types of databases, the schemas must be created before starting the messaging engines that depend on them.

If a database user ID can be configured to use multiple schemas, then only that user ID is needed for all messaging engines. Otherwise the user ID is restricted to using tables in its own schema. In this case there can be only one user ID per schema.

Procedure

1. Create the users and schema in accordance with the documentation for your chosen relational database management system (RDBMS). With DB2 databases, you create users and schema in separate steps. With the other databases, there is a one-to-one relationship between a schema and a user.
2. Ensure that the messaging engine user ID has the privileges required to enable the messaging engine to access the data store tables and, if required, create the data store tables automatically. See “Database privileges” on page 1967.

Creating data store tables:

When you create the data store tables, you have two options. You can either choose that WebSphere Application Server does it automatically, or that the database administrator does it manually.

Before you begin

Before you begin this task, decide whether you want WebSphere Application Server to create the tables automatically, or whether you want your database administrator to create the tables.

DB2 for z/OS restriction: The option for WebSphere Application Server to create the tables is not available with DB2 for z/OS. Refer to “Generating the DDL statements needed to create data store tables manually” on page 1960 if you use DB2 for z/OS.

Procedure

- If you want WebSphere Application Server to create the tables, complete the following steps:

1. Ensure that WebSphere Application Server has sufficient authority to create tables and indexes. For more information about the privileges required for your chosen database, see “Database privileges” on page 1967.
2. When you configure your messaging engine data store, ensure that the **Create tables** option is selected so that the messaging engine creates the tables in its chosen schema. For more information, see “Configuring a messaging engine data store to use a data source” on page 1899.

   DB2 for z/OS restriction: Do not select **Create tables**, otherwise an exception will be thrown when WebSphere Application Server attempts to create the tables.

- If you want your database administrator to create the database tables manually, use the sibDDLGenerator command to generate the DDL statements that the database administrator needs to create the tables for the messaging engine data store. For further information, see “Generating the DDL statements needed to create data store tables manually.”

Generating the DDL statements needed to create data store tables manually:

To enable your database administrator to create the data store tables manually, you must generate data definition language (DDL) statements.

Before you begin

Before you start this task, review the information in Configuration planning for a messaging engine to use a data store, and ensure that your database administrator has taken any appropriate action.

About this task

Use the sibDDLGenerator command to generate the DDL statements that the database administrator needs to create the tables for the messaging engine data store.

Procedure

1. At a command prompt, issue the sibDDLGenerator command and redirect the output to a file. Refer to “sibDDLGenerator command” on page 2425 for a description of the sibDDLGenerator command.

   Important: If you want to process the DDL statements with a command line processor that requires the statements to conform to a specific format, use the optional parameters that control the format of the DDL statements. For example, if each statement must end with a semicolon, use **-statementend** *;*

   To access the IBM i command line, or run an IBM i command line program, use the STRQSH command to start a Qshell session. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.
2. Send the output file to your database administrator to process the DDL statements that are generated. The DDL statements can be ported across operating systems, for example, you can generate the DDL statements on a machine running the Windows operating system and then run them on a machine running the z/OS operating system.

   Attention:

   - Your database administrator can modify the DDL statements, but *must not* modify the table names or the column names in any way because doing so might prevent the messaging engine from starting.
   - If the DDL statements are to be run on the z/OS operating system, your database administrator must change the VCAT name in the first line of the DDL statements (the create storage group statement) to a valid high-level qualifier for their system.

Configuring a JDBC data source for a messaging engine:

If you are using a data store for a messaging engine, the messaging engine uses an instance of JDBC data source to interact with the database containing the data store.

Before you begin

Restriction: When you are configuring a service integration bus member to use a data store, be aware that using a type 2 JDBC driver for the data store is not supported for configurations where WebSphere MQ server definitions are also used. If your configuration includes WebSphere MQ server definitions and you are using a data store, you must use type 4 JDBC drivers.

Apache Derby Tip: When you create a new Network Attached Apache Derby data store, by default you get a blank authentication alias.

Oracle Tip: Use the Oracle 10g thin driver for the service integration data store. This driver is compatible with earlier versions of Oracle.

About this task

Each messaging engine has its own file store or data store. If the data store is chosen the messaging engine uses an instance of a JDBC data source to interact with the database that contains the data store for that messaging engine.

Use the administrative console to set the data source configuration parameters. Note that your choice of relational database management system (RDBMS) determines the parameters you set.

Procedure

1. Create a JDBC provider. See “Configuring a JDBC provider using the administrative console” on page 273. Under **General Properties**, in the **Select the implementation type** field, ensure that you select *Connection pool data source*.

   For information about the settings for your chosen RDBMS, see “Data source minimum required settings, by vendor” on page 253.
2. Create a data source for the JDBC provider. Refer to “Configuring a data source using the administrative console” on page 280.
   a. Under **Additional Properties**, ensure that you select *Data sources*.
   b. Configure the connection pool for the JDBC data source. Set the **Maximum connections** to the number of connections you require, for example, at least 50. The default number of connections is 10. For more information, see ../ae/tjm0230_.dita.
3. Test the connection by using the test connection service provided for validating data source configurations See “Test connection service” on page 330.

Configuring a messaging engine data store to use a data source:

After configuring a JDBC data source, you can configure a messaging engine data store to use the data source.

Before you begin

To complete this task, you must have chosen or created a bus and a messaging engine, and the messaging engine must specify data store as its message store type.

You must also have configured a data source, as described in “Creating the database, schema and user ID for a messaging engine” on page 1899.

About this task

A messaging engine uses an instance of a JDBC data source to interact with the database that contains the data store for that messaging engine.

Use the WebSphere Application Server administrative console to set the data store configuration parameters.

Procedure

1. In the navigation pane, click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name***.
2. Check that the **Message store type** is *Data store*.
3. Click **[Additional Properties] Message store**. The data store configuration detail panel is displayed.
4. Specify the following data store configuration details:

   Data source JNDI name
   Type the JNDI name of the data source that provides access to database that holds the data store.

   Schema name
   Type the name of the database schema that contains the tables used by the data store.

   General tip: The schema name is usually the same as the user ID that is declared in the authentication alias. With some databases, for example DB2, you can provide an alternative schema name. For more information about the relationship between users and schema, refer to the documentation for your chosen RDBMS.

   Informix tip: When you configure your messaging engine to use an Informix database, you must specify the schema name in lowercase letters.

   When it is starting, a messaging engine that uses a data store checks to see if its data store exists. If the **Create tables** option is selected for the configuration, the messaging engine creates the tables in its chosen schema.

   The **Schema name** field is optional. If you require a schema name, consider the following:

   - The default schema name is `IBMWSSIB`.
   - If you delete the text so that field is blank, the messaging engine takes the user id defined in the authentication alias to be the schema name.
   - If you define a schema name explicitly, that schema name is used by the messaging engine.
   - If there are multiple messaging engines, you must configure each messaging engine to use a unique schema, otherwise FFDC error messages stating that `Connection cannot be provided as Datasource has been disabled!` might appear. This applies to DB2 in particular.

   Authentication alias
   Select the authentication alias that enables access to the data source.

   Apache Derby Tip: When you create a new Network Attached Apache Derby data store, by default you get a blank authentication alias.

   Create tables
   Select the check box if you want WebSphere Application Server to create the database tables automatically.

   Note: The user ID that the messaging engine uses to connect to the data source must have sufficient authority to create the database tables and indexes.

DB2 for z/OS restriction: Do not select **Create tables** if you are using DB2 for z/OS, otherwise an exception will be thrown when WebSphere Application Server attempts to create the tables.

Number of tables for permanent objects
Permanent tables contain persistent objects for the data store.

Note: You can only increase the number of permanent tables, not decrease them.

Number of tables for temporary objects
Temporary tables contain nonpersistent objects that have been saved to the data store to reduce the messaging engine memory requirement.

Note: You can only increase the number of temporary tables, not decrease them.

Backing up and restoring a messaging engine data store

Administering the data store for a messaging engine includes restoring and backing up the data store.

About this task

- "Backing up a data store"
- "Restoring a data store"

Backing up a data store:

Backing up a data store enables you to restore the data store from the backup if a failure occurs that cannot be dealt with by the system.

About this task

To back up the tables that comprise a data store, refer to the documentation for your chosen database.

Note: If your relational database management system (RDBMS) is DB2, and it is being used as the persistent data store, the backup process can use the suspended I/O feature of DB2. With other databases that do not possess this capability, the backup might present a longer interruption to service, or require that the messaging engine is stopped while the backup is made. If you attempt to back up the data store for a messaging engine that is still running, you might lose or corrupt important data.

Procedure

1. Unless your backup process uses the suspended I/O feature of DB2 stop the messaging engine.
2. Back up the data store in accordance with the documentation for your chosen database. Include the tables described in "Data store tables" on page 1967.

Restoring a data store:

If a failure occurs that cannot be dealt with by the system, you can restore the data store from a backup, if you are regularly backing up the data store tables.

About this task

To restore the tables that comprise a data store, refer to the documentation for your chosen database.

Note: You must stop the messaging engine before restoring the data store. If you attempt to restore the data store for a messaging engine that is still running, you might lose or corrupt important data.

Procedure

Restore the data store in accordance with the documentation for your chosen database. Include the tables described in “Data store tables” on page 1967.

Emptying the data store for a messaging engine

By emptying the data store of a messaging engine, you can discard persistent operating information without deleting the messaging engine.

About this task

Persistent operating information for a messaging engine is stored as persistent messages and associated information about message delivery and transmission. To discard this information without deleting the messaging engine and its destinations from the WebSphere Application Server configuration, you empty the messaging engine data store.

CAUTION:

- **When you empty the data store, all of the persistent messages that were held are lost and any destinations that you created continue to exist.**
- **Be very careful to completely empty the data store. You get unpredictable behavior if the data store is only partially emptied.**

Procedure

1. Ensure that the messaging engine and application server are stopped.
2. Empty the data store. There are several ways to achieve this:
   a. If you are using the **embedded Derby** database (as the default data store does) and the database contains just the tables for the messaging engine data store, delete the files that the database uses. This deletes the database. When the messaging engine is next started, it creates an empty database to replace it.

      Important: If you are using the same database for application data, you must instead empty the data store tables as described for any other RDBMS in a subsequent step.

      1) Find the database data directory in your file system. The name of the directory that contains the files used by the database is the same as the name of the database in the configuration of the JDBC data source used by the messaging engine data store. By default, this is

         `${USER_INSTALL_ROOT}/profiles/dmgr/databases/com.ibm.ws.sib/messagingEngineName`

      2) Delete the directory. If you have configured a separate log directory for your Derby database, delete this too. If you find that you cannot delete the files, confirm that the application server is also stopped (if you stop the messaging engine but not the application server, you cannot delete the files).

   b. If you are using the **Derby Network Server** database, use a similar procedure but also stop Derby Network Server before you delete the files. You must restart Derby Network Server before starting the messaging engine.

   c. If you are using any other RDBMS, empty the data store tables by using the administration tools of your RDBMS. You can either remove all data from the tables, or drop and recreate the tables.

      Most RDBMS support the TRUNCATE TABLE statement that removes all data from the tables. This is the preferred way of emptying the data store tables because it leaves the tables and their authorizations intact.

      If you RDBMS does not support the TRUNCATE TABLE statement (for example, DB2 does not), you can use the DELETE statement to delete all of the rows from all of the tables. However, if the tables contain a lot of data, this might not be practical because of resource limitations in the RDBMS. In this case, drop the tables and recreate them with the required indices and authorities.

Tip: If you have enabled WebSphere Application Server to create the data store tables, you can drop the tables by using the DROP TABLE statement. When the messaging engine is next started, it creates empty tables to replace them. If you have not enabled WebSphere Application Server (base) to create the data store tables, you must recreate the tables that you drop before you start the messaging engine.

Tip: You can use the **-drop** option of the sibDDLGenerator command to generate DDL to drop the tables.

Optional: If you have deleted the messaging engine by removing it from the bus, you can now recreate it.

3. Start the messaging engine and the application server.

Sharing connections to benefit from one-phase commit optimization

In some circumstances, you can configure your JMS application to share the JDBC connection that a messaging engine uses. Sharing connections enables you to use one-phase commit optimization. This can improve the performance of your application.

About this task

Messaging engines store persistent data in a database, and use a JDBC data source to interact with that database. Some JMS applications also store persistent data in a database, for example if the application uses entity enterprise beans. Typically, such applications use two-phase commit transactions to coordinate updates to the JMS and JDBC resources involved.

You can configure your application to share the JDBC connection used by a messaging engine, which enables you to use one-phase commit transactions and improve the performance of your application. You can benefit from the one-phase commit optimization in the following circumstances:

- Your application must use the assured persistent reliability attribute for its JMS messages.
- Your application must use container-managed persistence (CMP) entity beans that are bound to the same JDBC data source that the messaging engine uses for its data store.

Restriction: You cannot benefit from the one-phase commit optimization in the following circumstances:

- If your application uses a reliability attribute other than assured persistent for its JMS messages.
- If your application uses BMP entity beans, or JDBC clients.
- If your application uses DB2 High Availability Disaster Recovery (HADR).

Before you configure your system, ensure that you consider all of the components of your Java EE application that might be affected by one-phase commits.

Procedure

1. Select the assured persistent reliability attribute for your JMS messages.
2. Deploy all CMP enterprise beans involved in one-phase commit transactions with **res-auth** set to `Container`.
3. Deploy all CMP enterprise beans involved in one-phase commit transactions where **AccessIntent** maps to a transaction isolation level of `JDBC Read Committed`. You can choose any of the following values for **AccessIntent**:
   - `WSOptimisticUpdate`
   - `WSOptimisticRead`
   - `WSPessimisticUpdate-NoCollisions`

Oracle tip: All values for **AccessIntent**, except `WSPessimisticUpdateExclusive`, map to the `JDBC Read Committed` transaction isolation level.

DB2 tip: You can use any value for **AccessIntent**, because WebSphere Application Server exploits the DB2 dynamic transaction isolation level support.

4. Ensure that you use the same authentication alias for both your CMP enterprise beans and the messaging engine data store.
5. When you configure your JDBC data source, ensure that you select the **Use data source for CMP beans** option.
6. Set the value of the JDBC data source custom property **jmsOnePhaseOptimization** to `true`.
7. Use the JMS connection factory or activation specification panels to select the **Share data source with CMP** option.
8. When you create your JDBC provider and set the **Select the implementation type** field, ensure that you select `Connection pool data source` (and not `XA data source`).

Configuring messaging engine and server behavior when a data store connection is lost

If the connection between a running messaging engine and its data store is lost, either due to a failure or because you stop the database for maintenance, you can ensure that the messaging engine functions correctly after the connection is restored, by configuring the server to restart automatically.

About this task

The behavior described in this topic occurs only if the messaging engine is running and has established exclusive locks on its data store.

By setting the sib.msgstore.jdbcFailoverOnDBConnectionLoss custom property on a messaging engine, you can determine the behavior of the messaging engine and its hosting server in the event that the connection to the data store is lost.

Table 211. The behavior that is determined by the sib.msgstore.jdbcFailoverOnDBConnectionLoss custom property.. The first column of the table lists the sib.msgstore.jdbcFailoverOnDBConnectionLoss custom property values. The second column explains the behavior of the messaging engine when the data store connection is lost.

Property value	Behavior when the data store connection is lost
true (default)	The server shuts down and must be manually restarted.
false	The messaging engine continues to run and accept work, and periodically attempts to regain the connection to the data store. If work continues to be submitted to the messaging engine while the data store is unavailable, the results can be unpredictable, and the messaging engine can be in an inconsistent state when the data store connection is restored. **Note:** If work continues to be submitted to the messaging engine, even nonpersistent messaging can fail because the messaging engine might need to use the data store, for example to allocate a unique ID to a message, or to move nonpersistent messages out of memory.

Procedure

1. Click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional Properties] Custom properties** to navigate to the custom properties panel for the messaging engine.
2. Click **New**.
3. Type `sib.msgstore.jdbcFailoverOnDBConnectionLoss` in the Name field and `true` in the Value field.
4. Click **OK**.
5. Save your changes to the master configuration.
6. Restart the application server.

Results

If the connection between the messaging engine and its data store is lost, the application server that is hosting the messaging engine shuts down.

What to do next

After a server restart, click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines** to view the status of the messaging engine. Check that the messaging engine has been restarted and is running.

You might want to tune your system so that the loss of the database connection is detected quickly, and the messaging engine waits for a reasonable amount of time for the data store to become available again before attempting to start on another server.

Data store tables

A data store uses a relational database management system (RDBMS), working through JDBC, to store data as rows in a set of tables. This data is important when you are backing up or restoring a data store.

The following table summarizes the purpose of each data store table.

Table name	Purpose
SIBOWNER	Ensures exclusive access to the data store by an active messaging engine.
SIBOWNERO	Used for locking the data store. This table stores no data in its one EMPTY_COLUMN column.
SIBCLASSMAP	Catalogs the different object types in the data store.
SIBLISTING	Catalogs the SIB*nnn* tables.
SIBXACTS	Maintains the status of active two-phase commit transactions.
SIBKEYS	Assigns unique identifiers to objects in the messaging engine.
SIB*nnn*, where *nnn* is a number	Contains persistent objects such as messages and subscription information. These tables hold both persistent and nonpersistent objects, using separate tables for the different types of data.

Note: The SIBOWNERO table was introduced for WebSphere Application Server Version 7.0 and must be created when you are migrating to WebSphere Application Server Version 7.0 or later from an earlier version of WebSphere Application Server. See ../ae/tjm0004_.dita for things to consider when you are migrating a messaging engine based on a data store.

Database privileges

In order for a messaging engine to use its data store, the database user ID that the messaging engine uses must have sufficient privilege to enable the messaging engine to access the data store tables. If you want the messaging engine to create the data store tables automatically, the messaging engine user ID requires additional privileges.

The following table describes the database privileges that the messaging engine user ID requires to access the data store and create the data store tables.

Database management system	Minimum privilege required for the messaging engine to use the data store tables	Additional privilege required for the messaging engine to create the data store tables
DB2	The messaging engine user ID needs **SELECT**, **INSERT**, **UPDATE**, and **DELETE** privileges on the tables.	The messaging engine user ID needs **CREATETAB** authority on the database and **USE** privilege on the table space as well as **CREATEIN** privilege on the schema.
Oracle	The messaging engine user ID needs at least **SESSION** privilege to connect to the database. If the same user ID owns both the data store schema and the messaging engine that is connecting to the database, the messaging engine has sufficient privilege to manipulate the tables. Otherwise, the messaging engine needs **SELECT**, **INSERT**, **UPDATE** and **DELETE** object privileges on the tables that comprise the data store, and **DROP ANY TABLE** system privilege to enable use of the TRUNCATE TABLE statement.	The messaging engine user ID requires sufficient privilege to create relational tables and indexes in the data store schema. The messaging engine also requires a space quota in the default tablespace of the owner of that schema.
SQL Server	Configure the SQL Server for **SQL Server and Windows** authentication. This allows authentication to be based on an SQL server login ID and password. The messaging engine user ID can be the owner of the tables, or be a member of a group that has sufficient authority to issue TRUNCATE TABLE statements.	The messaging engine user ID needs **CREATE TABLE** statement privilege.
Sybase	The messaging engine user ID can be the owner of the tables, or can be a member of a group that has sufficient authority to issue TRUNCATE TABLE statements.	The messaging engine user ID needs **CREATE TABLE** permission.
Informix	The messaging engine user ID must have **CONNECT** privilege on the database. It must also have **SELECT**, **INSERT**, **UPDATE** and **DELETE** authority on the tables.	The messaging engine user ID must have **RESOURCE** privilege on the database.
Derby	If user authentication is enabled, you must authorize the messaging engine user ID to access the database. **Remember:** The default database that is generated by the messaging engine has no security mechanisms enabled.	You need no additional privileges.

If you do not grant TRUNCATE TABLE authority to the database user ID, you can force the messaging engine to delete rows individually instead of truncating the table. To force the messaging engine to delete rows individually, set **sib.msgstore.jdbcUseDeleteInsteadOfTruncateAtStartup** to true as a custom property of the messaging engine.

Note: If you use DELETE instead of TRUNCATE, startup is slower when there are many non-persistent messages in the datastore.

Avoiding message store errors when creating a messaging engine

Using different combinations of parameters can create a file store or a data store according your requirements. The outcome varies in server and cluster scopes.

Server scope

When you add a server as a new bus member take note of the following:

- If you do not specify the type of message store, then a file store is created by default. If you set **Create default data source** to *True* or supply a **Data source JNDI name**, then a data store is created.
- If you choose to use a **file store**, then only file store attributes are presented to be specified. For example the **log file directory**.
- If you choose to use a **data store**:
  - Only data store attributes are presented to be specified. For example the **Data source JNDI name**.
  - If you set **Create default data source** to *False* then you must specify a **Data source JNDI name**.

For more information about file store and data store refer to “Administering message stores” on page 1953.

Cluster scope

When you add a cluster as a new bus member take note of the following:

- If you choose to use a **file store**:
  - You must not use the default log file, permanent store file and temporary store file directories because they are not suitable for cluster engines.
  - You must specify the **Log directory**, **Permanent store directory** and **Temporary store directory** to be at locations that all members of the cluster can access on your file system.
- If you choose to use a **data store**:
  - You must not use the default data source because it is not suitable for cluster engines.
  - You must specify the **Data source JNDI name** of an existing data source.

For more information about file store and data store refer to “Administering message stores” on page 1953.

Avoiding errors when creating a messaging engine with a file store or a data store by using the wsadmin tool

Using different combinations of parameters can create a file store or a data store according your requirements. The outcome varies in server and cluster scopes.

Server scope

When you add a server as a new bus member by using administrative commands (by specifying `createSIBEngine -server`) take note of the following:

- If you do not specify the type of message store, then a file store is created by default. If you specify `-createDefaultDatasource` or `-dataSourceJndiName`, then a data store is created.
- If you choose to use a **file store** (by specifying `-filestore`), then only file store attributes can be specified.
- If you choose to use a **data store** (by specifying `-datastore`):
  - Only data store attributes can be specified.
  - If you set `-createDefaultDatasource` to `False` then you must specify `-dataSourceJndiName`.

Cluster scope

When you add a cluster as a new bus member by using administrative commands (by specifying `createSIBEngine -cluster`) take note of the following:

- If you choose to use a **file store** (by specifying `-filestore`):

  - You must not use the default log file, permanent store file and temporary store file directories because they are not suitable for cluster engines.
  - You must specify `-logDirectory`, `-permanentStoreDirectory` and `-temporaryStoreDirectory` to be at locations that all members of the cluster can access on your file system.
- If you choose to use a **data store** (by specifying `-datastore`):
  - You must not specify `-createDefaultDatasource` because the default data source is not suitable for cluster engines.
  - You must specify `-dataSourceJndiName`, giving the name of an existing data source.

Administering bus destinations

Configure service integration bus destinations, so that applications can attach to them to exchange messages as producers, consumers, or both.

Procedure

- ../ae/cjo_learning.dita
- “Configuring bus destinations” on page 1905
- “Configuring message points” on page 1999
- “Managing messages on message points” on page 595
- “Administering durable subscriptions” on page 2002

Configuring bus destinations

Use the following tasks to configure permanent bus destinations on service integration buses.

About this task

The steps involved in configuring a bus destination depend on the intended usage of the destination.

For example, the following figure shows a basic scenario based on an application using a JMS queue for point-to-point messaging. A producing application sends messages to a JMS queue from which a consuming application retrieves the messages. The JMS queue is assigned to a queue destination and its associated queue point, where messages are stored.

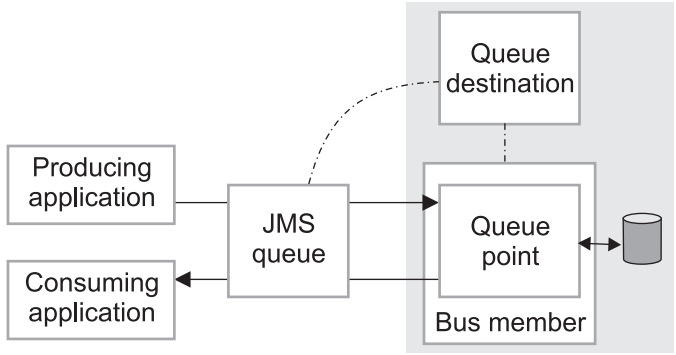

Figure 37. Application use of destinations - basic case

To enable the JMS applications to use a queue destination, you configure the following administrative destination objects:

1. A queue destination on a service integration bus. This configures the properties of the queue, such as the name, and associates the queue with one bus member (an application server). This also automatically configures, on the bus member, a queue point where messages for the queue are held and processed.
2. A JMS queue, which configures the name that applications can use to look up the queue in JNDI. The JMS queue encapsulates the name of the queue destination, as defined in the queue destination above, together with other properties to be used by applications.

After you have created a queue destination, you can optionally configure the queue point to override some properties configured on the queue destination. You can also undertake other configuration tasks on the destination and its queue point, and can act on the runtime view.

Each messaging engine has a default exception destination, named `_SYSTEM.Exception.Destinaton.`*`messaging_engine_name`*. This exception destination can be used to handle messages that cannot be delivered for all bus destinations that are localized to the messaging engine. Each bus destination can be configured with a non-default exception destination.

For more information about configuring bus destinations, see the following topics:
- Listing bus destinations
- Creating a bus destination
- Configuring qualities of service for a destination
- Deleting a non-topic space bus destination
- Deleting a topic space

Listing bus destinations

Use this task to display administrative lists of bus destinations for a service integration bus.

About this task

From the panel that lists bus destinations you can use the buttons provided to create, delete, or change the mediation of destinations, or can select a destination to browse details and options for that destination.

To list bus destinations on a bus, use the administrative console to complete the following steps.

Procedure

Click **Service integration -> Buses ->** ***bus_name*** **-> [Destination resources] Destinations**. This displays a list of the bus destinations on the bus.
Any temporary destination in the list is identified by the prefix `_Q` for temporary queues or `_T` for temporary topics.

What to do next

To browse or change the properties of a destination, click its name in the list displayed.

To act on one or more of the destination listed, select the check boxes next to the names of the destinations that you want to act on, then use the buttons provided.

To change what entries are listed, or to change what information is shown for entries in the list, use the Filter settings.

Creating a bus destination

Use the following tasks to create a new bus destination on a service integration bus.

About this task

The steps involved in defining a new destination depend on the intended usage of the destination.

These are permanent destinations, with their properties defined by administrative resources, and are in addition to any temporary destinations created at runtime by the bus for applications.
- Defining a bus destination for JMS queues.
- Defining a bus destination for JMS topics.
- Defining an alias bus destination.
- Defining a new exception bus destination

Creating a queue for point-to-point messaging:

You can create a queue, which is a bus destination that represents a message queue and that is used for point-to-point messaging.

Before you begin

During this task you must specify the name of a bus member to which the bus destination is assigned. That bus member is to host the queue point for the new bus destination, and must already have been configured.

About this task

To define a new queue for point-to-point messaging, you specify only a minimum set of properties. You can change these properties and configure further properties after you complete this task.

To define a queue, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click **Service integration -> Buses**.
2. In the content pane, click the name of the bus that is to provide the message point for the queue.
3. In the content pane, under Destination resources, click **Destinations**. A list of any existing bus destinations is displayed.
4. To create a destination, click **New**.
   a. On the Create new destination page, ensure that **Queue** is selected.
   b. Click **Next**.
   c. In the **Identifier** field, type the name that you want to give the queue destination for administrative purposes. Restrict the name to 48 characters or less, and restrict its character set to: numerics (0-9), period (.), forward slash (/), underscore (_), percent sign (%), uppercase A-Z, lowercase a-z (but there are restrictions on the use of lowercase letters for z/OS console support). On systems that use EBCDIC Katakana, you cannot use lowercase characters.
5. Optional: In the **Description** field, type a description of the destination, for administrative purposes.
6. Click **Next**.
7. On the Assign the queue to a bus member page, select the bus member that is to provide the queue point for the destination. The queue point is where the messages for the queue are held.
8. Click **Next**.
9. Optional: If the bus member is a WebSphere MQ server, set the WebSphere MQ queue point attributes:
   a. Specify a value in the **WebSphere MQ queue name filter** field, then click **Go**.

      The wizard automatically discovers available WebSphere MQ queues. However, some WebSphere MQ topologies have many thousands of queues defined to a queue manager. Use this filter to limit the number of queues that are listed.

The default filter value is an asterisk (*). If this value (or no value) is set then all queues, or all queues of a specific type (based on any queue type custom property that is set), are listed. Any other value that you specify must meet the following criteria:

- It must contain between 1 and 48 characters.
- It must conform to the WebSphere MQ queue naming rules (see the *Rules for naming WebSphere MQ objects* topic in the WebSphere MQ information center).

You can also use the wildcard character (*) with other text. For example, if you enter a value of PAYROLL*, then all available queues with names that start with PAYROLL are displayed.

b. Specify a WebSphere MQ queue name.

Select a queue name from the filtered list. If the list does not include the queue that you want, select the last entry in the list labeled **other, please specify**. A text entry box is displayed next to the drop-down list. Type the queue name into the text entry box.

If the queue is found on the remote WebSphere MQ system, the properties of the queue as defined within WebSphere MQ are displayed as read-only fields. This should help you to confirm that you have found the queue that you want, and that it is configured as you intend. If the queue is not found, these read-only fields are removed from view.

c. Specify the reliability levels that you require when inbound nonpersistent and inbound persistent WebSphere MQ messages are converted to service integration format messages. Applications receive messages direct from the specified WebSphere MQ queue, so in general the reliability level for a message is of no interest to the receiver because the message has already been delivered successfully. However, the message is converted to a service integration format message (and typically to a JMS format service integration message) as it is received, and this option specifies the reliability level for the service integration format message. For information about the available reliability levels, see “WebSphere MQ queue points [Settings]” on page 2241.

d. Specify whether you want WebSphere MQ to include an MQRFH2 message header when sending messages to the queue.

The MQRFH2 header stores service integration messaging information that does not have a corresponding WebSphere MQ message header field. When a message is sent to the destination, service integration instructs WebSphere MQ to write the message to the queue. This option specifies whether service integration instructs WebSphere MQ to write the message with an MQRFH2 header.

If the consumer of the message is a JMS application running in WebSphere MQ or service integration, or a WebSphere MQ XMS application, or a WebSphere MQ MQI application that expects an MQRFH2 header, select this option. If the consumer is a WebSphere MQ MQI application that does not expect an MQRFH2 header, do not select this option.

e. Click **Next**.

10. On the Confirm queue creation page, review the summary of actions.
    - To create the queue, click **Finish**.
    - If you want to change any of the properties that you have specified, click **Previous**, then change the properties on the preceding pages.
11. Save your changes to the master configuration.

What to do next

You can configure further properties of the queue, for example message reliability settings. See “Configuring bus destination properties” on page 1979. If you configure message reliability settings, remember that higher levels of reliability have a greater impact on performance.

By default, messages that cannot be delivered to the queue are sent to the default exception destination for the messaging engine that hosts the queue point. If you want to use a specific exception destination for

messages that cannot be delivered to this queue destination, that exception destination must be defined already. For more information about configuring exception destinations, see Configuring an exception bus destination.

If the queue is to be used for JMS point-to-point messaging, specify the queue identifier on a JMS queue, as described in “Configuring a queue for the default messaging provider” on page 522.

Creating a topic space for publish/subscribe messaging:

You can create a topic space, which is a bus destination that represents a set of “publish and subscribe” topics and that is used for publish/subscribe messaging.

About this task

You create a topic space when you deploy JMS applications that use publish/subscribe messaging.

To create a topic space, you specify only a minimum set of properties. You can change these properties and configure further properties after you complete this task.

To create a topic space, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click **Service integration -> Buses**.
2. In the content pane, click the name of the bus that is to provide the publication points for the topic space.
3. In the content pane, under Destination resources, click **Destinations**. A list of any existing bus destinations is displayed.
4. To create a topic space, click **New**.
   a. On the Create new destination page, select **Topic space**.
   b. Click **Next**.
   c. In the **Identifier** field, type the name that you want to give the topic space for administrative purposes.
5. Optional: In the **Description** field, type a description of the destination, for administrative purposes.
6. Click **Next**.
7. On the Confirm topic space creation page, review the summary of actions.
   - To create the topic space, click **Finish**.
   - If you want to change any of the properties that you have specified, click **Previous**, then change the properties on the preceding pages.
8. Save your changes to the master configuration.

What to do next

You can configure further properties of the topic space, for example message reliability settings. See “Configuring bus destination properties” on page 1979. If you configure message reliability settings, remember that higher levels of reliability have a greater impact on performance.

By default, messages that cannot be delivered to the topic space are sent the default exception destination for the messaging engine that is publishing the message. If you want to use a specific exception destination for messages that cannot be delivered to this topic space, you must have already defined that exception destination. For more information about configuring exception destinations, see “Configuring exception destination processing for a bus destination” on page 1980.

If the topic space is to be used for JMS publish/subscribe messaging, specify the topic space identifier on a JMS topic as described in “Configuring a topic for the default messaging provider” on page 523.

Creating an alias destination on a bus:

You can create an alias destination on a service integration bus. An alias destination maps an alternative name for a queue destination or a topic space destination. Any alias destination properties that you set override the destination defaults.

About this task

An alias destination maps an alias bus name and destination name (identifier) to a target bus name and destination name where the bus name, or the destination name, or both, are different.

To define a new alias destination, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click **Service integration -> Buses**.
2. In the content pane, click the name of the bus on which the alias destination is to be created.
3. In the content pane, under Destination resources, click **Destinations**. A list of any existing bus destinations is displayed.
4. To create a destination, click **New**.
   a. On the Create new destination page, select **Alias**.
   b. Click **Next**.
   c. In the **Identifier** field, type the name of the destination for applications to use to refer to the alias destination.
5. Specify the following properties for the destination:

   Bus The name of the bus for applications to use to refer to the alias destination. If you leave this field empty, the name of the local bus is used.

   Target identifier
   The identifier of the target destination that this alias destination represents.

   If the alias destination targets a queue that is provided by WebSphere MQ, type the value as a concatenation of the queue name and the queue manager name, *queue_name@qmanager_name*; for example: `Queue1@Qmgr2`.

   Target bus
   The name of the bus that hosts the target destination. This can be the local bus, a foreign service integration bus, or a foreign bus that represents a WebSphere MQ network. The default is the name specified for the **Bus** property.
6. Optional: Specify the following properties for the destination. These will override the destination defaults.

   Description
   An optional description of the destination, for administrative purposes.

   Enable producers to override default reliability
   Controls the quality of service for message flows between producers and the destination. Select this option to use the quality of service specified by producers instead of the quality defined for the destination.

   Default reliability
   The reliability assigned to a message produced to this destination when an explicit reliability has not been set by the producer.

INHERIT
Use the reliability configured on the target destination.

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages might be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

Note: Higher levels of reliability have higher impacts on performance.

For more information about service integration reliability levels, see Message reliability levels - JMS delivery mode and service integration quality of service.

Maximum reliability
The maximum reliability of messages accepted by this destination.

Producers cannot send messages to this destination with a reliability higher than the value specified for this property.

INHERIT
Use the reliability configured on the target destination.

Best effort nonpersistent

Express nonpersistent

Reliable nonpersistent

Reliable persistent

Assured persistent

For more information about service integration reliability levels, see Message reliability levels - JMS delivery mode and service integration quality of service.

Send allowed
Clear this option (setting it to false) to stop producers from being able to send messages to this destination.

INHERIT
Use the value configured on the target destination.

TRUE Producers can send messages to this destination.

FALSE
Producers cannot send messages to this destination.

Receive allowed
Clear this option (setting it to false) to prevent consumers from being able to receive messages from this destination.

INHERIT
Use the value configured on the target destination.

TRUE Consumers can receive messages from this destination.

FALSE
Consumers cannot receive messages from this destination.

Default forward routing path
The value to which a message's forward routing path will be set if the message contains no forward routing path. This identifies a sequential list of intermediary bus destinations that messages must pass through to reach a target bus destination. The format of the field is a list of line-delimited bus destinations specified as *bus*:*name*.

Delegate authorization check to target destination
Indicates which destination access role is checked when a user accesses the alias destination. When this option is selected, the destination access role of the target destination is checked. When this option is not selected, the destination access role of the alias destination is checked.

If you do not want to override the security of the target destination, select this option.

7. Click **Next**.
8. On the Confirm alias destination creation page, review the summary of actions.
   - To create the alias destination, click **Finish**.
   - To change any of the destination properties, click **Previous**, then change the properties on the preceding pages.
9. Save your changes to the master configuration.

What to do next

You can change properties or configure further properties of the alias destination. See “Configuring alias destination properties” on page 1985.

If you want to override security settings for the destination, see “Administering destination roles” on page 1991.

Creating a foreign destination on a bus:

You can create a foreign destination on a service integration bus. A foreign destination represents a destination that is defined in another bus (a foreign bus). You use a foreign destination when you need to override messaging defaults, security settings, or both for an individual destination on a foreign bus.

About this task

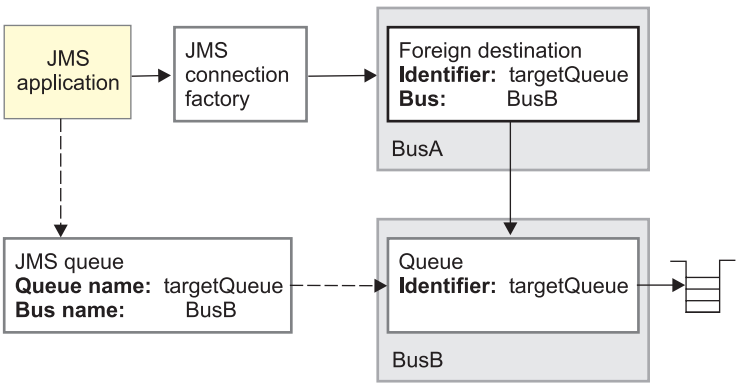

Figure 38. Creating a foreign destination on a service integration bus

This figure shows a foreign destination that points to a target destination on another bus. There is also a JMS connection factory and JMS queue that an application uses without being aware of the associated foreign destination.

The foreign destination encapsulates the name of the target destination that exists in the foreign bus (Identifier property) and the name of that foreign bus (Bus property). An application that is to use the foreign destination to exchange messages with the target destination must specify the Identifier and Bus properties.

For example, an administrator wants JMS applications to connect to one bus, BusA, and send messages to a JMS queue backed by a queue, targetQueue, on another bus, BusB. The administrator connects the buses, creates a foreign destination on BusA and sets the following properties on the foreign destination and JMS queue:

Table 212. Example property settings. The table provides an example of how the properties can be set when creating a foreign destination on a service integration bus. The first column of the table lists the JMS queue names. The second column contains the identifier and bus names of the foreign destination on a service integration bus, for example, BusA. The third column contains the identifier of the queue on a service integration bus, for example, BusB.

JMS queue	Foreign destination (on BusA)	Queue (on BusB)
Queue name targetQueue **Bus name** BusB	**Identifier** targetQueue **Bus** BusB	**Identifier** targetQueue

To define a new foreign destination, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click **Service integration -> Buses**.
2. In the content pane, click the name of the bus that you want to create the foreign destination on.
3. In the content pane, under Destination resources, click **Destinations**. A list of any existing bus destinations is displayed.
4. To create a destination, click **New**.
   a. On the Create new destination page, select **Foreign**.
   b. Click **Next**.
   c. In the **Identifier** field, type the name of the target destination that exists in the foreign bus. The Identifier must match the name of the target destination that exists in the foreign bus.
   d. In the **Bus** field, type the name of the foreign bus that hosts the target destination. On the bus where you are creating the foreign destination, a foreign bus connection that represents this foreign bus must be already defined.
5. Optional: Specify the following properties for the destination. These will override the destination defaults.

   Description
   An optional description of the destination, for administrative purposes.

   Enable producers to override default reliability
   Select this option to enable producers to override the default reliability that is set on the destination.

   Default reliability
   The reliability assigned to a message produced to this destination when an explicit reliability has not been set by the producer.

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages might be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

Note: Higher levels of reliability have higher impacts on performance.

For more information about service integration reliability levels, see Message reliability levels - JMS delivery mode and service integration quality of service.

Maximum reliability
The maximum reliability of messages accepted by this destination.

Best effort nonpersistent

Express nonpersistent

Reliable nonpersistent

Reliable persistent

Assured persistent

For more information about service integration reliability levels, see Message reliability levels - JMS delivery mode and service integration quality of service.

6. Click **Next**.
7. On the Confirm foreign destination creation page, review the summary of actions.
   - To create the foreign destination, click **Finish**.
   - If you want to change any of the destination properties, click **Previous**, then change the properties on the preceding pages.
8. Save your changes to the master configuration.

What to do next

Ensure that you have defined a foreign bus connection (to identify the target bus) and the target destination on that bus.

You can change properties or configure further properties of the foreign destination. See “Configuring bus destination properties.”

If you want to override security settings for the destination, see “Administering destination roles” on page 1991.

Configuring bus destination properties

You can view or change the configuration properties of a bus destination, that is, a queue, topic space, alias destination, or foreign destination.

About this task

For an overview of bus destinations, see ../ae/cjo_learning.dita.

To view or change the properties of a destination, use the administrative console to complete the following steps.

Procedure

1. From the navigation pane, click **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *destination_name***. The configuration page for the type of destination you selected is displayed, that is, one of the following pages:
   - Queue settings
   - Topic space settings
   - Alias destination settings
   - Foreign destination settings
2. Change the destination properties to suit your needs. For details of the properties, see the relevant settings topic for the type of destination you selected.
3. Click **OK**.
4. Save your changes to the master configuration.

Configuring exception destination processing for a bus destination:

You can configure the exception destination processing for a queue destination or topic space destination. You can configure whether any undeliverable messages are rerouted to an exception destination, and whether to use a system default exception destination or configure a specific exception destination.

Before you begin

To configure a specific exception destination for a queue destination or topic space destination, the exception destination must exist. An exception destination must be a queue destination. See “Creating a queue for point-to-point messaging” on page 1972.

About this task

An exception destination for a queue destination or topic space destination is the destination for a message when a message cannot be delivered because the number of delivery attempts to a transactional consumer is exceeded.

You can configure an exception destination for a bus destination as one of the following:

- None. The bus destination does not use an exception destination and undeliverable messages are not rerouted to an exception destination. Attempts to redeliver the message continue, up to the maximum failed deliveries limit set for the bus destination. Then attempts to redeliver the message continue with a time interval between retry attempts. This interval is either the Default blocked destination retry interval of the messaging engine that is associated with this destination, or the Blocked retry timeout in milliseconds that is set for this destination.
- System. The bus destination uses the default exception destination. Messages that cannot be delivered to the bus destination are rerouted to the system default exception destination for the messaging engine that detects the problem: _SYSTEM.Exception.Destination.*messaging_engine_name*. This option is the default option.
- Specify. The bus destination uses the specified exception destination. If the bus destination cannot use this exception destination, it uses the system exception destination.

Note:

- You cannot configure exception destination processing for a bus; you must configure exception destination processing for each destination on the bus.
- Do not modify or delete the default system exception destination.
- If you use an exception destination for a bus destination, it can affect message ordering in the bus. For more information, see Message ordering.
- Best-effort messages are always discarded if they cannot be delivered to their target destination, that is, they never use an exception destination.
- Any report options that are set in the properties of a message also affect exception destination processing. Depending on the report options, a message might be discarded if it is not delivered.

To configure the exception destination processing for a bus destination, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane of the administrative console, click **Service integration -> Buses** to display a list of buses.
2. Select the bus with the destination for which you want to configure an exception destination.
3. In the **Configuration** tab, under **Destination resources**, click **Destinations** to display a list of destinations for this bus.
4. Select the name of the bus destination you require from the list. The details of that destination are displayed.
5. In the **Configuration** tab, under **General properties**, in the Exception destination section, use the radio buttons to configure the exception destination processing that this bus destination uses:
   - Select **None** to specify that the bus destination does not use an exception destination.
   - Select **System** to use the default exception destination.
   - Select **Specify** and enter an exception destination to configure the exception destination you require.
6. Optional: If you selected **None**, you can set the time interval to apply between retry attempts, after the maximum failed deliveries limit is reached, for this destination. Select **Override messaging engine blocked retry timeout default**, then enter the value you require in **Blocked retry timeout in milliseconds**. Otherwise, the value set for the Default blocked destination retry interval of the associated messaging engine is used.
7. Optional: To change the number of delivery attempts for a message, enter a value in **Maximum failed deliveries per message**. When the exception destination is configured as **None**, this is the number of delivery attempts before a time interval between retry attempts is applied. When the exception destination is configured as **System** or **Specify**, this is the number of delivery attempts for a message that is backed out and tried again before the message is sent to the exception destination.
8. Save your changes to the master configuration.

Results

You have configured the exception destination processing for a bus destination.

What to do next

You can also configure exception destination processing for a service integration bus link or WebSphere MQ link.

Controlling whether applications can send or receive messages for a bus destination:

You can prevent applications from either sending messages to, or receiving messages from, a destination. To do this you use the **Receive allowed**, **Send allowed**, and **Receive exclusive** properties of destinations

to control access to destinations. When you save changes to those properties, this affects open producers and consumers attached to localization points for that destination.

About this task

Use this task to change the configuration properties of a bus destination to control whether applications can send messages to, or receive messages from, a destination. For example, some destinations only exist in order to be associated with mediations; applications should not be able to put to or get from such a destination.

The changes that you make affect the configuration of a bus destination and when saved, are automatically applied to all message points for that destination. You can make the same changes to an individual destination localization point to control access to only that one point.

When you save changes that affect the access to a bus destination, this affects producers or consumers attached to message points for that destination. For each producer or consumer, any existing operations are allowed to complete (except for one case, as described in the next paragraph). The producer or consumer then undergoes a state change to conform to the destination, and subsequent operations will fail with an exception. The exception message indicates the specific reason for the exception; that is, that the destination no longer accepts sending or receiving of messages.

The only case where this behavior does not occur is the receiveWithWait() method. Blocking receives are cancelled when the state change to the consumer is made, and an exception is thrown. So, a receiveWithWait() method that is outstanding at the time of the configuration change is not allowed to complete, although the exception still occurs asynchronously with the configuration change.

Procedure

1. Click **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *destination_name***.
2. Optional: Change one or more of the following properties:

   Receive allowed

   Clear this check box (setting to the option to false) to prevent messages from being received from message points for this destination. The effect depends on the type of destination:

   - Queue point. Any open consumers change state and an exception is thrown when the consumer requests a message.
   - Publication point. Any messages that have been published to the messaging engine for a publication point are stopped from proceeding either to local consumers or onwards to other messaging engines. Local consumers get the same exception as for a queue point.
   - Mediation point of a mediated destination. The bus stops the mediation instance that is running locally to the mediation point; other instances of the mediation running on other messaging engines continue as normal.

   In all cases, messages can continue to be sent, and accumulate on the destination localization point.

   Send allowed

   Clear this check box (setting the option to false) to prevent messages from being accepted onto the message points for this destination.

   - For a queue point of a non-mediated destination, or a mediation point of a mediated destination, new messages (from attached producers or forwarded from another destination) are redirected to any available message point. If no message points are available, then messages that have already been accepted onto the bus, and new messages from attached producers, are preserved by the bus until a message point becomes available. The only exception to this is the case of a destination with only one message point (queue point or mediation point depending on whether the destination is mediated or non-mediated), where

the producer is attached to the same messaging engine. In this case, an exception is thrown on each send call. The exception message indicates that the reason for the exception is that the only extant localization has been disabled for send. The producer remains open as normal, and any more send calls succeed if the **Send allowed** property of the localization is reselected (reset to true).

- For a queue point of a mediated destination, clearing this **Send allowed** property alters the behavior of the mediation instances that are sending to the destination in the same way as setting it to false on a non-mediated destination affects producing applications: Messages are sent instead to any alternative message point. If no localizations are available, are preserved by the bus until a message point becomes available. For any mediation instance (that is, on any server that has a mediation point), if the same server hosts a queue point, and that queue point is the only queue point for the destination, then the mediation changes to the “stopped on error” state.
- For a publication point, clearing this **Send allowed** property stops applications attached locally to the topic space from publishing messages. The send calls receive an exception, and the producer remains open.

Receive exclusive

If you select this check box (setting the option to `true`), then only one consumer can be attached to any message point. This property is particularly intended for use with queues, but can be used with any type of destination.

- For a queue, the bus chooses a queue point for each request to create a consumer. If the selected queue point already has an attached consumer, then the call fails with an exception (containing an exception message and linked exception that indicate the precise nature of the failure). There is no guarantee that all available queue points are used before the exception is thrown.
- For a topic space, only one consumer can attach to any given messaging engine.

If you change the **Receive exclusive** property from `false` to `true`, some consumers are selected to be the exclusive receivers in accordance with the rules above. All other consumers are detached from the destination, in the same way as is described above for a transition of the **Receive allowed** property from true to false.

3. Click **OK**.
4. Save your changes to the master configuration.

Specifying whether strict message order is preserved for a bus destination:

Use this task to change the configuration properties of a bus destination to control whether strict message order is preserved.

Before you begin

The changes made in this task affect the configuration of a bus destination. Before you begin this task, make sure that you fully understand the restrictions that apply to ordered destinations. For further details see Strict message ordering for bus destinations.

About this task

Although messages produced by a single producer to a single destination are seen by a consumer to that destination in the same order as they are produced, there are certain topologies and events, such as system failures, that can change the order of messages (see Message ordering). If strict message order is essential, you can configure a destination to preserve the order of the messages in a much more rigorous manner. Configuring a destination in this way, when used with restricted topologies, maintains message order in all circumstances (for further information, see Strict message ordering for bus destinations).

To preserve the order of the messages that are delivered to a destination, use the administrative console to complete the following steps:

Procedure

1. Click **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *destination_name***.
2. Select the **Maintain strict message order** check box (setting the option to `true`).
3. Click **OK**.
4. Save your changes to the master configuration.

Results

An ordered destination has priority over several other configuration properties, such as the number of consumers that are allowed to attach to the destination. The system overrides these configuration properties at run time, and generates a system log warning. For more information about the configuration properties that the system overrides at run time, and the impact of including an ordered destination in your system, see Strict message ordering for bus destinations.

Specifying whether messages are forwarded to WebSphere MQ as JMS messages:

Use this task to create a destination context property that determines whether an MQRFH2 header is added to WebSphere MQ JMS messages produced by foreign or alias destinations.

Before you begin

This task assumes that you have created an alias bus destination or a foreign bus destination. For more information, see “Creating an alias destination on a bus” on page 1975 or “Creating a foreign destination on a bus” on page 1977.

About this task

Carry out this task if you want JMS messages produced by foreign bus destinations or alias bus destinations forwarded to WebSphere MQ. In this task, you define a destination context property called _MQRFH2Allowed that adds an MQRFH2 header to JMS messages. If you do not configure _MQRFH2Allowed, the default value is NO, and an MQRFH2 header is not added to the message. WebSphere Application Server Version 5.1 users may be aware of a WebSphere MQ flag called TARGCLIENT that was used to add RFH2 headers to JMS messages. For more information about the use of the MQRFH2 header in interoperating with WebSphere MQ, see Mapping the message body to and from WebSphere MQ format and Point-to-point messaging with a WebSphere MQ network.

To create and configure a context property called _MQRFH2Allowed on a foreign or alias destination, use the administrative console to complete the following steps:

Procedure

1. Display the context properties for a selected foreign or alias destination:
   a. Click **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations**.
   b. Select the foreign or alias destination for which you want to create the context property.
   c. Under **Additional Properties**, click **Context properties**.
2. Click **New** to create a new context property.
3. Specify the following context information:

   Name Type the name `_MQRFH2Allowed`.

   Context type
   Select the information type `Boolean` in the drop-down list.

Context value
Type the value `true` .

4. Click **OK**.
5. Save your changes to the master configuration.

Results

An MQRFH2 header is added to all messages produced by the foreign or alias destination. This means that JMS messages will be forwarded to WebSphere MQ as JMS messages.

Configuring alias destination properties:

Use this task to browse or change the configuration properties of an alias destination on a service integration bus. An alias destination maps a bus name and destination name (identifier) to a target where the bus name, or the destination name, or both, are different. Any alias destination properties that you set override the destination defaults.

About this task

To browse or change the properties of an alias destination, use the administrative console to complete the following steps.

Procedure

1. In the navigation pane, click **Service integration -> Buses**.
2. In the content pane, click the name of the bus on which the alias destination was created.
3. In the content pane, under Destination resources, click **Destinations**. A list of existing bus destinations is displayed.
4. Select the alias destination that you want to configure.
5. You can view or change the following alias destination properties.

   Description
   An optional description for the bus destination, for administrative purposes.

   Target identifier
   The name of the destination for which this is an alias.

   Target bus
   The name of the bus on which the destination for which this is an alias exists.

   Use all target queue points
   This property is displayed only if the destination that the Target identifier and Target bus properties identifies has multiple queue points configured (that is, the destination is on a cluster bus member with multiple messaging engines) and the Target bus is the local bus.Whether to use all target queue points indicates whether all the queue points of the target queue can be used, including any queue points created after the alias is configured. When selected, the **Target queue points** menu is disabled.

   Unselected queue points
   A list of the queue points that are not addressable by the alias definition. The list is generated from the complete list of queue points for this queue. This list is enabled only when **Use all target queue points** is unchecked.

   Selected queue points
   A list of the queue points that are addressable by the alias definition. This list is enabled only when **Use all target queue points** is unchecked.
6. You can change the following alias destination properties to suit your needs. These values will override the destination defaults.

Enable producers to override default reliability
Controls the quality of service for message flows between producers and the destination. Select this option to use the quality of service specified by producers instead of the quality defined for the destination.

Default reliability
The reliability assigned to a message produced to this destination when an explicit reliability has not been set by the producer.

INHERIT
Use the reliability configured on the target destination.

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages might be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

Note: Higher levels of reliability have higher impacts on performance.

For more information about service integration reliability levels, see Message reliability levels - JMS delivery mode and service integration quality of service.

Maximum reliability
The maximum reliability of messages accepted by this destination.

Producers cannot send messages to this destination with a reliability higher than the value specified for this property.

INHERIT
Use the reliability configured on the target destination.

Best effort nonpersistent

Express nonpersistent

Reliable nonpersistent

Reliable persistent

Assured persistent

For more information about service integration reliability levels, see Message reliability levels - JMS delivery mode and service integration quality of service.

Default priority
The default priority for messages sent to the target destination, in the range 0 (lowest) through 9 (highest), or -1. The value -1 indicates that messages should use the default priority defined on the target destination. The default priority is used only if a message does not specify its own priority.

Send allowed
Clear this option (setting it to false) to stop producers from being able to send messages to this destination.

INHERIT
Use the value configured on the target destination.

TRUE Producers can send messages to this destination.

FALSE
Producers cannot send messages to this destination.

Receive allowed
Clear this option (setting it to false) to prevent consumers from being able to receive messages from this destination.

INHERIT
Use the value configured on the target destination.

TRUE Consumers can receive messages from this destination.

FALSE
Consumers cannot receive messages from this destination.

Reply destination
The name of a destination to be appended to any non-empty reverse routing path of messages sent to this destination.

Reply destination bus
The bus on which the reply destination exists.

Default forward routing path
The value to which a message's forward routing path will be set if the message contains no forward routing path. This identifies a sequential list of intermediary bus destinations that messages must pass through to reach a target bus destination. The format of the field is a list of line-delimited bus destinations specified as *bus*:*name*.

Delegate authorization check to target destination
Indicates which destination access role is checked when a user accesses the alias destination. When this option is selected, the destination access role of the target destination is checked. When this option is not selected, the destination access role of the alias destination is checked.

Include an RFH2 message header when sending messages to WebSphere MQ
Indicates whether messages sent to WebSphere MQ include an RFH2 header. The RFH2 header stores additional information to that which is stored in theWebSphere MQ message header. This property applies when the target bus is a WebSphere MQ queue manager.

7. Click **OK**.
8. Save your changes to the master configuration.

What to do next

If you want to enable correct processing of messages, under Additional Properties click **Context properties**. This information adds to the context information derived from processing the message header.

If you want an expandable tree view of all the applications and messaging resources that reference the current destination, both directly and indirectly, under Related Items click **Application resources topology**. As many of the references as possible are resolved to links to the associated configuration panel for the referenced object.

Configuring mediations

Use this task to configure one or more mediations for a selected bus destination in a service integration bus.

About this task

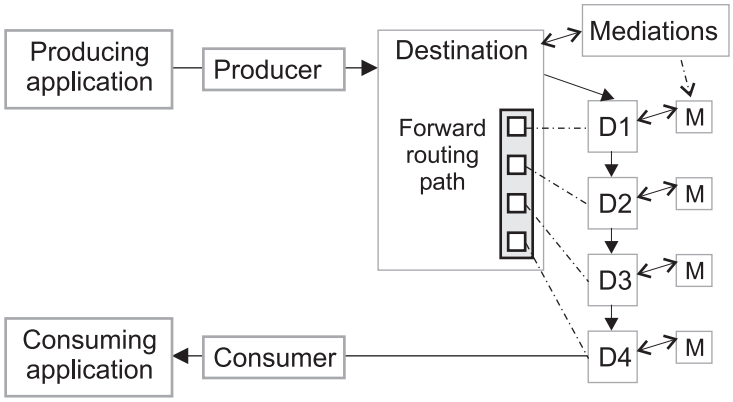
You can configure a destination with one or more mediations that refine how messages are handled by the destination, and can configure destination properties that affect how the mediations are used; for example, that they should run within a global transaction.

For more information about configuring mediations, see “Mediating a destination” on page 2017.

Configuring a destination forward routing path

Use this task to configure a forward routing path for a selected bus queue. The forward routing path identifies a sequence of bus destinations that a message should pass through after it has been delivered to the bus destination to which the producer is attached.

About this task



If producing and consuming applications both attach directly to the destination that is to host and process their messages, you do not have to use routing paths. You can still use mediations assigned to the destination to manipulate messages. However, if you want a more flexible architecture, you can assign mediations to several destinations then specify those destinations as the forward routing path for another destination. For example in the above diagram, on the destination called Destination, on the bus called myBus, you would set the Default forward routing path property to:

```
mybus:D1
mybus:D2
mybus:D3
mybus:D4
```

For each destination that should be visited by a reply message on its ways back to the producer application, you can specify the name of a *reply destination*, which is the next destination in the reverse routing path. If the same destinations are used for both the forward and return routing paths, you can configure the return routing path when you configure the forward routing path, as described in this topic. Otherwise, see “Configuring a destination reverse routing path” on page 1989.

To configure a forward routing path, you only have to change the properties of the destinations you want to use. This topic contains optional steps to create destinations, in case you have not already done so.

To configure a forward routing path for a destination, use the administrative console to complete the following steps:

Procedure

1. Optional: If you have not already done so, create the destination to which the producer applications attach. For this destination, you can create a queue or create a topic space.
2. Optional: If you have not already done so, create each destination in the path. Only the last destination in the path can be a topic space; all other destinations in the path must be queues.

   If the destination is also to be part of the return routing path for reply messages, specify the name of the next destination in the return routing path:

   a. Click **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *destination_name***.
   b. In the Reply destination bus field, type the name of the next destination in the return routing path.
   c. Save your changes to the master configuration.
3. Optional: If you have not already done so, assign mediations to the destinations in the path. You can include a destination without mediations in a routing path, to provide a future option to apply a mediation assigned to that destination.
4. Edit the properties of the destination to which the producer applications attach, to configure the forward routing path.

   a. Click **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *destination_name***.
   b. In the Default forward routing path field, type the names of the destinations in the path. Type a list of bus destinations, each on a separate line, of the form *bus_name*:*destination_name*

      Where

      bus_name
      Is the name of the service integration bus on which the destination is configured.

      destination_name
      is the name of the bus destination.

      For example:

      ```
      mybusA:queueA
      anobusB:queueB
      busC:queueC
      ```
   c. Save your changes to the master configuration.

Configuring a destination reverse routing path

Use this task to configure a reverse routing path between two bus destinations. The reverse routing path identifies the list of destinations to which a reply message should be sent when the consumer of a request message sends a reply message back to the producer of the reply message.

About this task

In the following figure, a producing application sends messages to a bus destination. Unknown to the application, the messages are then passed along a forward routing path of other bus destinations to a target destination where a consuming application retrieves the messages.

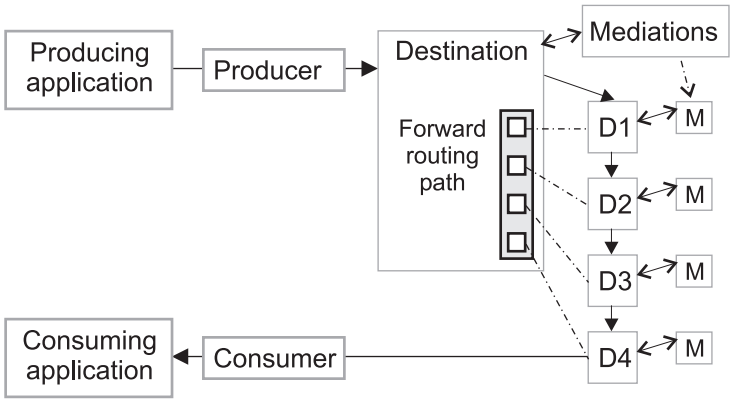


Figure 39. Example of a routing path

For each destination that is to be part of a reverse routing path back to the producer application, you can specify the name of a *reply destination*, which is the next destination in the reverse routing path. For example in the above diagram, if reply messages are to retrace the forward routing path back to the producing application, you would set reverse routing path as follows:

Destination	Reply destination bus
D4	D3
D3	D2
D2	D1
D1	Destination

You can specify a different reverse routing path to the forward routing path, to enable more mediations to be applied to reply messages, or to apply mediations in a different destination sequence.

If the same destinations are used for both the forward and reverse routing paths, you can configure the reverse routing path when you configure the forward routing path, as described in “Configuring a destination forward routing path” on page 1988. Otherwise, you can configure (or change) the reverse routing path as described in this topic.

To configure a reverse routing path, you only have to change the properties of the destinations you want to use. This topic contains optional steps to create destinations, in case you have not already done so.

To configure a reverse routing path for a destination, use the administrative console to complete the following steps:

Procedure

1. Optional: If you have not yet done so, create the destination to which the producer applications attaches. For this destination, you can create a queue or create a topic space.
2. Optional: If you have not already done so, create each destination in the path.
3. Optional: If you have not already done so, assign mediations to the destinations in the path. You can include a destination without mediations in a routing path, to provide a future option to apply a mediation assigned to that destination.
4. On each destination in the reverse routing path, specify the name of the next destination in the path:
   a. Click **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *destination_name***.
   b. In the Reply destination field, type the name of the next destination in the reverse routing path.

c. In the Reply destination bus field, type the name of the next destination in the reverse routing path.
d. Save your changes to the master configuration.

Configuring context properties for a bus destination

Use this task to configure context properties for a bus destination.

About this task

The context properties contribute to the mediation context that is used with the message header information to ensure that messages are processed correctly by a mediation assigned to this bus destination.

Note: Context properties on the destination take precedence over context properties on a mediation. For example, if a property with the same name is configured for a destination and a mediation, the property on the destination takes precedence.

To configure context information for a bus destination, use the administrative console to complete the following steps:

Procedure

1. Display the context properties for a selected bus destination:
   a. Click **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *destination_name***.
   b. Under **Additional Properties**, click **Context properties**.
2. Choose whether to create a new context property, configure an existing property, or delete one or more existing properties.
   - To create a new context property, click **New**.
   - To browse or change an existing context property, click the property name.
   - To delete one or more existing context properties, select the check box for each property you want to delete, then click **Delete**.
3. To create or change a context property, specify the following context information:

   Name Type a name for the context property.

   Context type
   Select the information type for the context property in the selection list.

   Context value
   Type a value for the context property.
4. Click **OK**.
5. Save your changes to the master configuration.

Administering destination roles

Service integration bus security uses role-based authorization. When messaging security is enabled, users and groups must have authority to undertake messaging operations, at a bus destination. By administering destination roles, you can control which users and groups can undertake operations at a bus destination, and the types of operations that they can perform.

About this task

You use the administrative console to administer users and groups in access roles for a destination. The access roles available for a destination depend on the type of destination. The table below lists the roles that you can assign for each destination type:

Table 213. Destination roles. The first column of the table contains the list of destination types. The second column contains the access roles that can be assigned for the destination types.

Destination type	Access roles
queue	sender, receiver, browser, creator
port	sender, receiver, browser, creator
webService	sender, receiver, browser, creator
topicSpace	sender, receiver
foreignDestination	sender
alias	sender, receiver, browser

In addition to controlling which users and groups have access to a specific local or foreign destination, you can also control the inheritance of access roles for a specific local destination. In this case, the default access roles that apply to all the destinations in the local bus namespace are added to any access roles that have been added for a specific destination.

Use the following tasks to administer destination roles.
- “listGroupsInDestinationRole command” on page 2396
- “addGroupToDestinationRole command” on page 2398
- “removeGroupFromDestinationRole command” on page 2400
- “listUsersInDestinationRole command” on page 2402
- “addUserToDestinationRole command” on page 2403
- “removeUserFromDestinationRole command” on page 2405
- “Defining destination defaults inheritance by using the wsadmin tool” on page 2417
- “Determining destination defaults inheritance by using the wsadmin tool” on page 2416

Adding users and groups to destination roles:

Service integration bus security uses role-based authorization. By adding users and groups to the destination roles for a secured bus, you can control which users and group members can undertake messaging operations at a bus destination.

Before you begin

Ensure that the following conditions are met:
- Security is enabled for the bus. For more information, see Securing buses.
- The users and groups that you want to add to destination roles must exist already in the user repository.

About this task

By adding users or groups to the destination role, you grant the users or groups authority to undertake the operation defined by the role at a selected destination. The destination roles are sender, receiver, browser, and creator, depending on the destination type.

In this task you use the administrative console Security wizard to retrieve selected users or groups from the user repository, and add them to destination roles for selected bus destinations.

Tip: To add a large number of users to destination roles, it is advisable to create a group in the user repository, and add the group to the destination roles.

Procedure
1. Start the administrative console.
2. Click **Service integration -> Buses -> *security_value* -> [Authorization Policy] Manage destination access roles**. A list of the destinations defined for the selected bus is displayed in the Destinations panel.

3. Select one or more destination to work with:
   - Click a single destination name.
   - Select the check boxes next to multiple destination names, and then click **Manage Access Roles**.

   The Destination access roles panel is displayed. The information for each destination you have selected is displayed in a collapsed section.
4. Expand a destination header to list the users and groups that have been assigned to roles for this destination. You can verify that the user or group you want to add does not already have a role at this destination.
5. Click **Add** to start the Security wizard. The wizard takes you through the following steps to add selected users or groups to access roles for the expanded destination:
   a. Search for the users or groups that you want to add to access roles for the expanded destination:

      Users or Groups
      Select either **Users** or **Groups** to specify whether you want to grant access roles to users or groups.

      Search pattern
      This field is mandatory. Specify a search string that is matched against user IDs or group names in the user repository. Only user IDs or group names that match the search pattern are retrieved, subject to the maximum number of search results. Wildcard characters are allowed.

      Maximum number of search results to display
      This field is mandatory. Specify the maximum number of user IDs or group names you want the administrative console to display.

   b. Click **Next**. The wizard displays the users or groups in the user repository that match the information that you provided in the previous step.
   c. Select the check boxes next to the user IDs or group names that you want to add to access roles for the currently expanded destination, and click **Next**. A list of user IDs or group names that you can add to destination roles is displayed. Note that some users or groups might already be assigned to access roles for this destination.
   d. Select the appropriate access role icon for the user ID or group name that you want to add to the role at this destination. For example, select the **Receiver** icon for a user ID or group name that you want to add to the receiver role. The icon changes from  to  to show that you have added the user or group to the access role for the resource.
   e. Repeat the previous step to add more users or groups to access roles for the currently expanded destination, and then click **Next**. A summary of your access role assignments is displayed.
   f. Click **Previous** to review and change your assignments, if required.
   g. Click **Finish** to confirm your assignments.
6. Repeat steps 4 and 5 for each destination you want to work with.
7. Save your changes to the master configuration.

Results

The selected users and groups are added to the access roles for the currently expanded destination. The new access role assignments are displayed in the Destination access roles panel.

Example

A group called MyGroup receives messages from three queues, Queue 1, Queue 2, and Queue 3. If you want the group MyGroup to produce and consume messages at an additional destination, Queue 4, you add MyGroup to Queue 4, and then add MyGroup to the sender and receiver roles for Queue 4.

What to do next

Use the administrative console to complete other security administrative tasks.

Removing users and groups from destination roles:

Service integration bus security uses role-based authorization. By removing users and groups from the destination roles for a secured bus, you can prevent those users and group members from performing messaging operations on the bus.

About this task

When selected users and groups no longer require access to a destination, you can remove them from all the roles for that destination.

Procedure

1. Log into the administrative console.
2. Click **Service integration -> Buses -> *security_value* -> [Authorization Policy] Manage destination access roles** A list of the destinations defined for the selected bus is displayed in the Destinations panel.
3. Select one or more destinations to work with:
   - Click a single destination name.
   - Select the check boxes next to multiple destination names, and then click **Manage Access Roles**.

   The Destination access roles panel is displayed. The information for each destination you have selected is displayed in a collapsed section.
4. Expand a destination header to list the users and groups that have been assigned to roles at this destination, and verify that the user or group that you want to remove has a role at this destination.
5. Select the users and groups that you want to remove from all role types at this destination, and click **Remove**.
6. Save your changes to the master configuration.

Results

The selected users and groups are removed from all role types at the selected destination. The Manage access roles for users and groups panel displays the updated role type assignments.

Example

The members of three groups, Group A, Group B, and Group C, belong to the sender role and the receiver role for two queue destination, Queue 1 and Queue 2. If Group B is no longer required to send and receive messages on Queue 2, you can use this task to remove Group B from all the role types on Queue 2.

What to do next

Use the administrative console to complete other security administrative tasks.

Listing users and groups in destination roles:

Service integration bus security uses role-based authorization. By listing the users and groups in the destination roles for a selected secured bus, you can find out which users and groups are authorized to access the bus, and its resources.

About this task

In this task you use the administrative console to list all the users and groups in destination roles for selected destinations. The list includes users and groups that have references in the service integration role-based configuration; it does not include all the users and groups that exist in the user repository. The permitted destination roles are sender, receiver, browser and creator, depending on the destination type. Icons are used in the administrative console to represent the roles to which users and groups have been assigned. For example, if the role type set icon () is displayed in the sender role for a group called Group 1, it means that Group 1 has been assigned to the sender role for a selected destination. For a complete description of all the icons used to represent role assignments in the administrative console, see "Access role assignments for bus security resources" on page 2429.

Procedure

1. Log into the administrative console.
2. Click **Service integration -> Buses -> *security_value* -> [Authorization Policy] Manage destination access roles**. The Destinations panel lists all the destinations defined for the selected bus.
3. Select one or more destinations to work with:
   - Click the name of a single destination.
   - Select the check boxes next to multiple destinations, and click **Manage Access Roles**.

   The Destination access roles panel is displayed. The information for each selected destination is displayed in a collapsed section.
4. Expand a destination header.

Results

The Destination access roles panel lists the users and groups in access roles for the expanded destination.

What to do next

You can now administer the users and groups in destination roles at this destination.

Restoring default inheritance for a destination:

Service integration bus security uses role-based authorization. By default, all local destinations inherit access roles from the default resource. If default inheritance has been previously overridden, you can restore it for a selected destination.

Before you begin

Default inheritance has been overridden for a selected secured destination. For more information, see Overriding inheritance from the default resource for a destination.

About this task

If default inheritance has been overridden for a particular destination, you can restore it. In this task, you use the administrative console to restore the role type assignments from the default resource to a selected destination. A destination can only inherit access roles that are allowed for that particular type of destination. For example, a topic space can inherit the sender and receiver roles, but it cannot inherit the browser role. Inherited access roles are added to any existing access roles for the destination.

Procedure

1. Log into the administrative console.
2. Click **Service integration -> Buses -> *security_value* -> [Authorization Policy] Manage destination access roles**. The Destinations panel lists all the destinations defined for the selected bus.
3. Select one or more destinations to work with:
   - Click the name of a single destination.
   - Select the check boxes next to multiple destinations, and click **Manage Access Roles**.

   The Destination access roles panel is displayed. The information for each selected destination is displayed in a collapsed section.
4. Expand a destination to list the users and groups that have been assigned to roles for this destination.
5. Select the **Inherit from default** check box.
6. Click **OK** to save your changes.
7. Save your changes to the master configuration.

Results

The role type assignments for the default resource are inherited by the selected destination. The Destination access roles panel displays the newly inherited default access roles for the destination, and any existing access roles.

Disabling inheritance from the default resource:

You can disable the inheritance of security access roles from the default resource for selected resources.

Before you begin

About this task

In this task, you use the administrative console to disable the inheritance of access roles from the default resource for selected resources. Disabling inheritance from the default access roles means that users or groups that have roles in the default access role no longer have access to this destination.

Use the administrative console to disable the inheritance of access roles from selected resources as follows:

Procedure

1. Use the administrative console to navigate to a list of the resources you want to work with for a specific bus. For example, to list all the known destinations for a selected bus, click **Service integration -> Buses -> *security_value* -> [Authorization Policy] Manage destination access roles**. The Destination panel lists all the destinations defined on the selected bus.
2. Do one of the following to select one or more resources:
   - Click the name of a single resource.
   - Select the check boxes next to multiple resources, and click **Manage Access Roles**.

   The Access Roles panel displays access role information for each selected resource within a collapsed section.
3. Expand a resource header to list the users and groups that have been assigned to roles for this resource.
4. Clear the **Inherit from default** check box.
5. Click **OK** to save your changes. The role types for the default resource are removed from the selected resource, and the Access Roles panel is updated.

6. Save your changes to the master configuration.

Deleting a bus destination

Use these tasks to delete a bus destination from a service integration bus.

About this task

The steps required depend on the type of destination.

Deleting a non-topic space bus destination:

Use this task to delete, from a service integration bus, a bus destination that is not for a topic space.

Before you begin

You cannot delete bus destinations that are required by the system; for example, the default exception destination for a messaging engine: `_SYSTEM.Exception.Destination.`*`messaging_engine_name`*.

Before you can completely delete a bus destination, you must ensure that the destination message point is empty of all messages. A delete action is rejected if there are any messages on the message point that are committed, uncommitted, indoubt, or locked.

Any reliable or durable messages that are sent after the delete action, but before the close of producers, are sent to one of the following destinations:

- Another message point of the destination, if possible.
- The exception destination for the deleted destination.

Note: Any attached producers or consumers are closed asynchronously, and do not prevent the delete action. Any messages sent after the delete action, but before close of producers might not be discarded. Depending on the options set, the messages might be moved to the exception destination. For more information see “Configuring exception destination processing for a bus destination” on page 1980 and ../ae/cjo0004_.dita.

About this task

To delete a destination, use the administrative console to complete the following steps.

Procedure

1. Click **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations**.
2. Select the check box next to the destination name.
3. Check for and resolve any locked messages. Messages that are locked, as part of in-flight transactions or as indoubt messages, are not deleted.
4. To clear all messages from the destination, click **Clear**. This action deletes all of the messages that it can access. Messages that are locked, part of in-flight transactions or are in doubt are not deleted. If there are messages that cannot be deleted, they are skipped and the operation indicates that it was partially successful.
5. To delete the empty destination, click **Delete**.
6. To confirm that you want to delete the destination click **OK**.

Results

The bus destination is deleted.

What to do next

Monitor the exception queue for the messaging engine to which the destination was assigned, to see if there are any in-transit messages that were not handled by clearing the destination before it was deleted.

Deleting a topic space:

Use this task to delete, from a service integration bus, a topic space.

Before you begin

Before you can delete a topic space, you must ensure that the publication points are empty. A delete action is rejected if there are any indoubt or uncommitted publications for a publication point.

Note: Any attached producers are closed asynchronously, and do not prevent the delete action. However, any messages sent after the delete action, but before close of producers are discarded.

The service integration bus topic space is the primary messaging object upon which WS-Notification depends at run time. For information about the effect that deleting a topic space has upon new and existing WS-Notification applications, see Failures as a result of changes in topic space and topic namespace configurations.

About this task

To delete a topic space, use the administrative console to complete the following steps.

Procedure

1. Click **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations**.
2. Select the check box next to the destination name.
3. Check for and resolve any undelivered publications (indoubt or uncommitted) for the topic space. Messages that are locked, as part of in-flight transactions or as indoubt messages, are not deleted.
4. To delete the empty topic space, click **Delete**.
5. To confirm that you want to delete the topic space, click **OK**.
6. Save your changes to the master configuration.

Results

The topic space is deleted.

Resetting a destination

Use this task to reset a bus destination.

About this task

You might need to reset a destination if, for example, it has become corrupt. To reset a destination, use a wsadmin AdminControl command.

Note: If a destination becomes corrupt, a CWSIK0027E message is reported, which indicates a serious error. If you see this message, refer to Diagnosing problems (using diagnosis tools) for advice about gathering and reviewing information that might be useful in diagnosing this error. Also refer to the *MustGather: Collect troubleshooting data for a Service Integration Bus (SIB) problems* document on the Must gather website before opening a PMR.

Procedure

1. Set the name of the messaging engine by using a wsadmin AdminControl command of the following form:
   - Using Jython:
     ```
     me = AdminControl.queryNames("type=SIBMessagingEngine,name=messaging_engine_name,* " )
     ```
   - Using Jacl:
     ```
     set me [$AdminControl queryNames type=SIBMessagingEngine,name=messaging_engine_name,*]
     ```

   where *messaging_engine_name* is the name of the messaging engine.
2. Ensure that the messaging engine is running. Start the messaging engine if it is not already running. Read “Starting a messaging engine” on page 1951 for more information.
3. Reset the destination by using a wsadmin AdminControl command of the following form:
   - Using Jython:
     ```
     AdminControl.invoke(me, "resetDestination", ["destination"] )
     ```
   - Using Jacl:
     ```
     $AdminControl invoke $me resetDestination {"destination"}
     ```

   where *destination* is the name of the destination.
4. To complete the resetting of the destination, restart the server that is hosting the messaging engine on which the destination is localized.

Results

The bus destination is reset ready for use.

Managing bus destinations with administrative commands

You can use these commands to manage bus destinations.

About this task

These commands provide an alternative to using the administrative console or using the more complex syntax of wsadmin and JACL.

Procedure

1. Open a wsadmin command session in local mode For example:
   ```
   wsadmin -conntype none -lang jython
   ```

   Note: The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.
2. Type `AdminTask.command`

   Where *command* is the command format as indicated in the related reference topics; for example:
   ```
   wsadmin>AdminTask.listSIBDestinations(["-bus", "abus"])
   '(cells/9994GKCCell01/buses/abus|sib-destinations.xml#SIBTopicSpace_1098181446388)
   (cells/9994GKCCell01/buses/abus|sib-destinations.xml#SIBQueue_1098181503600)
   (cells/9994GKCCell01/buses/abus|sib-destinations.xml#SIBQueue_1098184221748)'

   wsadmin>AdminTask.listSIBDestinations(["-bus", "abus", "-type", "TopicSpace"])
   '(cells/9994GKCCell01/buses/abus|sib-destinations.xml#SIBTopicSpace_1098181446388)'
   ```

Configuring message points

Use the following tasks to configure message points on service integration buses.

About this task

A message point is the location (for example, queue point or publication point) at which messages for a bus destination are held in a messaging engine. The runtime state of the message point represents a runtime instance of the destination.

When you define a new bus destination, its message point is created. You can then configure some properties of the message point to override the general properties defined for the destination.

You can also administer the messages on the runtime view of the message point.
- “Configuring a message point”
- “Listing message points for a bus destination”
- “Listing message points for a messaging engine”

Listing message points for a messaging engine

Use this task to list the message points for bus destinations on a selected messaging engine.

About this task

To display a list of message points for a messaging engine, use the administrative console to complete the following steps.

Procedure

1. Click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines**. This displays a list of messaging engines on the bus.
2. Click the name of the messaging engine.
3. Under Message Points, click the link for the type of point you want to list.

Results

A list of message points for the selected messaging engine is displayed in the content pane.

Listing message points for a bus destination

Use this task to list the message points for a selected bus destination.

About this task

To display a list of message points for a bus destination, use the administrative console to complete the following steps.

Procedure

1. Display the bus destination.
2. In the content pane, under Message Points, click the link for the type of point you want to list.

Results

A list of message points for the selected bus destination is displayed in the content pane.

Configuring a message point

Use this task to browse or change the configuration properties of a message point for a bus destination.

About this task

You can configure some properties of the message point to override the general properties defined for the destination.

To browse or change the properties of a message point, use the administrative console to complete the following steps:

Procedure

1. Click **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *destination_name***.
2. Under Message Points, click the link for the type of message point:
   - **Queue points**, for a queue
   - **Publication points**, for a topic space
   - **Mediation points**, for a mediated queue or topic space
3. In the content pane, click the name of the message point.
4. Optional: Change the message point settings.
5. Click **OK**.
6. Save your changes to the master configuration.

Managing messages on message points

Use these tasks to list and act on runtime messages that exist on message points in a service integration bus.

About this task

You can list the message points for bus destinations and messaging engines, and list the messages on a selected message point. You can use the list of messages as part of a troubleshooting task to find messages that need to be deleted.

- "Listing messages on a message point" on page 595
- "Deleting messages on a message point" on page 596

Listing messages on a message point

Use this task to list the messages that exist on a message point for a selected bus destination or messaging engine.

About this task

To display a list of messages on a message point, use the administrative console to complete the following steps:

Procedure

1. In the navigation pane, click **Service integration -> Buses**.
2. In the content pane, click the name of the service integration bus.
3. Optional: To list the message points for a bus destination, complete the following steps:
   a. In the content pane, under **Destination resources**, click **Destinations**.
   b. Click the destination name.
4. Optional: To list the message points for a messaging engine, complete the following steps:
   a. In the content pane, under **Topology**, click **Messaging engines**.
   b. Click the messaging engine name.
5. Under Additional Properties, click **Message points**. This displays a list of message points in the content pane.
6. Click the message point name. This displays the properties of the destination localization in the content pane.
7. Click the Runtime tab.

8. Under Additional Properties, click **Messages**.

Results

A list of messages on the selected message point is displayed in the content pane.

What to do next

You can select one or more messages to act on; for example, to display the message content, delete messages.

Deleting messages on a message point

Use this task to delete one or more messages that exist on a message point for a selected bus destination or messaging engine.

About this task

You should not usually have to delete messages on a message point. This task is intended as part of a troubleshooting procedure.

To delete one or messages on a message point, use the administrative console to complete the following steps:

Procedure

1. List the messages on the message point.
2. In the content pane, select the check box next to each message that you want to delete. Alternatively, you can select all messages in the list by clicking **Select all items**  .
3. Click **Delete**.

Results

The selected messages are removed from the list.

Administering durable subscriptions

Use the following tasks to display the durable subscriptions that exist, to enable a subscription to be changed, or to delete a subscription.

About this task

The default messaging provider supports the use of durable subscriptions to topics. This enables a subscriber to receive a copy of all messages published to a topic, even messages published during periods of time when the subscriber is not connected to the server.

If an application creates a durable subscription, it is added to the list that administrators can display and act upon by using the administrative console. Each durable subscription is created with a unique subscription identifier, *clientID##subName* where:

clientID
: The client identifier used to associate a connection and its objects with the messages maintained for applications (as clients of the JMS provider). You should use a naming convention that helps you identify the applications, in case you have to relate durable subscriptions to the associated applications for runtime administration. For more information about client identifiers, see section 4.3.2 of the JMS 1.1 specification.

subName
The JMS durable subscription name used to uniquely identify a durable subscription within a given client identifier. For more information about JMS durable subscription names, see section 6.11.1 of the JMS 1.1 specification.

For durable subscriptions created by message-driven beans, the subscription name value is set on the JMS activation specification. For other durable subscriptions, the value is set by the administrator on the JMS connection factory and by the JMS application on the createDurableSubscriber operation.

Note: The *server_name*-durableSubscriptions.ser file in the *WAS_HOME*/temp directory is used by the messaging service to keep track of durable subscriptions for message-driven beans. If you uninstall an application that contains a message-driven bean, this file is used to unsubscribe the durable subscription. If you have to delete the *WAS_HOME*/temp directory or other files in it, ensure that you preserve this file.

Procedure

- List durable subscriptions.
- Stop active subscribers for durable subscriptions.
- Enable providers to stream messages to cloned durable subscriptions.
- Delete durable subscriptions.

Listing subscriptions

Use this task to list the subscriptions that exist at runtime for a topic space.

About this task

The runtime state of a subscription is linked to the publication point for the messaging engine that is used to store messages delivered to the subscription. You can list subscriptions by first displaying the publication point, either from the messaging engine panel or the list of all publication points for a service integration bus.

To display a list of subscriptions for a publication point, use the administrative console to complete the following steps:

Procedure

1. Click **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations**. This displays any existing destinations in the content pane.
2. Click the name of the topic space.
3. Under Message Points, click **Publication points**. This displays the publication points for the topic space.
4. Click the name of the publication point.
5. Click the Runtime tab.
6. Under Additional Properties, click **Subscriptions**

Results

The list of subscriptions for the selected topic space is displayed in the content pane. For more information about the list of subscriptions, see “Subscriptions [Collection]” on page 2167.

Each subscription has a unique subscription identifier that has the form, *clientID##subName* where:

clientID
The client identifier used to associate a connection and its objects with the messages maintained for applications (as clients of the JMS provider). You should use a naming convention that helps

you identify the applications, in case you have to relate subscriptions to the associated applications for runtime administration. For more information about client identifiers, see section 4.3.2 of the JMS 1.1 specification.

subName
The JMS subscription name used to uniquely identify a durable subscription within a given client identifier. For more information about JMS subscription names, see section 6.11.1 of the JMS 1.1 specification.

What to do next

To display details of a subscription, click the name of the subscription in the list. To delete one or more subscriptions, select the check box next to the subscription names then click **Delete**.

Stopping active subscribers for durable subscriptions

Use this task to enable applications to change a cloned durable subscription. This task enables applications to connect to an existing cloned durable subscription, and to specify parameters that differ from those that were used to create the existing subscription.

About this task

When an application connects to an existing durable subscription, but specifies parameters that differ from those that were used to create the existing subscription, **the subscription is deleted then recreated with the new parameters**. A durable subscription can be changed in this way only when it has no active consumers.

Note: The *server_name*-durableSubscriptions.ser file in the *WAS_HOME*/temp directory is used by the messaging service to keep track of durable subscriptions for message-driven beans. If you uninstall an application that contains a message-driven bean, this file is used to unsubscribe the durable subscription. If you have to delete the *WAS_HOME*/temp directory or other files in it, ensure that you preserve this file.

To stop active subscribers for one or more durable subscriptions, complete the following steps:

Procedure

1. Use the administrative console to list the durable subscriptions
2. From the list, identify the client identifier of the durable subscription. The name column lists the unique subscription name for each durable subscription, in the form *clientID##subName* where:

   clientID
   The client identifier used to associate a connection and its objects with the messages maintained for the client by the JMS provider.

   subName
   The name used to uniquely identify a durable subscription within a given client identifier.
3. Use your client identifier naming convention to identify the application assigned to the client identifier.
4. List the applications that have active consumers for the durable subscription. In the navigation pane of the administrative console, click **Applications -> Application Types -> WebSphere enterprise applications**.
5. In the console pane, select the check box next to the name of each application that you want to stop.
6. Click **Stop**

Results

This stops the active consumers created by the applications, so applications can reconnect to the durable subscriptions with different parameters from those that were used to create the previous subscriptions.

Deleting durable subscriptions
Use this task to delete a durable subscription.

About this task

To delete one or more durable subscriptions, complete the following steps:

Procedure
1. Display the durable subscriptions
2. Select the check box for each subscription you want to delete.
3. Click **Delete**

Results

The selected durable subscriptions are deleted.

Administering mediations

These topics provide information about mediations, which are used to change how messages are handled at destinations on a service integration bus.

Procedure
- ../ae/cjp_learning.dita
- Mediation programming
- Programming mediations
- “Securing mediations”
- “Configuring mediations” on page 2007
- “Configuring mediation points” on page 2018
- “Managing mediations with administrative commands” on page 2020
- “Operating mediations at mediation points” on page 2020
- “Administering messages on mediation points” on page 2023
- “Message properties support for mediations” on page 2430
- “Error handling in mediations” on page 2434
- “Mediation thread pool properties” on page 2435

Securing mediations

Use the following tasks to secure mediations at an operations level. For example, a mediation inherits its identity from a the messaging engine, but you might want to specify an alternative identity for the mediation to use.

Configuring an alternative mediation identity for a mediation handler
Use this task to configure an alternative mediation identity for a mediation handler

About this task

By default, a mediation inherits the identity used by the messaging engine. In some cases, you might want to specify an alternative identity for a mediation handler to use. For example, for a single mediation that sends messages to a destination. To do this, you specify a "run-as" identity for the mediation handler at deployment, and map the mediation handler to an identity other than the default mediation identity by using a role name. Follow the steps below to specify an alternative mediation identity:

Procedure

1. Package your mediation handler as an EAR file.
2. Edit the deployment descriptor file to define the roles. For more information, see Configuring programmatic logins for Java Authentication and Authorization Service.
3. Assign users to the role. For more information, see Mapping users to RunAs roles using an assembly tool and Securing applications during assembly and deployment.
4. Deploy the mediation handler in WebSphere Application Server, and assign users to the RunAs role. For more information, see Assigning users to RunAs roles. You can confirm the mappings of users to roles, add new users and groups, and modify existing information during this step. For more information, see Deploying secured applications.

Example

What to do next

Next, you are ready to authorize mediations to access destinations. For more information, see Administering authorization permissions.

Configuring the bus to access secured mediations

Use this task to ensure that the service integration bus is authorized to access secured mediations.

Before you begin

The mediation is secured by using a Java Platform, Enterprise Edition (Java EE) Connector Architecture authentication alias. For information about creating a Java EE authentication alias, see ../ae/tsec_j2cauthdata.dita.

About this task

To configure the bus to access a secured mediation, you must add the mediation authentication alias for the secured mediation to the properties for the bus:

- If the bus has a Version 6 bus member, you must provide the principal and its associated password.
- If the bus has WebSphere Application Server Version 7.0 or later bus members only, you need only provide the principal.

Procedure

1. Log into the navigation pane.
2. Click **Service integration -> Buses -> *security_value***. The bus security configuration panel is displayed.
3. In the **Mediations authentication alias** field, select the principal for the mediation, and its associated password if required.
4. Click **OK**.
5. Save your changes to the master configuration.

Results

The selected bus is configured to access secured mediations.

What to do next

You can assign security roles to your mediation handlers to protect them from use by unauthorized users. For more information, see Deploying secured applications.

Configuring a bus to run mediations in a multiple security domain environment

Use this task to configure a secured bus so that it can run mediations successfully on bus members in different security domains.

Before you begin

The secured bus must be configured to use a non-global security domain. For more information about securing buses by using multiple security domains, refer to Securing buses.

About this task

If your bus topology has bus members in different security domains, you can configure the bus to allow mediations to run under the server identity. This means that a mediation can run on any server in any domain. You do not have to add a dedicated user ID for each mediation to the user repository, or maintain a mediation authentication alias.

Use the administrative console to configure a secured bus to run mediations successfully as follows:

Procedure

1. In the navigation pane, click **Service integration -> Buses -> *security_value***. The security settings for the selected bus are displayed.
2. Check the option **Use the Server ID when running mediations**.
3. Click **Apply**.
4. Save your changes to the master configuration.

Results

You have configured the bus to run mediations successfully across servers in multiple security domains.

What to do next

You can use the administrative console to control access to the bus by administering users and groups in the bus connector role.

Configuring mediations

Use the following tasks if you want to modify the behavior of a mediation, control which messages are mediated, or influence how messages are processed.

Installing a mediation

You can install an enterprise application (EAR file) containing a mediation on a server.

Before you begin

- You have an EAR file that you can deploy into WebSphere Application Server (base). The EAR file contains a mediation handler enterprise bean. You can use the tooling provided with IBM Rational Application Developer to assemble EAR files.
- For guidance on selecting the target application server for your mediation, see Mediation application installation.

About this task

In this task, you use the administrative console to install a mediation application into WebSphere Application Server (base). For additional information about installing enterprise applications, see Installing enterprise application files with the console. For information about installing a secure mediation handler, see Deploying secured applications.

Procedure

1. Click **Applications -> New Application -> New Enterprise Application**.
2. On the first Preparing for application install page, specify the full path name of your EAR file, and click **Next**.
3. On the second Preparing for application install page, choose to generate default bindings.
   a. Expand **Choose to generate default bindings and mappings**.
   b. Select **Generate default bindings**. Using the default bindings causes any incomplete bindings in the application to be completed with default values. The product does not change existing bindings.
   c. Click **Next**. The Select Installation options page is displayed.
4. Type the name of your EAR file in the **Application name** field, if it not already specified, and click **Next**. The Map modules to servers page is displayed.
5. Select the target application server where you want to install the modules that are contained in your application, and click **Next**.
6. Optional: If the panel **Deploy enterprise beans** is displayed, click**Apply**, and click **Next**.
7. Review the summary of the installation options you have chosen:
   a. If you want to make changes, click **Previous** to return to the appropriate page.
   b. When you are ready, click **Finish** to confirm your installation options.
8. Save your changes to the master configuration.

Results

Your mediation application is installed on your chosen server or cluster.

What to do next

You can configure the properties for the mediation in the administrative console. For more information, see “Configuring a new mediation.”

Configuring a new mediation

Use this task to configure a mediation in the administrative console.

Before you begin

This task assumes that you have installed a mediation application on the server where you want to run the mediation. For more information, see “Installing a mediation” on page 2007.

About this task

Configuring a new mediation makes it available for use in mediating one or more destinations.

In this task, you use the administrative console to configure a mediation:

Procedure

1. Click **Service integration -> Buses -> *bus_name* -> [Destination resources] Mediations**.
2. In the content pane, click **New**.
3. Specify the following properties for the mediation:

   Mediation name
   Type a name for the mediation that is unique to the service integration bus. This name is used to identify the mediation for administrative purposes.

   Description
   Optionally, type a description for the mediation.

Handler list name
Type the handler list name. This is the name that was used when the mediation handler was deployed. Handler list names are unique within the WebSphere Application Server administrative cell.

Global transaction
Optionally, select this option (setting it to `true`) if you want to start a global transaction for each message mediated by the mediation. By default, Global transaction is set to false, and a global transaction is not started when a message is mediated.

Allow concurrent mediation
Optionally, select this option (setting it to `true`) if you want to mediate multiple messages at the mediated destination.

By default, Allow concurrent mediation is set to false, and concurrent mediations are not allowed.

Note: Do not allow concurrent mediation if message ordering is important.

Selector
Optionally, type a message selector to control which messages are mediated by the mediation. The selector operates on the content of the message header. The syntax of the message selector is defined by the JMS specification.

If the message content meets the conditions of the selector, the message is mediated. Otherwise, the message is not mediated.

Discriminator
Optionally, type a message discriminator to control which messages are mediated by the mediation. Message discriminators conform to the publish/subscribe topicspace syntax.

If the message meets the conditions of the discriminator, the message is mediated. Otherwise, the message is not mediated.

4. Click **OK**.
5. Save your changes to the master configuration.

Results

You have configured a new mediation.

What to do next

You can use the mediation to mediate a destination. For more information, see “Mediating a destination” on page 2017.

Deleting a mediation

Use this task to delete a selected mediation in the administrative console.

Before you begin

Before deleting a mediation, you must ensure that it is not in use at a bus destination. You cannot delete a mediation that is in use at a destination; you must first unmediate the destination. For more information, see “Unmediating a destination” on page 2017.

About this task

Deleting a mediation removes it from the administrative console. To delete a mediation, use the administrative console to complete the following steps

Procedure

1. Click **Service integration -> Buses -> *bus_name* -> [Destination resources] Mediations**.
2. Select the mediations that you want to delete.
3. Click **Delete**.
4. Save your changes to the master configuration.

Results

The mediations are deleted.

Modifying the properties of a mediation

Use this task to set properties to control some aspects of the runtime behavior of an existing mediation.

Before you begin

You should ensure that the mediation exists. If you want to configure a new mediation, see "Configuring a new mediation" on page 2008.

About this task

Using the administrative console, you can specify the following options for a selected mediation:

- Each message processed by the mediation runs within a global transaction.
- The mediation processes messages concurrently.
- The mediation processes only those messages that meet some selection criteria.

Procedure

1. Click **Service integration -> Buses -> *bus_name* -> [Destination resources] Mediations -> *mediation_name***.
2. Select any of the following properties for the mediation:

   Description
   Optionally, type a description of the behavior of the mediation, taking into account any properties specified for the mediation.

   Handler list name
   Type the name of the handler list that was defined when the mediation was deployed. Handler list names start with an uppercase letter, and are unique within the service integration bus.

   Global transaction
   Optionally, select this option (setting it to `true`) if you want to start a global transaction for each message mediated by the mediation.

   By default, Global transaction is set to false, and a global transaction is not started when a message is mediated.

   Allow concurrent mediation
   Optionally, select this option (setting it to `true`) if you want to mediate multiple messages at the mediated destination.

   By default, Allow concurrent mediation is set to false, and concurrent mediations are not allowed.

   Note: Do not allow concurrent mediation if message ordering is important.

Selector

Optionally, type a message selector to control which messages are mediated by the mediation. The selector operates on the content of the message header. The syntax of the message selector is defined by the JMS specification.

If the message meets the conditions of the selector, the message is mediated. Otherwise, the message is not mediated.

For information about the properties that can be used in selectors, see "Message properties support for mediations" on page 2430.

Discriminator

Optionally, type a message discriminator to control which messages are mediated by the mediation. Message discriminators conform to the publish/subscribe topic space syntax.

If the message meets the conditions of the discriminator, the message is mediated. Otherwise, the message is not mediated.

3. Specify any additional properties.
4. Click **OK**.
5. Save your changes to the master configuration.

Results

You have changed the properties for the selected mediation.

What to do next

- If you want to configure the mediation context information, see "Configuring mediation context properties" on page 2013.
- To use the mediation to mediate a destination, see "Mediating a destination" on page 2017.

Adding mediation context information

Use this task to add a mediation context property for a selected mediation.

Before you begin

The mediation for which you want to add context information must exist in the administrative console. To create a mediation, see "Configuring a new mediation" on page 2008.

About this task

Mediation context information is used, in addition to the message header information, to determine how a message is processed at run time. New context information is defined by adding a mediation context property. A destination can also have context properties. If you add a context property for a mediation that has the same name as a destination context property, the property on the destination takes precedence.

You can add the following mediation context properties:

Property name	Description	Value	Additional information
sib:SkipWellFormedCheck	Omits the well formed check that is performed on messages after they have been processed by the mediation.	True or false	This property is overridden by the message delivery option assured persistent. A well formed check is always performed for messages that have the delivery option assured persistent.

Property name	Description	Value	Additional information
sib:GlobalTransactionLPSEnabled	Allows a mediation to contain resources for which Last Participant Support (LPS) is enabled. This enables a one-phase commit resource to participate in a global transaction that has two-phase commit resources.	True or false	

To add new mediation context information for a selected mediation, use the administrative console to complete the following steps:

Procedure

1. Display the Context Properties panel for a selected mediation: click **Service integration -> Buses -> *bus_name* -> [Destination resources] Mediations -> *mediation_name* -> [Additional Properties] Context properties**. Any mediation context properties that have already been defined for the selected mediation are displayed.
2. Click **New** in the content pane.
3. Specify the following information for the mediation context property:

   Name Type a name for the mediation context property. You must type the name exactly as it appears in the table above.

   Context type
   Select the type `Boolean` for the mediation context property.

   Context value
   Type `True` to set the property. The value is not case sensitive.
4. Click **OK**.
5. Save your changes to the master configuration.

Results

You have added new mediation context information for the selected mediation.

What to do next

You can repeat this task to add another mediation context property.

Listing mediation context properties

Use this task to list context properties for a selected mediation.

About this task

Mediation context information is used, in addition to the message header information, to determine how a message is processed at run time. The context information is provided by one or more of the following mediation context properties:

Property name	Description	Value	Additional information
sib:SkipWellFormedCheck	Omits the well formed check that is performed on messages after they have been processed by the mediation.	True or false	This property is overridden by the message delivery option assured persistent. A well formed check is always performed for messages that have the delivery option assured persistent.

Property name	Description	Value	Additional information
sib:GlobalTransactionLPSEnabled	Allows a mediation to contain resources for which Last Participant Support (LPS) is enabled. This enables a one-phase commit resource to participate in a global transaction that has two-phase commit resources.	True or false	

In this task, you use the administrative console to list the mediation context properties for a selected mediation, as follows:

Procedure

1. Log in to the administrative console.
2. Click **Service integration -> Buses -> *bus_name* -> [Destination resources] Mediations -> *mediation_name* -> [Additional Properties] Context properties**.

Results

The mediation context properties for the selected mediation are displayed.

What to do next

You can configure or delete the context information, or add a new context property for the selected mediation.

Configuring mediation context properties

Use this task to configure context properties for a selected mediation.

Before you begin

The mediation context property you want to configure must exist in the administrative console. To add a new mediation context property, see “Configuring a new mediation” on page 2008.

About this task

Mediation context information is used, in addition to the message header information, to determine how a message is processed at run time. By configuring the mediation context properties, you ensure that messages are processed correctly. A destination can also have context properties. If a context property is configured for both a destination and a mediation, with the same name for the property, the property on the destination takes precedence.

You can configure the following mediation context properties:

Property name	Description	Value	Additional information
sib:SkipWellFormedCheck	Omits the well formed check that is performed on messages after they have been processed by the mediation.	True or false	This property is overridden by the message delivery option assured persistent. A well formed check is always performed for messages that have the delivery option assured persistent.

Property name	Description	Value	Additional information
sib:GlobalTransactionLPSEnabled	Allows a mediation to contain resources for which Last Participant Support (LPS) is enabled. This enables a one-phase commit resource to participate in a global transaction that has two-phase commit resources.	True or false	

To configure an existing mediation context property, use the administrative console to complete the following steps:

Procedure

1. Display the mediation context property for a selected mediation: click **Service integration -> Buses -> *bus_name* -> [Destination resources] Mediations -> *mediation_name* -> [Additional Properties] Context properties**. The mediation context properties for the selected mediation are displayed.
2. Select the mediation context property you want to configure.
3. Specify the following information for the mediation context property:

   Name Type a name for the mediation context property. You must type the name exactly as it appears in the table above.

   Context type
   Select the type `Boolean` for the mediation context property.

   Context value
   Type a value for the mediation context property: either `True` to set the property, or `False` to unset it. The value is not case sensitive.
4. Click **OK**.
5. Save your changes to the master configuration.

Results

The context property is configured for the selected mediation.

What to do next

You can repeat this task to configure additional mediation context properties.

Deleting mediation context information

Use this task to delete a mediation context property for a selected mediation.

About this task

In this task, you delete a mediation context property. The mediation context information provided by the property is no longer used at runtime to process messages.

You can delete the following mediation context properties:

Property name	Description	Value	Additional information
sib:SkipWellFormedCheck	Omits the well formed check that is performed on messages after they have been processed by the mediation.	True or false	This property is overridden by the message delivery option assured persistent. A well formed check is always performed for messages that have the delivery option assured persistent.

Property name	Description	Value	Additional information
sib:GlobalTransactionLPSEnabled	Allows a mediation to contain resources for which Last Participant Support (LPS) is enabled. This enables a one-phase commit resource to participate in a global transaction that has two-phase commit resources.	True or false	

To delete mediation context information for a selected mediation, use the administrative console to complete the following steps:

Procedure

1. Display the Context Properties panel for a selected mediation: click **Service integration -> Buses -> *bus_name* -> [Destination resources] Mediations -> *mediation_name* -> [Additional Properties] Context properties**. The mediation context properties for the selected mediation are displayed.
2. Select the property you want to delete, and click **Delete**.
3. Click **OK**.
4. Save your changes to the master configuration.

Results

Your chosen mediation context property is deleted for the selected mediation.

What to do next

You can repeat this task to delete another mediation context property.

Configuring the mediation thread pool

Use this task to configure the mediation thread pool.

Before you begin

The wsadmin tool must be running. For more information, see Starting the wsadmin scripting client using wsadmin scripting.

About this task

You configure the mediation thread pool if you want to change the number of threads used when running mediations concurrently. The maximum size of the thread pool determines the maximum number of messages that can be mediated concurrently for a messaging engine.

The mediations thread pool, attribute name `mediationsThreadPool`, is an attribute of the messaging engine. By default, `mediationsThreadPool` does not exist, and a default thread pool is created and used at run time. In this task, use the wsadmin tool to create a thread pool object, and then modify its properties using JACL, as shown in the examples below:

Note: You use the wsadmin tool from within Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Procedure

1. Use this example to create a mediationThreadPool object:

```
AdminConfig.create("ThreadPool" , messagingEngine,
                   [["name" , "stitch.server1-bus2-mediationThreadPool"]] ,
                   "mediationThreadPool")
```

Tip: In this case, the thread pool name is based on the name of the messaging engine. Although it is not required to do this, it makes it easier to find the thread pool name when using Performance Monitoring Infrastructure (PMI).

2. Use this example to modify a mediationThreadPool object:

```
AdminConfig.modify(AdminConfig.showAttribute(messagingEngine,
  "mediationThreadPool"), [["maximumSize" , "10"]])
```

`maximumSize` can contain any of the mediationsThreadPool properties. To add additional parameters, insert [*attribute_name attribute_value*] within the outer brackets ([]).

Tip: There is a space between *attribute_name* and *attribute_value*.

Setting tuning properties for a mediation

Use this task to tune a mediation for performance by using the administrative console.

Before you begin

Review the guidance on when it is appropriate to tune a mediation for performance in the topic Performance tuning for mediations.

About this task

You can set the following tuning property in the administrative console to improve the performance of a mediation:

sib:SkipWellFormedCheck
Whether you want to omit the well formed check that is performed on messages after they have been processed by the mediation. Either true or false.

Note: This property is overridden for messages that have the delivery option assured persistent, and a well formed check is always performed.

To set, or unset, one or more tuning properties for a mediation, use the administrative console to complete the following steps:

Procedure

1. Display the mediation context information:
   a. Click **Service integration -> Buses -> *bus_name* -> [Destination resources] Mediations**.
   b. In the content pane, select the name of the mediation for which you want to configure tuning information.
   c. Click **[Additional Properties] Context information**.
2. In the content pane, click **New**.
3. Type the name of the property in the **Name** field.
4. Select the type `Boolean` from the drop-down list.
5. Type **true** in the **Context Value** field to set the property, or type **false** to unset the property.
6. Click **OK**.
7. Save your changes to the master configuration.

Mediating a destination

Use the administrative console to mediate a service integration destination with a mediation hosted by service integration. A mediation point is created for the mediated destination on the bus member where you want the mediation to run, and is used to process messages at runtime.

Before you begin

Ensure that the following resources exist:

- The mediation you want to apply to the destination. For more information, see “Configuring a new mediation” on page 2008.
- The bus member where the mediation point is to be created.

About this task

You can mediate a destination with a single mediation only, but you can associate the same mediation with more than one destination. This scenario mediates a destination with a service integration mediation point, and a service integration mediation. If you want to mediate a destination by using an WebSphere MQ program, or assign it to an WebSphere MQ queue point, see “Mediating a destination by using a WebSphere MQ queue as the mediation point” on page 581.

Procedure

1. Click **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations**. The bus destinations for the selected bus are displayed.
2. Select the destination you want to mediate, and click **Mediate**. A list of available mediations is displayed.
3. Select the mediation to associate with the destination, and click **Next**.
4. Select the bus member where you want the mediation to run, and click **Next**.
5. Click **Finish** to mediate the destination, or **Previous** to make any changes to your selections.
6. Save your changes to the master configuration.

Results

Your chosen destination is mediated with your chosen mediation, and a mediation point is created for the destination on the bus member.

What to do next

You can control some aspects of how the mediation processes messages at the mediation point. For example, whether the mediation run within a global transaction, or processes multiple messages concurrently. For more information, see “Modifying the properties of a mediation” on page 2010.

Unmediating a destination

Use this task to unmediate a selected bus destination.

Before you begin

Before you start this task, you should consider whether you want to preserve message ordering at the bus destination you intend to unmediate.

About this task

Unmediating a selected bus destination breaks the association between the bus destination and the mediation, and the mediation stops processing messages at the bus destination at run time. This task unmediates a bus destination, and optionally preserves message ordering at the bus destination.

To unmediate a bus destination use the administrative console to complete the following steps:

Tip: If you want to preserve message ordering, complete all the following steps. If message ordering is not important, you can omit steps 2 and 4:

Procedure

1. Display the bus destination you want to unmediate. Click **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *destination_name***.
2. Optional: If you want to preserve message ordering at the destination, take the following steps:
   a. Clear the **Send Allowed** check box (setting it to false) to stop sending messages to the message points for this destination.
   b. Wait until there are no messages listed for the mediation points.
   c. Stop all the mediation points, and wait for all the mediation points to enter the `stopped` state.
   d. Optional: If it is not already selected, select the bus destination you want to unmediate.
3. Click **Unmediate** to unmediate the destination.
4. Optional: Select the **Send Allowed** check box (setting it to `true`) to resume sending messages to the mediation points for this destination.
5. Save your changes to the master configuration.

Results

The destination is unmediated, and the mediation point is deleted from the destination.

If you did not preserve message ordering, any messages that remain on the mediation point after you have unmediated the destination are processed as for a non-mediated destination. Messages with an empty forward routing path are placed on the next appropriate message point for the destination. Messages with a non-empty forward routing path are sent to the destination specified in the forward routing path.

The unmediated destination now operates as a non-mediated destination, and new messages are sent to a message point on the destination.

Configuring mediation points

In service integration technologies, messages are held at specialized message points called mediation points before they are processed by a mediation. Use the following tasks to set properties at mediation points to route messages and start and stop mediations:

Configuring a mediation point

You can use the administrative console to browse or change the configuration properties for a selected mediation point for a selected bus destination.

Before you begin

You must first create a mediation point on a bus destination. For more information, see “Mediating a destination” on page 2017.

About this task

A mediation point is a specialized message point on a bus location where messages are stored and mediated. Configuring the properties of a mediation point enables you to control some aspects of how messages are sent to and received from a bus destination. In this task you use the administrative console to configure the properties for a selected mediation point for a selected bus destination.

Note: You should be aware that the mediation point properties Send allowed and Initial state override the general properties defined for the bus destination.

To browse or change the properties for a selected mediation point, use the administrative console to complete the following steps:

Procedure

1. Start the administrative console, and click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Message points] Mediation points -> *mediation_point_name***. The properties for the selected mediation point are displayed.
2. Optional: Browse or change the following properties for the mediation point:

   Identifier
   The identifier by which this message point is known for administrative purposes. This field is for display purposes only.

   UUID The universal unique identifier assigned to this mediation point for administrative purposes. This field is for display purposes only.

   High message threshold
   The maximum total number of messages that can be placed on this mediation point. This field is for display purposes only.

   Send allowed
   This property specifies whether messages are sent to this mediation point. By default, `True` is selected, and messages are sent to this mediation point. Select `False` to prevent messages from being sent to this mediation point.

   Initial state
   This property specifies the state of the mediation point when the host messaging engine is started for the first time. Permitted values are `Started` or `Stopped`. The default state is `Started`. The mediation does not start mediating messages until Initial state is `Started`.

   Target UUID
   The UUID of the bus destination where this mediation point is created. This field is for display purposes only.
3. Click **OK**.
4. Save your changes to the master configuration.

Results

You have browsed or changed the configuation properties for the selected mediation point.

Listing mediation points for a bus destination

Use this task to list mediation points for a selected bus destination.

About this task

This task lists the mediation points for a selected bus destination. You might want to do this, for example, to check that a destination is mediated.

To display a list of mediation points for a bus destination, use the administrative console to complete the following steps:

Procedure

1. Click **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *destination_name***.
2. Click **[Message Points] Mediation Points**.

Results

All the mediation points for the selected bus destination are displayed.

Listing mediation points for a messaging engine

You can use the administrative console to list all the known mediation points for a selected messaging engine. You can then view the properties for a mediation point, administer messages for a mediation point, or operate mediations at a mediation point.

About this task

To list the mediation points for a selected messaging engine, use the administrative console to complete the following steps:

Procedure

Start the administrative console, and click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Message points] Mediation points**.

Results

The Mediation points panel displays a list of all the mediation points for the selected messaging engine.

What to do next

You can click the name of a mediation point in the list to work with its properties, administer its messages or operate mediations.

Managing mediations with administrative commands

You can use wsadmin commands to administer service integration technologies mediations. For example you can create, delete and view mediations, configure mediation properties and mediate destinations.

About this task

These commands provide an alternative to using the administrative console.

Procedure

1. Open a wsadmin command session in local mode For example:

   ```
   wsadmin -conntype none -lang jython
   ```

   Note: The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

2. Type `AdminTask.`*`command`* where *command* is the command format as indicated in the related reference topics. For example:

   ```
   wsadmin>AdminTask.listSIBMediations("-bus abus")
   (cells/9994GKCCell01/buses/abus|sib-mediations.xml#SIBDestinationMediation_1098217858584)
   (cells/9994GKCCell01/buses/abus|sib-mediations.xml#SIBDestinationMediation_1098220051588)
   ```

Operating mediations at mediation points

Use these tasks to start, stop and restart mediations at runtime at specialized message points called mediation points.

Before you begin

These tasks assume that mediations are configured in the administrative console. For more information, see “Configuring mediations” on page 2007.

Starting a mediation

Use this task when you want a mediation to apply its message processing to messages at a selected specialized message point on a destination, at runtime.

Before you begin

The mediation you want to start must be associated with a destination. For more information, see “Mediating a destination” on page 2017.

About this task

Starting (and stopping) a mediation is a runtime operation. All mediation runtime operations are performed on specialized destination message points called mediation points. When you start a mediation, the mediation begins operating on messages at a selected mediation point. You can start a mediation after the server has started. A mediation cannot operate on new messages at a mediation point after server shutdown begins.

Tip: To ensure that a mediation operates on a specific message at a mediation point, remove all existing messages from the mediation point before you start the mediation. For more information, see “Deleting messages on a mediation point” on page 2023.

To start a mediation, complete the following steps in the administrative console:

Procedure

1. List the mediation points by using the administrative console:
   - To list the mediation points for a bus destination, click **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *destination_name* -> [Message Points] Mediation points**.
   - To list the mediation points for a messaging engine, click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Message points] Mediation points**.
2. Select the mediation name.
3. Click **Start**.

Results

The mediation starts operating on messages at the selected mediation point.

What to do next

To list or delete messages at selected mediation points, see “Administering messages on mediation points” on page 2023. To restart a mediation, refer to “Restarting a mediation that has stopped on error” on page 2022.

Stopping a mediation

Use this task to stop a selected mediation at a mediation point.

Before you begin

Before you can operate a mediation, it must be associated with a destination. For more information, see “Mediating a destination” on page 2017.

About this task

Stopping a mediation, as with all runtime operations on mediations, is carried out at a specialized message point on the destination, called a mediation point. By stopping a mediation, you stop any further messages from being delivered to the mediation point. Messages sent to the destination are held at the pre-mediated part of the destination. The messages are not mediated and are not made available to message consumers until the mediation is restarted. Note that mediations starts operating on messages after the server has started and no new messages are mediated after server shutdown begins.

To stop a selected mediation, use the administrative console to complete the following steps:

Procedure

1. List the mediation points.
   - To list the mediation points for a bus destination, click **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *destination_name* -> [Message Points] Mediation points**.
   - To list the mediation points for a messaging engine, click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Message points] Mediation points**.
2. Select the mediation name.
3. Click **Stop**.

Results

The mediation is stopped at the mediation point. Messages arriving at the mediation point are not processed by the mediation. The messages are stored at the mediation point until the mediation is restarted.

Restarting a mediation that has stopped on error

You must restart a mediation that has stopped on error so that the mediation can continue processing messages. When the mediation is restarted, the mediation resumes mediating messages on the pre-mediated part of the destination.

About this task

Changes in the state of a mediation usually occur as the result of operations performed by the administrator. If the state of a mediation moves from `Started` to `Stopped on error`, and you have not stopped it intentionally, you should investigate the cause of the problem, and resolve it before attempting to restart the mediation.

To restart a mediation that has stopped on error, use the administrative console to complete the following steps:

Procedure

1. List the mediation points.
   - To list the mediation points for a bus destination, click **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *destination_name* -> [Message Points] Mediation points**.

- To list the mediation points for a messaging engine, click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Message points] Mediation points**.

2. In the content pane, select the mediation name.
3. Click the **Runtime** tab.
4. Under **General Properties**, view the information in the **Reason** field.
5. Resolve the problem.
6. Restart the mediation so that it can continue processing messages.

Administering messages on mediation points

Use these tasks to list and delete runtime messages held at mediation points in a service integration bus.

Listing messages at a mediation point

Use this topic to list messages at a mediation point.

About this task

The mediation point is a specialized message point that defines the association between a mediation and a destination. You can browse and delete messages on a mediation point for a selected bus destination or messaging engine.

To display a list of messages on a selected mediation point, use the administrative console to complete the following steps:

Procedure

1. List the mediation points.
   - To list the mediation points for a bus destination, click **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *destination_name* -> [Message Points] Mediation points**.
   - To list the mediation points for a messaging engine, click **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Message points] Mediation points**.
2. Click the mediation point name. This displays the properties of the mediation point.
3. Click the **Runtime** tab.
4. Click **[Additional Properties] Messages**.

Results

A list of messages on the selected mediation point is displayed in the content pane.

Deleting messages on a mediation point

Use this topic to delete messages that exist on a mediation point for a selected bus destination.

About this task

The mediation point is a specialized message point that defines the association between a mediation and a destination. As with other message points, you can delete messages on a mediation point for a selected bus destination or messaging engine. For example, if you want to preserve message ordering at a destination before it is unmediated, you can delete all the messages at that destination.

Procedure

1. List the messages at the mediation point. For more information, see “Listing messages at a mediation point.”

2. In the content pane, select the check box next to each message you want to delete. Alternatively, select all the messages in the list by clicking **Select All Items**.
3. Click **Delete**.

Results

The selected messages are removed from the destination.

Example: Using mediations to trace, monitor and log messages

The most straightforward use of a mediation is for tracing, monitoring or logging messages that pass through a destination or topics spaces. This type of mediation does not modify the message; it only extracts information from the message and saves or displays the information elsewhere.

For example, the following mediation handler displays the API message and correlation IDs for each message it is sent:

```
public boolean(MessageContext context)
{
  SIMessageContext   msgCtx  = (SIMessageContext)context;
  SIMediationSession session = msgCtx.getSession();
  SIMessage          msg     = msgCtx.getMessage();
  String             msgId   = msg.getApiMessageId();
  String             corrId  = msg.getCorrelationId();
  String             dest    = session.getDestinationName();

  System.out.println(msgId+" (correlation id="+corrid) is passing through "+dest+".");

  return true;
}
```

SIB service [Settings]

The service that provides service integration functions.

To view this page in the console, click the following path:

Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] SIB service.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Enable service at server startup:

Specifies whether or not the server attempts to start the specified service when the server starts.

If you want applications to use service integration technologies provided by this application server, including JMS resources of the default messaging provider of this application server, this option must be selected. The SIB Service is enabled automatically when you add a server to a service integration bus. You can choose to disable the SIB service, for example if you have removed the only bus member for a server.

For information about using service integration technologies, see Administering service integration.

Required	No
Data type	Boolean

Configuration reload enabled:

Select this option to enable the dynamic reloading of the SIB configuration files for this server.

The information that defines the configuration of service integration buses and their resources is saved in a set of configuration files. When a server starts up, it uses the current information about service integration read from those configuration files. When a messaging engine is started, it uses the information in the server that it is running in.

If the information in the configuration files is changed while the server is running, the server must either be dynamically updated or restarted to use the updated information.

With dynamic reloading of configuration files, any updates to the configuration information are dynamically passed to the server, and therefore made available to messaging engines whether or not they are started. You can enable dynamic reloading of configuration files for servers and for service integration buses.

If you choose not to enable dynamic reloading of configuration files, you must restart the server to pick up any changes to the configuration files.

In a cluster deployment with failover, the configuration information is likely to be updated between the initialization and start up of a messaging engine (A messaging engine is initialized when the server starts, but might not get started for a long time after that). Therefore you should enable dynamic reloading of configuration files in a cluster deployment with failover, because restarting a server to pick up configuration changes causes a failover. To get predictable behavior on failover, you must ensure that the standby (inactive) servers had been updated and recycled before the active server.

Required	No
Data type	Boolean

Add a transport to the list of permitted transports [Settings]

Add a transport to the list of permitted transports.

To view this page in the console, click the following path:

Service integration -> Buses -> *security_value* -> [Additional Properties] Permitted transports -> *member_name*.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Transport chain name:

Select the transport name from the list of chain names.

You can manage inbound chains through the administrative console by selecting either **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] Messaging engine**

inbound transports or **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] WebSphere MQ link inbound transports**. You can also use these administrative console panels to define new transport chains from a set of templates.

The outbound chains that an application server uses for bootstrap operations are defined when the server is defined. They can be altered, or new bootstrap chains can be defined, by using the wsadmin tool.

Required
No

Data type
drop-down list

Range

InboundBasicMessaging
This transport chain allows communication through the TCP protocol. The default port used by this chain for the first server on the node is 7276. You should verify that the selected port is not already used, for example if you are configuring a second server with the same name as the first server. Messaging engines hosted in other application servers and JMS applications running in a client container can communicate with the messaging engines of the server by using this transport chain.

InboundSecureMessaging
This transport chain provides secure communication by using the secure sockets layer (SSL) based encryption protocol over a TCP network. The default port used by this chain for the first server on the node is 7286. You should verify that the selected port is not already used, for example if you are configuring a second server with the same name as the first server. The SSL configuration information for this chain is based on the default SSL repertoire for the application server. Messaging engines hosted in other application servers and JMS applications running in the client container can communicate using this transport chain.

InboundBasicMQLink
This transport chain supports WebSphere MQ queue manager sender channels and applications by using the WebSphere MQ JMS provider connecting over a TCP network. The default port used by this chain is 5558, although this can be automatically adjusted to avoid conflicts.

InboundSecureMQLink
This transport chain enables WebSphere MQ queue manager sender channels and applications by using the WebSphere MQ JMS provider to establish SSL based encrypted connections over a TCP network. The default port used by this chain is 5578, although this is automatically adjusted to avoid conflicts.

Range (continued)

BootstrapBasicMessaging
This transport chain is used to establish bootstrap connections to inbound chains configured for TCP-only connections to an application server, such as the InboundBasicMessaging chain.

BootstrapSecureMessaging
This transport chain is used to establish secure connections by using secure sockets layer (SSL) based encryption. The SSL configuration used is taken from the default SSL repertoire when used in an application server environment or from a configuration file when used by the client container. This chain can be used for establishing bootstrap connections to inbound chains that are configured to use SSL, for example, the InboundSecureMessaging chain. Success in establishing such a connection depends on a compatible set of SSL credentials being associated with both this bootstrap outbound chain and also with the inbound chain to which the connection is being made.

BootstrapTunneledMessaging
This transport chain is used to establish bootstrapping connections that are tunneled through HTTP. This transport chain tunnels JFAP and uses HTTP wrappers. Before you can use this bootstrap transport chain, you must define a corresponding server transport chain on the bootstrap server. (See **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] Messaging engine inbound transports**.)

BootstrapTunneledSecureMessaging
This transport chain tunnels JFAP and uses HTTP wrappers. Used to establish bootstrapping connections that are tunneled through secure HTTP (HTTPS). Like the BootstrapSecureMessaging outbound chain, this chain also derives its SSL configuration from the default SSL repertoire when used in an application server or from a configuration file when used in the client container.

Range (continued)

OutboundBasicMQLink
This transport chain is used to establish connections with WebSphere MQ queue manager receiver channels. It is used when communicating with WebSphere MQ through a WebSphere MQ link.

OutboundSecureMQLink
This transport chain is used to establish connections with WebSphere MQ queue manager receiver channels that have been secured by using SSL. It is used when communicating with WebSphere MQ through a WebSphere MQ link. The SSL configuration used is taken from the default SSL repertoire for the application server being used to contact the queue manager.

OutboundBasicWMQClient
This transport chain is used when communicating with WebSphere MQ receiver channels. It is used when communicating with WebSphere MQ through a WebSphere MQ server.

OutboundSecureWMQClient
This transport chain is used when communicating with WebSphere MQ receiver channels that have been secured by using SSL. It is used when communicating with WebSphere MQ through a WebSphere MQ server.

Alias destination [Settings]

An alias destination makes a destination available by another name and, optionally, overrides the parameters of the destination.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *destination_name*.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Identifier:

The identifier by which this destination is known for administrative purposes.

The identifier and bus are used to identify this destination to applications.

Required	No
Data type	String

Bus:

The name of the bus on which this destination is known to applications.

The identifier and bus are used to identify this destination to applications.

Required	No
Data type	String

UUID:

The universal unique identifier assigned by the system to this destination for administrative purposes.

Required	No
Data type	String

Type:

Whether this bus destination is for a queue, topic space, or some other type of destination.

Required	No
Data type	String

Description:

An optional description for the bus destination, for administrative purposes.

Required	No
Data type	Text area

Target identifier:

The name of the destination for which this is an alias.

Note: The targetIdentifier field is read-only and cannot be modified; if you want to change the target of an alias, you must delete the alias destination then re-create it.

Required	No
Data type	String

Target bus:

The name of the bus on which the destination for which this is an alias exists.

If you do not specify a bus name, the target destination is assumed to be on the same bus as the alias destination.

Note: The targetBus field is read-only and cannot be modified; if you want to change the target of an alias, you must delete the alias destination then re-create it.

Required	No
Data type	String

Enable producers to override default reliability:

Select this option to enable producers to override the default reliability that is set on the destination.

- If an application is producing messages to a destination and that application does NOT specify a reliability for the message, then the Default reliability setting is used.
- If an application is producing messages to a destination and that application specifies a reliability, then the application reliability is ONLY applicable if the Enable producers to override default reliability property is set to True. Otherwise, the Default reliability setting is used.

Required No
Data type drop-down list
Range

Inherit The alias destination uses (inherits) the value of the corresponding property on the target destination.

True The alias destination uses the delivery option value specified by producers.

False The alias destination uses the delivery option value specified by the Reliability property of the destination.

Default reliability:

The reliability assigned to a message produced to this destination when an explicit reliability has not been set by the producer.

This reliability setting is used if a message has not set a reliability or if the “Enable producers to override default reliability” is set to False.

- If an application is producing messages to a destination and that application does NOT specify a reliability for the message, then the Default reliability setting is used.
- If an application is producing messages to a destination and that application specifies a reliability, then the application reliability is ONLY applicable if the Enable producers to override default reliability property is set to True. Otherwise, the Default reliability setting is used.

Required No
Data type drop-down list

Range

Inherit The alias destination uses (inherits) the value of the corresponding property on the target destination.

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages might be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

Maximum reliability:

The maximum reliability of messages accepted by this destination.

Producers cannot send messages to this destination with a reliability higher than the value specified for this property.

Required No
Data type drop-down list

Range

Inherit The alias destination uses (inherits) the value of the corresponding property on the target destination.

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages might be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

Default priority:

The default priority assigned to messages sent to this destination when a priority has not been set by the producer.

Required No
Data type Integer
Range -1 through 9

Send allowed:

Clear this option (setting it to false) to stop producers from being able to send messages to this destination.

Required No
Data type drop-down list
Range

Inherit The alias destination uses (inherits) the value of the corresponding property on the target destination.

True The alias destination uses the delivery option value specified by producers.

False The alias destination uses the delivery option value specified by the Reliability property of the destination.

Receive allowed:

Clear this option (setting it to false) to prevent consumers from being able to receive messages from this destination.

Required No
Data type drop-down list
Range

Inherit The alias destination uses (inherits) the value of the corresponding property on the target destination.

True The alias destination uses the delivery option value specified by producers.

False The alias destination uses the delivery option value specified by the Reliability property of the destination.

Reply destination:

The name of a destination to be appended to any non-empty reverse routing path of messages sent to this destination.

This property is intended for use with mediations on reply messages.

For more information about the use of this property, see “Configuring a destination reverse routing path” on page 1989.

Required No
Data type String

Reply destination bus:

The bus on which the reply destination exists.

This property is intended for use with mediations on reply messages.

For more information about the use of this property, see “Configuring a destination reverse routing path” on page 1989.

Required No
Data type String

Default forward routing path:

The value to which a message's forward routing path will be set if the message contains no forward routing path. This identifies a sequential list of intermediary bus destinations that messages must pass through to reach a target bus destination. The format of the field is a list of line-delimited bus destinations specified as *bus*:*name*.

If you want to forward messages to one or more bus destinations, type a list of bus destinations. Type each destination entry on a separate line, and in the form *bus_name*:*destination_name* or :*destination_name*

Where

bus_name
: Is the name of the service integration bus on which the destination is configured. If you do not specify a bus name, the destination is assumed to be on the same bus as the destination for which you are setting this property.

destination_name
: is the name of a bus destination.

Required No
Data type Text area

Delegate authorization check to target destination:

Indicates whether the authorization check is performed on the alias or the target destination.

Indicates which destination access role is checked when a user accesses the alias destination. When this option is selected, the destination access role of the target destination is checked. When this option is not selected, the destination access role of the alias destination is checked. If you do not want to override the security of the target destination, select this option.

Required No
Data type Boolean

Include an RFH2 message header when sending messages to WebSphere MQ:

If selected, messages sent to WebSphere MQ include an RFH2 header. The RFH2 header stores additional information to that which is stored in theWebSphere MQ message header.

This property applies when the target bus is a WebSphere MQ queue manager or queue-sharing group. When service integration converts a message from the service integration format to WebSphere MQ format, by default it includes an MQRHF2 header in the WebSphere MQ message. This header contains message attributes, such as JMS message attributes, that are not WebSphere MQ message attributes and therefore do not appear in the WebSphere MQ message descriptor (MQMD). Some WebSphere MQ applications cannot process messages that include an MQRFH2 header. If messages sent to this destination will be processed by WebSphere MQ applications that cannot tolerate an MQRFH2, clear this option.

Dynamic updates to this property are effective immediately.

Required No
Data type Boolean

Use all target queue points:

Whether to use all target queue points

Note: This option is only visible when an alias destination is defined to point at a destination with multiple queue points.

Indicates whether all the queue points of the target queue can be used, including any queue points created after the alias is configured. When selected, the **Target queue points** menu is disabled.

Required Yes

Data type	Boolean

Unselected queue points:

This is a list of the queue points that are not addressable by the alias definition. The list is generated from the complete list of queue points for this queue.

Note: This option is only visible when an alias destination is defined to point at a destination with multiple queue points.

This list is enabled only when **Use all target queue points** is unchecked.

Required	No
Data type	drop-down list

Selected queue points:

This is a list of the queue points that are addressable by the alias definition. Messages produced to or consumed from this alias apply to only these queue points.

Note: This option is only visible when an alias destination is defined to point at a destination with multiple queue points.

This list is enabled only when **Use all target queue points** is unchecked.

Required	No
Data type	drop-down list

Additional Properties

Context properties
Context information passed to the mediation.

Related Items

Application resources topology
A expandable tree view of all applications and messaging resources that reference the current destination.

Application resources for this destination

This pane provides an expandable tree view of all the applications and messaging resources that reference the current destination, both directly and indirectly. As many of the references as possible are resolved to links to the associated configuration panel for the referenced object.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *queue_name* -> [Related Items] Application resources topology**
- **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *topic_space_name* -> [Related Items] Application resources topology**

Use this panel to inspect the configuration from the queue or topic space (destination) to the application or other JMS resources to ensure that the configuration is correct.

Using the default messaging provider, a JMS activation specification refers to a JMS destination (either a JMS Queue or JMS Topic) that in turn points to a service integration bus destination (either a queue destination or a topic space destination). JMS resources are referenced through Java Naming and Directory Interface (JNDI) names and service integration resources are referenced through bus and resource identifiers. This panel enables you to review the dependencies within your configuration, making it easier to detect inconsistencies, for example as a result of references being entered incorrectly, or JNDI or resource names being changed or deleted without the associated configuration having been updated.

Problems with the configuration are usually detected in one of two ways:

- An application can no longer send or receive messages.
- A destination becomes full and can no longer receive messages because the existing messages are not being consumed.

This panel can help you find the cause of the problem by giving you a high level view of many relevant resources.

Note: For a related view of the JMS resources for a given application, see the following panel:
"Messaging resources for this application" on page 2129.

- "Local Topology tab"

Local Topology tab

Topology properties for this object. These properties detail how this object relates to other objects in the system topology.

Bootstrap members [Collection]

Bus members, servers and clusters that client applications can target to bootstrap into the given bus.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Bootstrap members.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

This panel displays the bootstrap members for the selected bus. A bootstrap member is an application server or cluster that has been configured to accept bootstrap requests into the bus. The bootstrap member authenticates a connection request, and directs the request to a bus member. Select a bootstrap member policy to restrict which of the following types of server can service requests to bootstrap into the bus:

All members of the cell with the Service Integration Bus Service enabled
This the default policy. Use any server in the cell that has the Service Integration Bus Service enabled to service bootstrap requests.

Bus members and nominated bootstrap members
Use bus members and nominated cell members to service bootstrap requests.

Bus members only
Use bus members only to service bootstrap requests.

Click **Apply** for the policy to take effect.

Name The server or cluster name for the bootstrap member.

Type The type of bootstrap member. Values are Bus member, Nominated member or SIB Service enabled.

SIB Service
Whether SIB Service is enabled on this member. Values are Enabled or Disabled.

Host The host name for the node on which the bootstrap member is located.

Ports The ports from which the server can accept bootstrap requests.

Buttons

New	This button is only displayed if you have applied the bootstrap member policy option “Bus members and nominated bootstrap members”. Click to start the Add bootstrap member wizard.
Delete	Click to remove the selected bootstrap member. This button is only displayed if you have applied the bootstrap member policy option “Bus members and nominated bootstrap members”. You cannot remove bus members, or members for which SIB Service is enabled.

Bus members [Settings]

Bus members are the servers, WebSphere MQ servers and clusters that have been added to the bus.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Bus members -> *bus_member_name*.

Use this pane to view or change messaging engine settings for a cluster when you are using messaging engine policy assistance.

You can change the currently selected messaging engine policy assistance, view the configuration diagram for the cluster, undertake further messaging engine configuration steps by using the links available in Additional Properties, or disable messaging engine policy assistance.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the bus member.

This field is read-only.

Required No
Data type String

Type:

The resource type of the bus member (Server, Server Cluster, or WebSphere MQ Server).

This field is read-only.

Required	No
Data type	String

Enable messaging engine policy assistance:

A value that shows whether messaging engine policy assistance is set for the server cluster. This option is always selected when you first view this pane. To disable messaging engine policy assistance, deselect this option. The list of messaging engine policy assistance types and the configuration diagram are no longer displayed.

Policy name:

A value that shows the currently selected messaging engine policy assistance type for the server cluster. To change the selection, click the required radio button in the Select column, then click **Apply** or **OK**. For each messaging engine policy assistance type, except Custom, the **Is further configuration required?** column shows `No` if the number of messaging engines and their behavior are correctly configured. Otherwise, this column shows one or more messages with suggested actions to achieve the number of messaging engines and the required messaging engine behavior for each messaging engine policy assistance type. A diagram shows the servers, the currently configured messaging engines, and an indication of messaging engine behavior in the cluster. It also shows any changes required to support the currently selected messaging engine policy assistance type.

Additional Properties

Messaging engines
Use the **Messaging engines** option to view or change the messaging engines in this cluster. For example, you can add, remove, start or stop a messaging engine.

Messaging engine policy maintenance
Use the **Messaging engine policy maintenance** option to view or correct the policy settings for the messaging engines in this cluster, that is, the settings that affect messaging engine behavior.

Redundant core group policies
Use the **Redundant core group policies** option to view or delete any core group policies that are associated with this cluster, but that are not associated with any messaging engine in this cluster. When you use messaging engine policy assistance, you do not have to create or manage core group policies directly. A redundant core group policy might occur if messaging engine policy assistance is not enabled and you remove a messaging engine without deleting its associated core group policy, or create a core group policy that is not associated with a messaging engine.

Bus members [Collection]

Bus members are the servers, WebSphere MQ servers and clusters that have been added to the bus.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Bus members.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Server clusters can be used as bus members only in WebSphere Application Server environments that support server clusters.

Name The name of the bus member.

Type The resource type of the bus member (Server, Server Cluster, or WebSphere MQ Server)

Messaging engine policy assistance
A value that shows whether messaging engine policy assistance is set for the bus member when the bus member is a server cluster. If the **Type** is Server or WebSphere MQ Server, the value is Not applicable. For a **Type** of Cluster, the value can be Disabled, Enabled (High availability), Enabled (Scalability), Enabled (Scalability with high availability), or Enabled (Custom). The words in parentheses show the type of messaging engine policy assistance that is set. If the current configuration of the cluster is either not suitable or not complete for the type of messaging engine policy assistance that is set, a warning icon is also displayed.

Buttons

Add	Add a server, a cluster, or a WebSphere MQ server to a bus.
Remove	Remove the selected bus members from the bus.

Buses [Collection]

A service integration bus supports applications using message-based and service-oriented architectures. A bus is a group of interconnected servers and clusters that have been added as members of the bus. Applications connect to a bus at one of the messaging engines associated with its bus members.

To view this page in the console, click the following path:

Service integration -> Buses.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

A messaging engine manages messaging resources and, through destinations assigned to the messaging engine, provides a connection point to which both local and remote applications connect to access messaging resources on the bus. If you add an application server or a server cluster as a bus member, a messaging engine is automatically created for this new member. If you add the same server as a member of multiple buses, the server is associated with multiple messaging engines (one messaging engine for each bus). You can create additional messaging engines for use with server clusters that are bus members, for availability and scalability reasons. However, in its simplest form a bus can be realized by a single engine.

The functions of service integration buses comprise the *SIB service*, which is available on each application server in the WebSphere Application Server environment. By default, the SIB service is disabled, so when a server starts it cannot undertake any messaging. If you add the server to a service integration bus, the SIB service is automatically enabled. If required, you can disable the service again by configuring the server.

The bus appears to its applications as if it were a single logical entity, which means applications only have to connect to the bus and do not have to be aware of the bus topology. In many cases the knowledge of how to connect to the bus and of which bus resources are defined are handled by a suitable API abstraction, such as the administered JMS connection factory and JMS destination objects

Name The name of the service integration bus. Choose a unique name.

Note: The system is unable to differentiate between upper and lowercase characters in bus names. For example, you will not be able to create two buses named `BUS1` and `bus1` because they will not be recognized as different to each other.

Description
An optional description for the bus, for administrative purposes.

Security
Security of your service integration bus can be managed from here.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Buses [Settings]

A service integration bus supports applications using message-based and service-oriented architectures. A bus is a group of interconnected servers and clusters that have been added as members of the bus. Applications connect to a bus at one of the messaging engines associated with its bus members.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name*.

Server clusters can be used as bus members only in WebSphere Application Server environments that support server clusters.

- “Configuration tab”
- “Local Topology tab” on page 2044

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the service integration bus. Choose a unique name.

Note: The system is unable to differentiate between upper and lowercase characters in bus names. For example, you will not be able to create two buses named `BUS1` and `bus1` because the names will not be recognized as different to each other.

Required	No
Data type	String

UUID:

The universal unique identifier assigned by the system to this bus for administrative purposes.

Required	No
Data type	String

Description:

An optional description for the bus, for administrative purposes.

Required	No
Data type	Text area

Inter-engine transport chain:

The transport chain used for communication between messaging engines in this bus.

The transport chain must correspond to one of the transport chains defined in the Messaging engine inbound transports settings for the server. All servers automatically have a number of transport chains defined to them, and it is also possible to create new transport chains.

The default transport chain is InboundBasicMessaging.

For more information see ../ae/cjr0490_.dita.

Required	No
Data type	String

Discard messages:

Whether messages on a deleted message point should be retained at a system exception destination or can be discarded.

Required	No
Data type	Boolean

Configuration reload enabled:

Select this option to enable certain changes to the bus configuration to be applied without requiring the messaging engines to be restarted.

Select this option to enable automatic update of configuration information about all the messaging engines on the bus.

Changes to bus destinations or mediations are applied when destinations or mediations are added to or removed from the bus.

Changes to the modifiable configuration information for any foreign bus connections are also updated automatically. The time when these changes take effect varies:

Foreign Bus Connection properties
Immediately

WebSphere MQ link properties
On channel restart, except Description (immediately), and Initial State (on messaging engine restart)

MQ sender channel properties
On channel restart, except Initial State (on messaging engine restart or sender channel creation)

MQ receiver channel properties
On channel restart, except Initial State (on messaging engine restart or receiver channel creation)

Publish/subscribe broker profile (0 to n) properties
Immediately

Service integration bus link properties
On link restart, except Description (immediately), and Initial State (on messaging engine restart or link creation)

The **Configuration reload enabled** property also needs to be set on the SIB Service of the application server. To ensure that dynamic configuration updates are made on an application server, click **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] SIB service** to display the Application Servers window, then select **Configuration reload enabled**.

To ensure that dynamic configuration updates are made to each node, click **System administration -> Console Preferences** to display the Console Preferences window then select **Synchronize changes with Nodes**.

Required	No
Data type	Boolean

Default messaging engine high message threshold:

A threshold above which the messaging system will take action to limit the addition of more messages to a message point.

When a messaging engine is created on this bus, the value of this property is used to set the default high message threshold for the messaging engine.

Required	No
Data type	Long
Range	1 through 9223372036854775807

Bootstrap members:

Bus members, servers and clusters that client applications can target to bootstrap into the given bus.

Select one of the following bootstrap member policies to limit the range of available bootstrap members:

All members of the cell with the Service Integration Bus Service enabled
This the default policy. Use any server in the cell that has the Service Integration Bus Service enabled to service bootstrap requests.

Bus members and nominated bootstrap members
Use bus members and nominated cell members to service bootstrap requests.

Bus members only
Use bus members only to service bootstrap requests.

Required	No
Data type	Radio button

Topology

Bus members
New bus member link

Messaging engines
A messaging engine manages bus resources and provides a connection point for applications.

Foreign bus connections
A foreign bus is another bus with which this bus can exchange messages.

Bootstrap members
Bus members, servers and clusters that client applications can target to bootstrap into the given bus.

Destination resources

Destinations
A bus destination is a logical address within a service integration bus.

Mediations
Mediations define the information needed by a messaging engine to perform the mediation processing for associated destinations.

Services

Inbound services
An inbound service describes the web service enablement of a service destination. It provides the configuration of endpoint listeners within a port.

Outbound services
An outbound service represents a WSDL-described service.

WS-Notification services
A WS-Notification service provides access to service integration bus resources for web services publish and subscribe clients.

Reliable messaging state
Use this page to view and manage the WS-ReliableMessaging runtime state.

Additional Properties

Custom properties
Arbitrary name-value pairs of data, where the name is a property key and the value is a string value that can be used to set internal system configuration properties. Defining a new property enables you to configure a setting beyond that which is available in the administrative console.

Security
Security of your service integration bus can be managed from here.

Local Topology tab

Topology properties for this object. These properties detail how this object relates to other objects in the system topology.

Context properties [Collection]

Context information used to enable correct processing of messages. This information adds to the context information derived from processing the message header.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Additional Properties] Destination defaults -> [Additional Properties] Context information**
- **Service integration -> Buses -> *bus_name* -> [Destination resources] Mediations -> *mediation_name* -> [Additional Properties] Context properties**
- **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *destination_name* -> [Additional Properties] Context information**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Dynamic updates to this list are effective immediately.

Name The name of this context property. The mediation will retrieve the context property using this name.

Context type
The type of the context property, for example, Boolean, Byte, or Character.

Context value
The value of the context property.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Context properties [Settings]

Context information used to enable correct processing of messages. This information adds to the context information derived from processing the message header.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Additional Properties] Destination defaults -> [Additional Properties] Context information -> *context_information_item_name***
- **Service integration -> Buses -> *bus_name* -> [Destination resources] Mediations -> *mediation_name* -> [Additional Properties] Context properties -> *context_information_item_name***

- **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *destination_name* -> [Additional Properties] Context information -> *context_information_item_name***

You can use this panel to view or change context information settings. This panel is useful for configuring extra context information, because it is not possible to anticipate in advance all of the context information that might be required to allow correct processing of messages.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of this context property. The mediation will retrieve the context property using this name.

Required Yes
Data type String

Context type:

The type of the context property, for example, Boolean, Byte, or Character.

Required No
Data type drop-down list
Range

Boolean This context has a Boolean information type.

Byte This context has a byte information type.

Character This context has a character information type.

Double This context has a double information type.

Float This context has a floating point information type.

Integer This context has an integer information type.

Long This context has a long information type.

Short This context has a short information type.

String This context has a string information type.

Context value:

The value of the context property.

Required Yes
Data type String

Custom properties [Collection]

Use this page to specify an arbitrary name and value pair. The value that is specified for the name and value pair is a string that can set internal system configuration properties.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Additional Properties] Custom properties.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Custom properties [Collection]

Use this page to specify an arbitrary name and value pair. The value that is specified for the name and value pair is a string that can set internal system configuration properties.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional Properties] Custom properties.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Custom properties [Settings]

Arbitrary name-value pairs of data, where the name is a property key and the value is a string value that can be used to set internal system configuration properties. Defining a new property enables you to configure a setting beyond that which is available in the administrative console.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional Properties] Custom properties -> *property_name*.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

Specifies the name of the property.

Required	Yes
Data type	String

Value:

Specifies the value that is paired with the specified name.

Required	Yes
Data type	String

Description:

Specifies a description of the name and value pair. The description should help to differentiate this pair for other defined pairs.

Required	No
Data type	Text area

Optional:

Specifies an optional attribute that determines whether this property must have a value.

Required	No
Data type	Boolean

Validation Expression:

Specifies a value that the administrative console and some host tools use to validate the contents of the value of this property.

Required	No
Data type	String

Data store [Settings]

The persistent store for messages and other state managed by the messaging engine.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional Properties] Message store.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

UUID:

The universal unique identifier assigned by the system to this data store for administrative purposes.

Required	No
Data type	String

Data source JNDI name:

The JNDI name of the data source that the messaging engine uses to access the relational database management system (RDBMS) for the data store.

Required	Yes
Data type	Text

Schema name:

The name of the database schema used to contain the tables for the data store.

Each messaging engine stores its resources, such as tables, in a single schema. Each database schema is used by one messaging engine only. Although every messaging engine uses the same table names, its relationship with the schema gives each messaging engine exclusive use of its own tables.

Required	No
Data type	String

Authentication alias:

The name of the authentication alias used by the messaging engine to access the data source.

Required	No
Data type	drop-down list

Create tables:

If this option is selected, the messaging engine creates the database tables for the data store automatically. Otherwise, the database administrator must create the database tables manually.

Required	No
Data type	Boolean

Number of tables for permanent objects:

Number of database tables to use for storage of permanent objects.

Required	No
Data type	Integer
Range	1 through 2147483647

Number of tables for temporary objects:

Number of database tables to use for storage of temporary objects.

Required	No
Data type	Integer
Range	1 through 2147483647

Related Items

JAAS - J2C authentication data
Specifies a list of user identities and passwords for Java 2 connector security to use.

Default access roles [Settings]

This pane shows the role type assignments for the default access.

To view this page in the console, click the following path:

Service integration -> Buses -> *security_value* -> [Authorization Policy] Manage default access roles.

security_value is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.

This pane displays users and groups that have been assigned access roles for the default resource. Use this pane to add users and groups to the appropriate default role or roles, and to manage users and groups that have already been assigned role types for the default resource. Adding a user or group to any of the default roles grants the user or group the authorization permissions for that role for all the local destinations that are allowed to inherit defaults.

The information for each user and group is contained within a section that you can expand and collapse.

Expand/Collapse
Click to expand the section and display users and groups that have been assigned role types for the default resource.

General Properties

Select A check box that you can use to select the users and groups for which you want to manage access roles.

Name The name of the user or group that has an access role for the selected resource. If the user is a group member, the user ID and the group name is displayed.

Type The type of the user or group. There are three types of user or group: “user”, “group” and “member”. A user that inherits its access roles from a group has the type “member”.

Sender
Whether a user, group or member is in the sender role for a selected resource.

Receiver
Whether a user, group or member is in the receiver role for a selected resource.

Browser
Whether a user, group or member is in the browser role for a selected resource.

Creator
Whether a user, group or member is in the creator role for a selected resource.

Security access roles

In the administrative console, access role icons are used to represent whether a user or a group is in a particular access role. You can click an icon to add or remove selected users and groups to a particular access role for a selected resource.

An access role icon has three states:

- Access role type set.
- Access role type not set.
- Access role type inherited from group.

The following table describes how the access role icons represent these states, and how to change between them:

Table 214. Interacting with access role icons

Access role icon	Access role assignment state	User action
	Role type not set.	Click to change to role type set  .
	Role type set.	Click to change to role type not set. The icon changes to role type not set  if the user or group does not inherit access roles, or to role type inherited  if the role type does inherit access roles.
	Role type inherited from group.	Click to change to role type set  .
	Role type not set for a group. The group to which a user belongs does not have a role type.	Read only.
	Role type set for a group. The group to which a user belongs has a role type.	Read only.
	Role type not applicable.	Read only.

Buttons

Add	Click to add users and groups to this resource.
Remove	Click to remove selected users and groups from all the role types for this resource.

Destinations access roles [Collection]

This pane displays a list of all destinations known by the bus: aliases, foreign destinations, ports, queues, temporary destination prefixes, topic spaces and web services.

To view this page in the console, click the following path:

Service integration -> Buses -> *security_value* -> [Authorization Policy] Manage destination access roles.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

In the path, *security_value* is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.

This pane displays the name and type of all the bus destination defined for the selected service integration bus. Use this pane to view and change the access roles defined for selected destinations:

- To act on a single destination, click its name in the list.
- To act on more than one destination, first select the check box next to the name of each destination you want to act on, and then click **Manage Access Roles**.

Destination
The name of each destination defined for the selected bus.

Type The type of destination defined for the selected bus.

Buttons

Manage Access Roles	Click to view and manage users and groups assigned to the access role types for the selected resources.

Destinations access roles [Settings]

This pane displays the role type assignments for the selected destinations.

To view this page in the console, click the following path:

Service integration -> Buses -> *security_value* -> [Authorization Policy] Manage destination access roles -> *destination_name* > Manage access roles.

In the path, *security_value* is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.

This pane lists users and groups that have been assigned role types for the destinations selected in the **Manage destination access roles** panel. You can use this pane to add and remove users and groups, and manage role type assignments and inheritance for a destination.

The information for each destination is contained within a section that you can expand and collapse. For each destination, a section header displays the type of destination, for example whether it is a queue, topic space, or some other type of destination and the destination name.

Expand/Collapse
Click the icon to expand the section and display the collection of users and groups that have been assigned role types for the selected destination.

Inherit from default
Select the check box to have the selected destination inherit access roles for users and groups from the default resource. Only access roles that apply to the selected destination can be inherited.

General Properties

Select A check box that you can use to select the users and groups for which you want to manage access roles.

Name The name of the user or group that has an access role for the selected resource. If the user is a group member, the user ID and the group name is displayed.

Type The type of the user or group. There are three types of user or group: “user”, “group” and “member”. A user that inherits its access roles from a group has the type “member”.

Sender
Whether a user, group or member is in the sender role for a selected resource.

Receiver
Whether a user, group or member is in the receiver role for a selected resource.

Browser
Whether a user, group or member is in the browser role for a selected resource.

Creator
Whether a user, group or member is in the creator role for a selected resource.

Security access roles

In the administrative console, access role icons are used to represent whether a user or a group is in a particular access role. You can click an icon to add or remove selected users and groups to a particular access role for a selected resource.

An access role icon has three states:

- Access role type set.
- Access role type not set.
- Access role type inherited from group.

The following table describes how the access role icons represent these states, and how to change between them:

Table 215. Interacting with access role icons

Access role icon	Access role assignment state	User action
	Role type not set.	Click to change to role type set  .
	Role type set.	Click to change to role type not set. The icon changes to role type not set  if the user or group does not inherit access roles, or to role type inherited  if the role type does inherit access roles.
	Role type inherited from group.	Click to change to role type set  .

Table 215. Interacting with access role icons (continued)

Access role icon	Access role assignment state	User action
	Role type not set for a group. The group to which a user belongs does not have a role type.	Read only.
	Role type set for a group. The group to which a user belongs has a role type.	Read only.
	Role type not applicable.	Read only.

Buttons

Add	Click to add users and groups to this resource.
Remove	Click to remove selected users and groups from all the role types for this resource.

Destinations [Collection]

A bus destination is defined on a service integration bus, and is hosted by one or more locations within the bus. Applications can attach to the destination as producers, consumers, or both to exchange messages.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Identifier
The identifier by which this destination is known for administrative purposes.

Bus A service integration bus supports applications using message-based and service-oriented architectures. A bus is a group of interconnected servers and clusters that have been added as members of the bus. Applications connect to a bus at one of the messaging engines associated with its bus members.

Type Whether this bus destination is for a queue, topic space, or some other type of destination.

Description
An optional description for the bus destination, for administrative purposes.

Mediation
The name of the mediation that mediates this destination.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.
Mediate	Apply a mediation to a destination, to modify the destination handling of messages.

Unmediate	Remove a mediation from the destination, to remove the effect of the mediation from the destination handling of messages.

Destination defaults [Settings]

Properties to be applied when applications use destinations on this foreign bus when there is no explicit foreign destination definition.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Additional Properties] Destination defaults.

These properties apply when there is no explicit foreign destination or alias destination defined on the local bus to provide destination defaults.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Default priority:

The default priority assigned to messages sent to this destination when a priority has not been set by the producer.

Dynamic updates to this property are effective immediately.

Required	No
Data type	Integer
Range	0 through 9

Default reliability:

The reliability assigned to a message produced to this destination when an explicit reliability has not been set by the producer.

This reliability setting is used if a message has not set a reliability or if the Enable producers to override default reliability is set to False.

- If an application is producing messages to a destination and that application does NOT specify a reliability for the message, then the Default reliability setting is used.
- If an application is producing messages to a destination and that application specifies a reliability, then the application reliability is ONLY applicable if the Enable producers to override default reliability property is set to True. Otherwise, the Default reliability setting is used.

Dynamic updates to this property are effective immediately.

Required	No
Data type	drop-down list

Range

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages might be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

Maximum reliability:

The maximum reliability of messages accepted by this destination.

Producers cannot send messages to this destination with a reliability higher than the value specified for this property.

This attribute is not used for a temporary destination.

If the message exceeds the maximum reliability and the producer is local to the messaging engine, an exception is thrown.

If the message exceeds the maximum reliability and the producer is not local to the messaging engine, the message is sent to the exception destination that is defined for the target destination.

Dynamic updates to this property are effective immediately.

Required No
Data type drop-down list

Range

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages might be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

Send allowed:

Clear this option (setting it to false) to stop producers from being able to send messages to destinations on this foreign bus.

Dynamic updates to this property are effective immediately.

Required	No
Data type	Boolean

Enable producers to override default reliability:

Select this option to enable producers to override the default reliability that is set on the destination.

- If an application is producing messages to a destination and that application does NOT specify a reliability for the message, then the Default reliability setting is used.
- If an application is producing messages to a destination and that application specifies a reliability, then the application reliability is ONLY applicable if the Enable producers to override default reliability property is set to True. Otherwise, the Default reliability setting is used.

Dynamic updates to this property are effective immediately.

Required	No
Data type	Boolean

Include an RFH2 message header when sending messages to WebSphere MQ.:

If selected, messages sent to WebSphere MQ includes an RFH2 header. The RFH2 header stores additional information to that which is stored in theWebSphere MQ message header.

This property applies when a foreign bus connection represents a WebSphere MQ queue manager or queue-sharing group. When service integration converts a message from the service integration format to

WebSphere MQ format, by default it includes an MQRHF2 header in the WebSphere MQ message. This header contains message attributes, such as JMS message attributes, that are not WebSphere MQ message attributes and therefore do not appear in the WebSphere MQ message descriptor (MQMD). Some WebSphere MQ applications cannot process messages that include an MQRFH2 header. If messages sent to this destination will be processed by WebSphere MQ applications that cannot tolerate an MQRFH2, clear this option.

Dynamic updates to this property are effective immediately.

Required	No
Data type	Boolean

Additional Properties

Context properties
Context information passed to the mediation.

File store [Settings]

The persistent store for messages and other state managed by the messaging engine.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional Properties] Message store.

If you make any changes to the properties of a file store, you must restart the messaging engine to make those changes take effect.

For more information on the log file, permanent store file, and temporary store file and appropriate parameter values refer to ../ae/cjm1450_.dita.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

UUID:

The universal unique identifier assigned by the system to this data store for administrative purposes.

Required	No
Data type	String

Log size:

Size in megabytes of the log file.

Required	Yes
Data type	Long
Range	10 through 9223372036854775807

Log directory path:

Name of the log files directory.

When creating a messaging engine with a file store, you can select the Default log directory path radio button for this property. This option causes, the following default directory value to be used: `${USER_INSTALL_ROOT}/filestores/com.ibm.ws.sib/`*`messagingEngineName-messagingEngineUuid`*`/log` where *messagingEngineName* and *messagingEngineUuid* are substituted from the Name and UUID properties of the messaging engine.

After you have created the file store, the Log directory path field displays the directory path used for log files.

Important: When adding a cluster as a bus member, you must configure the log file to be on a file system that is accessible to all members of a cluster.

Required	No
Data type	Text

Minimum permanent store size:

The minimum number of megabytes reserved by each of the permanent store files. The permanent store files are never smaller than the log file.

For more information about the store files and appropriate values for the log file parameters refer to ../ae/cjm1450_.dita.

Required	Yes
Data type	Long
Range	0 through 9223372036854775807

Unlimited permanent store size:

Indicates whether the permanent store files are unlimited in size.

Required	No
Data type	Custom

Maximum permanent store size:

The maximum size in megabytes for the permanent store files.

Required	Yes
Data type	Long
Range	50 through 9223372036854775807

Permanent store directory path:

Name of the permanent store files directory.

When creating a messaging engine with a file store, you can specify a non-default directory to be used for permanent store files. To do this, select the **Permanent store directory path** radio button, then type a directory path value in the field provided.

When creating a messaging engine with a file store, you can select the **Default permanent store directory path** radio button for this property. This option causes the following default directory value to be used: `${USER_INSTALL_ROOT}/filestores/com.ibm.ws.sib/`*`messagingEngineName-messagingEngineUuid`*`/store` where *messagingEngineName* and *messagingEngineUuid* are substituted from the Name and UUID properties of the messaging engine.

After you have created the file store, the **Permanent store directory path** field displays the directory path used for permanent store files.

Important: When adding a cluster as a bus member, you must configure the permanent store file to be on a file system that is accessible to all members of a cluster.

Required	No
Data type	Text

Minimum temporary store size:

The minimum number of megabytes reserved by each of the temporary store files. The temporary store files are never smaller than the log file.

Required	Yes
Data type	Long
Range	0 through 9223372036854775807

Unlimited temporary store size:

Indicates whether the temporary store files are unlimited in size.

Required	No
Data type	Boolean

Maximum temporary store size:

The maximum size in megabytes for the temporary store files.

Required	Yes
Data type	Long
Range	50 through 9223372036854775807

Temporary store directory path:

Name of the temporary store files directory.

When creating a messaging engine with a file store, you can specify a non-default directory to be used for temporary store files. To do this, select the Temporary store directory path radio button, then type a directory path value in the field provided.

When creating a messaging engine with a file store, you can select the **Default temporary store directory path** radio button for this property. This option causes the following default directory value to be used: `${USER_INSTALL_ROOT}/filestores/com.ibm.ws.sib/`*`messagingEngineName`*`-`*`messagingEngineUuid`*`/store` where *messagingEngineName* and *messagingEngineUuid* are substituted from the Name and UUID properties of the messaging engine.

After you have created the file store, the **Temporary store directory path** field displays the directory path used for temporary store files.

Important: When adding a cluster as a bus member, you must configure the temporary store file to be on a file system that is accessible to all members of a cluster.

Required	No
Data type	Text

Foreign bus connections [Collection]

A foreign bus connection allows communication with another bus. The foreign bus can represent another Service Integration Bus, an instance of WebSphere MQ, or an indirect connection to another foreign bus.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

The physical link (also known as the routing type) between buses can be one of the following types:

- A *service integration bus link* from a messaging engine in the local bus to a messaging engine in the foreign bus.
- A *WebSphere MQ link* from a messaging engine in the local bus to a WebSphere MQ gateway queue manager. To the local bus the linked WebSphere MQ network appears as a foreign bus.
- An *indirect link*, which is a link that is made through one or more intermediate foreign buses.

Name The name of the bus with which this bus will exchange messages. This name must match exactly the name of the existing service integration bus that is defined as the foreign bus.

Routing type
Routing type defines the type of link used to make the connection to the foreign bus. Use a service integration bus link for a connection to a foreign service integration bus, a WebSphere MQ link for a connection to a foreign WebSphere MQ network, or an indirect routing if the connection to the foreign bus is via another foreign bus.

Description
An optional description for the foreign bus, for administrative purposes.

Configuration Status
Indicates that the configuration was deleted with remaining runtime data. Select this foreign bus connection (by clicking the **Name** column) to resolve the remaining runtime data.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.
Test connection	Test the foreign bus connection. This button does not work if the selected foreign bus uses a WebSphere MQ link that is running on an application server on which WebSphere MQ has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

Foreign bus [Settings]

This pane shows the role type assignments for the selected foreign buses.

To view this page in the console, click the following path:

Service integration -> Buses -> *security_value* -> [Authorization Policy] Manage foreign bus access roles -> *foreign_bus_name* > **Manage access roles**.

In the path, *security_value* is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.

This panel lists the users and groups that have been assigned access roles on the one or more selected foreign buses. Use this panel to add and remove users and groups to foreign bus access roles, and to manage existing role type assignments and inheritance for foreign buses.

The information for each foreign bus is contained within a section that you can expand and collapse. When collapsed, the section header displays the foreign bus name. When expanded, in addition to the header, the section displays an **Inherit from default** check box and a list of the users and groups that have been assigned role types on the foreign bus. Note that the only permitted role type for a foreign bus is Sender role.

Expand/Collapse
Click icon to expand the section and display a list of users and groups that have been assigned role types for the selected foreign bus.

Inherit from default
Select check box to have the selected foreign bus inherit access roles for users and groups from the default resource. Only access roles that apply to the selected foreign bus can be inherited.

General Properties

Select A check box that you can use to select the users and groups for which you want to manage access roles.

Name The name of the user or group that has an access role for the selected resource. If the user is a group member, the user ID and the group name is displayed.

Type The type of the user or group. There are three types of user or group: “user”, “group” and “member”. A user that inherits its access roles from a group has the type “member”.

Sender
Whether a user, group or member is in the sender role for a selected resource.

Security access roles

In the administrative console, access role icons are used to represent whether a user or a group is in a particular access role. You can click an icon to add or remove selected users and groups to a particular access role for a selected resource.

An access role icon has three states:

- Access role type set.
- Access role type not set.
- Access role type inherited from group.

The following table describes how the access role icons represent these states, and how to change between them:

Table 216. Interacting with access role icons

Access role icon	Access role assignment state	User action
	Role type not set.	Click to change to role type set .
	Role type set.	Click to change to role type not set. The icon changes to role type not set  if the user or group does not inherit access roles, or to role type inherited  if the role type does inherit access roles.
	Role type inherited from group.	Click to change to role type set .
	Role type not set for a group. The group to which a user belongs does not have a role type.	Read only.
	Role type set for a group. The group to which a user belongs has a role type.	Read only.
	Role type not applicable.	Read only.

Buttons

Add	Click to add users and groups to this resource.
Remove	Click to remove selected users and groups from all the role types for this resource.

Foreign bus connections [Settings]

A foreign bus connection allows communication with another bus. The foreign bus can represent another Service Integration Bus, an instance of WebSphere MQ, or an indirect connection to another foreign bus.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name*.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the bus with which this bus will exchange messages. This name must match exactly the name of the existing service integration bus that is defined as the foreign bus. Precise guidelines for naming a foreign bus connection can be found in the related concept topic Foreign buses.

Required	No
Data type	String

UUID:

The universal unique identifier assigned by the system to this foreign bus for administrative purposes.

Required	No
Data type	String

Routing type:

Routing type defines the type of link used to make the connection to the foreign bus. Use a service integration bus link for a connection to a foreign service integration bus, a WebSphere MQ link for a connection to a foreign WebSphere MQ network, or an indirect routing if the connection to the foreign bus is via another foreign bus.

Required	No
Data type	String

Description:

An optional description for the foreign bus, for administrative purposes.

Dynamic updates to this property are effective immediately.

Required	No
Data type	Text area

Send allowed:

Clear this option (setting it to false) to stop producers from being able to send messages to this foreign bus.

Dynamic updates to this property are effective immediately.

Required	No
Data type	Boolean

Additional Properties

Destination defaults
Properties to apply when applications use destinations on this foreign bus and there is no explicit foreign destination or alias destination defined on the local bus to provide destination defaults.

Additional property for when the routing definition is not yet defined:

Create a routing definition
Select this link to define the routing definition for this foreign bus.

Additional property for direct service integration bus link foreign bus connections:

Service integration bus link routing properties
The routing properties for a service integration bus link to a foreign service integration bus.

Additional property for direct WebSphere MQ link foreign bus connections:

WebSphere MQ link routing properties
The routing properties for a link to a foreign bus that represents a WebSphere MQ network.

Additional property for indirect foreign bus connections:

Indirect routing properties
The routing definition for the next service integration bus in a sequence of connected buses.

Related Items

Related item for direct service integration bus link foreign bus connections:

Service integration bus links
The associated service integration bus links for this foreign bus.

Related item for direct WebSphere MQ link foreign bus connections:

WebSphere MQ links
The associated WebSphere MQ links for this foreign bus.

Foreign destination [Settings]

The name by which this foreign destination is known for administrative purposes.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *destination_name*.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Identifier:

The identifier by which this destination is known for administrative purposes.

Type the name of the destination as configured on the foreign bus. This must match exactly the name of the target destination that exists in the foreign bus.

Required	No
Data type	String

Bus:

The name of the foreign bus on which this destination is defined.

This must match exactly the name of a foreign bus administrative object that is already defined on the bus on which this foreign destination is being created.

Required	No
Data type	String

UUID:

The universal unique identifier assigned by the system to this destination for administrative purposes.

Required	No
Data type	String

Type:

Whether this bus destination is for a queue, topic space, or some other type of destination.

Required	No
Data type	String

Description:

An optional description for the bus destination, for administrative purposes.

Required	No
Data type	Text area

Enable producers to override default reliability:

Select this option to enable producers to override the default reliability that is set on the destination.

- If an application is producing messages to a destination and that application does NOT specify a reliability for the message, then the Default reliability setting is used.
- If an application is producing messages to a destination and that application specifies a reliability, then the application reliability is ONLY applicable if the Enable producers to override default reliability property is set to True. Otherwise, the Default reliability setting is used.

Required	No
Data type	Boolean

Default reliability:

The reliability assigned to a message produced to this destination when an explicit reliability has not been set by the producer.

This reliability setting is used if a message has not set a reliability or if the SIBDestination.overrideOfQOSByProducerAllowed is set to False.

- If an application is producing messages to a destination and that application does NOT specify a reliability for the message, then the Default reliability setting is used.
- If an application is producing messages to a destination and that application specifies a reliability, then the application reliability is ONLY applicable if the Enable producers to override default reliability property is set to True. Otherwise, the Default reliability setting is used.

Required
No

Data type
drop-down list

Range

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages might be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

Maximum reliability:

The maximum reliability of messages accepted by this destination.

Producers cannot send messages to this destination with a reliability higher than the value specified for this property.

Required
No

Data type
drop-down list

Range

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages might be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

Default priority:

The default priority assigned to messages sent to this destination when a priority has not been set by the producer.

Required	No
Data type	Integer
Range	0 through 9

Send allowed:

Clear this option (setting it to false) to stop producers from being able to send messages to this destination.

Required	No
Data type	Boolean

Include an RFH2 message header when sending messages to WebSphere MQ:

If selected, messages sent to WebSphere MQ include an RFH2 header. The RFH2 header stores additional information to that which is stored in theWebSphere MQ message header.

This property applies when the foreign bus that hosts the target destination is a WebSphere MQ queue manager or queue-sharing group. When service integration converts a message from the service integration format to WebSphere MQ format, by default it includes an MQRHF2 header in the WebSphere MQ message. This header contains message attributes, such as JMS message attributes, that are not WebSphere MQ message attributes and therefore do not appear in the WebSphere MQ message descriptor (MQMD). Some WebSphere MQ applications cannot process messages that include an MQRFH2 header. If messages sent to this destination will be processed by WebSphere MQ applications that cannot tolerate an MQRFH2, clear this option.

Dynamic updates to this property are effective immediately.

Required	No
Data type	Boolean

Additional Properties

Context properties
Context information passed to the mediation.

Related Items

Application resources topology
A expandable tree view of all applications and messaging resources that reference the current destination.

Inbound messages [Collection]

The inbound message streams from the remote queue point.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> Runtime > **[Remote message points] Remote queue points -> *identifier_name* -> [Additional Properties] Inbound messages**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

This is the collection of inbound message streams by quality of service (priority and reliability) for messages being sent to this queue point from the remote messaging engine.

Priority
The stream priority.

Reliability
The stream reliability.

Number of messages
The current number of messages on the stream.

Last delivered message sequence ID
The sequence ID of the last message delivered.

Status
The status of the stream.

Messages
View the messages on the stream.

Indirect routing properties [Settings]

The routing definition for the next service integration bus in a sequence of connected buses.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Additional Properties] Indirect routing properties.

You configure an indirect link when a service integration bus needs to communicate with a foreign bus through one or more intermediate buses.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Next bus in route:

The name of the next service integration bus in the sequence of connected buses.

An intermediate bus can be a WebSphere MQ system rather than a service integration bus.

Required	No
Data type	drop-down list

JFAP inbound channel [Settings]

A channel which can be used in combination with the TCP Channel - or other channels that support the same application interface to accept inbound connections to a WebSphere system integration bus messaging engine.

To view this page in the console, click the following path:

Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] Messaging engine inbound transports -> *chain_name* > **JFAP inbound channel**.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Transport channel name:

Specifies the unique name for a given layer in a network protocol stack.

Required	Yes
Data type	String

Discrimination weight:

Specifies the discrimination weight that is used to determine the order in which the channels obtain access to the incoming connection if the transport channels are shared amongst several transport chains. The transport channel with the lowest discrimination weight has the first opportunity to accept the incoming connection.

Required	No
Data type	Integer
Range	0 through 2147483647

Heart beat interval:

The amount of idle time, in seconds, before the channel attempts to solicit a response from its peer to check that the peer is still active. The sum of this value and the heartbeat timeout value determines the maximum amount of time that it can take to discover that some types of network failure have occurred.

Required	No
Data type	Integer
Range	0 through 2147483647

Heart beat timeout:

The amount of time, in seconds, to wait for a response from a peer after deciding to check that the peer is still alive.

Required	No
Data type	Integer
Range	0 through 2147483647

Additional Properties

Custom properties

Specifies additional custom properties for this runtime component. Some components use custom configuration properties that can be defined here.

Known link transmitter inbound streams [Collection]

This pane displays the inbound message streams from messaging applications that are connected to the remote messaging engine, and that are producing messages to this WebSphere MQ link sender channel transmitter.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional properties] Sender channel transmitters -> *WebSphere_MQ_sender_channel_name* -> Known link transmitters -> *messaging_engine_name***
- **Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Related Items] WebSphere MQ links -> *link_name* -> [Additional properties] Sender channel -> *sender_channel_link_name* -> Known link transmitters -> *messaging_engine_name***

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Priority
The priority of the messages on the given inbound stream.

Reliability
The reliability of the messages on the given inbound stream.

Number of messages
The number of messages pending receipt on the given inbound stream.

Last delivered message sequence
The sequence identifier of the last message delivered from the inbound stream to the sender channel transmitter.

Status
The runtime status of the inbound stream. Green (running), Amber (running but a problem exists), Red (stopped).

Messages
Select this link to view the message collection for messages on the given inbound stream.

Known link transmitter stream messages [Collection]

This pane displays current messages on the inbound message stream.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional properties] Sender channel transmitters -> *WebSphere_MQ_sender_channel_name* -> Known link transmitters -> *messaging_engine_name* -> Messages**
- **Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Related Items] WebSphere MQ links -> *link_name* -> [Additional properties] Sender channel -> *sender_channel_link_name* -> Known link transmitters -> *messaging_engine_name* -> Messages**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Maximum messages displayed
The maximum number of messages retrieved and displayed.

Position
The position on the inbound stream from the known link transmitter.

Identifier
The identifier of the message. Select this link to view the message detail panel for the selected message.

Previous sequence identifier
The identifier of the previous message on the queue point.

State The state of the message on the inbound stream (“Awaiting delivery”).

Buttons

Refresh	Refresh the collection with the current set of messages on the inbound stream. Only the number of messages up to the specified **Maximum messages displayed** are retrieved and displayed.

Known link transmitters [Collection]

This pane displays the inbound receiver queues for messaging applications connected to remote messaging engines, that are producing messages to this WebSphere MQ link sender channel transmitter.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional properties] Sender channel transmitters -> *WebSphere_MQ_sender_channel_name* -> Known link transmitters**
- **Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Related Items] WebSphere MQ links -> *link_name* -> [Additional properties] Sender channel -> *sender_channel_link_name* -> Known link transmitters**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Messaging engine
The messaging engine that has a link transmitter that is transmitting messages to this sender channel transmitter. Select the link to view the inbound streams for the messages from the known link transmitter.

Current inbound messages
The total number of messages currently pending receipt on the inbound streams from this known link transmitter.

Inbound messages received
The total number of messages that have been received on the inbound streams from this known link transmitter since the messaging engine started.

Known remote publication points [Collection]

The remote messaging engines that have remote producers connected to this publication point.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> Runtime > **[Message Points] Publication points** > ***identifier_name* -> [Additional Properties] Known remote publication points**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

This collection represents all the remote publication points at remote messaging engines where there are applications or clients connected that are publishing messages to this local publication point.

Messaging engine
The messaging engine where the remote publication point is located.

Current inbound messages
The current number of queued inbound messages for the publication point.

Inbound messages received
The total number of messages received on this publication point since the messaging engine started.

Known remote publication points [Settings]

The remote messaging engines that have remote producers connected to this publication point.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> Runtime > **[Message Points] Publication points** > ***identifier_name*** **-> [Additional Properties] Known remote publication points -> *messaging_engine_name***.

- "Runtime tab"

Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Messaging engine:

The messaging engine where the remote publication point is located.

Required	No
Data type	String

Current inbound messages:

The current number of queued inbound messages for the publication point.

Required	No
Data type	String

Inbound messages received:

The total number of messages received on this publication point since the messaging engine started.

Required	No
Data type	String

Additional Properties

Inbound messages
The inbound message streams from the remote publication point.

Queue [Settings]

A queue for point-to-point messaging.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *queue_name*.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Identifier:

The identifier by which this destination is known for administrative purposes.

Do not use an underscore character "_" as the first character, because this naming convention is reserved for system use.

You can use a naming convention to suggest a hierarchical structure for destinations; for example, by using dotted notation for a destination name `Library.Shelf.Book1A`. Such structure can be useful for organizing queues into logical groups for ease of association, and to permit the use of wildcard notation in filters; for example, `Library.Shelf.*` or `*.Queue.accountXYZ`.

Required	No
Data type	String

UUID:

The universal unique identifier assigned by the system to this destination for administrative purposes.

Required	No
Data type	String

Type:

Whether this bus destination is for a queue, topic space, or some other type of destination.

A queue for point-to-point messaging.

Required	No
Data type	String

Description:

An optional description for the bus destination, for administrative purposes.

Required No
Data type Text area

Mediation:

The name of the mediation that mediates this destination.

Required No
Data type String

Enable producers to override default reliability:

Select this option to enable producers to override the default reliability that is set on the destination.

Required No
Data type Boolean

Default reliability:

The reliability assigned to a message produced to this destination when an explicit reliability has not been set by the producer.

Required No
Data type drop-down list
Range

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages might be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

Maximum reliability:

The maximum reliability of messages accepted by this destination.

Required No

Data type drop-down list

Range

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages might be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

Default priority:

The default priority assigned to messages sent to this destination when a priority has not been set by the producer.

Required No
Data type Integer
Range 0 through 9

Exception destination:

Use these properties to define what happens to any messages that cannot be delivered to this destination.

None:

The bus destination does not use an exception destination and undeliverable messages are not rerouted to an exception destination.

Attempts to redeliver the message continue, up to the maximum failed deliveries limit set for the bus destination. Then, attempts to redeliver the message continue with a time interval between retry attempts. This interval is either the Default blocked destination retry interval of the messaging engine that is associated with this destination, or the Blocked retry timeout that is set for this destination. The Default blocked destination retry interval value can be used by all queue and topic destinations associated with this messaging engine. To set a time interval specifically for this destination, select **Override messaging engine blocked retry timeout default**, then enter a blocked retry timeout value for this destination.

Required No
Data type Radio button
Default Not selected

Override messaging engine blocked retry timeout default:

Override the blocked queue retry interval configured on the messaging engine owning the destination.

Select this property to set the blocked retry timeout for this destination. This property is available only when **None** is selected for the exception destination.

Required	Yes, if **None** is selected.
Data type	Boolean
Default	Unchecked. The Default blocked destination retry interval value of the associated messaging engine is used.

Blocked retry timeout in milliseconds:

When no exception destination is configured, the time interval to apply between retry attempts, after the maximum failed deliveries limit is reached, for this destination.

This property is available only when **Override messaging engine blocked retry timeout default** is selected in the exception destination properties.

Required	Yes, if Override messaging engine blocked retry timeout default is checked.
Data type	Integer

System:

The bus destination uses the system default exception destination.

Undeliverable messages are routed to the system default exception destination of the messaging engine that detects the problem: _SYSTEM.Exception.Destination.*messaging_engine_name*.

Required	No
Data type	Radio button
Default	Selected

Specify:

The bus destination uses the exception destination specified in this field.

The exception destination must be a queue, on the same bus or a foreign bus, and must exist when the exception destination processing is configured.

Required	No
Data type	Radio button
Default	Not selected

Maximum failed deliveries per message:

The maximum number of failed attempts to process a message. After this number of failed attempts, if an exception destination is configured, the message is forwarded from the intended destination to its exception destination. If an exception destination is not configured, a time interval between retry attempts is applied.

This interval is either the Default blocked destination retry interval of the messaging engine that is associated with this destination, or the Blocked retry timeout that is set for this destination.

Required	Yes, if an exception destination has been configured.
Data type	Integer
Default	5
Range	0 through 2147483647

Send allowed:

Clear this option (setting it to false) to stop producers from being able to send messages to this destination.

Required	No
Data type	Boolean

Receive allowed:

Clear this option (setting it to false) to prevent consumers from being able to receive messages from this destination.

Required	No
Data type	Boolean

Receive exclusive:

Select this option to allow only one consumer to attach to each message point. If this option is not selected multiple consumers will be allowed to attach and receive messages from each message point.

Required	No
Data type	Boolean

Maintain strict message order:

Enabling this option will maintain the strict ordering of messages for this destination.

Required	No
Data type	Boolean

Reply destination:

The name of a destination to be appended to any non-empty reverse routing path of messages sent to this destination.

This property is intended for use with mediations on reply messages.

For more information about the use of this property, see “Configuring a destination reverse routing path” on page 1989.

Required	No
Data type	String

Reply destination bus:

The bus on which the reply destination exists.

This property is intended for use with mediations on reply messages.

For more information about the use of this property, see “Configuring a destination reverse routing path” on page 1989.

Required	No
Data type	String

Default forward routing path:

The value to which a message's forward routing path will be set if the message contains no forward routing path. This identifies a sequential list of intermediary bus destinations that messages must pass through to reach a target bus destination. The format of the field is a list of line-delimited bus destinations specified as *bus*:*name*.

If you want to forward messages to one or more bus destinations, type a list of bus destinations. Type each destination entry on a separate line, and in the form *bus_name*:*destination_name* or :*destination_name*

Where

bus_name
: Is the name of the service integration bus on which the destination is configured. If you do not specify a bus name, the destination is assumed to be on the same bus as the destination for which you are setting this property.

destination_name
: is the name of a bus destination.

Required	No
Data type	Text area

Message points

Queue points
: Displays a list of queue points used to hold messages pending delivery to receiving applications.

Mediation points
: Displays a list of mediation points created when a mediation is associated with a bus destination.

Additional Properties

Context properties
: Context information passed to the mediation.

Mediation execution points
: Mediation execution points for the processing of messages from mediation message points that are on a WebSphere MQ server.

Related Items

Application resources for this destination
: This pane provides an expandable tree view of all the applications and messaging resources that reference the current destination, both directly and indirectly. As many of the references as possible are resolved to links to the associated configuration panel for the referenced object.

  Use this panel to inspect the configuration from the queue or topic space (destination) to the application or other JMS resources to ensure that the configuration is correct.

Remote queue points [Collection]

The remote queue points that are producing or consuming messages to or from queue points on remote messaging engines.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> Runtime > **[Remote message points] Remote queue points**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

This panel applies only to WebSphere Application Server Network Deployment or WebSphere Application Server for z/OS, with multiple messaging engines.

A remote queue point represents a remote proxy for a queue point that exists on a remote messaging engine (any other messaging engine on this bus). Messages are sent to or received from an application or client connected to the remote messaging engine. The remote queue point manages an outbound message stream to the queue point on the remote messaging engine, and an inbound message retrieval request stream for messages received from the queue point.

This collection gives an indication of the applications using these remote queue points, where the applications are connected and the associated message flow from each messaging engine.

Identifier
The remote queue point identifier.

Messaging engine
The remote messaging engine where this queue point is localized.

Current outbound messages
The current number of outbound messages queued to the queue point.

Outbound messages sent
The total number of messages sent to the queue point since the messaging engine started.

Current message requests
The current number of active message retrieval requests sent to the queue point from this remote queue point.

Completed message requests
The total number of completed message retrieval requests sent to the queue point from this remote queue point since the messaging engine started.

Buttons

Delete all messages	Delete all messages from the outbound message stream of the selected remote queue point. Messages in “Pending Acknowledgment” state might already have been received at the remote queue point. You cannot delete messages in “Committing” state; you must first commit their transactions.

Move all messages	Move all messages from the outbound message stream of the selected remote queue point to the exception destination configured for the destination. Messages in "Pending Acknowledgment" state might already have been received at the remote queue point. Moving these messages to the exception destination results in two copies of the message in the bus. You cannot move messages in "Committing" state; you must first commit their transactions.

Known remote queue points [Collection]

The remote messaging engines that have remote producers or consumers connected to this queue point.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> Runtime > **[Message Points] Queue points** > ***identifier_name*** **-> Known remote queue points**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

This collection represents all the remote queue points at remote messaging engines that have applications or clients connected, where those applications or clients are either sending messages to or receiving messages from this local queue point.

Messaging engine
The messaging engine where the remote queue point is located.

Current inbound messages
The current number of queued inbound messages for the queue point.

Inbound messages received
The total number of messages received on this queue point since the messaging engine started.

Current messages requests
The current number of active message retrieval requests from the remote queue point.

Completed messages requests
The total number of completed message retrieval requests from the remote queue point since the messaging engine started.

Remote queue points [Settings]

The remote queue points that are producing/consuming messages to/from queue points on remote messaging engines.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> Runtime > **[Remote message points] Remote queue points -> *identifier_name*** .

- "Runtime tab" on page 2082

Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Identifier:

The remote queue point identifier.

Required	No
Data type	String

Messaging engine:

The remote messaging engine where this queue point is localized.

Required	No
Data type	String

Current outbound messages:

The current number of outbound messages queued to the queue point.

Required	No
Data type	String

Outbound messages sent:

The total number of messages sent to the queue point since the messaging engine started.

Required	No
Data type	String

Current message requests:

The current number of active message retrieval requests sent to the queue point from this remote queue point.

Required	No
Data type	String

Completed message requests:

The total number of completed message retrieval requests sent to the queue point from this remote queue point since the messaging engine started.

Required	No
Data type	String

Message requests issued:

The total number of active and completed message retrieval requests sent to the queue point from this remote queue point since the messaging engine started.

Required	No
Data type	String

Additional Properties

Outbound messages
The outbound message streams from this remote message point to the remote localized message point.

Message Requests
A snapshot of the current message retrieval requests from the message point.

Known remote queue points [Settings]

The remote messaging engines that have remote producers or consumers connected to this queue point.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> Runtime > **[Message Points] Queue points** > ***identifier_name*** **-> Known remote queue points -> *messaging_engine_name*** .

- “Runtime tab”

Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Messaging engine:

The messaging engine where the remote queue point is located.

Required	No
Data type	String

Current inbound messages:

The current number of queued inbound messages for the queue point.

Required	No
Data type	String

Inbound messages received:

The total number of messages received on this queue point since the messaging engine started.

Required	No
Data type	String

Current messages requests:

The current number of active message retrieval requests from the remote queue point.

Required	No
Data type	String

Completed messages requests:

The total number of completed message retrieval requests from the remote queue point since the messaging engine started.

Required	No
Data type	String

Message requests received:

The total number of active and completed message retrieval from the remote queue point since the messaging engine started.

Required	No
Data type	String

Additional Properties

Inbound messages
The inbound message streams from the remote queue point.

Message requests
The message retrieval requests from the remote queue point.

Known remote subscription points [Collection]

The remote messaging engines that have remote consumers connected to this subscription point.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> Runtime > **[Message points] Publication points** > ***identifier_name*** **-> [Additional Properties] Known remote subscriptions**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

This collection represents all the remote subscription points (at remote messaging engines) where there are applications or clients connected that are receiving messages from a subscription that has its home on this local topic space.

Messaging engine
The messaging engine where the remote subscription point is located.

Current messages requests
The current number of active message retrieval requests from the remote subscription point.

Completed messages requests
The total number of completed message retrieval requests from the remote subscription point since the messaging engine started.

Known remote subscription points [Settings]

The remote messaging engines that have remote consumers connected to this subscription point.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> Runtime > **[Message points] Publication points** > ***identifier_name*** **-> [Additional Properties] Known remote subscriptions -> *messaging_engine*** .

- "Runtime tab"

Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Messaging engine:

The messaging engine where the remote subscription point is located.

Required	No
Data type	String

Current messages requests:

The current number of active message retrieval requests from the remote subscription point.

Required	No
Data type	String

Completed messages requests:

The total number of completed message retrieval requests from the remote subscription point since the messaging engine started.

Required	No
Data type	String

Message requests received:

The total number of active and completed message retrieval from the remote subscription point since the messaging engine started.

Required	No
Data type	String

Additional Properties

Message requests
The message retrieval requests from the remote subscription point.

Link receiver stream messages [Collection]

This pane displays the current messages on the link receiver stream.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Related Items] Service integration bus links -> *link_name* -> [Related Items] Link receivers -> *foreign_messaging_engine* -> Messages

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Position
The position in the queue of any pending messages that are waiting to be received.

Identifier
The identifier of this message.

Previous sequence identifier
The sequence identifier of the previous message.

State The state of the given message ("Awaiting delivery").

Target bus
The target bus for the message.

Target destination
The target destination for the message.

Time on queue
The time since the message arrived on this messaging engine.

Link receiver streams [Collection]

This pane displays the inbound message streams from messaging applications on the foreign bus for the link receiver.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Related Items] Service integration bus links -> *link_name* -> [Related Items] Link receivers -> *foreign_messaging_engine***
-

- **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional Properties] Service integration bus link receivers**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Priority
The priority of the messages on the given stream.

Reliability
The reliability of the messages on the given stream.

Current inbound messages
The number of messages pending receipt on this message stream.

Messages received
The number of messages received on this message stream since the messaging engine started.

Last delivered message sequence ID
The sequence identifier of the last message to be received.

Status
The status of the link receiver stream. Green (running), Amber (running but a problem exists), Red (stopped).

Messages
A link to view the messages on this link receiver stream.

Link receivers [Collection]

A link can have multiple link receivers. For applications that use point-to-point messaging, there is one link receiver for each messaging engine in the foreign bus, that is, the bus that sends messages across the link. For applications that use publish/subscribe messaging, there is one link receiver for each topic space in the foreign bus. The link receiver acts as an inbound receiver queue for a messaging engine that has applications attached and that is producing messages across this service integration bus link.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional Properties] Service integration bus links -> *link_name* -> [Related Items] Link receivers**
- **Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Related Items] Service integration bus links -> *link_name* -> [Related Items] Link receivers**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Foreign messaging engine
The name of the messaging engine in the foreign bus that sends messages across the service integration bus link.

Type The message domain type of this link receiver, that is, point-to-point or publish/subscribe.

Topic space
For a publish/subscribe link receiver, the topic space from which this link receiver is receiving messages across the link. This field does not apply to point-to-point link receivers.

Status
The status of the link receiver. Green (running), Amber (running but a problem exists), Red (stopped).

Current inbound messages
The current number of messages pending receipt on the link receiver.

Messages received
The total number of messages received on the link receiver since the messaging engine started.

Time since last message received
The time since the last message was received on the link receiver or since the messaging engine started.

Link transmitters [Collection]

A link can have multiple link transmitters. For applications that use point-to-point messaging, there is one link transmitter on each messaging engine in the source bus. For applications that use publish/subscribe messaging, there is one link transmitter for each topic space in the source bus. The link transmitter acts as a transmission queue where produced messages are persisted before transmission across the service integration bus link or WebSphere MQ link to the foreign bus.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Related Items] Service integration bus links -> *link_name* -> [Related Items] Link transmitters**
- **Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Related Items] WebSphere MQ links -> *link_name* -> [Related Items] Link transmitters**
- **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Related Items] Link transmitters**
- **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional properties] Sender channel -> *sender_channel_link_name* -> [Related Items] Link transmitters**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Messaging engine
The name of the messaging engine that hosts the link transmitter.

Type The message domain type of this link transmitter, that is, point-to-point or publish/subscribe.

Topic space
For a publish/subscribe link transmitter, the topic space to which this link transmitter is transmitting messages across the link. This field does not apply to point-to-point link transmitters.

Status
The status of the link transmitter. Green (running), Amber (running but a problem exists), Red (stopped).

Current outbound messages
The number of currently queued messages that are to be transmitted.

Messages sent
The number of messages sent from this link transmitter since the messaging engine started.

Time since last message sent
The time since the last message was transmitted over the link or the messaging engine was started.

Buttons

Delete all messages	Delete all available messages that are queued for the selected link transmitters.
Move all messages	Move all available messages that are queued for the selected link transmitters to the messaging engine exception destination that is local to the link transmitter.

Link transmitter stream messages [Collection]

This pane displays the outbound messages to the foreign bus link, on the link transmitter stream.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Related Items] Service integration bus links -> *link_name* -> [Related Items] Link transmitters -> *messaging_engine* -> Messages**
- **Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Related Items] WebSphere MQ links -> *link_name* -> [Related Items] Link transmitters -> *messaging_engine_name* -> Messages**
- **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Related Items] Link transmitters -> *messaging_engine_name* -> Messages**
- **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional properties] Sender channel -> *sender_channel_link_name* -> [Related Items] Link transmitters -> *messaging_engine_name* -> Messages**
- **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional Properties] WebSphere MQ link transmitters -> *link_name* -> Messages**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Position
The position of the message in the queue on this message stream.

Identifier
The message identifier.

State The state of the queued message.

Committing
The message is currently being added under a transaction. The message will be in this state until the transaction commits or rolls back. If this state persists, investigate the state of the transaction. While this message is in this state, no subsequent messages will be accepted by the queue point for which it is intended. There might be a build up of messages on this remote queue point.

Complete
Transmission of the message to the queue point has been completed. The local copy of the message is deleted automatically.

Pending send
The message is waiting to be sent to the queue point. Messages will be in this state if either of the following conditions apply:

- The messaging engine that owns the queue point is not currently available or accepting messages (for example, if its queue point has reached its high message threshold).
- The queue point already has a significant number of messages pending acknowledgement.

The message is sent when the condition no longer applies.

Pending acknowledgement
The message has been transmitted to the queue point and the messaging engine is waiting for an acknowledgement that the queue point has received the message correctly. If this state persists, the messaging engine to which the message was transmitted might not be reachable or a previous message on the remote queue point is still committing, and needs resolving.

Transaction ID
The transaction identifier if the message is locked within a transaction.

Target bus
The name of the target bus.

Target destination
The name of the target bus destination.

Approximate message length (bytes)
The approximate length of the message in bytes.

Buttons

Move	Move the selected messages to the local exception destination of the link transmitter.
Delete	Delete the selected messages.

Link transmitter streams [Collection]

This pane displays the outbound message streams, by quality of service, for the link transmitter.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Related Items] Service integration bus links -> *link_name* -> [Related Items] Link transmitters -> *messaging_engine***
- **Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Related Items] WebSphere MQ links -> *link_name* -> [Related Items] Link transmitters -> *messaging_engine_name***
- **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Related Items] Link transmitters -> *messaging_engine_name***
- **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional properties] Sender channel -> *sender_channel_link_name* -> [Related Items] Link transmitters -> *messaging_engine_name***

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Priority
The priority of the messages on the given stream.

Reliability
The reliability of the messages on the given stream.

Number of messages queued
The number of messages on this message stream.

Number of messages sent
The number of messages sent from this message stream since the messaging engine started.

Status
The status of the message stream. Green (running), Amber (running but a problem exists), Red (stopped).

Messages
A link to view the messages on this message stream.

Manage foreign bus access roles [Collection]

A foreign bus is another bus with which this bus can exchange messages.

To view this page in the console, click the following path:

Service integration -> Buses -> *security_value* -> [Authorization Policy] Manage foreign bus access roles.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

In the path, *security_value* is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.

This pane displays the names of all the foreign buses defined on the selected bus. Use this pane to view and change the access roles defined for selected buses:

- To view and change the access roles defined for a single foreign bus, click the foreign bus name.
- To view and change the access roles defined for more than one foreign bus, select the check box in the **Select** column for each foreign bus, and click **Manage Access Roles**.

Foreign bus
The name of each foreign bus defined for the selected bus.

Buttons

Manage Access Roles	Click to view and manage users and groups assigned to the access role types for the selected resources.

Mediation points [Collection]

Bus member (server or cluster) where the mediations for the destination run.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Message points] Mediation points.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Identifier
The system-generated name by which this message point is known.

Status
The runtime status of the mediation point.

Reason

Buttons

Start	Start selected items.
Stop	Stop selected items.

Mediation points [Collection]

Bus member (server or cluster) where the mediations for the destination run.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Message points] Mediation points -> Runtime.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Identifier
The system-generated name by which this message point is known.

Status
The runtime status of the mediation point.

Reason

Buttons

Start	Start selected items.
Stop	Stop selected items.

Mediation points [Settings]

Bus member (server or cluster) where the mediations for the destination run.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Message points] Mediation points -> *mediation_point_name*.

- "Configuration tab"
- "Runtime tab" on page 2094

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

Buttons

Refresh	Refresh the number of messages.

General Properties

Identifier:

The system-generated name by which this message point is known.

Required	No
Data type	String

UUID:

The universal unique identifier assigned by the system to this message point for administrative purposes.

Required No
Data type String

High message threshold:

A threshold above which the messaging system will take action to limit the addition of more messages to this message point.

Required No
Data type Long
Range 1 through 9223372036854775807

Send allowed:

Clear this option (setting it to false) to stop messages from being put onto this message point. This value will be overridden by the parent destination if that destination has sendAllowed disabled, which stops messages from being put onto all its message points.

Required No
Data type Boolean

Initial state:

Whether the mediation point is started or stopped when the hosting messaging engine is first started. Until started, the mediation point is unavailable.

Required No
Data type drop-down list
Range

Started
When the associated messaging engine is started, the mediation is started and is available to process messages.

Stopped
When the associated messaging engine is started, the mediation is stopped and is not available to process messages.

Target UUID:

The UUID of the bus destination for which this is a message point.

Required No
Data type String

Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime

property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

Buttons

Refresh	Refresh the number of messages.

General Properties

Identifier:

The system-generated name by which this message point is known.

Required No
Data type String

Run-time ID:

The internal runtime identifier assigned to this message point.

Required No
Data type String

High message threshold:

A threshold above which the messaging system will take action to limit the addition of more messages to this message point.

Required No
Data type String

Send allowed:

Clear this option (setting it to false) to stop messages from being put onto this message point. This value will be overridden by the parent destination if that destination has sendAllowed disabled, which stops messages from being put onto all its message points.

Required No
Data type Boolean

Status:

The runtime status of the mediation point.

Required No
Data type drop-down list

Range

Waiting
The mediation is waiting to start. This might be because the application server is not yet open for e-business, or because a previous instance of the mediation has not yet been deleted.

Started
The mediation is started and is available to process messages.

Stopping
The mediation is in the process of stopping.

Stopped
The mediation is stopped. The reason why the mediation is stopped is shown in the Reason attribute.

Deleting
The mediation is in the process of being deleted.

Reason:

Required	No
Data type	Text area

Current message depth:

The number of messages on the message point.

Required	No
Data type	String

Additional Properties

Messages
Messages queued on the mediation point.

Mediation thread pool [Settings]

The thread pool used to allocate threads for the execution of mediation handlers.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional Properties] Mediation thread pool.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Minimum size:

Minimum size of thread pool.

Required	No
Data type	Integer
Range	0 through 2147483647

Maximum size:

Maximum size of thread pool.

Required	No
Data type	Integer
Range	0 through 2147483647

Thread inactivity timeout:

Specifies the number of milliseconds of inactivity that should elapse before a thread is reclaimed.

Required	No
Data type	Integer
Range	0 through 2147483647

Allow thread allocation beyond maximum thread pool size:

Specifies whether the number of threads can increase beyond the maximum number configured for the thread pool.

Required	No
Data type	Boolean

Mediations [Collection]

A mediation that is associated with a bus destination to apply processing to messages on that destination.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Destination resources] Mediations.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Mediation name
The name by which this mediation is known for administrative purposes.

Handler list name
The name of the handler list that was defined when the mediation was deployed.

Description
An optional description for the mediation, for administrative purposes.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Mediations [Settings]

A mediation that is associated with a bus destination to apply processing to messages on that destination.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Destination resources] Mediations -> *mediation_name*.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Mediation name:

The name by which this mediation is known for administrative purposes.

Required	No
Data type	String

UUID:

The universal unique identifier assigned by the system to this mediation for administrative purposes.

Required	No
Data type	String

Description:

An optional description for the mediation, for administrative purposes.

Required	No
Data type	Text area

Handler list name:

The name of the handler list that was defined when the mediation was deployed.

Required Yes
Data type String

Global transaction:

Whether or not a global transaction is started for each message processed.

Cleared
A local transaction is started for each message processed. You only need to select this option for mediations that access other resource managers such as databases, or interact with Enterprise JavaBeans that require a global transaction.

Selected
A global transaction is started for each message processed.

Required No
Data type Boolean

Allow concurrent mediation:

Select this option (setting it to true) to apply the mediation to multiple messages concurrently. Message ordering is not preserved. The default option is false.

Selected
Apply the mediation to multiple messages concurrently, and preserve message ordering.

Cleared
Apply the mediation to a single message at a time. This setting is required to ensure that message ordering is preserved.

Required No
Data type Boolean

Selector:

Controls which messages are sent to the mediation. If a message matches the rule defined by the selector text string, then the mediation is applied to the message.

If the message does not match the rule defined by the selector text string, then the message is not mediated. If a message contains both Selector and Discriminator, it must match both rules for the message to be mediated. If either the Selector or the Discriminator rule does not match, the message is not mediated.

You should base the content of the selector text string on an understanding of which messages should be processed by the mediation. The format of the selector string is the same as for JMS selectors.

Required No
Data type String

Discriminator:

Controls which messages have the mediation applied to them. If the topic of a message matches the rule specified by the discriminator text string, then the mediation is applied to the message. If both the selector and discriminator are specified, the message must match both rules for the mediation to be applied to the message.

Compare this property with the Selector property. The rule specified by the Selector examines the header and properties of the message, whereas the discriminator examines the topic of the message. If a message contains both Selector and Discriminator, it must match both rules for the message to be mediated. If either the Selector or the Discriminator rule does not match, the message is not mediated.

You should base the content of the discriminator text string on an understanding of which message topics should be processed by the mediation. The format of the discriminator is the same as the topic discriminator specification.

Required	No
Data type	String

Additional Properties

Context properties
Context information passed to the mediation.

Message body [Settings]

The contents of the message body.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *queue_name* -> [Message points] Queue points -> *queue_point_name* -> Runtime > **Messages -> *message_name* -> Message body**.

Message points [Collection]

Queue points and publication points for the messaging engine.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional Properties] Message points.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Identifier
The system-generated name by which this message point is known.

Destination type
Whether the message point is a queue or topic space.

Message Requests [Collection]

A snapshot of the current message retrieval requests from the message point.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> Runtime > [Remote Message Points] Remote publication points > *identifier_name* -> [Inbound Properties] Remote subscriptions -> *subscription_name* -> [Additional Properties] Message requests.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

The collection represents the currently active message retrieval requests by applications or clients connected to this messaging engine, for messages on the message point at the remote messaging engine. A message retrieval request represents a request from a client or application connected to one messaging engine, for a message from a queue point or a subscription on a different messaging engine. When the remote messaging engine has satisfied the message retrieval request, the application or client receives the message for processing.

Request ID
The request identifier.

Times out at
The time at which the message retrieval request will timeout.

Selector
The retrieval request message selection criteria.

Status
The state of the message retrieval request.

Message requests [Collection]

A snapshot of the current message retrieval requests from the remote message point.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> Runtime > [Remote message points] Remote queue points -> *identifier_name* -> [Additional Properties] Message requests.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

The collection represents the currently active message retrieval requests for messages on this message point, by applications or clients connected to the remote messaging engine. When a message satisfying a message retrieval request becomes available on this message point, the message is exclusively assigned to the request and sent to the remote messaging engine to be delivered to the requesting application. If the requesting application accepts the message, the local message is deleted from the message point. If the message is rejected, the local message is made available again for other applications to request.

Request ID
The request identifier.

Times out at
The time at which the message retrieval request will timeout.

Selector
The retrieval request message selection criteria.

State The state of the message retrieval request.

Buttons

Cancel request	Cancel the selected message retrieval request and make any message that is allocated to the request available to other application requests.
Cancel request and delete message	Cancel the selected message retrieval request and delete any message that is allocated to the request.

Messages [Collection]

A snapshot of the current outbound messages for the message point.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> Runtime > **[Remote message points] Remote queue points -> *identifier_name* -> [Additional Properties] Outbound messages**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Sequence ID
The message sequence identifier.

API message ID
The API message identifier.

Time produced
The time the message was produced.

State The state of the queued message.

Committing
The message is currently being added under a transaction. The message will be in this state until the transaction commits or rolls back. If this state persists, investigate the state of the transaction. While this message is in this state, no subsequent messages will be accepted by the queue point for which it is intended. There might be a build up of messages on this remote queue point.

Complete
Transmission of the message to the queue point has been completed. The local copy of the message is deleted automatically.

Pending send
The message is waiting to be sent to the queue point. Messages will be in this state if either of the following conditions apply:

- The messaging engine that owns the queue point is not currently available or accepting messages (for example, if its queue point has reached its high message threshold).
- The queue point already has a significant number of messages pending acknowledgement.

The message is sent when the condition no longer applies.

Pending acknowledgement
The message has been transmitted to the queue point and the messaging engine is waiting for an acknowledgement that the queue point has received the message correctly. If this state persists, the messaging engine to which the message was transmitted might not be reachable or a previous message on the remote queue point is still committing, and needs resolving.

Buttons

Delete	Delete the selected items.
Move	Move the selected outbound messages to the exception destination configured for the destination. Messages in "Pending Acknowledgment" state might already have been accepted to the remote queue point. Moving these messages to the exception destination results in two copies of the message in the bus. You cannot move messages in "Committing" state; you must first commit their transaction.

Messages [Collection]

A snapshot of the current outbound messages for the message point.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> Runtime > **[Remote message points] Remote publication points -> *identifier_name* -> [Outbound Properties] Messages**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Sequence ID
The message sequence identifier.

API message ID
The API message identifier.

Time produced
The time the message was produced.

State The state of the queued message.

Committing
The message is currently being added under a transaction. The message will be in this state until the transaction commits or rolls back. If this state persists, investigate the state of the transaction. While this message is in this state, no subsequent messages will be accepted by the queue point for which it is intended. There might be a build up of messages on this remote queue point.

Complete
Transmission of the message to the queue point has been completed. The local copy of the message is deleted automatically.

Pending send
The message is waiting to be sent to the queue point. Messages will be in this state if either of the following conditions apply:

- The messaging engine that owns the queue point is not currently available or accepting messages (for example, if its queue point has reached its high message threshold).
- The queue point already has a significant number of messages pending acknowledgement.

The message is sent when the condition no longer applies.

Pending acknowledgement
The message has been transmitted to the queue point and the messaging engine is waiting for an acknowledgement that the queue point has received the message correctly. If this state persists, the messaging engine to which the message was transmitted might not be reachable or a previous message on the remote queue point is still committing, and needs resolving.

Buttons

Delete	Delete the selected items.

Messages [Collection]

The messages on the message point.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *queue_name* -> [Message points] Queue points -> *queue_point_name* -> Runtime** > **Messages**
- **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Message points] Mediation points -> *mediation_point_name* -> Runtime** > **Messages**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

A snapshot of the set of messages queued on the message point. You can display or remove selected messages from the list.

Because this is a snapshot of the message point, a message listed might no longer exist when you attempt to display it or act on it.

Position
The position of the message on the message point list.

Messaging engine message identifier
Messaging engine message identifier.

State The current state of the message related to a transaction that the message is part of. If the message is part of a transaction, the transaction identifier is shown in the Transaction ID field. The possible states are:

Available
The message is available for consumption.

Locked
The message is currently unavailable. The message is in this state temporarily, possibly because it is being consumed by a non-transacted consumer.

Remote lock
The message is currently locked to a consumer attached to another, remote, messaging engine in the bus. The message will remain locked until the remote messaging engine responds with a decision on the message. If the remote messaging engine is stopped, the message will remain locked until the messaging engine is restarted. A corresponding message request for a “known remote queue point” will identify the remote messaging engine that is making the request.

Removing
The message is currently being removed under a transaction. The message will be in this state until the transaction commits or rolls back. If this state persists, investigate the state of the transaction identified by **Transaction ID**.

Committing
The message is currently being added under a transaction. The message will be in this state until the transaction commits or rolls back. If this state persists, investigate the state of the transaction identified by **Transaction ID**.

Pending retry
The message is currently unavailable before being eligible for a retry. This might be because a message-driven bean is configured to delay failing message retries.

Blocked
This message is currently unavailable because the message point is blocked by the first message on the queue. The first message has reached its maximum failed delivery limit but no exception destination is configured. Identify the first message and resolve the problem that is preventing it from being consumed.

Transaction ID
The local transaction identifier of the transaction that this message is currently part of.

Buttons

Delete	Delete the selected items.
Delete all	Delete all items in the list.
Refresh	Refresh the number of messages.

Messages [Settings]

The properties for a message on the message point.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *queue_name* -> [Message points] Queue points -> *queue_point_name* -> Runtime > Messages -> *message_name*.

- "Runtime tab"

Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Messaging engine message identifier:

Messaging engine message identifier.

Required	No
Data type	String

State:

The current state of the message related to a transaction that the message is part of. If the message is part of a transaction, the transaction identifier is shown in the Transaction ID field.

Table 217. Message transaction state.. The first column of the table lists the transaction state of the messages. The second column provides the transaction identifier if the message is part of a transaction. The third column provides the comments.

State	Transaction ID	Comments
Locked	An identifier is shown.	The message is locked as part of the transaction identified. The message has not been consumed and the transaction is still in progress.
Locked	An identifier is not shown.	The message is locked, but the transaction has completed, so the message might not have been consumed. This indicates that some error might have occurred.

Required	No
Data type	drop-down list

Range

Available
The message is available for consumption.

Locked
The message is currently unavailable. The message is in this state temporarily, possibly because it is being consumed by a non-transacted consumer.

Remote lock
The message is currently locked to a consumer attached to another, remote, messaging engine in the bus. The message will remain locked until the remote messaging engine responds with a decision on the message. If the remote messaging engine is stopped, the message will remain locked until the messaging engine is restarted. A corresponding message request for a "known remote queue point" will identify the remote messaging engine that is making the request.

Removing
The message is currently being removed under a transaction. The message will be in this state until the transaction commits or rolls back. If this state persists, investigate the state of the transaction identified by **Transaction ID**.

Committing
The message is currently being added under a transaction. The message will be in this state until the transaction commits or rolls back. If this state persists, investigate the state of the transaction identified by **Transaction ID**.

Pending retry
The message is currently unavailable before being eligible for a retry. This might be because a message-driven bean is configured to delay failing message retries.

Blocked
This message is currently unavailable because the message point is blocked by the first message on the queue. The first message has reached its maximum failed delivery limit but no exception destination is configured. Identify the first message and resolve the problem that is preventing it from being consumed.

Transaction ID:

The local transaction identifier of the transaction that this message is currently part of.

This field combined with the State field shows the state of the message related to the transaction. For more information about the combination of these fields, see Table 217 on page 2106.

Required No
Data type String

Run-time message properties:

Message type:

The type of the message (JMS, SDO, SUBSCRIPTION, TRM, BROKER_CONTROL, BROKER_RESPONSE, BROKER_ADMIN).

Required	No
Data type	String

Approximate length:

The approximate length of the message.

Required	No
Data type	String

Time stamp:

The time stamp of when the message was originally sent.

Required	No
Data type	String

Message wait time:

The time the message has been waiting to be consumed.

Required	No
Data type	String

Current messaging engine arrival time:

The time that the message arrived on the current messaging engine.

Required	No
Data type	String

Redelivered count:

The number of times that the message has been redelivered.

Required	No
Data type	String

Security user ID:

The security user ID.

Required	No
Data type	String

Producer type:

The producer type (API, Core, TRM).

Required	No
Data type	String

Exception destination timestamp:

The timestamp at which the message was put to the exception destination.

Required	No
Data type	String

Exception destination reason:

The reason the message was put to the exception destination.

Required	No
Data type	Text area

API Message properties:

Message ID:

The message ID.

Required	No
Data type	String

Correlation ID:

The API correlation ID for request/response correlation.

Required	No
Data type	String

User ID:

The user ID.

Required	No
Data type	String

Format:

The Format of the message.

Required	No
Data type	String

JMS Message properties:

JMS delivery mode:

The JMS delivery mode (Persistent, Non-persistent).

Required	No
Data type	String

JMS expiration:

The JMS expiration.

Required	No
Data type	String

JMS destination:

The JMS destination.

Required	No
Data type	String

JMS reply to destination:

The JMS reply to destination.

Required	No
Data type	String

JMS redelivered:

The JMS redelivered flag.

Required	No
Data type	String

JMS type:

The JMS type field (Text, Byte, Stream, Object, Map).

Required	No
Data type	String

JMSX delivery count:

The JMSX delivery count.

Required	No
Data type	String

JMSX application ID:

The JMSX application ID.

Required	No

Data type String

Bus message properties:

Topic:

The bus discriminator.

Required No
Data type String

Priority:

The bus priority (0-9).

Required No
Data type String

Reliability:

The bus reliability (Assured persistent, Reliable persistent, Reliable non-persistent, Express non-persistent, Best effort non-persistent).

Required No
Data type String

Time to live:

The time to live of the message.

Required No
Data type String

Reply discriminator:

The reply discriminator value of the bus.

Required No
Data type String

Reply priority:

The reply priority value of the bus (0-9).

Required No
Data type String

Reply reliability:

The reply reliability value of the bus (Assured persistent, Reliable persistent, Reliable non-persistent, Express non-persistent, Best effort non-persistent).

Required No
Data type String

Reply time to live:

The reply time to live value of the bus.

Required No
Data type String

System message ID:

The unique id of the message, assigned by the bus.

Required No
Data type String

Additional Properties

Message body
The contents of the message body.

Messages [Settings]

The properties for a message on the message point.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *queue_name* -> [Message points] Queue points -> *queue_point_name* -> Runtime > **Messages -> *message_name***.

- "Runtime tab"

Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Messaging engine message identifier:

Messaging engine message identifier.

Required No
Data type String

State:

The current state of the message related to a transaction that the message is part of. If the message is part of a transaction, the transaction identifier is shown in the Transaction ID field.

Required No

Data type drop-down list

Range

Available
The message is available for consumption.

Locked
The message is currently unavailable. The message is in this state temporarily, possibly because it is being consumed by a non-transacted consumer.

Remote lock
The message is currently locked to a consumer attached to another, remote, messaging engine in the bus. The message will remain locked until the remote messaging engine responds with a decision on the message. If the remote messaging engine is stopped, the message will remain locked until the messaging engine is restarted. A corresponding message request for a "known remote queue point" will identify the remote messaging engine that is making the request.

Removing
The message is currently being removed under a transaction. The message will be in this state until the transaction commits or rolls back. If this state persists, investigate the state of the transaction identified by **Transaction ID**.

Committing
The message is currently being added under a transaction. The message will be in this state until the transaction commits or rolls back. If this state persists, investigate the state of the transaction identified by **Transaction ID**.

Pending retry
The message is currently unavailable before being eligible for a retry. This might be because a message-driven bean is configured to delay failing message retries.

Blocked
This message is currently unavailable because the message point is blocked by the first message on the queue. The first message has reached its maximum failed delivery limit but no exception destination is configured. Identify the first message and resolve the problem that is preventing it from being consumed.

Transaction ID:

The local transaction identifier of the transaction that this message is currently part of.

Required No
Data type String

Run-time message properties:

Message type:

The type of the message (JMS, SDO, SUBSCRIPTION, TRM, BROKER_CONTROL, BROKER_RESPONSE, BROKER_ADMIN).

Required	No
Data type	String

Approximate length:

The approximate length of the message.

Required	No
Data type	String

Time stamp:

The time stamp of when the message was originally sent.

Required	No
Data type	String

Message wait time:

The time the message has been waiting to be consumed.

Required	No
Data type	String

Current messaging engine arrival time:

The time that the message arrived on the current messaging engine.

Required	No
Data type	String

Redelivered count:

The number of times that the message has been redelivered.

Required	No
Data type	String

Security user ID:

The security user ID.

Required	No
Data type	String

Producer type:

The producer type (API, Core, TRM).

Required	No
Data type	String

Exception destination timestamp:

The timestamp at which the message was put to the exception destination.

Required	No
Data type	String

Exception destination reason:

The reason the message was put to the exception destination.

Required	No
Data type	Text area

API Message properties:

Message ID:

The message ID.

Required	No
Data type	String

Correlation ID:

The API correlation ID for request/response correlation.

Required	No
Data type	String

Data type	String

Additional Properties

Message body
The contents of the message body.

Messaging engines [Collection]

A messaging engine is a component, running inside a server, that manages messaging resources for a bus member. Applications are connected to a messaging engine when they access a service integration bus.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Name The name of the messaging engine.

Description
An optional description for the messaging engine, for administrative purposes.

Status
The current status of the messaging engine. Status settings are started or stopped.

Buttons

Enable policy assistance	This button only applies to messaging engines in a clustered environment. Start the wizard that provides messaging engine policy assistance, that is, guidance about creating one or more messaging engines for the cluster and configuring the messaging engine behavior. This button is available only when messaging engine policy assistance is not enabled already.
Add messaging engine	This button only applies to messaging engines in a clustered environment. Add a new messaging engine to the server cluster.

Remove messaging engine	This button only applies to messaging engines in a clustered environment. Remove the selected messaging engines from the server cluster.
Start	Start selected items.
Stop	Stop the selected messaging engines. You must first select the messaging engines to be stopped. You can select a Stop mode: **Immediate** The messaging engine stops after all messaging operations that are occurring at the time of the stop request have completed. After a stop request is issued, no new messaging operations can start. For each existing connection, the messaging engine waits for the current operation to complete, unless the operation is one that blocks processing in the messaging engine, such as a receive operation. In this case, the operation is interrupted. Asynchronous consumers can complete, even though they might take an arbitrary amount of time to process the current message. The messaging engine then backs out of active transactions and disallows any further operations on that connection. When all connections are in this invalidated state, the messaging engine stops. **Force** The messaging engine stops without allowing messaging operations to complete. Applications are forcefully disconnected. This mode completes the shutdown of the messaging engine in as short a time as possible. When a messaging engine that was stopped by using force mode is restarted, the restart might take longer than if it was stopped using immediate mode, because more recovery actions are needed. For example, messages might be left in an indoubt state and you must deal with these messages to resolve any indoubt transactions. **Tip:** If an immediate stop takes too long, you can select the Force option to escalate it to a force stop. This overrides your previous selection of the Immediate option.

Messaging engines [Settings]

A messaging engine is a component, running inside a server, that manages messaging resources for a bus member. Applications are connected to a messaging engine when they access a service integration bus.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name*.

- “Configuration tab”
- “Runtime tab” on page 2128

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the messaging engine.

Required No
Data type String

UUID:

The universal unique identifier assigned by the system to this messaging engine for administrative purposes.

Required No
Data type String

Description:

An optional description for the messaging engine, for administrative purposes.

Required No
Data type Text area

Initial state:

The initial state determines whether the messaging engine is started automatically.

If this property is selected, the messaging engine starts automatically when its associated application server is started. Until the messaging engine starts, it is unavailable.

Required No
Data type drop-down list
Range

Stopped
When the associated application server is started, the messaging engine is stopped and is not available to process messages.

Started
When the associated application server is started, the messaging engine is started and is available to process messages.

Message store type:

The type of message store used. Either file store or data store. Once the messaging engine has been created this cannot be changed, only configured.

Required No
Data type drop-down list
Range

File store
A file store is a type of message store that directly uses files in a file system through the operating system.

Data store
A data store consists of the set of tables that a messaging engine uses to store persistent data in a database.

High message threshold per message point:

The number of messages queued on a message point on this messaging engine, at which point new messages are not accepted on the message point. However, certain messages that are already in the bus and that are being transmitted to this messaging engine might be accepted.

When the messaging engine is created, the high message threshold of the bus is used to set the default value for this property. When a message point is created on this messaging engine, the value of this property is used to set the default high message threshold for the message point.

Required No
Data type Integer
Range 1 through 9223372036854775807

Note: There are implications for the Java Virtual Machine (JVM) heap size when using a high message threshold, if large numbers of messages are held on a queue (each message consumes approximately 200 bytes of storage). Therefore if you increase the high message threshold because you are expecting large numbers of messages on your queues, you should also modify the JVM heap size of the server as appropriate.

Default blocked destination retry interval:

The time delay, in milliseconds, that is introduced by the system under certain circumstances before a failed message delivery to an application will be retried. This delay can be overridden by individual Queue destination configurations.

When you configure a bus destination, you can specify an associated exception destination and a maximum number of times that an individual message fails to be consumed before it is put on that exception destination. Alternatively, if you do not specify an associated exception destination, the system continues to try to deliver the message. In this situation, the system attempts to deliver the message, without applying any delay, until it reaches the maximum failed deliveries limit set for the bus destination (a queue or a topic space). After the maximum failed deliveries limit is reached, the default blocked destination retry interval is applied before the message is retried.

The Default blocked destination retry interval specifies the time interval between retry attempts, which will be used by all queue and topic destinations that are associated with this messaging engine. You can override this default value when you configure an individual queue or topic destination.

Required	No
Data type	Integer (milliseconds)
Default	The value taken from the sib.processor.blockedRetryTimeout custom property, if set. Otherwise it is set to 5000.
Range	1 through 9223372036854775807

Target groups:

A list of names of target groups with which the messaging engine will register.

Custom target groups are a type of target group used by JMS connection factories. When an application creates a connection to a service integration bus, it uses connection factory properties to specify suitable messaging engines to connect to. When a target type of “Custom” is specified in the connection factory **targetType** property, the application is connected to one of the messaging engines in the specified custom target group. A particular messaging engine is selected from the group according to the other connection factory properties that are specified.

Required	No
Data type	Text area

Bus name:

The name of the service integration bus on which the messaging engine is configured.

Required	No
Data type	String

Bus UUID:

The universal unique identifier of the service integration bus on which the messaging engine is configured.

Required	No
Data type	String

Message points

Mediation points

A mediation point is created on each messaging engine to which the mediation of a mediated destination is assigned. It is used to hold messages pending delivery to the mediation.

Queue points

A queue point is created on each messaging engine to which a point-to-point destination is assigned. It is used to hold messages pending delivery to receiving applications.

Publication points

A publication point is created on each messaging engine in the bus when a publish/subscribe destination is created. The publication point on a messaging engine is used to hold messages published by applications connected to that messaging engine until they are delivered to subscribers.

Additional Properties

Mediation execution points
Mediation execution points for the processing of messages from mediation message points that are on a WebSphere MQ server.

Service integration bus links
A communications link between this messaging engine and a messaging engine in a foreign service integration bus.

Mediation thread pool
The thread pool for allocating mediation handler threads.

Message store
The properties for the message store in use by this messaging engine as determined by the message store type field. The message store can be either a file store or a data store.

WebSphere MQ client links
A WebSphere MQ client link enables JMS client applications to connect, via this messaging engine, to the service integration bus, as though it were a WebSphere MQ queue manager.

WebSphere MQ links
Links between the messaging engine and WebSphere MQ networks. Each WebSphere MQ link connects the messaging engine as a queue manager to WebSphere MQ, providing a bridge between the bus and a WebSphere MQ network.

Custom properties
Arbitrary name-value pairs of data, where the name is a property key and the value is a string value that can be used to set internal system configuration properties. Defining a new property enables you to configure a setting beyond that which is available in the administrative console.

Reliable messaging state
Use this page to view and manage the WS-ReliableMessaging runtime state.

Related Items

Bus member
The bus member associated with this messaging engine.

Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Status:

The current status of the messaging engine. Status settings are started or stopped.

To be able to retrieve the status of messaging engines, you must be logged into the administrative console with at least monitor authority. If you do not have this authority, the messaging engine status is displayed as "Unavailable", even if the messaging engine has started.

Required	No
Data type	String

Message points

Queue points
A queue point is created on each messaging engine to which a point-to-point destination is assigned. It is used to hold messages pending delivery to receiving applications.

Publication points
A publication point is created on each messaging engine in the bus when a publish/subscribe destination is created. The publication point on a messaging engine is used to hold messages published by applications connected to that messaging engine until they are delivered to subscribers.

Mediation points
A mediation point is created on each messaging engine to which the mediation of a mediated destination is assigned. It is used to hold messages pending delivery to the mediation.

Remote message points

Remote queue points
The remote queue points that are producing/consuming messages to/from queue points on remote messaging engines.

Remote mediation points
The remote mediation points that are producing messages for mediation points on remote messaging engines.

Remote publication points
The remote publication points that are producing messages for publication points on remote messaging engines.

Messaging resources for this application

This pane provides an expandable tree view of all the references to messaging resources declared in the deployment descriptors for the current application. As many of the references as possible are resolved to links to the associated configuration panel for the referenced object.

To view this page in the console, click the following path:

Applications -> Application Types -> WebSphere enterprise applications -> *application_name* -> [Enterprise Java Bean Properties] Default messaging provider references.

Use this panel to inspect the configuration from the application to the queue (destination) to ensure that the configuration is correct.

Using the default messaging provider, a JMS activation specification refers to a JMS destination (either a JMS Queue or JMS Topic) that in turn points to a service integration bus destination (either a queue destination or a topic space destination). JMS resources are referenced through Java Naming and Directory Interface (JNDI) names and service integration resources are referenced through bus and resource identifiers. This panel enables you to review the dependencies within your configuration, making it easier to detect inconsistencies, for example as a result of references being entered incorrectly, or JNDI or resource names being changed or deleted without the associated configuration having been updated.

Problems with the configuration are usually detected in one of two ways:

- An application can no longer send or receive messages.
- A destination becomes full and can no longer receive messages because the existing messages are not being consumed.

This panel can help you find the cause of the problem by giving you a high level view of many relevant resources.

Note: For a related view of the applications and JMS resources for a given destination, see the following panel: “Application resources for this destination” on page 2035.

- “Local Topology tab”

Local Topology tab

Topology properties for this object. These properties detail how this object relates to other objects in the system topology.

Permitted transports [Collection]

A permitted transport is a transport mechanism that this bus will allow remote clients to use.

To view this page in the console, click the following path:

Service integration -> Buses -> *security_value* -> [Additional Properties] Permitted transports.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Transport Name
The name of the permitted transport.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Port [Settings]

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *port_name*.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Identifier:

The identifier by which this destination is known for administrative purposes.

Required	No
Data type	String

UUID:

The universal unique identifier assigned by the system to this destination for administrative purposes.

Required	No
Data type	String

Type:

Whether this bus destination is for a queue, topic space, or some other type of destination.

Required	No
Data type	String

Description:

An optional description for the bus destination, for administrative purposes.

Required	No
Data type	Text area

Mediation:

The name of the mediation that mediates this destination.

Required	No
Data type	String

Default reliability:

The reliability assigned to a message produced to this destination when an explicit reliability has not been set by the producer.

Required	No
Data type	drop-down list

Range

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages might be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

Maximum reliability:

The maximum reliability of messages accepted by this destination.

Required No
Data type drop-down list
Range

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages might be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

Enable producers to override default reliability:

Select this option to enable producers to override the default reliability that is set on the destination.

Required	No
Data type	Boolean

Default priority:

The default priority assigned to messages sent to this destination when a priority has not been set by the producer.

Required	No
Data type	Custom

Exception destination:

Use these properties to define what happens to any messages that cannot be delivered to this destination.

Use this property to define what happens to any messages that cannot be delivered to this destination.

By default, such messages are routed to the system default exception destination of the messaging engine that discovers the problem: _SYSTEM.Exception.Destination.*engine_name*.

If you want messages to be sent to another exception destination, select Specify then type the exception destination name. The exception destination must be a queue, on the same bus or a foreign bus, and must exist when the destination is created.

If you do not want undeliverable messages to be sent to an exception destination, select None.

Required	No
Data type	String and Boolean

Send allowed:

Clear this option (setting it to false) to stop producers from being able to send messages to this destination.

Required	No
Data type	Boolean

Receive allowed:

Clear this option (setting it to false) to prevent consumers from being able to receive messages from this destination.

Required	No
Data type	Boolean

Receive exclusive:

Select this option to allow only one consumer to attach to each message point. If this option is not selected multiple consumers will be allowed to attach and receive messages from each message point.

Required	No
Data type	Boolean

Maintain strict message order:

Enabling this option will maintain the strict ordering of messages for this destination.

Required	No
Data type	Custom

Additional Properties

Context properties
Context information passed to the mediation.

Message points

Queue points
A queue point is created on each messaging engine to which a point-to-point destination is assigned. It is used to hold messages pending delivery to receiving applications.

Mediation points
A mediation point is a location in a messaging engine at which messages are mediated. A mediation point is created when a mediation is associated with a bus destination.

Property [Settings]

Use this page to specify an arbitrary name and value pair. The value that is specified for the name and value pair is a string that can set internal system configuration properties.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Additional Properties] Custom properties -> *property_name*.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

Specifies the name of the property.

Required	Yes
Data type	String

Value:

Specifies the value that is paired with the specified name.

Required	Yes
Data type	String

Description:

Specifies a description of the name and value pair. The description should help to differentiate this pair for other defined pairs.

Required	No
Data type	Text area

Optional:

Specifies an optional attribute that determines whether this property must have a value.

Required	No
Data type	Boolean

Validation Expression:

Specifies a value that the administrative console and some host tools use to validate the contents of the value of this property.

Required	No
Data type	String

Publication points [Collection]

The message point for a topic space, for publish/subscribe messaging.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *topic_space_name* -> [Message points] Publication points.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Identifier
The system-generated name by which this message point is known.

Queue Depth
The total set of messages currently queued by the publication point for the attached subscriptions.

These messages can be:

- Shared across multiple local subscriptions
- Queued for a single subscription
- Queued for transmission to one or more remote publication points

Investigate the reason for queued messages, as follows:

- Display the runtime collection of subscriptions for this publication point and identify the subscriptions with non-zero queue depths.

- Also display the Remote publication point collection panel for this messaging engine and identify any remote publication points for the same topic space as this publication point that have a non-zero current outbound message value. If these exist, ensure that the target messaging engines are started.

Publication points [Collection]

The message point for a topic space, for publish/subscribe messaging.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *topic_space_name* -> [Message points] Publication points -> Runtime.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Identifier
The system-generated name by which this message point is known.

Publication points [Settings]

The message point for a topic space, for publish/subscribe messaging.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *topic_space_name* -> [Message points] Publication points -> *publication_point_name*.

- "Configuration tab"
- "Runtime tab" on page 2137

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Identifier:

The system-generated name by which this message point is known.

Required	No
Data type	String

UUID:

The universal unique identifier assigned by the system to this message point for administrative purposes.

Required	No

Data type String

Destination type:

Whether the message point is a queue or topic space.

Required No
Data type String

High message threshold:

A threshold above which the messaging system will take action to limit the addition of more messages to this message point.

A publication point stores a single copy of each message that is currently queued to a subscription on this publication point. Multiple subscriptions that are queueing the same message will result in a single copy of the message on the publication point. A publication point can reach its high message threshold because a single subscription has many messages queued to it or because many subscriptions have a few, different messages queued to them. If the high message threshold is reached, investigate the state of the individual subscriptions on this publication point to identify the cause.

Required No
Data type Long
Range 1 through 9223372036854775807

Send allowed:

Clear this option (setting it to false) to stop messages from being put onto this message point. This value will be overridden by the parent destination if that destination has sendAllowed disabled, which stops messages from being put onto all its message points.

Required No
Data type Boolean

Target UUID:

The UUID of the bus destination for which this is a message point.

Required No
Data type String

Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Identifier:

The system-generated name by which this message point is known.

Required	No
Data type	String

Run-time ID:

The internal runtime identifier assigned to this message point.

Required	No
Data type	String

High message threshold:

A threshold above which the messaging system will take action to limit the addition of more messages to this message point.

Required	No
Data type	String

Send allowed:

Clear this option (setting it to false) to stop messages from being put onto this message point. This value will be overridden by the parent destination if that destination has sendAllowed disabled, which stops messages from being put onto all its message points.

Required	No
Data type	Boolean

Additional Properties

Subscriptions
The active subscriptions for the topic space.

Known remote publication points
The remote messaging engines that have remote producers connected to this publication point.

Publish/subscribe broker profiles [Collection]

Profiles used to define the topic mappings and transactionality for publishing and receiving (by subscription) topics across the publish/subscribe bridge between WebSphere Application Server and a message broker in a WebSphere MQ network.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional Properties] Publish/subscribe broker profiles.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Name The name of the publish/subscribe broker profile.

Description
An optional description for the publish/subscribe broker profile, for administrative purposes.

Broker queue manager
The name of the queue manager for the WebSphere MQ broker.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Publish/subscribe broker profiles [Settings]

Profiles used to define the topic mappings and transactionality for publishing and receiving (by subscription) topics across the publish/subscribe bridge between WebSphere Application Server and a message broker in a WebSphere MQ network.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional Properties] Publish/subscribe broker profiles -> *profile_name*.

- "Runtime tab"
- "Configuration tab" on page 2140

Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Number of subscriptions:

The current number of broker subscriptions for this broker profile.

Required No
Data type String

Additional Properties

Subscriptions
The list of current broker subscriptions for this broker profile.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the publish/subscribe broker profile.

This name is only for administrative purposes. If you created this broker profile by using the foreign bus connection wizard, then this name is generated automatically by adding "_broker_profile" to the end of the broker queue manager name.

Required	Yes
Data type	String

Description:

An optional description for the publish/subscribe broker profile, for administrative purposes.

Dynamic updates to this property are effective immediately.

Required	No
Data type	Text area

Broker queue manager:

The name of the queue manager for the WebSphere MQ broker.

This identifies the queue manager to which the message broker is connected in the WebSphere MQ network. It does not have to be the WebSphere MQ gateway queue manager.

Required	No
Data type	String

Additional Properties

Topic mappings

Topic mappings for publishing and receiving (by subscription) messages across the publish/subscribe bridge between WebSphere Application Server and a message broker in a WebSphere MQ network.

Queue points [Collection]

The message point for a queue, for point-to-point messaging.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *queue_name* -> [Message points] Queue points.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Identifier
The system-generated name by which this message point is known.

Queue points [Collection]

The message point for a queue, for point-to-point messaging.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *queue_name* -> [Message points] Queue points -> Runtime.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Identifier
The system-generated name by which this message point is known.

Queue points [Settings]

The message point for a queue, for point-to-point messaging.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *queue_name* -> [Message points] Queue points -> *queue_point_name*.

Clear this option (setting it to false) to stop messages from being put onto this message point. This value will be overridden by the parent destination if that destination has sendAllowed disabled, which stops messages from being put onto all its message points.

Required No
Data type Boolean

Current message depth:

The number of messages on the message point.

Required No
Data type String

Additional Properties

Messages
Messages queued on the queue point.

Known remote queue points
The remote messaging engines that have remote producers or consumers connected to this queue point.

Remote mediation points [Collection]

The remote mediation points that are producing messages to mediation points on remote messaging engines.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> Runtime > **[Remote message points] Remote mediation points**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

A remote mediation point represents a remote proxy for a mediation point that exists at a remote messaging engine to which messages are sent by an application or client connected to this messaging engine. The remote mediation point manages an outbound message stream to the mediation point at the remote messaging engine.

Identifier
The remote mediation point identifier.

Messaging engine
The remote messaging engine where this mediation point is localized.

Current outbound messages
The current number of outbound messages queued to the mediation point.

Outbound messages sent
The total number of messages sent to the mediation point since the messaging engine started.

Buttons

Delete all messages	Delete all messages from the outbound message stream of the selected remote queue point. Messages in “Pending Acknowledgment” state might already have been received at the remote queue point. You cannot delete messages in “Committing” state; you must first commit their transactions.
Move all messages	Move all messages from the outbound message stream of the selected remote queue point to the exception destination configured for the destination. Messages in “Pending Acknowledgment” state might already have been received at the remote queue point. Moving these messages to the exception destination results in two copies of the message in the bus. You cannot move messages in “Committing” state; you must first commit their transactions.

Remote mediation points [Settings]

The remote mediation points that are producing messages to mediation points on remote messaging engines.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> Runtime > **[Remote message points] Remote mediation points** -> *identifier_name* .

- "Runtime tab"

Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Identifier:

The remote mediation point identifier.

Required	No
Data type	String

Messaging engine:

The remote messaging engine where this mediation point is localized.

Required	No
Data type	String

Current outbound messages:

The current number of outbound messages queued to the mediation point.

Required	No
Data type	String

Outbound messages sent:

The total number of messages sent to the mediation point since the messaging engine started.

Required	No
Data type	String

Additional Properties

Outbound messages

The outbound message streams from this remote message point to the remote localized message point.

Outbound messages [Collection]

The outbound message streams from this remote message point to the remote localized message point.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> Runtime > **[Remote message points] Remote queue points -> *identifier_name* -> [Additional Properties] Outbound messages**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

The collection of outbound message streams ordered by quality of service (priority and reliability) for messages sent to a message point on a remote messaging engine.

Priority
The stream priority.

Reliability
The stream reliability.

Number of messages
The current number of messages on the stream.

Status
The status of the stream.

Messages
View the messages on the selected stream.

Remote Publication Points [Collection]

The remote publication points that are producing messages to publication points on remote messaging engines.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> Runtime > **[Remote message points] Remote publication points**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

A remote publication point represents a remote proxy for a publication point that exists at a remote messaging engine, for which publications are published to by an application or client connected to this messaging engine. The remote publication point manages an outbound message stream to the publication point at the remote messaging engine

Identifier
The remote publication point identifier.

Message engine
The remote messaging engine where this publication point is localized.

Current outbound messages
The current number of outbound messages queued to the publication point.

Outbound messages sent
The total number of messages sent to the publication point since the messaging engine started.

Buttons

Delete all messages	Delete all messages from the outbound message stream of the selected remote queue point. Messages in "Pending Acknowledgment" state might already have been received at the remote queue point. You cannot delete messages in "Committing" state; you must first commit their transactions.

Remote Publication Points [Settings]

The remote publication points that are producing messages to publication points on remote messaging engines.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> Runtime > **[Remote message points] Remote publication points -> *identifier_name*** .

- "Runtime tab"

Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Identifier:

The remote publication point identifier.

Required No
Data type String

Message engine:

The remote messaging engine where this publication point is localized.

Required No
Data type Text area

Current outbound messages:

The current number of outbound messages queued to the publication point.

Required	No
Data type	String

Outbound messages sent:

The total number of messages sent to the publication point since the messaging engine started.

Required	No
Data type	String

Outbound properties

Messages
The messages queued outbound to the publication point on the remote messaging engine.

Topics
The topics that have been subscribed to from this remote messaging engine.

Inbound properties

Remote subscriptions
The subscriptions that have been made from this messaging engine to subscription homes on remote messaging engines.

Remote subscription [Collection]

The subscription that has been made from this messaging engine to a subscription home on a remote messaging engine.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> Runtime > **[Remote Message Points] Remote publication points** > ***identifier_name*** **-> [Inbound Properties] Remote subscriptions**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

The subscriptions that have been made by subscribing applications, or clients connected to this messaging engine, to the remote messaging engine where the subscriptions' "Homes" exist.

Name The name of the remote subscription.

Current message requests
The current number of active message retrieval requests sent to the publication point from this remote subscription point.

Completed message requests
The total number of completed message retrieval requests sent to the publication point from this remote subscription point since the messaging engine started.

Remote subscription [Settings]

The subscription that has been made from this messaging engine to a subscription home on a remote messaging engine.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> Runtime > **[Remote Message Points] Remote publication points** > ***identifier_name*** **-> [Inbound Properties] Remote subscriptions -> *subscription_name*** .

- “Runtime tab”

Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the remote subscription.

Required	No
Data type	String

Current message requests:

The current number of active message retrieval requests sent to the publication point from this remote subscription point.

Required	No
Data type	String

Completed message requests:

The total number of completed message retrieval requests sent to the publication point from this remote subscription point since the messaging engine started.

Required	No
Data type	String

Additional Properties

Message requests

The total number of active and completed message retrieval requests sent to the publication point from this remote subscription point since the messaging engine started.

WebSphere MQ sender channel saved batch status [Collection]

The saved status of message batches for the sender channel saved for transmission to WebSphere MQ. You can choose to commit or rollback each batch.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional Properties] Sender channel -> *channel_name* -> Runtime > **Saved batch status**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Virtual queue manager name
The virtual queue manager name by which the local bus is known to a WebSphere MQ network.

MQ channel name
The name of the channel used for the WebSphere MQ link sender channel.

In doubt
Whether or not the saved batch is in doubt.

Current LUWID
The current logical unit-of-work identifier for the saved batch.

Current sequence number
The current sequence number for the saved batch.

Last LUWID
The last logical unit-of-work identifier for the saved batch.

Last sequence number
The last sequence number for the saved batch.

Buttons

Commit	Commit the logical unit-of-work for the message batch.
Roll back	Roll back the logical unit-of-work for the message batch.

WebSphere MQ receiver channel saved batch status [Collection]

The runtime status of message batches for the receiver channel of the WebSphere MQ link.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional Properties] Receiver channel -> *channel_name* -> Runtime > **Saved batch status**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

WebSphere MQ Queue Manager name
The name of the WebSphere MQ queue manager from which the message batch was received.

MQ channel name
The name of the WebSphere MQ sender channel from which the message batch was received.

Last LUWID
The last unit of work identifier for the message batch.

Last sequence number
The last sequence number for the message batch.

Security domain configuration. [Settings]

Configure the security settings for the security domain to which your service integration bus is assigned.

To view this page in the console, click the following path:

Service integration -> Buses -> *security_value* -> [Bus security domain] Configure security domain.

In the path, *security_value* is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.

Use this pane to create a customized security domain for the selected bus. By having a customized security domain for each bus in your bus topology, you can configure different security attributes for each bus within a cell. You can view the current security settings for the security domain to which the selected service integration bus is assigned, and to make changes to the existing domain configuration.

• “Configuration tab”

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Domain name:

The unique name for this security domain.

You must type a unique name for the security domain.

Required	No
Data type	String

Domain description:

A description of this security domain.

Required	No
Data type	String

User Realm::

Specifies the settings for the user realm.

Click the **Expand** icon to display the options for configuring the user realm.

You can use existing global security settings, or customize a user realm specifically for this domain. If you customize a user realm, you must select the type of realm, and you might have to configure the user registry.

Required	No
Data type	Expand

JAAS System Logins::

Specifies the settings for the JAAS system logins.

Click the **Expand** icon to display the options for configuring JAAS system logins.

Required	No
Data type	Expand

JAAS J2C Authentication Data::

Specifies the settings for the JAAS J2C authentication data.

Click the **Expand** icon to display the options for configuring authentication data for JAAS Java Platform Enterprise Edition (Java EE) Connector Architecture authentication data.

Required	No
Data type	Expand

Security for bus *bus_name* [Settings]

Configure the security settings for your service integration bus.

To view this pane in the console, click one of the following paths:

Service integration -> Buses -> *bus_name* > **[Additional Properties] Security**.

Service integration -> Buses -> *security_value*.

The value of *security_value* is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

Launch Bus Security Wizard

Click to start a wizard to configure the security settings bus for a bus. If the wizard detects that bus security is disabled, you are prompted to enable it.

General Properties

Enable bus security:

Select this option to inherit the secure administration setting of the cell. Deselect this option if you always wish to disable bus security.

Required	No
Data type	Boolean

Inter-engine authentication alias:

The name of the authentication alias used to authorize communication between messaging engines on the bus.

You must specify an inter-engine authentication alias if the bus contains a WebSphere Application Server Version 6 bus member. When bus security is enabled, the bus uses the inter-engine authentication alias to authenticate incoming connections from other messaging engines. An unauthorized messaging engine cannot connect to the bus.

Required	No
Data type	drop-down list

Permitted transports:

Select the type of allowed permitted transports.

Allow the use of all defined transport channel chains

Restrict the use of defined transport channel chains to those protected by SSL

Restrict the use of defined transport channel chains to the list of permitted transports

To ensure that all ports used by the bus are secure, select **Restrict the use of defined transport channel chains to those protected by SSL** , or if your permitted transport chains are secure, select **Restrict the use of defined transport channel chains to the list of permitted transports**. This prevents the InboundBasicMessaging port being opened. Changes to this setting are effective when the server is restarted.

Required	No
Data type	Radio button

Use the Server ID when running mediations:

Check this option if you want to run mediations using the server identity, instead of using a mediation authentication alias.

Select this option if you want to run mediations on multiple servers in different domains. Using the server identity enables you to run mediations successfully across multiple security domains without having to specify a mediation authentication alias for each domain. You can also use this option when multiple domains are not in use.

Required No
Data type Boolean

Mediations authentication alias:

The name of the authentication alias used to authorize mediations to access the bus.

You must specify a mediation authentication alias if the bus contains a WebSphere Application Server Version 6 bus member. The mediations authentication alias ensures that the bus operates securely. If a mediation authentication alias is specified for a bus that contains no Version 6 bus members, it is ignored.

Required No
Data type drop-down list

Bus security domain:

Select one of the following options to assign the bus to a security domain:

Use the global security domain
Select this option to assign the bus to the global security domain. If you have a mixed-version bus, you must assign it to the global security domain.

Required No
Data type Radio button

Inherit the cell level security domain
Select this option to let the bus inherit the cell level security domain. If no cell level domain is specified then the global security domain will be used.

Required No
Data type Radio button

Use the selected domain
Select a custom security domain for this bus. This domain will be used for authentication and determining other security information.

Required No
Data type Radio button

Configure Security Domain...
Select this link to configure security settings for a custom security domain. This link becomes active only after you have applied or saved the option to use a non-global domain.

Performance:

Group cache timeout:

The length of time, in minutes, that a security group will be cached for.

Increasing the timeout decreases the load on the user registry and improves performance but makes the system less responsive to changes in a user's group membership. To tune the user's group cache to the optimum setting, you have to balance the need for responsiveness with the registry load. The default value is 120 minutes. If the system must respond quickly to changes in a user's group membership, specify a timeout of approximately 15 minutes. If it is acceptable to update a user's group membership only once a

day, for example, as an overnight process, specify a timeout of 1440 minutes (24 hours). With a setting of 0, entries in the cache do not timeout, and so remain until the server is next restarted.

A change to this value is effective immediately and only affects the group cache of the bus for which the configuration was changed.

Required	No
Data type	Long
Range	0 through 99999

Audit:

Enable the auditing service for this bus:

Required	No
Data type	Boolean

Authorization Policy

Users and groups in the bus connector role
The list of users and groups in the bus connector role.

Manage default access roles
Manage the assignment of default role types to users and groups

Manage destination access roles
Manage the assignment of destination role types to users and groups

Manage foreign bus access roles
Manage the assignment of foreign bus role types to users and groups

Manage temporary destination prefix access roles
Manage the assignment of temporary destination prefix role types to users and groups

Manage topic access roles
Manage the assignment of topic role types to users and groups

Manage users and groups not known to the user repository
Manage users and groups not known to the user repository

Additional Properties

Permitted transports
The list of permitted transports.

Sender channel transmitters [Collection]

This pane displays the transmission queue for a WebSphere MQ link sender channel.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Related Items] WebSphere MQ links -> *link_name* -> [Additional properties] Sender channel transmitters**
- **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional properties] Sender channel transmitters**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

WebSphere MQ link sender channel
The name of the WebSphere MQ link sender channel for which this is the channel transmitter. Select this link to view the message collection panel for the messages on the sender channel transmitter.

Status
The runtime status of the WebSphere MQ link sender channel transmitter. Green (running), Amber (running but a problem exists), Red (stopped).

Current outbound messages
The current number of messages on the sender channel transmitter.

Outbound messages sent
The current number of messages on the sender channel transmitter.

Time since last message sent
The amount of time since the last message was sent across the sender channel or since the messaging engine started.

Known link transmitters
Select this link to view the known link transmitters for the sender channel transmitter.

Buttons

Move all messages	Move all messages on the selected WebSphere MQ link sender channel to the link exception destination.
Delete all messages	Delete all messages on the selected WebSphere MQ link sender channel.

WebSphere MQ link sender channel transmitter messages [Collection]

This pane displays the messages queued for transmission across the WebSphere MQ link sender channel.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional properties] Sender channel transmitters -> *WebSphere_MQ_sender_channel_name***

- **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional properties] Sender channel -> *sender_channel_link_name* -> Sender channel transmitter -> *WebSphere_MQ_sender_channel_name***
- **Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Related Items] WebSphere MQ links -> *link_name* -> [Additional properties] Sender channel transmitters -> *WebSphere_MQ_link_sender_channel_name***
- **Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Related Items] WebSphere MQ links -> *link_name* -> [Additional properties] Sender channel -> *sender_channel_link_name* -> Sender channel transmitter -> *WebSphere_MQ_link_sender_channel_name***

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Maximum messages displayed
The maximum number of messages retrieved and displayed.

Position
The position in the queue of the sender channel transmitter messages.

Identifier
The identifier of the message. Select this link to view the message detail panel for the selected message.

State The transaction state of the message (“Pending send”, “Pending acknowledgement”, “Committing”).

Transaction ID
The transaction identifier, if the message is locked under a transaction.

Target bus
The bus to which the message is targeted.

Target destination
The destination in the bus to which the message is targeted.

Approximate message length (bytes)
The approximate length of the message in bytes.

Buttons

Move	Move the selected available messages to the link exception destination. Only messages with a **State** of “Pending send” are moved.
Delete	Delete the selected available messages. Only messages with a **State** of “Pending send” are deleted.
Commit Pending Acknowledge Batch	Commit the pending acknowledgement message batch as being received successfully by the WebSphere MQ network. The messages are removed from the sender channel transmitter.

Rollback Pending Acknowledge Batch	Roll back the pending acknowledgement message batch as not being received successfully by the WebSphere MQ network. The messages are restored to the sender channel transmitter.
Refresh	Refresh the collection with the current set of messages on the sender channel transmitter. Only the number of messages up to the specified "Maximum displayed messages" are retrieved and displayed.

Service integration bus link routing properties [Settings]

The routing properties for a service integration bus link to a foreign service integration bus.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Additional Properties] Service integration bus link routing properties.

After a routing definition is configured, service integration bus links must be created between messaging engines in the services integration buses to be connected.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name by which the routing definition is known.

Required No
Data type String

UUID:

The universal unique identifier assigned by the system to the routing definition (virtual link) for administrative purposes.

Required No
Data type String

Inbound user ID:

The user ID applied to messages arriving from the foreign bus and used to authorize their access to destinations.

The inbound user ID is used to authorize individual messages arriving from the foreign bus to destinations in this bus. If this is not a secure bus, this property has no affect on messages. You might want to specify an inbound user ID:

- if the foreign bus is in a different security domain from this bus and user IDs from the foreign bus are not recognized in this bus

- to locally-control access of inbound messages to this bus.

If this is a secure bus and the foreign bus is not secure, and no inbound user ID is set, any inbound messages from the foreign bus will only be authorized to destinations that allow unauthenticated users access.

Dynamic updates to this property are effective immediately.

Required	No
Data type	String

Outbound user ID:

The user ID applied to messages sent to the foreign bus.

The outbound user ID replaces the user ID that identifies the source of a message in all messages being sent to the foreign bus. This user ID is also be used by the foreign bus to authorize the message to its destination if both buses are secure buses and the foreign bus has not overridden the user ID with its own inbound user ID.

Dynamic updates to this property are effective immediately.

Required	No
Data type	String

Additional Properties

Topic space mapping
The mapping between topic spaces in the local bus and topic spaces in the foreign bus.

Service integration bus links [Collection]

This pane displays links between this messaging engine and messaging engines in foreign service integration buses.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Related Items] Service integration bus links

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

An individual messaging engine can have links to messaging engines in a number of different foreign buses. However, you can have only one service integration bus link between a pair of buses.

Status can take the following values:

Table 218. Status values and definitions. The first column of the table lists the status values of the service integration bus link. The second column contains a brief definition of the status.

Status	Meaning
Starting	The service integration bus link is started on the local messaging engine but has no connection to the foreign bus. The service integration bus link is attempting to activate a connection to the foreign bus. The service integration bus link on the foreign bus must also be started to enable the successful activation of a connection between the buses.
Started	The service integration bus link is started on the local messaging engine and has an active connection to the foreign bus.
Stopped	The service integration bus link is stopped on the local messaging engine and there is no connection to the foreign bus.
Unknown	The administrative console cannot contact the server to determine the status.

Name The name of the service integration bus link. In order to work, the name must be the same as the name of the corresponding service integration bus link configured on the target foreign bus.

Description
An optional description for the service integration bus link, for administrative purposes.

UUID The universal unique identifier assigned by the system to the service integration bus link for administrative purposes.

Local messaging engine
The local messaging engine that this service integration bus link is hosted on.

Foreign messaging engine
The messaging engine on the foreign bus to which this service integration bus link connects.

Status
The runtime status of the service integration bus link.

Current outbound messages
The current total number of messages queued on the link transmitters to this service integration bus link.

Messages sent
The total number of messages sent on the link transmitters to this service integration bus link since the messaging engine was started.

Current inbound messages
The current total number of messages queued pending receipt on the link receivers for this service integration bus link.

Messages received
The total number of messages received on the link receivers for this service integration bus link since the messaging engine was started.

Buttons

Start	Start selected items.
Stop	Stop selected items.

Service integration bus links [Settings]

This pane displays links between this messaging engine and messaging engines in foreign service integration buses.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Related Items] Service integration bus links -> *link_name*

The messaging engine in the foreign bus must also have a service integration bus link to the local bus. For a connection to be active, the service integration bus links at both ends must be started.

- "Configuration tab"
- "Runtime tab" on page 2163

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the service integration bus link. In order to work, the name must be the same as the name of the corresponding service integration bus link configured on the target foreign bus.

Required	Yes
Data type	String

UUID:

The universal unique identifier assigned by the system to the service integration bus link for administrative purposes.

Required	No
Data type	String

Description:

An optional description for the service integration bus link, for administrative purposes.

Dynamic updates to this property are effective immediately.

Required	No
Data type	Text area

UUID:

The universal unique identifier assigned by the system to the service integration bus link for administrative purposes.

Required	Yes
Data type	drop-down list

Local messaging engine:

The local messaging engine that this service integration bus link is hosted on.

Required Yes
Data type drop-down list

Foreign messaging engine:

The messaging engine on the foreign bus to which this service integration bus link connects.

Required Yes
Data type String

Initial state:

The initial state of the link, which shows whether the link is started automatically when the messaging engine is started.

Dynamic updates to this property are effective when the messaging engine is restarted or the service integration bus link is created. Use the Runtime tab to check the current state.

Required No
Data type drop-down list
Range

Stopped
When the associated messaging engine is started, the gateway link is in a stopped state and cannot process any new requests for connections.

Started
When the associated messaging engine is started, the gateway link is in a started state and can process any new requests for connections.

Exception destination:

The destination for an inbound message when the service integration bus link cannot deliver the message to its target bus destination, or to the exception destination that is configured for that target destination, or when the target destination does not exist.

Dynamic updates to this property are effective immediately.

Select a radio button as required to configure the exception destination that this service integration bus link uses:

- Select **None** to specify that the service integration bus link does not use an exception destination. Undeliverable messages are not rerouted to an exception destination and can block the processing of other messages waiting for delivery to the same destination. This option can be used to preserve message ordering.

- Select **System** to use the default exception destination. Messages that cannot be delivered to the bus destination are rerouted to the system default exception destination for the messaging engine that this link is assigned to: _SYSTEM.Exception.Destination*messaging_engine_name*.
- Select **Specify** and enter an exception destination to use the exception destination specified here. If the service integration bus link cannot use this exception destination, it uses the system exception destination.

Required	No
Data type	Radio button
Default	System

Prefer queue points local to this link's messaging engine:

When this check box is selected, the link prefers to send inbound messages to available queue points of target destinations that are located on the messaging engine on which the link is hosted.

When this check box is not selected, or if no local queue point is available for a target destination, the link workload balances the messages across all available queue points of the target destination. By default the check box is selected.

This option is supported on links running on WebSphere Application Server Version 7.0 or later. If you are running on an earlier version, the default behavior of preferring local queue points is applied.

Required	Yes
Data type	Boolean

Related Items

JAAS - J2C authentication data .
Specifies a list of user identities and passwords for Java 2 connector security to use. Refer to Java 2 Connector authentication data entry settings.

Foreign bus connection
The associated foreign bus connection for this service integration bus link.

Messaging engine
The remote messaging engine where this queue point is localized.

Link transmitters
For applications that use point-to-point messaging, there is one link transmission message point located on each messaging engine in the source bus. For applications that use publish/subscribe messaging, there is one link transmission message point located on each topic space in the source bus. The link transmitter acts as a transmission queue where produced messages are persisted before transmission across the inter-bus link to the foreign bus.

Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Status:

The runtime status of the service integration bus link.

Status can take the following values:

Table 219. Status values and definitions. The first column of the table lists the status values of the service integration bus link. The second column contains a brief definition of the status.

Status	Meaning
Starting	The service integration bus link is started on the local messaging engine but has no connection to the foreign bus. The service integration bus link is attempting to activate a connection to the foreign bus. The service integration bus link on the foreign bus must also be started to enable the successful activation of a connection between the buses.
Started	The service integration bus link is started on the local messaging engine and has an active connection to the foreign bus.
Stopped	The service integration bus link is stopped on the local messaging engine and there is no connection to the foreign bus.
Unknown	The administrative console cannot contact the server to determine the status.

Required No
Data type String

Transmitter/Receiver Queues

Link receivers

For applications that use point-to-point messaging, there is one link receiver for each messaging engine in the foreign bus. For applications that use publish/subscribe messaging, there is one link receiver for each topic space in the foreign bus. The link receiver acts as an inbound receiver queue for a message engine that has applications attached and that is producing messages across this service integration bus link.

Link transmitters

For applications that use point-to-point messaging, there is one link transmission message point located on each messaging engine in the source bus. For applications that use publish/subscribe messaging, there is one link transmission message point located on each topic space in the source bus. The link transmitter acts as a transmission queue where produced messages are persisted before transmission across the inter-bus link to the foreign bus.

Target inbound transport chain

The type of transport chain used for communication with the foreign bus.

The transport chain name must be the name of the transport chain as defined on the server on which the target messaging engine is hosted.

Dynamic updates to this property are effective when the link is restarted. Use the Runtime tab to check the current state.

Required No
Data type String

Bootstrap endpoints

A comma-separated list of endpoint triplets, with the syntax hostName:portNumber:chainName, used to connect to a bootstrap server. For example Merlin:7276:BootstrapBasicMessaging,Gandalf:5557:BootstrapSecureMessaging. If hostName is not specified, the default is localhost. If portNumber is not specified, the default is 7276. If chainName is not specified, the default is BootstrapBasicMessaging. Refer to the information center for more information.

This property is set in the same way as the **Provider endpoint** property in the JMS connection factory settings.

The port for the bootstrap endpoint is the port defined on the service integration bus endpoint address that is configured on the target application server on the foreign bus.

Dynamic updates to this property are effective when the link is restarted. Use the Runtime tab to check the current state.

You only have to modify this property if you have client applications running outside of an application server, or applications on a server in another cell, that want to use this connection factory to connect to the target service integration bus specified on the connection factory.

To use JMS destinations of the default messaging provider, an application connects to a messaging engine on the target service integration bus to which the destinations are assigned. For example, a JMS queue is assigned to a queue destination on a service integration bus.

Client applications running outside of an application server - for example, running in a client container or outside the WebSphere Application Server environment - cannot locate directly a suitable messaging engine to connect to in the target bus. Similarly, an application running on a server in one cell to connect to a target bus in another cell cannot locate directly a suitable messaging engine to connect to in the target bus.

In these scenarios, the clients (or servers in another bus) must complete a bootstrap process through a *bootstrap server* that is a member of the target bus. A bootstrap server is an application server running the SIB Service, but does not have to be running any messaging engines. The bootstrap server selects a messaging engine that is running in an application server that supports the required *target transport chain*. For the bootstrap process to be possible, you must configure one or more *provider end points* in the connection factory used by the client.

A bootstrap server uses a specific port and bootstrap transport chain. The port is the **SIB_ENDPOINT_ADDRESS** (or **SIB_ENDPOINT_SECURE_ADDRESS** if security is enabled), of the messaging engine that hosts the remote end of the link. Together with host name, these form the *endpoint address* of the bootstrap server.

The properties of a JMS connection factory used by an application control the selection of a suitable messaging engine and how the application connects to the selected messaging engine.

- If no security credentials are provided, then by default
  - If no host is specified then localhost is used
  - If no port is specified then port 7276 is used
  - If no bootstrap channel chain is specified then bootstrap transport chain called BootstrapBasicMessaging is used
- If security credentials are provided, then by default
  - If no host is specified then localhost is used
  - If no port is specified then port 7286 is used
  - If no bootstrap channel chain is specified then bootstrap transport chain called BootstrapBasicMessaging is used

Note: For the IBM i platform, you must (at least) change the default host name from localhost to *your.server.name*.

If you want an application to use a bootstrap server with a different endpoint address, you must specify the required endpoint address on the **Provider endpoints** property of the JMS connection factories that the client application uses. You can specify one or more endpoint addresses of bootstrap servers.

The endpoint addresses for bootstrap servers must be specified in every JMS connection factory that is used by applications outside of an application server. To avoid having to specify a long list of bootstrap servers, you can provide a few highly-available servers as dedicated bootstrap servers. Then you only have to specify a short list of bootstrap servers on each connection factory.

Note: When configuring a connection to a non-default bootstrap server, specify the required values for the endpoint address and use colons as separators.

For example: for a server assigned non-secure port 7278, on host boothost1, that uses the default transport chain BootstrapBasicMessaging:

```
boothost1:7278:BootstrapBasicMessaging
or
boothost1:7278
```

and for a server assigned secure port 7289, on host boothost2, that uses the predefined transport chain BootstrapTunneledSecureMessaging:

```
boothost2:7289:BootstrapTunneledSecureMessaging
```

The syntax for an endpoint address is as follows:

```
[ [host_name] [ ":" [port_number] [ ":" chain_name] ] ]
```

where:

host_name
: is the name of the host on which the server runs. It can be an IP address. For an IPv6 address, put square braces ([]) around *host_name* as shown in the example below:

  ```
  [2002:914:fc12:179:9:20:141:42]:7276:BootstrapBasicMessaging
  ```

  . If a value is not specified, the default is localhost.

  Note: For the IBM i platform, you must (at least) change the default host name from localhost to *your.server.name*.

port_number
: where specified, is one of the following addresses of the messaging engine that hosts the remote end of the link:

  - **SIB_ENDPOINT_ADDRESS** if security is not enabled
  - For secure connections, **SIB_ENDPOINT_SECURE_ADDRESS** if security is enabled.

  If *port_number* is not specified, the default is 7276.

  To find either of these values by using the administrative console, click **Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Communications] Ports**.

chain_name
: is the name of a predefined bootstrap transport chain used to connect to the bootstrap server. If not specified, the default is BootstrapBasicMessaging.

  The following predefined bootstrap transport chains are provided:

  BootstrapBasicMessaging
  : This corresponds to the server transport chain InboundBasicMessaging (JFAP-TCP/IP)

  BootstrapSecureMessaging
  : This corresponds to the server transport chain InboundSecureMessaging (JFAP-SSL-TCP/IP)

  BootstrapTunneledMessaging
  : Before you can use this bootstrap transport chain, you must define a corresponding server transport chain on the bootstrap server. (See **Servers -> Server Types -> WebSphere**

application servers -> *server_name* -> [Server messaging] Messaging engine inbound transports.) This transport chain tunnels JFAP and uses HTTP wrappers.

BootstrapTunneledSecureMessaging
Before you can use this bootstrap transport chain, you must define a corresponding server transport chain on the bootstrap server. (See**Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] Messaging engine inbound transports**.) This transport chain tunnels JFAP and uses HTTP wrappers.

Specifying *host_name* : *chain_name* instead of *host_name* : : *chain_name* (with two colons) is incorrect. It is valid to enter nothing, or to enter any of the following: "a", "a:", ":7276", "::chain", and so on. The default value applies if you do not specify a value, but you must separate the fields with ":"s.

If you want to provide more than one bootstrap server, identify all the required endpoint addresses. Separate each endpoint address by a comma character. For example, to use the servers from the earlier example:

```
boothost1:7278:BootstrapBasicMessaging,
  boothost2:7289:BootstrapTunneledSecureMessaging,
  [2002:914:fc12:179:9:20:141:42]:7276:BootstrapBasicMessaging
```

Required	No
Data type	Text area

Authentication alias
The name of the authentication alias, used to authenticate access to the foreign bus.

You must have predefined a Java Platform, Enterprise Edition (Java EE) Connector Architecture (JCA) authentication alias.

Dynamic updates to this property are effective when the link is restarted. Use the Runtime tab to check the current state.

Modified aliases are only visible after a server restart.

Required	No
Data type	drop-down list

Subscriptions [Collection]
The active subscriptions for the topic space.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *topic_space_name* -> [Message points] Publication points -> *publication_point_name* -> Runtime -> Subscriptions.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Name The name by which the active subscription is known for administrative purposes.

Identifier
The identifier by which this destination is known for administrative purposes.

Topic The name of the topic that this subscription is for.

Queue Depth
The number of messages currently associated with this subscription.

Buttons

Delete	Delete the selected items.

Broker profile subscriptions [Collection]

The list of current broker subscriptions for this broker profile.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional Properties] Publish/subscribe broker profiles -> *profile_name* -> Runtime > **Subscriptions**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Topic name
The topic name for this subscription.

Topic space
The topic space for this subscription.

Direction
Whether the subscription is for message flows to or from WebSphere MQ.

Broker stream queue
The name of the WebSphere MQ broker stream queue that the topic publishes messages to.

Subscription point
The name of the WebSphere MQ broker subscription point that the topic consumes messages from.

Message count
The count of messages for this subscription.

Status
The current status of this subscription.

Buttons

Unsubscribe	Cancel all subscriptions.

Subscriptions [Settings]

The active subscriptions for the topic space.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *topic_space_name* -> [Message points] Publication points -> *publication_point_name* -> Runtime -> Subscriptions -> *subscription_name*.

- "Runtime tab"

Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

Buttons

Refresh	Refresh the number of messages.

General Properties

Name:

The name by which the active subscription is known for administrative purposes.

Required No
Data type String

Identifier:

The identifier by which this destination is known for administrative purposes.

Required No
Data type String

Topic:

The name of the topic that this subscription is for.

Required No
Data type Text area

Selector:

The text string that must be present in a message for the mediation to process the message.

Required No
Data type String

Current message depth:

The number of messages on the message point.

Required	No
Data type	String

Subscriber ID:

Required	No
Data type	String

Additional Properties

Messages
Messages being handled by this subscription.

Known remote subscription points
The remote messaging engines that have remote consumers connected to this subscription point.

Temporary destination prefixes [Collection]

A temporary destination prefix is a user-defined string that is used to create a temporary destination. When messaging security is enabled, users and groups require authority to create messages and send them to temporary destinations. The authority is configured in the temporary destination prefix.

To view this page in the console, click the following path:

Service integration -> Buses -> *security_value* -> [Authorization Policy] Manage temporary destination prefix access roles

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

In the path, *security_value* is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.

A list of all the temporary destination prefixes defined for the selected service integration bus is displayed. By default, the list is empty. Use this pane to create a new temporary destination prefix, and define its role type assignments, or remove existing temporary destination prefixes. You can also manage the role type assignments for existing temporary destination prefixes:

- To act on a single temporary destination prefix, click its name in the list.
- To act on more than one temporary destination prefix, select the check box next to the name of each destination you want to act on, then click **Manage Access Roles**.

Temporary destination prefix
The name of each temporary destination prefix defined for the selected bus.

Buttons

Manage Access Roles	Click to view and manage users and groups assigned to the access role types for the selected resources.

Add	Click to create a temporary destination prefix, and add users and groups to it.
Remove	Click to remove selected users and groups from all the role types for this resource.

Temporary destination prefixes [Settings]

This pane displays the role type assignments for the selected temporary destination prefixes.

To view this page in the console, click the following path:

Service integration -> Buses -> *security_value* -> [Authorization Policy] Manage temporary destination prefix access roles -> *temporary_destination_prefix* > **Manage access roles**

In the path, *security_value* is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.

A list of users and groups that have been added to access roles for the selected temporary destination prefixes is displayed. The access role information for the selected temporary destination prefix is contained within an expandable section. The access roles for temporary destination prefixes are creator and receiver. Users and groups in the creator role can create a new temporary destination prefix. You cannot remove users and groups from the creator role.

Use this pane to complete the following tasks:

- View users and groups that have creator and sender roles for a selected temporary destination prefix.
- Add or remove users and groups in the sender role for a selected temporary destination prefix.

General Properties

Select A check box that you can use to select the users and groups for which you want to manage access roles.

Name The name of the user or group that has an access role for the selected resource. If the user is a group member, the user ID and the group name is displayed.

Type The type of the user or group. There are three types of user or group: “user”, “group” and “member”. A user that inherits its access roles from a group has the type “member”.

Sender
Whether a user, group or member is in the sender role for a selected resource.

Creator
Read only. The user or group is in the creator role for a selected temporary destination prefix. You cannot change this role type assignment.

Security access roles

In the administrative console, access role icons are used to represent whether a user or a group is in a particular access role. You can click an icon to add or remove selected users and groups to a particular access role for a selected resource.

An access role icon has three states:

- Access role type set.
- Access role type not set.
- Access role type inherited from group.

The following table describes how the access role icons represent these states, and how to change between them:

Table 220. Interacting with access role icons

Access role icon	Access role assignment state	User action
	Role type not set.	Click to change to role type set  .
	Role type set.	Click to change to role type not set. The icon changes to role type not set  if the user or group does not inherit access roles, or to role type inherited  if the role type does inherit access roles.
	Role type inherited from group.	Click to change to role type set  .
	Role type not set for a group. The group to which a user belongs does not have a role type.	Read only.
	Role type set for a group. The group to which a user belongs has a role type.	Read only.
	Role type not applicable.	Read only.

Topic Mapping [Collection]

The mapping between a topic on the service integration bus and a stream queue and subscription point provided by a WebSphere MQ broker.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional Properties] Publish/subscribe broker profiles -> *profile_name* -> [Additional Properties] Topic mappings.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Dynamic updates to this list are effective immediately.

Topic name
The name of the topic on the service integration bus. The name must be the same as the topic name on the message broker in a WebSphere MQ network.

Topic space
The name of the topic space that contains the topic.

Direction
Whether the mapping is for publishing message flows in both directions, or only to, or only from, WebSphere MQ.

Broker stream queue
The name of the stream queue at the message broker in a WebSphere MQ network.

Subscription point
The name of the WebSphere MQ broker subscription point that the topic consumes messages from.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Topic Mapping [Settings]

The mapping between a topic on the service integration bus and a stream queue and subscription point provided by a WebSphere MQ broker.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional Properties] Publish/subscribe broker profiles -> *profile_name* -> [Additional Properties] Topic mappings -> *mapping_name*.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Topic name:

The name of the topic on the service integration bus. The name must be the same as the topic name on the message broker in a WebSphere MQ network.

You can specify wildcard characters in topic name strings.

Required Yes
Data type String

Topic space:

The name of the topic space that contains the topic.

Required No
Data type drop-down list

Direction:

Whether the mapping is for publishing message flows in both directions, or only to, or only from, WebSphere MQ.

Required No

Data type drop-down list

Range

Bi-directional
Messages flow in both directions between the bus and WebSphere MQ.

To WebSphere MQ
Messages flow only from the bus to WebSphere MQ.

That is, from WebSphere Application Server to a message broker in the WebSphere MQ network.

From WebSphere MQ
Messages flow only to the bus from WebSphere MQ.

That is, from a message broker in the WebSphere MQ network to WebSphere Application Server.

Broker stream queue:

The name of the stream queue at the message broker in a WebSphere MQ network.

The broker stream queue in this instance is a queue on the WebSphere MQ queue manager to which the message broker is connected. This queue is being used as the input node for a message flow containing a publication node. Messages sent to this queue are processed by the message broker, then published to applications that have subscribed on the topic specified in the message.

Stream names are case sensitive.

After you type a new name, then save your changes, the name becomes available for selection in the drop-down list.

Required No
Data type Custom

Subscription point:

The name of the WebSphere MQ broker subscription point that the topic consumes messages from.

Type the name of the WebSphere MQ message broker subscription point from which the service integration bus receives messages.

After you type a new name, then save your changes, the name becomes available for selection in the drop-down list.

Required No
Data type Custom

Topic [Settings]

This pane displays the role type assignments for a topic. You can use this pane to add new assignments, and to modify and remove existing assignments.

To view this page in the console, click the following path:

Service integration -> Buses -> *security_value* -> [Authorization Policy] Manage topic access roles -> *topic_space_name* > *topic_name*.

In the path, *security_value* is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.

This pane lists users and groups that have been assigned role types on the selected topic. The permitted access roles for topics are sender and receiver. Use this panel to view existing topic role assignments, add new users and groups to topic access roles, and remove users and groups from topic access roles.

The information for the selected topic is contained within a section that you can expand to display all the users and groups that have been assigned role types for the topic. The following options are available:

Inherit sender role from parent topic
Select the check box if you want the topic to inherit sender role assignments from the parent topic.

Inherit receiver role from parent topic
Select the check box if you want the topic to inherit receiver role assignments from the parent topic.

General Properties

Select A check box that you can use to select the users and groups for which you want to manage access roles.

Name The name of the user or group that has an access role for the selected resource. If the user is a group member, the user ID and the group name is displayed.

Type The type of the user or group. There are three types of user or group: “user”, “group” and “member”. A user that inherits its access roles from a group has the type “member”.

Sender
Whether a user, group or member is in the sender role for a selected resource.

Receiver
Whether a user, group or member is in the receiver role for a selected resource.

Security access roles

In the administrative console, access role icons are used to represent whether a user or a group is in a particular access role. You can click an icon to add or remove selected users and groups to a particular access role for a selected resource.

An access role icon has three states:

- Access role type set.
- Access role type not set.
- Access role type inherited from group.

The following table describes how the access role icons represent these states, and how to change between them:

Table 221. Interacting with access role icons

Access role icon	Access role assignment state	User action
	Role type not set.	Click to change to role type set  .
	Role type set.	Click to change to role type not set. The icon changes to role type not set  if the user or group does not inherit access roles, or to role type inherited  if the role type does inherit access roles.
	Role type inherited from group.	Click to change to role type set  .
	Role type not set for a group. The group to which a user belongs does not have a role type.	Read only.
	Role type set for a group. The group to which a user belongs has a role type.	Read only.
	Role type not applicable.	Read only.

Buttons

Add	Click to add users and groups to this resource.
Remove	Click to remove selected users and groups from all the role types for this resource.

Topic space map entries [Collection]

The mapping between a topic space in the local bus and a topic space in the foreign bus.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Additional Properties] Service integration bus link routing properties -> [Additional Properties] Topic space map entries.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

A topic space mapping allows subscribers on the local topic space to receive messages published in the foreign topic space. For publications to flow from the local topic space into the foreign bus, an equivalent topic space mapping is required by the foreign bus.

Dynamic updates to this list are effective immediately.

Local topic space
The name of the topic space on this (local) bus that is mapped to the remote topic space on the foreign bus.

Remote topic space
The name of the topic space on the foreign bus that is mapped to the local topic space.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Topic space map entries [Settings]

The mapping between a topic space in the local bus and a topic space in the foreign bus.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Additional Properties] Service integration bus link routing properties -> [Additional Properties] Topic space map entries -> *map_entry_name*.

A topic space mapping allows subscribers on the local topic space to receive messages published in the foreign topic space. For publications to flow from the local topic space into the foreign bus an equivalent topic space mapping is required by the foreign bus.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Local topic space:

The name of the topic space on this (local) bus that is mapped to the remote topic space on the foreign bus.

Required Yes
Data type Custom

Remote topic space:

The name of the topic space on the foreign bus that is mapped to the local topic space.

Required Yes
Data type String

Topic space mapping [Settings]

The mapping between topic spaces in the local bus and topic spaces in the foreign bus.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional Properties] Publish/subscribe broker profiles -> *profile_name* -> [Additional Properties] Topic space mapping.

A topic space mapping allows subscribers on the local topic space to receive messages published in the foreign topic space. For publications to flow from the local topic space into the foreign bus an equivalent topic space mapping is required by the foreign bus.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Description:

An optional description for the topic space mapping, for administrative purposes.

Dynamic updates to this property are effective immediately.

Required	No
Data type	Text area

Additional Properties

Topic space map entries
The mapping between topic spaces in the local bus and topic spaces in the foreign bus.

Topic space [Settings]

A topic space is a location for publish/subscribe messaging.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *topic_space_name*.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Identifier:

The identifier by which this destination is known for administrative purposes.

Required	No
Data type	String

UUID:

The universal unique identifier assigned by the system to this destination for administrative purposes.

Required	No
Data type	String

Type:

Whether this bus destination is for a queue, topic space, or some other type of destination.

A topic space for publish/subscribe messaging.

Required	No
Data type	String

Description:

An optional description for the bus destination, for administrative purposes.

Required	No
Data type	Text area

Mediation:

The name of the mediation that mediates this destination.

Required	No
Data type	String

Enable producers to override default reliability:

Select this option to enable producers to override the default reliability that is set on the destination.

Required	No
Data type	Boolean

Default reliability:

The reliability assigned to a message produced to this destination when an explicit reliability has not been set by the producer.

Required	No
Data type	drop-down list

Range

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages might be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

Maximum reliability:

The maximum reliability of messages accepted by this destination.

Required No
Data type drop-down list
Range

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages might be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

Default priority:

The default priority assigned to messages sent to this destination when a priority has not been set by the producer.

Required	No
Data type	Integer
Range	0 through 9

Exception destination:

Use these properties to define what happens to any messages that cannot be delivered to this destination.

None:

The bus destination does not use an exception destination and undeliverable messages are not rerouted to an exception destination.

Attempts to redeliver the message continue, up to the maximum failed deliveries limit set for the bus destination. Then, attempts to redeliver the message continue with a time interval between retry attempts. This interval is either the Default blocked destination retry interval of the messaging engine that is associated with this destination, or the Blocked retry timeout that is set for this destination. The Default blocked destination retry interval value can be used by all queue and topic destinations associated with this messaging engine. To set a time interval specifically for this destination, select **Override messaging engine blocked retry timeout default**, then enter a blocked retry timeout value for this destination.

Required	No
Data type	Radio button
Default	Not selected

Override messaging engine blocked retry timeout default:

Override the blocked queue retry interval configured on the messaging engine owning the destination.

Select this property to set the blocked retry timeout for this destination. This property is available only when **None** is selected for the exception destination.

Required	Yes, if **None** is selected.
Data type	Boolean
Default	Unchecked. The Default blocked destination retry interval value of the associated messaging engine is used.

Blocked retry timeout in milliseconds:

When no exception destination is configured, the time interval to apply between retry attempts, after the maximum failed deliveries limit is reached, for this destination.

This property is available only when **Override messaging engine blocked retry timeout default** is selected in the exception destination properties.

Required	Yes, if Override messaging engine blocked retry timeout default is checked.
Data type	Integer

System:

The bus destination uses the system default exception destination.

Undeliverable messages are routed to the system default exception destination of the messaging engine that detects the problem: _SYSTEM.Exception.Destination.*messaging_engine_name*.

Required	No
Data type	Radio button
Default	Selected

Specify:

Select this property to configure a specific exception destination.

The exception destination must be a queue, on the same bus or a foreign bus, and must exist when the exception destination processing is configured.

Required	No
Data type	Radio button
Default	Not selected

Maximum failed deliveries per message:

The maximum number of failed attempts to process a message. After this number of failed attempts, if an exception destination is configured, the message is forwarded from the intended destination to its exception destination. If an exception destination is not configured, a time interval between retry attempts is applied.

This interval is either the Default blocked destination retry interval of the messaging engine that is associated with this destination, or the Blocked retry timeout that is set for this destination.

Required	Yes, if an exception destination has been configured.
Data type	Integer
Default	5
Range	0 through 2147483647

Send allowed:

Clear this option (setting it to false) to stop producers from being able to send messages to this destination.

Required	No
Data type	Boolean

Receive allowed:

Clear this option (setting it to false) to prevent consumers from being able to receive messages from this destination.

Required	No
Data type	Boolean

Maintain strict message order:

Enabling this option will maintain the strict ordering of messages for this destination.

Required	No
Data type	Custom

Reply destination:

The name of a destination to be appended to any non-empty reverse routing path of messages sent to this destination.

Required	No
Data type	String

Reply destination bus:

The bus on which the reply destination exists.

Required	No
Data type	String

Allow auditing of Topic access checks:

This option is only available if bus and cell level auditing are enabled. Check to enable auditing of Topic access checks.

Required	No
Data type	Boolean

Topic access check required

Whether or not authorization checks are required for access to topics.

When security is on, authorization checks are always performed at the topic space level. To add additional control, you can select this property to enable authorization checks at the topic level.

Required	No
Data type	Boolean

Message points

Publication points

A publication point is created on each messaging engine in the bus when a publish/subscribe destination is created. The publication point on a messaging engine is used to hold messages published by applications connected to that messaging engine until they are delivered to subscribers.

Mediation points

The mediation points for the topic space. The locations in the messaging engine at which messages on the topic space are mediated.

Additional Properties

Context properties

Context information passed to the mediation.

Related Items

Application resources topology
A expandable tree view of all applications and messaging resources that reference the current destination.

Audit Service
Configure the global audit settings

Topic spaces [Collection]

Topics are defined hierarchically within topic spaces. To view the access roles for a topic, first select the topic space that contains the topic to be viewed.

To view this page in the console, click the following path:

Service integration -> Buses -> *security_value* -> [Authorization Policy] Manage topic access roles.

In the path, *security_value* is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.

The Topic spaces pane displays a list of topic spaces defined on the selected bus. A topic space is a hierarchy of topics used for publish/subscribe messaging. Use this pane to select the topic space that contain the topics for which you want to add, remove or modify role type assignments.

Topic space
The name of each topic space defined for the selected bus.

Topics [Collection]

Topics are defined hierarchically within topic spaces. To view a topic's access roles, select the topic from the hierarchical list of topics below.

To view this page in the console, click the following path:

Service integration -> Buses -> *security_value* -> [Authorization Policy] Manage topic access roles

In the path, *security_value* is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.The Topics pane displays a list of topics defined for the selected topic space. The topics are displayed hierarchically beneath the root (/) topic. You can expand the topic space name to display all the topics, or collapse it to display the root topic only. By default, a topic space does not contain any topics. Use **Add** to add a new topic to the selected topic space, and to define its role type assignments.

Topic The name of each topic defined in the selected topic space.

Buttons

Add	Click to create a topic, and add users and groups to it.
Show all	Click to expand a section to display a hierarchical list of all the topics defined in the topic space, starting with the root (/) topic.
Hide all	Click to collapse a section to display the root (/) topic only.

Topics [Collection]

The topics that have been subscribed to from this remote messaging engine.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> Runtime > **[Remote message points] Remote publication points** > > ***identifier_name*** **-> [Outbound properties] Topics**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Topic View the outbound topics for this publication point.

Buttons

Clear all	Clear all messages from this message point.

Unknown user or group [Settings]

This panel lists users and groups that do not exist in the user repository but have access role definitions.

To view this page in the console, click the following path:

Service integration -> Buses -> *security_value* -> [Authorization Policy] Manage users and groups not known to the user repository -> *user_name* > **Remove roles**

The Unknown users and groups pane lists access roles for bus resources that have been assigned to selected unknown users and groups.

The access role information for each unknown user or group is contained within an expandable section.

General Properties

Resource
The selected unknown user or group has access roles for this bus resource.

Sender
Whether a user, group or member is in the sender role for a selected resource.

Receiver
Whether a user, group or member is in the receiver role for a selected resource.

Browser
Whether a user, group or member is in the browser role for a selected resource.

Creator
Whether a user, group or member is in the creator role for a selected resource.

Bus connector
Whether a user, group or member is in the bus connector role for a selected resource.

Security access roles

In the administrative console, access role icons are used to represent whether a user or a group is in a particular access role. You can click an icon to add or remove selected users and groups to a particular access role for a selected resource.

An access role icon has three states:

- Access role type set.
- Access role type not set.
- Access role type inherited from group.

The following table describes how the access role icons represent these states, and how to change between them:

Table 222. Interacting with access role icons

Access role icon	Access role assignment state	User action
	Role type not set.	Click to change to role type set  .
	Role type set.	Click to change to role type not set. The icon changes to role type not set  if the user or group does not inherit access roles, or to role type inherited  if the role type does inherit access roles.
	Role type inherited from group.	Click to change to role type set  .
	Role type not set for a group. The group to which a user belongs does not have a role type.	Read only.
	Role type set for a group. The group to which a user belongs has a role type.	Read only.
	Role type not applicable.	Read only.

Buttons

Remove	Click to remove access roles from the selected user or group.

Unknown users and groups [Collection]

The users and groups displayed here are not defined in the user registry, but do have roles defined. This could be because they were removed from the user repository after the role assignments were made.

To view this page in the console, click the following path:

Service integration -> Buses -> *security_value* -> [Authorization Policy] Manage users and groups not known to the user repository

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

In the path, *security_value* is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.

This pane displays a list of user and group names that were previously created in the user repository, and granted access roles to selected resources, but the user and group names have since been removed from the user repository. Use this pane to remove the role type assignments from one or more users and groups that no longer exist in the user repository:

- To work with a single unknown user or group name, click the user or group name.
- To work with more than one unknown user or group name, select the check box in the **Select** column for each unknown user or group name, and click **Remove roles**.

Name The name of a user that has an access role definition, but is not defined in the user registry.

Type Whether the user is a user, a group, or a group member.

Buttons

Remove roles	Click to remove access roles from the selected user or group.

Users and groups in the bus connector role [Collection]

Users in the bus connector role are able to connect to the bus to perform messaging operations. Users can have this role either by specifically having that role, or because they are in a group with that role.

To view this page in the console, click the following path:

Service integration -> Buses -> *security_value* -> [Authorization Policy] Users and groups in the bus connector role.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

In the path, *security_value* is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.

Name The name of the user or group in the bus connector role.

Type The type of the user or group in the bus connector role.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Add a user or group to the bus connector role [Settings]

Create a user or group in the bus connector role.

To view this page in the console, click the following path:

Service integration -> Buses -> *security_value* -> [Authorization Policy] Users and groups in the bus connector role -> *member_name*.

In the path, *security_value* is either **Enabled** if messaging security is enabled, or **Disabled** if messaging security is not enabled.

When messaging security is enabled, users must be authorized to connect to a local service integration bus before they can carry out messaging operations. To authorize a user or a group to connect to a local bus, you add the user or group name to the bus connector role for the bus. After the user connects to the bus, then can access local bus destinations, and send messages to destinations on foreign buses.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Bus Connector Role:

The bus connector role. Users in this role are able to connect to the bus to perform messaging operations.

Select one of the options provided to choose the bus connector role. A user in the bus connector role has the authority to connect to the local service integration bus, and can carry out messaging operations at destinations on the bus.

Required	No
Data type	Custom

Range

Group name
Give a specific group the bus connector role. All users in the group can connect to the bus, and use it to undertake messaging operations. Type the name of the group in the field provided.

User name
Give a user the bus connector role. Users with the specified user ID can connect to the bus, and use it to perform messaging operations. Type the user ID in the field provided.

Server - Allow servers to connect to the bus
Give all application servers the bus connector role. This represents the identity of a WebSphere Application Server. This can be used by message-driven beans that want message delivery, without specifying an authentication alias, in a secured bus.

All Authenticated - Allow all authenticated users to connect to the bus
Give only *authenticated* users the bus connector role. All users that have authenticated to the bus can use it to undertake messaging operations. This results in the group “AllAuthenticated” being added to the authorization model.

Everyone - Allow unauthenticated users to connect to the bus
Give all users the bus connector role. All users that have connected to the bus can use it to undertake messaging operations. If this option is selected, then users are able to connect to the bus without authenticating. These users are treated as anonymous users.

Web service [Settings]

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Destination resources] Destinations -> *web_service_name*.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Identifier:

The identifier by which this destination is known for administrative purposes.

Required No
Data type String

UUID:

The universal unique identifier assigned by the system to this destination for administrative purposes.

Required	No
Data type	String

Type:

Whether this bus destination is for a queue, topic space, or some other type of destination.

Required	No
Data type	String

Description:

An optional description for the bus destination, for administrative purposes.

Required	No
Data type	Text area

Mediation:

The name of the mediation that mediates this destination.

Required	No
Data type	String

Default reliability:

The reliability assigned to a message produced to this destination when an explicit reliability has not been set by the producer.

Required	No
Data type	drop-down list

Range

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages might be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

Maximum reliability:

The maximum reliability of messages accepted by this destination.

Required No
Data type drop-down list
Range

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages might be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

Enable producers to override default reliability:

Select this option to enable producers to override the default reliability that is set on the destination.

Required No
Data type Boolean

Default priority:

The default priority assigned to messages sent to this destination when a priority has not been set by the producer.

Required No
Data type Custom

Exception destination:

Use these properties to define what happens to any messages that cannot be delivered to this destination.

Use this property to define what happens to any messages that cannot be delivered to this destination.

By default, such messages are routed to the system default exception destination of the messaging engine that discovers the problem: _SYSTEM.Exception.Destination.*engine_name*.

If you want messages to be sent to another exception destination, select Specify then type the exception destination name. The exception destination must be a queue, on the same bus or a foreign bus, and must exist when the destination is created.

If you do not want undeliverable messages to be sent to an exception destination, select None.

Required No
Data type String and Boolean

Send allowed:

Clear this option (setting it to false) to stop producers from being able to send messages to this destination.

Required No
Data type Boolean

Receive allowed:

Clear this option (setting it to false) to prevent consumers from being able to receive messages from this destination.

Required No
Data type Boolean

Receive exclusive:

Select this option to allow only one consumer to attach to each message point. If this option is not selected multiple consumers will be allowed to attach and receive messages from each message point.

Required No
Data type Boolean

Maintain strict message order:

Enabling this option will maintain the strict ordering of messages for this destination.

Required	No
Data type	Custom

Additional Properties

Context properties
Context information passed to the mediation.

Message points

Mediation points
A mediation point is a location in a messaging engine at which messages are mediated. A mediation point is created when a mediation is associated with a bus destination.

Client connections [Collection]

The connection between a WebSphere MQ client and the bus.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional Properties] WebSphere MQ client links -> *link_name* [Additional Properties] Client connections.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

This panel lists all the connections for clients that use the related WebSphere MQ client link. You can select one or more connections to display more detail about their runtime status, or to stop them while leaving other connections active.

IP address
The TCP/IP IP address of the WebSphere MQ client.

Status
The runtime status of the WebSphere MQ client connection.

WebSphere MQ client connection [Settings]

The connection between a WebSphere MQ client and the bus.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional Properties] WebSphere MQ client links -> *link_name* [Additional Properties] Client connections -> *connection_name*.

• “Runtime tab” on page 2194

Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

IP address:

The TCP/IP IP address of the WebSphere MQ client.

Required No
Data type String

Status:

The runtime status of the WebSphere MQ client connection.

Required No
Data type drop-down list
Range

Inactive
The WebSphere MQ client link is ready and enabled to receive inbound connections from clients, but no client connections have yet been established.

Stopped
The WebSphere MQ client link is in a stopped state and cannot process any new requests for inbound connections from clients.

Starting
The WebSphere MQ client link has received an inbound connection from a client, and is in the process of starting this connection.

Binding
The WebSphere MQ client link is performing channel negotiation and is not yet ready to transfer messages.

Running
The WebSphere MQ client link has an active session with a client, and data can be flowing between the client and the WebSphere MQ client link.

Stopping
The WebSphere MQ client link, or a connection with that link, is in the process of being stopped.

Multiple
The WebSphere MQ client link has established sessions with several clients, and the sessions can be in different states: Starting, Running, Stopping, or Stopped.

Number of messages sent:

The number of messages sent on the WebSphere MQ client link over the connection to a specific client.

Required	No
Data type	String

Number of messages received:

The number of messages received on the WebSphere MQ client link over the connection from a specific client.

Required	No
Data type	String

Number of buffers sent:

The number of message buffers sent on the WebSphere MQ client link over the connection to a specific client.

Required	No
Data type	String

Number of buffers received:

The number of message buffers received on the WebSphere MQ client link over the connection from a specific client.

Required	No
Data type	String

Number of bytes sent:

The number of bytes sent on the WebSphere MQ client link over the connection to a specific client.

Required	No
Data type	String

Number of bytes received:

The number of bytes received on the WebSphere MQ client link over the connection from a specific client.

Required	No
Data type	String

Channel start time:

The time at which the client connection channel was started.

Required	No
Data type	String

Channel start date:

The date on which the client connection channel was started.

Required	No
Data type	String

Last message send time:

The time at which the last message was sent on the client connection channel.

Required	No
Data type	String

Last message send date:

The date on which the last message was sent on the client connection channel.

Required	No
Data type	String

Last message receive time:

The time at which the last message was received on the client connection channel.

Required	No
Data type	String

Last message receive date:

The date on which the last message was sent on the client connection channel.

Required	No
Data type	String

Heartbeat interval:

The time, in seconds, between heartbeat flows passed from the WebSphere MQ client link to the WebSphere MQ classes for JMS that process JMS requests issued by the client application. This allows the WebSphere MQ client link to handle situations where the client connection created by the WebSphere MQ classes for JMS fails during a request.

Required	No
Data type	String

Maximum message length:

The maximum message length, in bytes, that can be transmitted using the WebSphere MQ client link. This is compared with the value for the partner WebSphere MQ client channel and the actual maximum used is the lower of the two values.

Required	No
Data type	String

Stop requested:

Whether or not a manual stop request has been made for the WebSphere MQ client link connection.

Required No
Data type drop-down list
Range

true The channel is in doubt about which messages have been committed by WebSphere MQ for the unit of work that it has sent.

false The channel is not in doubt about which messages have been committed by WebSphere MQ.

Local address:

The local address of the WebSphere MQ client connection.

Required No
Data type String

Number of API calls serviced:

The number of API calls serviced for the WebSphere MQ client connection.

Required No
Data type String

WebSphere MQ client link advanced properties [Settings]

Advanced configurable properties, such as message reliability and broker queue names, for the WebSphere MQ client link.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional Properties] WebSphere MQ client links -> *link_name* -> [Advanced properties] > ***property_name***.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Inbound persistent message reliability:

The acceptable reliability of message delivery for inbound persistent message flows from WebSphere MQ through this WebSphere MQ client link, from Reliable to Assured, in order of increasing reliability.

Required No
Data type drop-down list
Range

Reliable
Messages might be discarded when a messaging engine fails.

Assured
Messages are not discarded.

Inbound nonpersistent message reliability:

The acceptable reliability of message delivery for inbound nonpersistent message flows from WebSphere MQ through this WebSphere MQ link, from Reliable to Assured, in order of increasing reliability.

Required No
Data type drop-down list
Range

Best effort
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable
Messages are discarded when a messaging engine stops or fails.

Broker control queue:

The name of the message broker control queue to which all command messages (except publications and requests to delete publications) are sent.

Publisher and subscriber applications, and other brokers, send all command messages (except publications and requests to delete publications) to this queue.

Required No
Data type Text

Broker publication queue:

The name of the message broker publication queue to which all publication messages for the default stream are sent.

This is the name of the broker input queue (stream queue) that receives all publication messages for the default stream. Applications can also send requests to delete publications on the default stream to this queue.

Required	No
Data type	Text

Broker subscription queue:

The name of the message broker subscription queue from which nondurable subscription messages are retrieved.

This is the broker queue from which nondurable subscription messages are retrieved. The subscriber specifies the name of the queue when it registers a subscription.

Required	No
Data type	Text

Broker durable subscription queue:

The name of the message broker durable subscription queue from which durable subscription messages are retrieved.

This is the broker queue from which durable subscription messages are retrieved. The subscriber specifies the name of the queue when it registers a durable subscription.

Required	No
Data type	Text

Broker connection consumer subscription queue:

The name of the message broker connection consumer subscription queue from which nondurable subscription messages are retrieved for a connection consumer request.

This is the name of the broker queue from which nondurable subscription messages are retrieved for a ConnectionConsumer request.

Required	No
Data type	Text

Broker connection consumer durable subscription queue:

The name of the message broker connection consumer durable subscription queue from which nondurable subscription messages are retrieved for a connection consumer request.

This is the name of the broker queue from which durable subscription messages are retrieved for a ConnectionConsumer request.

Required	No
Data type	Text

Default topic space:

The name of the default topic space for the WebSphere MQ client link.

This topic space is used for publish/subscribe messages sent to Version 5.1 JMS topics for which the JMS topic connection factory connects to the node on which this WebSphere MQ client link is configured.

Required	No
Data type	Text

WebSphere MQ client links [Collection]

A WebSphere MQ client link presents the messaging engine, and therefore the bus, as a WebSphere MQ queue manager to which WebSphere MQ clients can attach. This behavior enables WebSphere Application Server Version 5 JMS clients to use messaging resources on the bus.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional Properties] WebSphere MQ client links.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

If WebSphere MQ functionality has been disabled at any scope, an informational message indicating that WebSphere MQ has been disabled is displayed. In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

Name The name of the WebSphere MQ client link.

Description
An optional description for the WebSphere MQ client link, for administrative purposes.

MQ channel name
The name of the channel for the WebSphere MQ client link, used to flow messages between WebSphere MQ clients and the bus.

Queue manager name
The name of the WebSphere MQ queue manager on which the WebSphere MQ sender channel, that is connected to this MQ link receiver channel connection instance, is running.

Default queue manager
Whether or not this is the default queue manager for the WebSphere MQ clients.

Status
The runtime status of the WebSphere MQ client link.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.
Start	Start selected items. This button does not work if the selected WebSphere MQ client link is running on an application server on which WebSphere MQ has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

Table 223. Stop modes. The table contains information about the target states and the corresponding stop mode behavior. There are two target states such as inactive and stopped, and there are two stop modes such as quiesce and force. The two rows in the table represent the two target states, and the two columns describes the two stop mode behaviors for each of the target state.

		Stop mode	
		Quiesce	Force
Target state	Inactive	The sender channel becomes inactive either when it has finished processing its current batch, or when it reaches a heartbeat interval.	The sender channel immediately becomes inactive.
	Stopped	The sender channel becomes stopped either when it has finished processing its current batch, or when it reaches a heartbeat interval.	The sender channel immediately becomes stopped.

This button does not work if the selected WebSphere MQ client link is running on an application server on which WebSphere MQ has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

WebSphere MQ client link [Settings]

A WebSphere MQ client link presents the messaging engine, and therefore the bus, as a WebSphere MQ queue manager to which WebSphere MQ clients can attach. This behavior enables WebSphere Application Server Version 5 JMS clients to use messaging resources on the bus.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional Properties] WebSphere MQ client links -> *link_name*.

If WebSphere MQ functionality has been disabled at any scope, an informational message indicating that WebSphere MQ has been disabled is displayed. In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

- “Runtime tab”
- “Configuration tab” on page 2202

Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Status:

The runtime status of the WebSphere MQ client link.

Required No

Data type drop-down list

Range

Inactive
The WebSphere MQ client link is ready and enabled to receive inbound connections from clients, but no client connections have yet been established.

Stopped
The WebSphere MQ client link is in a stopped state and cannot process any new requests for inbound connections from clients.

Starting
The WebSphere MQ client link has received an inbound connection from a client, and is in the process of starting this connection.

Binding
The WebSphere MQ client link is performing channel negotiation and is not yet ready to transfer messages.

Running
The WebSphere MQ client link has an active session with a client, and data can be flowing between the client and the WebSphere MQ client link.

Stopping
The WebSphere MQ client link, or a connection with that link, is in the process of being stopped.

Multiple
The WebSphere MQ client link has established sessions with several clients, and the sessions can be in different states: Starting, Running, Stopping, or Stopped.

Additional Properties

Client connections
The client connections that exist on the WebSphere MQ client link.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the WebSphere MQ client link.

Required Yes
Data type String

UUID:

The universal unique identifier assigned by the system to this WebSphere MQ client link for administrative purposes.

Required	No
Data type	String

Description:

An optional description for the WebSphere MQ client link, for administrative purposes.

Required	No
Data type	Text area

MQ channel name:

The name of the channel for the WebSphere MQ client link, used to flow messages between WebSphere MQ clients and the bus.

The name of the WebSphere MQ server connection channel that this client link will use to represent itself to clients. It must exactly match the value specified by the client for a connection to be established. For Version 5 embedded messaging clients a value of "WAS.JMS.SVRCONN" must be specified. You should not define two MQ client links that share both channel name and queue manager name. However , it is possible to have client links with identical channel names if they specify different queue manager names.

.

Required	Yes
Data type	String

Queue manager name:

The name of the WebSphere MQ queue manager on which the WebSphere MQ sender channel, that is connected to this MQ link receiver channel connection instance, is running.

The WebSphere MQ client link for use by JMS applications on WebSphere Application Server Version 5.1 has the queue manager name `WAS_nodeName_jmsserver`. You should not use this name on any other WebSphere MQ client link that is assigned to a messaging engine on the same node.

Required	Yes
Data type	String

Default queue manager:

Whether or not this is the default queue manager for the WebSphere MQ clients.

If a client does not specify the name of the queue manager it is to connect to, it will be connected to an MQ client link with a matching channel name that has been marked as being the default, if one matching this criterion can be found.

Required	No
Data type	Boolean

Maximum message size:

The maximum message length, in bytes, that can be transmitted using the WebSphere MQ client link.

Required	No
Data type	Long
Range	0 through 104857600

Heartbeat interval:

The time, in seconds, to wait before checking that a client requesting an operation is still active.

This heartbeat interval allows a sending channel to verify that the receiving channel is still active just before committing a batch of messages. If the receiving channel is not active, the batch can be backed out rather than becoming indoubt, as would otherwise be the case. By backing out the batch, the messages remain available for processing so they can, for example, be redirected to another channel.

If the sending channel has had a communication from the receiving channel within the batch heartbeat interval, the receiving channel is assumed to be still active, otherwise a “heartbeat” signal is sent to the receiving channel to check.

Required	No
Data type	Integer
Range	0 through 999999 A value of 0 (zero) indicates that the heartbeat mechanism is not used.

Initial state:

Whether the WebSphere MQ client link is started or stopped when the associated messaging engine is first started. Until started, the WebSphere MQ client link is unavailable.

Required	No
Data type	drop-down list
Range	**Stopped** When the associated messaging engine is started, the WebSphere MQ client link is in a stopped state and cannot process any new requests for inbound connections from clients. **Started** When the associated messaging engine is started, the WebSphere MQ client link is ready and enabled to receive inbound connections.

Additional Properties

Advanced properties

Advanced configurable properties, such as message reliability and broker queue names, for the WebSphere MQ client link.

WebSphere MQ links [Collection]

The WebSphere MQ link connects the messaging engine as a queue manager to WebSphere MQ, providing a bridge between the bus and a WebSphere MQ network.

To view this page in the console, click one of the following paths:

- **Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> [Related Items] WebSphere MQ links**
- **Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links**

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

If WebSphere MQ functionality has been disabled at any scope, an informational message indicating that WebSphere MQ has been disabled is displayed. In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

Name The name of the WebSphere MQ link, used for administrative purposes.

Description
An optional description for the WebSphere MQ link, for administrative purposes.

Local messaging engine
The local messaging engine that this WebSphere MQ link is hosted on.

Virtual queue manager name
The virtual queue manager name by which the local bus is to be known to a WebSphere MQ network. It is generally recommended that you set the virtual queue manager name to match the name of the local bus. As WebSphere MQ queue manager names can be no longer than 48 characters, you must ensure that the length of the local bus name does not exceed 48 characters.

Status
The runtime status of the WebSphere MQ link.

Status can take the following values:

Table 224. Status definitions. The first column of the table lists the status values of WebSphere MQ link. The second column contains a brief definition of the status.

Status	Meaning
Running	The WebSphere MQ link is running.
Stopped	The WebSphere MQ link is stopped.

Current outbound messages
The current total number of messages queued on the sender channel transmitter and link transmitters for this WebSphere MQ link.

Messages sent
The total number of messages sent, since the start of the messaging engine, on the sender channel transmitter to the foreign bus.

Messages received
The total number of messages received, since the start of the messaging engine, on the link receiver connections for this WebSphere MQ link.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.
Start	Start selected items. This button does not work if the selected WebSphere MQ link is running on an application server on which WebSphere MQ has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.
Stop	Stop a selected WebSphere MQ link. You must first have selected the link to be stopped. You can choose the mode of stop action and the required state when the link has been stopped: **Stop mode:** **Force** Stop the link immediately. You should only use this mode if a quiesce action does not work. **Quiesce** Stop the link in a controlled manner. **Target state:** **Inactive** Stop the link and set its state to Inactive. If an application tries to use the link, the link is started again. **Stopped** Stop the link and set its state to Stopped. The link can only be started again by administrator action. This button does not work if the selected WebSphere MQ link is running on an application server on which WebSphere MQ has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

WebSphere MQ link MQFAP inbound channel [Settings]

A channel that can be used in combination with the TCP Channel or other channels within the confines of WebSphere MQ support to facilitate communications between a WebSphere system integration bus and a WebSphere MQ client or queue manager.

To view this page in the console, click the following path:

Servers -> Server Types -> WebSphere application servers -> *server_name* -> [Server messaging] WebSphere MQ link inbound transports -> *chain_name* -> MQFAP inbound channel.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Transport channel name:

Specifies the unique name for a given layer in a network protocol stack.

Required	Yes
Data type	String

Discrimination weight:

Specifies the discrimination weight that is used to determine the order in which the channels obtain access to the incoming connection if the transport channels are shared amongst several transport chains. The transport channel with the lowest discrimination weight has the first opportunity to accept the incoming connection.

Required	No
Data type	Integer
Range	0 through 2147483647

Additional Properties

Custom properties

Specifies additional custom properties for this runtime component. Some components use custom configuration properties that can be defined here.

WebSphere MQ link receiver channel [Collection]

The receiver channel that receives messages from the gateway WebSphere MQ queue manager. The receiver channel communicates with a WebSphere MQ sender channel on the gateway queue manager, and converts MQ format messages to service integration bus messages.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional Properties] Receiver channel.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

WebSphere MQ link receiver channel name

The name of the receiver channel for the WebSphere MQ link, used to receive messages from WebSphere MQ onto the bus.

Status

The runtime status of the receiver channel.

Buttons

Start	Start selected items. This button does not work if the selected WebSphere MQ link is running on an application server on which WebSphere MQ has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.
Stop	Stop a selected channel on this link. You must first have selected the channel to be stopped. You can choose the mode of stop action and the required state when the channel has been stopped: **Stop mode:** **Force** Stop the channel immediately. You should only use this mode if a quiesce action does not work. **Quiesce** Stop the channel in a controlled manner. **Target state:** **Inactive** Stop the channel and set its state to Inactive. If an application tries to use the link, the channel is started again. **Stopped** Stop the channel and set its state to Stopped. The channel can only be started again by administrator action. This button does not work if the selected WebSphere MQ link is running on an application server on which WebSphere MQ has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

WebSphere MQ link receiver channel [Settings]

The receiver channel that receives messages from the gateway WebSphere MQ queue manager. The receiver channel communicates with a WebSphere MQ sender channel on the gateway queue manager, and converts MQ format messages to service integration bus messages.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional Properties] Receiver channel -> *channel_name*.

- “Configuration tab” on page 2209
- “Runtime tab” on page 2210

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

WebSphere MQ link receiver channel name:

The name of the receiver channel for the WebSphere MQ link, used to receive messages from WebSphere MQ onto the bus.

This name must be the same as the name of the sender channel on WebSphere MQ.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Required No
Data type String

Inbound nonpersistent message reliability:

The acceptable reliability of message delivery for nonpersistent message flows from WebSphere MQ through this WebSphere MQ link, from Best effort to Reliable, in order of increasing reliability.

This reliability delivery option is assigned to all WebSphere MQ nonpersistent messages flowing over this receiver channel.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Required No
Data type drop-down list
Range

Best effort
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable
Messages are discarded when a messaging engine stops or fails.

Inbound persistent message reliability:

The acceptable reliability of message delivery for inbound persistent message flows from WebSphere MQ through this WebSphere MQ link, from Reliable to Assured, in order of increasing reliability.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Required No
Data type drop-down list
Range

Reliable
Messages might be discarded when a messaging engine fails.

Assured
Messages are not discarded.

Prefer queue points local to this link's messaging engine:

When this check box is selected, the link prefers to send inbound messages to available queue points of target destinations that are located on the messaging engine on which the link is hosted.

When this check box is not selected, or if no local queue point is available for a target destination, the link workload balances the messages across all available queue points of the target destination. By default the check box is selected.

This option is supported on links running on WebSphere Application Server Version 7.0 or later. If you are running on an earlier version, the default behavior of preferring local queue points is applied.

Required Yes
Data type Boolean

Initial state:

Whether the receiver channel is started or stopped when the associated WebSphere MQ link is first started. Until started, the channel is unavailable.

Dynamic updates to this property are effective on messaging engine restart or receiver channel creation. Use the Runtime tab to check the current state.

Required No
Data type drop-down list
Range

Stopped
When the associated messaging engine is started, the WebSphere MQ link is in a stopped state and cannot communicate with the WebSphere MQ network.

Started
When the associated messaging engine is started, the WebSphere MQ link is started automatically and is enabled for communication with the WebSphere MQ network.

Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime

property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Status:

The runtime status of the receiver channel.

This shows the overall status for all receiver channels for the link.

Required No

Data type drop-down list

Range

Inactive
The WebSphere MQ link is ready and enabled to create connections, but no connections have yet been established.

Stopped
The WebSphere MQ link is in a stopped state and cannot process any new requests for connections.

Multiple
The WebSphere MQ link has established several sessions with WebSphere MQ, and the sessions can be in different states: Starting, Running, Stopping, or Stopped.

Additional Properties

Receiver channel connections
The connections that exist on the receiver channel of the WebSphere MQ link.

Saved batch status
The runtime status of message batches for the receiver channel of the WebSphere MQ link.

WebSphere MQ link routing properties [Settings]

The routing properties for a link to a foreign bus that represents a WebSphere MQ network.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Foreign bus connections -> *foreign_bus_name* -> *link_name*.

You must create one of these routing definitions before you can create a WebSphere MQ link.

For information about setting up communication with WebSphere MQ, see the *Intercommunication* section of the WebSphere MQ information center.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name by which the routing definition is known.

Required	No
Data type	String

UUID:

The universal unique identifier assigned by the system to the routing definition (virtual link) for administrative purposes.

Required	No
Data type	String

Inbound user ID:

The user ID applied to messages arriving from the foreign bus and used to authorize their access to destinations.

If you to want to authenticate messages entering this bus, this user ID replaces the user ID in the inbound messages. You can specify an inbound user ID if this bus is to assign its own user IDs for all messages received from the foreign bus. If you do not authenticate inbound messages, all messages can enter this bus.

Dynamic updates to this property are effective immediately.

Required	No
Data type	String

Outbound user ID:

The user ID applied to messages sent to the foreign bus.

The definitive check for access to the destination on the foreign bus takes place when the message enters the foreign bus. The check is against the permissions defined on the foreign bus by its administrator. The check is based on the user ID that is stored in the message. That user ID starts off as the user ID of the sender, but this bus might want to assign the same outbound user ID for all messages sent to the foreign bus.

Dynamic updates to this property are effective immediately.

Required	No
Data type	String

WebSphere MQ link sender channel [Collection]

This pane displays the sender channel that sends messages to the gateway queue manager. The sender channel communicates with a WebSphere MQ receiver channel on the gateway queue manager, and converts service integration bus messages to MQ format messages.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional Properties] Sender channel.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

WebSphere MQ link sender channel name
The name of the sender channel for the WebSphere MQ link, used to send messages from the bus to WebSphere MQ.

Host name
The hostname or TCP/IP IP address for the gateway queue manager that is used to connect into the WebSphere MQ network.

Port The TCP/IP port number on which the gateway queue manager is listening for the WebSphere MQ link.

Status
The runtime status of the sender channel.

Buttons

Reset	Reset a selected channel sequence number to 1. If the channel is running, the reset request will take effect only when the channel has been stopped and restarted. This button does not work if the selected WebSphere MQ link is running on an application server on which WebSphere MQ has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.
Start	Start selected items. This button does not work if the selected WebSphere MQ link is running on an application server on which WebSphere MQ has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

Stop	Stop a selected channel on this link. You must first have selected the channel to be stopped. You can choose the mode of stop action and the required state when the channel has been stopped: **Stop mode:** **Force** Stop the channel immediately. You should only use this mode if a quiesce action does not work. **Quiesce** Stop the channel in a controlled manner. **Target state:** **Inactive** Stop the channel and set its state to Inactive. If an application tries to use the link, the channel is started again. **Stopped** Stop the channel and set its state to Stopped. The channel can only be started again by administrator action. This button does not work if the selected WebSphere MQ link is running on an application server on which WebSphere MQ has been disabled. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

WebSphere MQ link sender channel [Settings]

This pane displays the sender channel that sends messages to the gateway queue manager. The sender channel communicates with a WebSphere MQ receiver channel on the gateway queue manager, and converts service integration bus messages to MQ format messages.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional Properties] Sender channel -> *channel_name*.

- “Configuration tab”
- “Runtime tab” on page 2219

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

WebSphere MQ link sender channel name:

The name of the sender channel for the WebSphere MQ link, used to send messages from the bus to WebSphere MQ.

This name must be the same as the name of the receiver channel on WebSphere MQ.

For information about choosing channel names, see the description of the Channel name (CHANNEL) property in the *Intercommunication* section of the WebSphere MQ information center.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

If the previous channel is unknown, restart is delayed until the uncertainty is resolved.

Required	No
Data type	String

Single Connection:

Use Single connection for the gateway queue manager that is used to connect into the WebSphere MQ network.

Select Single Connection to specify the host name and port for one target queue manager. If you have a high availability configuration, with one or more failover gateway queue managers available in the WebSphere MQ network in addition to the target queue manager, select **Multiple Connection Names List** instead.

If you do not specify any host names, either as a single connection or in a list of multiple connections, the gateway queue manager is assumed to be running on the same host as the messaging engine on which the WebSphere MQ link is defined.

Required	No
Data type	Radio button

Host name:

The hostname or TCP/IP IP address for the gateway queue manager that is used to connect into the WebSphere MQ network.

This is the host name or IP address of the target queue manager in the WebSphere MQ network.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Required	No
Data type	String

Port:

The TCP/IP port number on which the gateway queue manager is listening for the WebSphere MQ link.

This is the port number on which the gateway queue manager is listening for the inbound communication requests.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Required	No

Data type	Integer
Range	0 through 65535
Default	1414

Multiple Connection Names List:

Select Multiple Connection Names List if you have one or more failover gateway queue managers available in the WebSphere MQ network in addition to the target queue manager. If no failover gateway queue manager is available, you can select Single Connection instead.

If you do not specify any host names, either as a single connection or in a list of multiple connections, the gateway queue manager is assumed to be running on the same host as the messaging engine on which the WebSphere MQ link is defined.

Required	No
Data type	Radio button

Connection Names List:

List of hostnames or TCP/IP IP address for the gateway queue manager that is used to connect into the WebSphere MQ network.

Specify a list of host names, or IP addresses, and ports for the active and standby WebSphere MQ queue managers in a high availability configuration. You may also use this field to specify a single host name and port.

Specify the host names, or IP addresses, and ports in the format `hostname1(nnnn),hostname2(nnnn)` separating each pair with a comma. Specify IP addresses in IPv4 format.

If you specify a port alone as an entry in the list, WebSphere Application Server uses the default host name `localhost` with the port. If you specify a host name alone as an entry in the list, WebSphere Application Server uses the default port number 1414 with the host name. For example, a connection names list consisting of the values `(1422),example.com` is interpreted as `localhost(1422),example.com(1414)`.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Required	No
Data type	Custom

Transport chain:

The type of channel chain used for communication with the foreign bus.

This must be one of the outbound transport chains in the application server, to be used when establishing a network connection to a WebSphere MQ queue manager receiver channel.

By default, this property can take one of the following values:

OutboundBasicMQLink
Used to establish connections with WebSphere MQ queue manager receiver channels.

OutboundSecureMQLink
Used to establish connections with WebSphere MQ queue manager receiver channels that have

been secured by using SSL. The SSL configuration used is taken from the default SSL repertoire for the application server being used to contact the queue manager.

You can also choose to specify another outbound transport chain that you have defined separately on the TransportChannelService object of the application server used for WebSphere MQ interoperation.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Modified transport chains are visible only after a server restart.

Required	Yes
Data type	Custom

Disconnect interval:

The time in seconds for which the sender channel waits for new messages to arrive on the transmission queue after sending a batch of messages. The channel disconnects after this interval, and must be restarted manually or by triggering.

The default value is a reasonable interval. Change this value only if you understand the implications for performance, and you need a different value for the requirements of the traffic flowing down your channels.

Performance is affected by the value specified for the disconnect interval. A very low value (a few seconds) can cause an unacceptable amount of processing in constantly starting up the channel. A very large value (more than an hour) might mean that system resources are unnecessarily held up.

If you want your channels to be active only when there are messages for them to transmit, you should set the disconnect interval to a fairly low value. Note that the default setting is quite high and so is not recommended for channels where this level of control is required. Because it is difficult to interrupt the receiving channel, the most economical option is to have the channel automatically disconnect and reconnect as the workload demands. For most channels, the appropriate setting of the disconnect interval can be established heuristically.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Required	No
Data type	Integer
Range	0 through 999999 A value of 0 (zero) means never disconnect; the channel waits indefinitely for messages.

Short retry count:

The maximum number of times that the sender channel tries to restart after a communication or partner failure. If the connection name list is provided, during each retry the connections are tried in the order in which they are specified in the connection list until a connection is successfully established. If the count of remaining retries reaches zero, and the channel has not restarted, then the long retry mechanism is invoked.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Required	No
Data type	Integer
Range	0 through 999999999

Short retry interval:

The number of seconds between attempts by the sender channel to restart after a communication or partner failure.

For more information about using retry mechanisms with WebSphere MQ, see the *Intercommunication* section of the WebSphere MQ information center.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Required	No
Data type	Integer
Range	0 through 999999999

Long retry count:

The maximum number of times that the sender channel tries to restart after the short retry mechanism did not recover from a communication or partner failure. If the connection name list is provided, during each retry the connections are tried in the order in which they are specified in the connection list until a connection is successfully established. If the count of remaining retries reaches zero, and the channel has not restarted, then an error is logged and the channel is stopped.

For more information about about using retry mechanisms with WebSphere MQ, see the *Intercommunication* section of the WebSphere MQ information center.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Required	No
Data type	Long
Range	0 through 999999999

Long retry interval:

The number of seconds between attempts by the sender channel to restart after the short retry mechanism did not recover from a communication or partner failure.

For more information about using retry mechanisms with WebSphere MQ, see the *Intercommunication* section of the WebSphere MQ information center.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Required	No

Data type Long
Range 0 through 999999999

Initial state:

Whether the sender channel is started or stopped when the associated WebSphere MQ link is first started. Until started, the channel is unavailable.

Dynamic updates to this property are effective on messaging engine restart or sender channel creation. Use the Runtime tab to check the current state.

Required No
Data type drop-down list
Range

Stopped
When the associated messaging engine is started, the WebSphere MQ link is in a stopped state and cannot communicate with the WebSphere MQ network.

Started
When the associated messaging engine is started, the WebSphere MQ link is started automatically and is enabled for communication with the WebSphere MQ network.

Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

WebSphere MQ link sender channel name:

The name of the sender channel for the WebSphere MQ link, used to send messages from the bus to WebSphere MQ.

For more information, see the description of this property for the Configuration tab.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

If the previous channel is unknown, restart is delayed until the uncertainty is resolved.

Virtual queue manager name:

The virtual queue manager name by which the local bus is to be known to a WebSphere MQ network. It is generally recommended that you set the virtual queue manager name to match the name of the local bus. As WebSphere MQ queue manager names can be no longer than 48 characters, you must ensure that the length of the local bus name does not exceed 48 characters.

The bus appears to WebSphere MQ as if it is a WebSphere MQ queue manager or queue-sharing group. This field gives the queue manager name that WebSphere MQ uses to address the virtual queue manager represented by this bus.

Required	No
Data type	String

I/P address:

The TCP/IP IP address of the host on which the target queue manager runs.

Required	No
Data type	String

Status:

The runtime status of the sender channel.

Required	No
Data type	drop-down list

Range

Inactive
The WebSphere MQ link is ready and enabled to create connections, but no connections have yet been established.

Starting
The WebSphere MQ link has received a connection request, and is in the process of starting this connection.

Binding
The WebSphere MQ link is performing channel negotiation and is not yet ready to transfer messages.

Initializing
The WebSphere MQ link is initializing the session for a connection and is not yet ready to transfer messages.

Retrying
The WebSphere MQ link is retrying a failed connection.

Standby
The channel is being used for standby purposes. Messages can be transferred only when the channel is active.

Running
The WebSphere MQ link has an active session with WebSphere MQ, and data can be flowing between WebSphere MQ and the WebSphere MQ link.

Stopping
The WebSphere MQ link, or a connection with that link, is in the process of being stopped.

Paused
The channel is waiting for the message-retry interval to finish.

Stopped
The WebSphere MQ link is in a stopped state and cannot process any new requests for connections.

Multiple
The WebSphere MQ link has established several sessions with WebSphere MQ, and the sessions can be in different states: Starting, Running, Stopping, or Stopped.

Host name:

The hostname or TCP/IP IP address for the gateway queue manager that is used to connect into the WebSphere MQ network.

For more information, see the description of this property for the Configuration tab.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Port:

The TCP/IP port number on which the gateway queue manager is listening for the WebSphere MQ link.

For more information, see the description of this property for the Configuration tab.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Transport chain:

The type of channel chain used for communication with the foreign bus.

This must be one of the outbound transport chains in the application server, to be used when establishing a network connection to a WebSphere MQ queue manager receiver channel. For more information, see the description of this property for the Configuration tab.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Modified transport chains are visible only after a server restart.

Disconnect interval:

The time in seconds for which the sender channel waits for new messages to arrive on the transmission queue after sending a batch of messages. The channel disconnects after this interval, and must be restarted manually or by triggering.

For more information, see the description of this property for the Configuration tab.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Short retry count:

The maximum number of times that the sender channel tries to restart after a communication or partner failure. If the connection name list is provided, during each retry the connections are tried in the order in which they are specified in the connection list until a connection is successfully established. If the count of remaining retries reaches zero, and the channel has not restarted, then the long retry mechanism is invoked.

For more information, see the description of this property for the Configuration tab.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Short retry interval:

The number of seconds between attempts by the sender channel to restart after a communication or partner failure.

For more information, see the description of this property for the Configuration tab.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Long retry count:

The maximum number of times that the sender channel tries to restart after the short retry mechanism did not recover from a communication or partner failure. If the connection name list is provided, during each retry the connections are tried in the order in which they are specified in the connection list until a connection is successfully established. If the count of remaining retries reaches zero, and the channel has not restarted, then an error is logged and the channel is stopped.

For more information, see the description of this property for the Configuration tab.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Long retry interval:

The number of seconds between attempts by the sender channel to restart after the short retry mechanism did not recover from a communication or partner failure.

For more information, see the description of this property for the Configuration tab.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Batch size:

The maximum number of messages that a batch can contain.

Required	No
Data type	String

Channel start time:

The time at which the channel was last started.

Required	No
Data type	String

Channel start date:

The date on which the channel was last started.

Required	No
Data type	String

Heartbeat interval:

The negotiated time, in seconds, between heartbeat flows passed from the WebSphere MQ link sender channel to the WebSphere MQ receiver channel when there are no messages on the transmission queue.

Required	No
Data type	Integer

Sequence wrap:

The value at which message sequence numbers wrap to start again at 1.

This is the highest number the message sequence number reaches before it restarts at 1. The default value is 999999999.

For more information about choosing the value for this property, see the description of the Sequence Number wrap (SEQWRAP) property in the *Intercommunication* section of the WebSphere MQ information center.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Required No
Data type Long
Range 100 through 999999999

Maximum message length:

The negotiated maximum message length, in bytes, that can be transmitted on the channel. This value is compared with the value from the partner WebSphere MQ receiver channel, and the maximum message length used is the lower of the two values.

Required No
Data type Integer

Stop requested:

Whether or not a manual stop request has been made for the sender channel.

To make a stop request, use the buttons provided on the WebSphere MQ link sender channel collection panel.

Required No
Data type drop-down list
Range

true The channel is in doubt about which messages have been committed by WebSphere MQ for the unit of work that it has sent.

false The channel is not in doubt about which messages have been committed by WebSphere MQ.

Current LUWID:

The current logical unit-of-work identifier for the message on the channel.

Indoubt channel problems are usually resolved automatically. Sequence number and logical unit of work ID (LUWID) records are kept to help resolve indoubt channel problems when communication has been re-established. For information resolving indoubt channels, see the *Intercommunication* section of the WebSphere MQ information center.

Required No
Data type String

Current sequence number:

The current sequence number for the message on the channel.

Indoubt channel problems are usually resolved automatically. Sequence number and logical unit of work ID (LUWID) records are kept to help resolve indoubt channel problems when communication has been re-established. For information resolving indoubt channels, see the *Intercommunication* section of the WebSphere MQ information center.

Required No
Data type String

In doubt:

Whether the message on the channel is in an indoubt state.

Problems with a channel that is in an indoubt state are usually resolved automatically. Sequence number and logical unit of work ID (LUWID) records are kept to help resolve problems with an indoubt channel when communication has been re-established. For information about resolving indoubt channels, see the *Intercommunication* section of the WebSphere MQ information center.

Required No
Data type drop-down list
Range

true The channel is in doubt about which messages have been committed by WebSphere MQ for the unit of work that it has sent.

false The channel is not in doubt about which messages have been committed by WebSphere MQ.

Last LUWID:

The last logical unit-of-work identifier for a message on the channel.

To determine the last-committed logical unit of work ID (LUWID) for the channel, compare this value to the last-committed LUWID for the receiving side of the channel.

- If the two LUWIDs are the same, the receiving side has committed the unit of work that the sender considers to be in doubt. The sending side can now remove the indoubt messages from the transmission queue and re-enable it.
- If the two LUWIDs are different, the receiving side has not committed the unit of work that the sender considers to be in doubt. The sending side needs to retain the indoubt messages on the transmission queue and re-send them.

Required No
Data type String

Last sequence number:

The last sequence number for a message on the channel.

WebSphere MQ channels cannot initialize successfully if the channel negotiation detects that the message sequence number is different at each end. You might have to reset this manually.

To be effective, the sequence number must be reset in both the sender and the receiver channel definitions. The starting sequence number is not negotiated when a channel starts up, nor is there a default provided.

Required	No
Data type	String

Messages in current batch:

The number of messages in the current batch on the channel.

Required	No
Data type	String

Number of batches sent:

The number of batches that have been sent on the channel.

Required	No
Data type	String

Number of messages sent:

The number of messages that have been sent on the channel.

Required	No
Data type	String

Buffers sent:

The number of message buffers sent.

Required	No
Data type	String

Buffers received:

The number of message buffers received.

Required	No
Data type	String

Bytes sent:

The number of bytes sent.

Required	No
Data type	String

Bytes received:

The number of bytes received.

Required No
Data type String

Last message send time:

The time at which the last message was sent on the channel.

Required No
Data type String

Last message send date:

The date on which the last message was sent on the channel.

Required No
Data type String

Remaining short retry starts:

The remaining number of short retry attempts that can be used to start the sender channel. If the count of remaining retries reaches zero, and the channel has not restarted, then the long retry mechanism is invoked.

Required No
Data type String

Remaining long retry starts:

The remaining number of long retry attempts that can be used to start the sender channel. If the count of remaining retries reaches zero, and the channel has not restarted, then an error is logged and the channel is stopped.

Required No
Data type String

Nonpersistent message speed:

The class of service for nonpersistent messages on the sender channel.

Required No
Data type drop-down list
Range

Fast Nonpersistent messages can be lost if there is a transmission failure or if the channel stops when the messages are in transit.

Normal Nonpersistent messages are not lost if there is a transmission failure or if the channel stops when the messages are in transit.

Additional Properties

Saved batch status

The runtime status of message batches for the sender channel of the WebSphere MQ link. You can choose to commit or roll back each batch.

WebSphere MQ link [Settings]

The WebSphere MQ link connects the messaging engine as a queue manager to WebSphere MQ, providing a bridge between the bus and a WebSphere MQ network.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name*

For more information about choosing settings, see the *Intercommunication* section of the WebSphere MQ information center.

If WebSphere MQ functionality has been disabled at any scope, an informational message indicating that WebSphere MQ has been disabled is displayed. In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

- “Configuration tab”
- “Runtime tab” on page 2233

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The name of the WebSphere MQ link, used for administrative purposes.

Required	Yes
Data type	String

UUID:

The universal unique identifier assigned by the system to this WebSphere MQ link for administrative purposes.

Required	No
Data type	String

Description:

An optional description for the WebSphere MQ link, for administrative purposes.

Dynamic updates to this property are effective immediately.

Required No
Data type Text area

Foreign bus connection name:

The foreign bus to which this link connects.

If you do not see the foreign bus connection name that you expected to see, you must create a new foreign bus connection.

Required Yes
Data type drop-down list

Local messaging engine:

The local messaging engine that this WebSphere MQ link is hosted on.

Required Yes
Data type drop-down list

Virtual queue manager name:

The virtual queue manager name by which the local bus is to be known to a WebSphere MQ network. It is generally recommended that you set the virtual queue manager name to match the name of the local bus. As WebSphere MQ queue manager names can be no longer than 48 characters, you must ensure that the length of the local bus name does not exceed 48 characters.

The bus appears to WebSphere MQ as if it is a WebSphere MQ queue manager or queue-sharing group. This field gives the queue manager name that WebSphere MQ uses to address the virtual queue manager represented by this bus. Any value that you specify must meet the following criteria:

- It must contain between 1 and 48 characters.
- It must conform to the WebSphere MQ queue naming rules (see the *Rules for naming WebSphere MQ objects* topic in the WebSphere MQ information center).

Required Yes
Data type String

Batch size:

The maximum number of messages that can be sent through a channel before taking a checkpoint.

The batch size does not affect the way the sender and receiver channels for this link transfer messages; messages are always transferred individually, but are committed or backed out as a batch.

For information about choosing the batch size, see the description of the Batch size (BATCHSZ) property in the *Intercommunication* section of the WebSphere MQ information center.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Required No
Data type Integer

Range 1 through 9999

Maximum message size:

The maximum message length, in bytes, that can be transmitted on any channel for the WebSphere MQ link. This is compared with the value for the corresponding partner WebSphere MQ channel and the actual maximum used is the lower of the two values.

For more information about choosing a value for the maximum message size, see the description of the Maximum message length (**MAXMSGL**) property in the *Intercommunication* section of the WebSphere MQ information center.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Required No
Data type Integer
Range 0 through 104857600

Heartbeat interval:

The negotiated time, in seconds, between heartbeat flows passed from the WebSphere MQ link sender channel to the WebSphere MQ receiver channel when there are no messages on the transmission point being served by the WebSphere MQ link sender channel.

Heartbeats give the receiving channel the opportunity to quiesce the channel connection.

For more information about choosing a value for this property, see the *Intercommunication* section of the WebSphere MQ information center.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Required No
Data type Integer
Range 0 through 999999

Sequence wrap:

The value at which message sequence numbers wrap to start again at 1.

For more information about choosing a value for this property, see the description of the Sequence Numberwrap (**SEQWRAP**) property in the *Intercommunication* section of the WebSphere MQ information center.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Required No

Data type	Long
Range	100 through 999999999

Adoptable:

Whether or not a running instance of a WebSphere MQ link receiver channel (associated with this MQ link) should be adopted or not. In the event of a communications failure, it is possible for a running instance of a WebSphere MQ link receiver channel to be left waiting for messages. When communication is re-established, and the partner WebSphere MQ sender channel next attempts to establish a session with the WebSphere MQ link receiver channel, the request will fail as there is already a running instance of the WebSphere MQ link receiver channel that believes it is in session with the partner WebSphere MQ sender channel. You can overcome this problem by selecting this option, which causes the already running instance of the WebSphere MQ link receiver channel to be stopped and a new instance to be started.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Required	No
Data type	Boolean

Exception destination:

The destination for an inbound message when the WebSphere MQ link cannot deliver the message to its target bus destination, or to the exception destination that is configured for that target destination, or when the target destination does not exist.

Select a radio button as required to configure the exception destination that this WebSphere MQ link uses:

- Select **None** to specify that the WebSphere MQ link does not use an exception destination. Undeliverable messages are not rerouted to an exception destination and can block the processing of other messages waiting for delivery through that link to the same bus. This option can be used to preserve message ordering.
- Select **System** to use the default exception destination. Messages that cannot be delivered to the bus destination are rerouted to the system default exception destination for the messaging engine that this link is assigned to: _SYSTEM.Exception.Destination*messaging_engine_name*.
- Select **Specify** and enter an exception destination to use the exception destination specified here. If the WebSphere MQ link cannot use this exception destination, it uses the system exception destination.

Required	No
Data type	Custom
Default	System

Initial state:

Whether the WebSphere MQ link is started or stopped when the hosting messaging engine is first started. Until it is started, the WebSphere MQ link is unavailable.

Dynamic updates to this property are effective when the messaging engine restarts. Use the Runtime tab to check the current state.

Required	No
Data type	drop-down list

Range

Stopped
When the associated messaging engine is started, the WebSphere MQ link is in a stopped state and cannot communicate with the WebSphere MQ network.

Started
When the associated messaging engine is started, the WebSphere MQ link is started automatically and is enabled for communication with the WebSphere MQ network.

Nonpersistent message speed:

The class of service for nonpersistent messages on channels of this WebSphere MQ link.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Required No
Data type drop-down list
Range

Fast Nonpersistent messages can be lost if there is a transmission failure or if the channel stops when the messages are in transit.

Normal
Nonpersistent messages are not lost if there is a transmission failure or if the channel stops when the messages are in transit.

Additional Properties

Publish/subscribe broker profiles
Profiles used to define the topic mappings and transactionality for publishing and receiving (by subscription) topics across the publish/subscribe bridge between WebSphere Application Server and a WebSphere MQ network.

Receiver channel
The receiver channel that receives messages from the gateway queue manager. The receiver channel communicates with a WebSphere MQ sender channel on the gateway queue manager, and converts MQ format messages to service integration bus messages.

Sender channel
The sender channel that sends messages to the gateway queue manager. The sender channel communicates with a WebSphere MQ receiver channel on the gateway queue manager, and converts service integration bus messages to MQ format messages.

Sender channel transmitters
The sender channel transmitters for the queueing of messages across the WebSphere MQ link.

Related Items

Foreign bus connection
The associated foreign bus for this WebSphere MQ link.

Link transmitters

For applications that use point-to-point messaging, there is one link transmission message point located on each messaging engine in the source bus. For applications that use publish/subscribe messaging, there is one link transmission message point located on each topic space in the source bus. The link transmitter acts as a transmission queue where produced messages are persisted before transmission across the inter-bus link to the foreign bus.

Runtime tab

The Runtime tab shows runtime properties for this object. These properties directly affect the current runtime environment, but are not preserved when that environment is stopped. To preserve runtime property values, change the equivalent property values on the Configuration tab. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Status:

The runtime status of the WebSphere MQ link.

Required	No
Data type	drop-down list

Range

Inactive
The WebSphere MQ link is ready and enabled to create connections, but no connections have yet been established.

Starting
The WebSphere MQ link has received a connection request, and is in the process of starting this connection.

Binding
The WebSphere MQ link is performing channel negotiation and is not yet ready to transfer messages.

Initializing
The WebSphere MQ link is initializing the session for a connection and is not yet ready to transfer messages.

Retrying
The WebSphere MQ link is retrying a failed connection.

Standby
The channel is being used for standby purposes. Messages can be transferred only when the channel is active.

Running
The WebSphere MQ link has an active session with WebSphere MQ, and data can be flowing between WebSphere MQ and the WebSphere MQ link.

Stopping
The WebSphere MQ link, or a connection with that link, is in the process of being stopped.

Paused
The channel is waiting for the message-retry interval to finish.

Stopped
The WebSphere MQ link is in a stopped state and cannot process any new requests for connections.

Multiple
The WebSphere MQ link has established several sessions with WebSphere MQ, and the sessions can be in different states: Starting, Running, Stopping, or Stopped.

Additional Properties

Sender channel transmitters
The sender channel transmitters for the queueing of messages across the WebSphere MQ link.

Related Items

Link transmitters
For applications that use point-to-point messaging, there is one link transmission message point

located on each messaging engine in the source bus. For applications that use publish/subscribe messaging, there is one link transmission message point located on each topic space in the source bus. The link transmitter acts as a transmission queue where produced messages are persisted before transmission across the inter-bus link to the foreign bus.

Mediation execution points [Collection]

Mediation execution points for the processing of messages from mediation message points that are on a WebSphere MQ server.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Remote message points] WebSphere MQ Mediation Execution points.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Identifier
The system-generated name by which this message point is known.

Status
The runtime status of the mediation point.

Buttons

Start	Start selected items.
Stop	Stop selected items.

Mediation points [Collection]

Bus member (server or cluster) where the mediations for the destination run.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> Runtime > **[Message points] WebSphere MQ Mediation Execution points**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Buttons

Start	Start selected items.
Stop	Stop selected items.

Mediation points [Settings]

Bus member (server or cluster) where the mediations for the destination run.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Remote message points] WebSphere MQ Mediation Execution points -> *mediation_name* .

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages might be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

Include an RFH2 message header when sending messages to WebSphere MQ :

If selected, messages sent to WebSphere MQ will include an RFH2 header. The RFH2 header stores additional information to that which is stored in the WebSphere MQ message header.

Required	No
Data type	Boolean
Data type	Boolean

WebSphere MQ queue points [Collection]

A WebSphere MQ queue point is used when sending messages to and receiving messages from a WebSphere MQ queue.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> Runtime > **[Message points] WebSphere MQ Queue points**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

Identifier
The system-generated name by which this message point is known.

WebSphere MQ queue points [Settings]

A WebSphere MQ queue point is used when sending messages to and receiving messages from a WebSphere MQ queue.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> Runtime > **[Message points] WebSphere MQ Queue points -> *queue_point_name***.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Identifier:

The system-generated name by which this message point is known.

Required	No
Data type	String

UUID:

The universal unique identifier assigned by the system to this message point for administrative purposes.

Required	No
Data type	String

Target UUID:

The UUID of the bus destination for which this is a message point.

Required	No
Data type	String

WebSphere MQ queue name :

The WebSphere MQ queue name as defined in WebSphere MQ.

Required	Yes
Data type	String

Inbound nonpersistent reliability :

The level of reliability to apply when a nonpersistent WebSphere MQ message is received.

The messages in a WebSphere MQ network have their own quality of service level. This is either persistent or non-persistent. When these messages are received by a service integration application, they are assigned a service integration quality of service level that depends on their WebSphere MQ quality of service level.

For nonpersistent WebSphere MQ messages received, you will probably choose one of the nonpersistent service integration qualities of service, that is reliable nonpersistent, best effort nonpersistent or express nonpersistent. However, you can choose any of the five possible service integration qualities of service:

Best effort nonpersistent

Express nonpersistent

Reliable nonpersistent

Reliable persistent

Assured persistent

For more information, see ../ae/rjc0014_.dita.

Required No

Data type drop-down list

Range

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages might be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

Inbound persistent reliability :

The level of reliability to apply when a persistent WebSphere MQ message is received.

The messages in a WebSphere MQ network have their own quality of service level. This is either persistent or non-persistent. When these messages are received by a service integration application, they are assigned a service integration quality of service level that depends on their WebSphere MQ quality of service level.

For persistent WebSphere MQ messages received, you will probably choose one of the persistent service integration qualities of service, that is either assured persistent or reliable persistent. However, you can choose any of the five possible service integration qualities of service:

Best effort nonpersistent

Express nonpersistent

Reliable nonpersistent

Reliable persistent

Assured persistent

For more information, see ../ae/rjc0014_.dita.

Required No
Data type drop-down list
Range

Best effort nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express nonpersistent
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable nonpersistent
Messages are discarded when a messaging engine stops or fails.

Reliable persistent
Messages might be discarded when a messaging engine fails.

Assured persistent
Messages are not discarded.

Include an RFH2 message header when sending messages to WebSphere MQ :

If selected, messages sent to WebSphere MQ will include an RFH2 header. The RFH2 header stores additional information to that which is stored in the WebSphere MQ message header.

Required No
Data type Boolean

WebSphere MQ link receiver channel connections [Collection]

A connection that exists on the receiver channel of the WebSphere MQ link.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional Properties] Receiver channel -> *channel_name* -> Runtime > **Receiver channel connections**.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

WebSphere MQ Queue Manager name
The name of the WebSphere MQ queue manager on which the WebSphere MQ sender channel, that is connected to this MQ link receiver channel connection instance, is running.

IP address
The IP address of the queue manager for the WebSphere MQ link receiver channel connection.

Status
The runtime status of the WebSphere MQ link receiver channel connection.

WebSphere MQ link receiver channel connections [Settings]

A connection that exists on the receiver channel of the WebSphere MQ link.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Messaging engines -> *engine_name* -> [Additional properties] WebSphere MQ links -> *link_name* -> [Additional Properties] Receiver channel -> *channel_name* -> Runtime > **Receiver channel connections -> *channel_connection_name***.

Runtime tab

The Runtime tab shows runtime properties and current runtime state for this MQ link receiver channel connection. These properties are not preserved when the current runtime environment is stopped.

General Properties

WebSphere MQ link receiver channel name:

The name of the receiver channel for the WebSphere MQ link, used to receive messages from WebSphere MQ onto the bus.

This name must be the same as the name of the sender channel on WebSphere MQ.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Required	No
Data type	String

WebSphere MQ Queue Manager name:

The name of the WebSphere MQ queue manager on which the WebSphere MQ sender channel, that is connected to this MQ link receiver channel connection instance, is running.

Required	No
Data type	String

IP address:

The IP address of the queue manager for the WebSphere MQ link receiver channel connection.

Required	No
Data type	String

Status:

The runtime status of the WebSphere MQ link receiver channel connection.

Required No
Data type drop-down list
Range

Inactive
The WebSphere MQ link is ready and enabled to create connections, but no connections have yet been established.

Starting
The WebSphere MQ link has received a connection request, and is in the process of starting this connection.

Binding
The WebSphere MQ link is performing channel negotiation and is not yet ready to transfer messages.

Initializing
The WebSphere MQ link is initializing the session for a connection and is not yet ready to transfer messages.

Retrying
The WebSphere MQ link is retrying a failed connection.

Standby
The channel is being used for standby purposes. Messages can be transferred only when the channel is active.

Running
The WebSphere MQ link has an active session with WebSphere MQ, and data can be flowing between WebSphere MQ and the WebSphere MQ link.

Stopping
The WebSphere MQ link, or a connection with that link, is in the process of being stopped.

Paused
The channel is waiting for the message-retry interval to finish.

Stopped
The WebSphere MQ link is in a stopped state and cannot process any new requests for connections.

Multiple
The WebSphere MQ link has established several sessions with WebSphere MQ, and the sessions can be in different states: Starting, Running, Stopping, or Stopped.

Batch size:

The maximum number of messages that a batch can contain.

Required	No
Data type	String

Channel start time:

The time at which the channel was last started.

Required	No
Data type	String

Channel start date:

The date on which the channel was last started.

Required	No
Data type	String

Heartbeat interval:

The negotiated time, in seconds, between heartbeat flows passed from the WebSphere MQ sender channel to the WebSphere MQ link receiver channel when there are no messages on the transmission queue being served by the WebSphere MQ sender channel.

Required	No
Data type	String

Sequence wrap:

The value at which message sequence numbers wrap to start again at 1.

This is the highest number the message sequence number reaches before it restarts at 1. The default value is 999999999.

For information about how to choose an appropriate value for this property, see the description of the Sequence Numberwrap (SEQWRAP) property in the *WebSphere MQ Intercommunication* book.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Required	No
Data type	Long
Range	100 through 999999999

Adoptable:

Whether or not a running instance of a WebSphere MQ link receiver channel (associated with this MQ link) should be adopted or not. In the event of a communications failure, it is possible for a running instance of a WebSphere MQ link receiver channel to be left waiting for messages. When communication is re-established, and the partner WebSphere MQ sender channel next attempts to establish a session with the WebSphere MQ link receiver channel, the request will fail as there is already a running instance

of the WebSphere MQ link receiver channel that believes it is in session with the partner WebSphere MQ sender channel. You can overcome this problem by selecting this option, which causes the already running instance of the WebSphere MQ link receiver channel to be stopped and a new instance to be started.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Required No
Data type drop-down list
Range

true

false

Maximum message length:

The maximum message length, in bytes, that can be transmitted on the channel. This is compared with the value from the partner Websphere MQ sender channel and the actual maximum used is the lower of the two values.

Required No
Data type String

Stop requested:

Whether or not a manual stop request has been made for the receiver channel.

Required No
Data type drop-down list
Range

true The channel is in doubt about which messages have been committed by WebSphere MQ for the unit of work that it has sent.

false The channel is not in doubt about which messages have been committed by WebSphere MQ.

Current LUWID:

The current logical unit-of-work identifier of the WebSphere MQ link receiver channel connection.

Required No
Data type String

Current sequence number:

The current sequence number for the message on the channel.

You can reset the sequence number of an MQLinkReceiver channel by resetting the sequence number of the partner WebSphere MQ sender channel. For details of how to reset the sequence number of a WebSphere MQ sender channel, see the *WebSphere MQ Intercommunications Guide* section of the WebSphere MQ library.

Required No

Data type String

Last LUWID:

The last logical unit-of-work identifier for a message on the channel.

Required No
Data type String

Last Sequence number:

The last sequence number for a message on the channel.

Required No
Data type String

Messages in current batch:

The number of messages in the current batch on the channel.

Required No
Data type String

Number of batches received:

The number of batches received on the channel.

Required No
Data type String

Number of messages received:

The number of messages received on the channel.

Required No
Data type String

Buffers sent:

The number of buffers sent on the channel.

Required No
Data type String

Buffers received:

The number of buffers received on the channel.

Required No
Data type String

Bytes sent:

The number of bytes sent on the channel.

Required	No
Data type	String

Bytes received:

The number of bytes received on the channel.

Required	No
Data type	String

Last message receive time:

The time at which the last message was received on the receiver channel connection.

Required	No
Data type	String

Last message receive date:

The date on which the last message was received on the receiver channel connection.

Required	No
Data type	String

nonpersistent message speed:

The class of service for nonpersistent messages on the receiver channel.

Required	No
Data type	drop-down list
Range	**Fast** Nonpersistent messages can be lost if there is a transmission failure or if the channel stops when the messages are in transit.
	Normal Nonpersistent messages are not lost if there is a transmission failure or if the channel stops when the messages are in transit.

Inbound nonpersistent message reliability:

The acceptable reliability of message delivery for nonpersistent message flows from WebSphere MQ through this WebSphere MQ link, from Best effort to Reliable, in order of increasing reliability.

This reliability delivery option is assigned to all WebSphere MQ nonpersistent messages flowing over this receiver channel.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Required No
Data type drop-down list
Range

Best effort
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable or as a result of constrained system resources.

Express
Messages are discarded when a messaging engine stops or fails. Messages might also be discarded if a connection used to send them becomes unavailable.

Reliable
Messages are discarded when a messaging engine stops or fails.

Inbound persistent message reliability:

The acceptable reliability of message delivery for inbound persistent message flows from WebSphere MQ through this WebSphere MQ link, from Reliable to Assured, in order of increasing reliability.

Dynamic updates to this property are effective when the channel restarts. Use the Runtime tab to check the current state.

Required No
Data type drop-down list
Range

Reliable
Messages might be discarded when a messaging engine fails.

Assured
Messages are not discarded.

WebSphere MQ server bus member [Settings]

A WebSphere MQ server bus member is used for assigning queue points and mediation points to WebSphere MQ queues.

To view this page in the console, click the following path:

Service integration -> Buses -> *bus_name* -> [Topology] Bus members -> *member_name*.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The administrative name of the WebSphere MQ server bus member.

Required	No
Data type	String

UUID:

The universal unique identifier is assigned automatically, for administrative purposes, when you create a new WebSphere MQ server definition.

Required	No
Data type	String

Connection settings

Virtual queue manager name:

When sending messages to WebSphere MQ, the WebSphere MQ gateway queue manager sees the bus as a remote queue manager. The virtual queue manager name is passed to WebSphere MQ as the name of the remote queue manager.

The default value is the name of the Service Integration bus. If this bus name is not a valid name for a WebSphere MQ queue manager, or if another WebSphere MQ queue manager already has the same name, replace the default value with a unique, valid name for a WebSphere MQ queue manager.

- It must contain between 1 and 48 characters.
- It must conform to the WebSphere MQ queue naming rules (see the *Rules for naming WebSphere MQ objects* topic in the WebSphere MQ information center).

Required	Yes
Data type	String

Override WebSphere MQ Server connection properties:

When you select this checkbox, the bus-specific properties override the WebSphere MQ server connection properties. To reset the connection settings to the WebSphere MQ server default values, deselect this checkbox and apply the change.

Required	No
Data type	Boolean

WebSphere MQ Host:

The name of the WebSphere MQ server's host.

This is either the symbolic name or the IP address of the host to which a connection is established for communicating with the queue manager or queue-sharing group that this WebSphere MQ server represents. The value is a string and must be one of the following:

- Symbolic host name
- IPv4 address

- IPv6 address

Required No
Data type String

Port:

The WebSphere MQ server port. This value is the TCP/IP port number on which the queue manager or queue-sharing group that this WebSphere MQ server represents listens. This value is used when attempting to establish client transport mode connections to WebSphere MQ. The default value is 1414

Required No
Data type Integer

Transport chain name:

The name of the WebSphere MQ server transport chain. This is the transport chain that is used to establish an outbound network connection to the WebSphere MQ server.

Required No
Data type drop-down list

WebSphere MQ channel:

The name of the WebSphere MQ server's channel. This value is the WebSphere MQ client channel name to use when connecting to the queue manager or queue-sharing group that this WebSphere MQ server represents. The default value is SYSTEM.DEF.SVRCONN

Required No
Data type String

Messaging authentication alias:

The name of WebSphere MQ server's authentication alias. This is the name that is used for exchanging messages with WebSphere MQ.

Required No
Data type drop-down list

Trust user identifiers received in messages:

The WebSphere MQ server's trust user identifier setting. This value determines whether user identifiers that are received in messages from WebSphere MQ are propagated into the message (that is, whether user identifiers that are received as part of message data are used in the service integration bus).

If you select this checkbox, user identifiers that are received as part of WebSphere MQ messages are propagated into messages and used for security purposes within the bus. If you do not select this checkbox, the user identifier is overwritten with the WebSphere MQ server name.

Required No
Data type Boolean

Test connection:

After you have configured the Connection properties, click this button to test the connection to WebSphere MQ.

Message points

WebSphere MQ mediation points
Displays a list of WebSphere MQ mediation points assigned to this WebSphere MQ server bus member.

WebSphere MQ queue points
Displays a list of WebSphere MQ queue points assigned to this WebSphere MQ server bus member.

Related Items

WebSphere MQ server
The WebSphere MQ server that was used to create this bus member.

JAAS - J2C authentication data
Specifies a list of user identities and passwords for Java 2 connector security to use.

WebSphere MQ servers [Collection]

A WebSphere MQ server represents a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group.

To view this page in the console, click the following path:

Servers -> Server Types -> WebSphere MQ servers.

To browse or change the properties of a listed item, select its name in the list.

To act on one or more of the listed items, select the check boxes next to the names of the items that you want to act on, then use the buttons provided.

To change which entries are listed, or to change the level of detail that is displayed for those entries, use the Filter settings.

If WebSphere MQ functionality has been disabled at any scope, an informational message indicating that WebSphere MQ has been disabled is displayed. In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

Name The administrative name of the WebSphere MQ Server.

Description
An optional description for the WebSphere MQ server, for administrative purposes.

Buttons

New	Create a new administrative object of this type.
Delete	Delete the selected items.

Test connection	Test the connection to WebSphere MQ. In a single server environment, any attempt to test the connection fails if WebSphere MQ functionality has been disabled. In a network deployment environment, any attempt to test the connection fails if WebSphere MQ functionality has been disabled at either the cell or deployment manager node scope. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

WebSphere MQ server [Settings]

A WebSphere MQ server represents a WebSphere MQ queue manager or (for WebSphere MQ for z/OS) queue-sharing group. Use this panel to view or modify the details of a WebSphere MQ server definition.

To view this page in the console, click one of the following paths:

- **Servers -> New server**, choose a server type of “WebSphere MQ server”, then click **Next**.
- **Servers -> Server Types -> WebSphere MQ servers -> New**
- **Servers -> Server Types -> WebSphere MQ servers -> *server_name***
- **Service integration -> Buses -> *bus_name* -> [Topology] Bus members -> *member_name* -> [Related Items] WebSphere MQ server**

If WebSphere MQ functionality has been disabled at any scope, an informational message indicating that WebSphere MQ has been disabled is displayed. In a single server environment this informational message is only displayed when the server is restarted after WebSphere MQ functionality has been disabled. In a network deployment environment the informational message is displayed immediately. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

Configuration tab

The Configuration tab shows configuration properties for this object. These property values are preserved even if the runtime environment is stopped then restarted. See the information center task descriptions for information about how to apply configuration changes to the runtime environment.

General Properties

Name:

The administrative name of the WebSphere MQ Server.

The name that you use for this WebSphere MQ server definition must be unique.

Required Yes
Data type String

UUID:

The universal unique identifier assigned by the system to this WebSphere MQ server for administrative purposes.

This identifier is assigned automatically when you create a new WebSphere MQ server definition.

Required No
Data type String

Description:

An optional description for the WebSphere MQ server, for administrative purposes.

Required No
Data type Text area

WebSphere MQ server name:

The name of the WebSphere MQ queue manager or queue sharing group, as defined in WebSphere MQ.

Required Yes
Data type String

Server Type:

A server can be either a queue manager or queue sharing group. Select the appropriate type for the server you want to establish a connection to.

Required No
Data type Radio button
Range

Queue manager
A WebSphere MQ queue manager on the WebSphere MQ network with which WebSphere Application Server applications undertake messaging.

Queue sharing group
A WebSphere MQ for z/OS queue-sharing group on the WebSphere MQ network with which WebSphere Application Server applications undertake messaging.

Use bindings transport mode if available:

When selected, bindings transport mode will be used in preference to client transport mode when establishing connections to the WebSphere MQ server. Otherwise client transport mode will always be used.

To connect to a WebSphere MQ queue manager or queue-sharing group in bindings mode, WebSphere Application Server needs to know where to load native libraries from. This information is stored in the **Native library path** property of the WebSphere MQ messaging provider. If you want to use a direct binding to WebSphere MQ, rather than a TCP/IP network connection, select this option and configure the **Native library path** property as described in “Configuring the WebSphere MQ messaging provider with native libraries information” on page 723.

Note: If you are using Resource Access Control Facility (RACF) as the security manager on your WebSphere MQ for z/OS system, and using bindings transport mode, you must specify in uppercase characters the user names and passwords for authentication aliases. If you are using RACF and client transport mode, you can specify the user names and passwords in either upper or lowercase characters.

Required	No
Data type	Boolean

WebSphere MQ host:

WebSphere MQ server host defined by either its symbolic host name or an IP address.

Required	Yes
Data type	String

WebSphere MQ port:

This is the port that will be used when attempting to establish client transport mode connections to WebSphere MQ.

Required	Yes
Data type	Integer
Range	0 through 65535

Transport chain name:

The transport chain used to establish an outbound network connection to the WebSphere MQ server.

Required	Yes
Data type	Custom

WebSphere MQ channel:

The WebSphere MQ server connection channel, as defined in WebSphere MQ.

Required	Yes
Data type	String

Test connection:

Test the connection to WebSphere MQ.

In a single server environment, any attempt to test the connection fails if WebSphere MQ functionality has been disabled. In a network deployment environment, any attempt to test the connection fails if WebSphere MQ functionality has been disabled at either the cell or deployment manager node scope. For more information see “Disabling WebSphere MQ functionality in WebSphere Application Server” on page 868.

Messaging authentication alias:

WebSphere MQ server authentication alias name used when exchanging messages with WebSphere MQ.

Required	No
Data type	drop-down list

Trust user identifiers received in messages:

If selected user identifiers received as part of WebSphere MQ messages will be used for security purposes within the bus.

Select this option if you do not want the user IDs in messages to be overwritten with the administrative name of the WebSphere MQ server.

Required	No
Data type	Boolean

Automatic discovery of resources :

When selected this enables the discovery of WebSphere MQ queue names to assist the administrator.

Required	No
Data type	Boolean

Resource discovery authentication alias:

WebSphere MQ server authentication alias used for WebSphere MQ resource discovery.

Required	No
Data type	drop-down list

Reply-to queue :

WebSphere MQ queue name used by the system to obtain messages used in the resource discovery process.

Required	No
Data type	Text

Related Items

JAAS - J2C authentication data
Specifies a list of user identities and passwords for Java 2 connector security to use.

This item is not available until after the WebSphere MQ server definition has been created.

Service integration custom properties

Use custom properties to configure advanced settings for service integration objects such as messaging engines.

You can use the custom properties page to define the following service integration properties:

- “sib.msgstore.cachedDataBufferSize” on page 2258
- “sib.msgstore.discardableDataBufferSize” on page 2258
- “sib.msgstore.jdbcFailoverOnDBConnectionLoss” on page 2258
- “sib.msgstore.jdbcInitialDatasourceWaitTimeout” on page 2259
- “sib.msgstore.jdbcResAuthForConnections” on page 2259
- “sib.msgstore.jdbcStaleConnectionRetryDelay” on page 2259
- “sib.msgstore.storeFullWaitForCheckPoint” on page 2259
- “sib.msgstore.transactionSendLimit” on page 2260
-

- “sib.trm.retry” on page 2260
- “sib.wsrm.tokenLockTimeout” on page 2260

sib.msgstore.cachedDataBufferSize

The size in bytes of the data buffer that the messaging engine uses to contain data for which the quality of service attribute is *better than* best effort nonpersistent and that is held in the data store. The default value is 320000, which is approximately 320 kilobytes.

The purpose of the cached data buffer is to optimize the performance of the messaging engine by caching in memory the data that the messaging engine might otherwise have to read from the data store. As it writes data to the data store and reads from the data store, the messaging engine attempts to add that data to the cached data buffer. The messaging engine might discard data already in the buffer to make space.

Data type	Bytes
Default	40000000

sib.msgstore.discardableDataBufferSize

The size in bytes of the data buffer that the messaging engine uses to contain data for which the quality of service attribute is best effort nonpersistent. The default value is 320000, which is approximately 320 kilobytes.

The discardable data buffer contains all data for which the quality of service attribute is best effort nonpersistent. That data comprises both data that is involved in active transactions, and any other best effort nonpersistent data that the messaging engine has neither discarded nor consumed. The messaging engine holds this data entirely within this memory buffer and never writes the data to the data store. When the messaging engine adds data to the discardable data buffer, for example when the messaging engine receives a best effort nonpersistent message from a client, the messaging engine might discard data already in the buffer to make space. The messaging engine can discard only data that is not involved in active transactions. This behavior enables the messaging engine to discard best effort nonpersistent messages.

Increasing the size of the discardable data buffer allows more best effort nonpersistent data to be handled before the messaging engine begins to discard messages.

If the messaging engine attempts to add data to the discardable data buffer when insufficient space remains after discarding all the data that is not involved in active transactions, the messaging engine throws a `com.ibm.ws.sib.msgstore.OutOfCacheSpace` exception. Client applications can catch this exception, wrapped inside API-specific exceptions such as javax.jms.JMSException.

Data type	Bytes
Default	1280000

sib.msgstore.jdbcFailoverOnDBConnectionLoss

The property determines the behavior of the messaging engine and its hosting server in the event that the connection to the data store is lost.

Property value	**Behavior when the data store connection is lost**
true (default)	The server shuts down and must be manually restarted.

Property value	Behavior when the data store connection is lost
false	The messaging engine continues to run and accept work, and periodically attempts to regain the connection to the data store. If work continues to be submitted to the messaging engine while the data store is unavailable, the results can be unpredictable, and the messaging engine can be in an inconsistent state when the data store connection is restored. **Note:** If work continues to be submitted to the messaging engine, even nonpersistent messaging can fail because the messaging engine might need to use the data store, for example to allocate a unique ID to a message, or to move nonpersistent messages out of memory.

sib.msgstore.jdbcInitialDatasourceWaitTimeout

The time, in milliseconds, to wait for the data store to become available. This time includes the time required to establish a connection to the database and to obtain the required table locks.

Data type	Milliseconds
Default	900000 (15 minutes)

sib.msgstore.jdbcResAuthForConnections

The messaging engine resource authorization mechanism used when sharing connections. Default value is Container.

Data type	String
Default	Container

sib.msgstore.jdbcStaleConnectionRetryDelay

The time, in milliseconds, to wait between attempts to connect to the data store.

For example, if you set the sib.msgstore.jdbcInitialDatasourceWaitTimeout property to 600000, and the sib.msgstore.jdbcStaleConnectionRetryDelay property to 3000, the messaging engine will attempt to connect every 3 seconds for 10 minutes.

Data type	Milliseconds
Default	2000 (2 seconds)

sib.msgstore.storeFullWaitForCheckPoint

This property determines the action a messaging engine takes when a file store is full and applications try to send further messages.

When a file store is full, the messaging engine carries out a checkpoint of the log file to reconcile all message sends and receives since the last checkpoint. This process might take some time to complete. Between the time when the file store becomes full and the time when the checkpoint is complete, if applications try to send a message, the messaging engine throws the exception ObjectStoreFullException and issues message CWSOM1042E.

When an application thread that is sending a message finds that the file store is full, it requests a checkpoint. The default behavior, with the property value set to false, is that the application thread then throws the exception ObjectStoreFullException to the application immediately and returns. You can select an alternative behavior by setting the property value to true. With this property value, the application thread does not throw the exception, but waits until the checkpoint has completed. If the checkpoint frees space in the file store, the application thread proceeds and sends the messages before returning. If the file store is still full after the checkpoint, the application thread throws the exception to the application.

Set the property value to true, and make application threads wait for the checkpoint to be completed, if your applications delete all the messages in the file store, and so they logically know that the file store is no longer full. Although the applications must still wait until the checkpoint is complete, they do not receive exceptions while the checkpoint is being carried out, and they do not have to retry the send.

Data type	Boolean
Default	False

sib.msgstore.transactionSendLimit

The maximum number of operations that the messaging engine includes in each transaction. For example, each JMS send or receive is an operation that counts towards the transaction send limit. The default value is 100.

Data type	Integer
Default	100

sib.trm.retry

The messaging engine to messaging engine connection retry interval, in seconds. The retry interval is the time delay left between attempts to contact neighboring messaging engines with which communications exist. The default retry interval is 30 seconds.

Data type	Seconds
Default	30

sib.wsrm.tokenLockTimeout

This property affects WS-ReliableMessaging managed qualities of service. Set this property on the messaging engine that is specified in the policy binding for the WS-ReliableMessaging application.

This property is the amount of time, in milliseconds, that a lock is held on a WS-ReliableMessaging message. If a server fails while processing a message, the lock is released at the end of this timeout period, so that other servers can continue the processing. If the original server recovers before the timeout period ends, it continues processing the message. The lock is released at the end of the timeout period even if the message is still being processed.

If your system is processing large messages, you might want to increase the value of this property. For example, if a message takes 12 minutes to process, the lock is released 2 minutes before processing is complete. To avoid this situation, change the property to a value that is greater than 12 minutes.

If your system is processing small messages, you might want to decrease the value of this property, so that if a failure occurs the lock is released more quickly, and other servers can continue the processing without delay.

Data type	Milliseconds
Default	600000 (10 minutes)

SIBAdminCommands: Bus administrative commands for the AdminTask object

You can use these administrative commands to manage service integration buses.

To run these commands, use the AdminTask object of the wsadmin scripting client. Each command acts on multiple objects in one operation. The commands are provided to allow you to make the most commonly-required types of update in a consistent manner, where modifying the underlying objects directly would be error-prone.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

createSIBus command

Use the createSIBus command to create a new service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command creates a new service integration bus.

Target object

None

Required parameters

-bus *busname*
The name by which you want the service integration bus to be known. Choose a unique name.

Conditional parameters

None.

Optional parameters

-description *text*
An optional description for the bus, for administrative purposes.

-secure TRUE | FALSE
This parameter is deprecated for this version.

interEngineAuthAlias *name*
The name of the authentication alias used to authorize communication between messaging engines on the bus.

You must specify an inter-engine authentication alias if the bus contains a WebSphere Application Server Version 6.x bus member. When bus security is enabled, the bus uses the inter-engine authentication alias to authenticate incoming connections from other messaging engines. An unauthorized messaging engine cannot connect to the bus.

-mediationsAuthAlias *name*
The name of the authentication alias used to authorize mediations to access the bus.

-securityGroupCacheTimeout *timeout_value*
The length of time, in minutes, that a security group will be cached for. *timeout_value* can be in the range 0 through 99999. The default value is 120.

Increasing the timeout decreases the load on the user registry and improves performance but makes the system less responsive to changes in a user's group membership. To tune the group cache to the optimum setting, you need to balance the need for responsiveness with the registry load. For example, if the system must respond quickly to changes in a user's group membership, specify a timeout of 15 minutes. If the system needs to respond less frequently, for example to respond to overnight changes, specify a timeout of 1440 minutes (24 hours). With a setting of 0, entries in the cache do not timeout, and so remain until the server is next restarted.

A change to this value is effective immediately and only affects the group cache of the bus for which the configuration was changed.

-protocol *protocol*
The transport chain used for communication between messaging engines in this bus.

The transport chain must correspond to one of the transport chains defined in the Messaging engine inbound transports settings for the server. All servers automatically have a number of transport chains defined to them, and it is also possible to create new transport chains.

The default transport chain is InboundBasicMessaging.

-discardOnDelete TRUE | FALSE
Set this option to TRUE if messages on a deleted message point can be discarded. Set this option to FALSE if messages on a deleted message point should be retained at a system exception destination.

highMessageThreshold *number*
The maximum total number of messages that any messaging engine on the bus can place on its message points.

This value is used to set the default high message threshold for a messaging engine when the messaging engine is created.

configurationReloadEnabled TRUE | FALSE
Set this option to TRUE to dynamically reload configuration files for this bus.

When this option is TRUE, certain changes to the bus configuration are applied without requiring the messaging engines to be restarted. These changes are applied when destinations or mediations are added to, or removed from, the bus. This option also controls whether automatic updates occur on all the messaging engines on the bus.

-busSecurity TRUE | FALSE
Set this option to TRUE to enforce the authorization policy for the bus, which also requires administrative security to be enabled. Set this option to FALSE if you always want to disable bus security. If administrative security is disabled, the bus is insecure.

-bootstrapPolicy SIBSERVICE_ENABLED | MEMBERS_AND_NOMINATED | MEMBERS_ONLY
Set one of three options to enforce a bus members policy for the bus.

SIBSERVICE_ENABLED
Any server in the cell that has the SIB service enabled can service bootstrap requests.

MEMBERS_AND_NOMINATED
Only bus members or a nominated bootstrap server can service bootstrap requests.

MEMBERS_ONLY
Only bus members can service bootstrap requests.

-useServerIdForMediations TRUE | FALSE
Set this option to TRUE if you want to run mediations using a single server identity for the bus. This option enables you to run mediations across multiple security domains without the need to specify a mediation authentication alias for each domain. You can use a server identity to run mediations on the global domain. Set this option to FALSE if you want to run mediations using a mediations authentication alias.

-auditAllowed TRUE | FALSE
Set this option to be TRUE to enable security auditing for the bus. Set this option to be FALSE to disable security auditing for the bus. The default value is TRUE. You must have Audit Administrator privileges to use this parameter.

Example

```
AdminTask.createSIBus('[-bus bus1 -description [A new bus] -busSecurity false ]')
'bus1(cells/cell01/buses/bus1|sib-bus.xml#SIBus_1213019988044)'
```

deleteSIBus command

Use the deleteSIBus command to delete a specified service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('SIBAdminCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command deletes a specified service integration bus, and deletes the artifacts that are related to the bus including queue points, publication points, and mediation points. This command also deletes the new artifacts that are created when queues are assigned or mediated to a WebSphere MQ server bus member, including the WebSphere MQ server bus members. This command does not delete the following:

- Queue managers that are associated with the bus through WebSphere MQ server definitions.
- Messages residing on WebSphere MQ queue managers.
- WebSphere MQ queues.

CAUTION:
This command deletes everything on and related to the bus. There is no confirmation prompt before deleting the bus.

Target object

The specified service integration bus.

Required parameters

-bus *busname*
The name by which the service integration bus is known. You can use the listSIBuses command to list the names of existing buses.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.deleteSIBus('[-bus bus1 ]')
```

listSIBuses command

Use the listSIBuses command to list all service integration buses for a given scope.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('SIBAdminCommands')
  ```
- For overview help on a given command, enter the following command at the wsadmin prompt:
  ```
  print AdminTask.help('command_name')
  ```

Purpose

This command lists the names of all service integration buses for a given scope.

Target object

A given scope.

Required parameters

None.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.listSIBuses()
'bus1(cells/cell01/buses/bus1|sib-bus.xml)
bus2(cells/cell01/buses/bus2|sib-bus.xml)'
```

modifySIBus command

Use the modifySIBus command to modify the properties of a service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

This command modifies the properties of a service integration bus.

Target object

A bus.

Required parameters

-bus *busname*
The name by which the service integration bus is known. You can use the listSIBuses command to list the names of existing buses.

Conditional parameters

None.

Optional parameters

-description *text*
An optional description for the bus, for administrative purposes.

-secure TRUE | FALSE
This parameter is deprecated for this version.

-mediationsAuthAlias *name*
The name of the authentication alias used to authorize mediations to access the bus.

-securityGroupCacheTimeout *timeout_value*
The length of time, in minutes, that a security group will be cached for. *timeout_value* can be in the range 0 through 99999. The default value is 120.

Increasing the timeout decreases the load on the user registry and improves performance but makes the system less responsive to changes in a user's group membership. To tune the group cache to the optimum setting, you need to balance the need for responsiveness with the registry load. For example, if the system must respond quickly to changes in a user's group membership, specify a timeout of 15 minutes. If the system needs to respond less frequently, for example to respond to overnight changes, specify a timeout of 1440 minutes (24 hours). With a setting of 0, entries in the cache do not timeout, and so remain until the server is next restarted.

A change to this value is effective immediately and only affects the group cache of the bus for which the configuration was changed.

-protocol *protocol*
The transport chain used for communication between messaging engines in this bus.

-discardOnDelete TRUE | FALSE
Set this option to TRUE if messages on a deleted message point can be discarded. Set this option to FALSE if messages on a deleted message point should be retained at a system exception destination.

-busSecurity TRUE | FALSE
Set this option to TRUE to enforce the authorization policy for the bus, which also requires administrative security to be enabled. Set this option to FALSE if you always want to disable bus security. If administrative security is disabled the bus is not secured.

-permittedChains ALL | SSL_ENABLED | LISTED
Set one of three options to enforce a transport policy for the bus.

ALL Allow the use of all defined transport channel chains.

SSL_ENABLED
Restrict the use of defined transport channel chains to those protected by SSL.

LISTED
Restrict the use of defined transport channel chains to the list of protected transports.

-bootstrapPolicy SIBSERVICE_ENABLED | MEMBERS_AND_NOMINATED | MEMBERS_ONLY
Set one of three options to enforce a bus members policy for the bus.

SIBSERVICE_ENABLED
Any server in the cell that has the SIB service enabled can service bootstrap requests.

MEMBERS_AND_NOMINATED
Only bus members or a nominated bootstrap server can service bootstrap requests.

MEMBERS_ONLY
Only bus members can service bootstrap requests.

-useServerIdForMediations TRUE | FALSE
Set this option to TRUE if you want to run mediations using a single server identity for the bus. This option enables you to run mediations across multiple security domains without the need to specify a mediation authentication alias for each domain. You can use a server identity to run mediations on the global domain. Set this option to FALSE if you want to run mediations using a mediations authentication alias.

-auditAllowed TRUE | FALSE
Set this option to be TRUE to enable security auditing for the bus. Set this option to be FALSE to disable security auditing for the bus. The default value is TRUE. You must have Audit Administrator privileges to use this parameter.

Example

```
AdminTask.modifySIBus('[-bus bus1 -description [A new description of the bus]]')
'bus1(cells/cell01/buses/bus1|sib-bus.xml)'
```

showSIBus command

Use the showSIBus command to show the properties of a service integration bus.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('SIBAdminCommands')`
- For overview help on a given command, enter the following command at the wsadmin prompt:
  `print AdminTask.help('command_name')`

Purpose

This command lists details about the properties of a service integration bus.

Target object

A bus.

Required parameters

-bus *busname*
The name by which the service integration bus is known. You can use the listSIBuses command to list the names of existing buses.

Conditional parameters

None.

Optional parameters

None.

Example

```
AdminTask.showSIBus('[-bus bus1]')
'{secure=false, useServerIdForMediations=false, discardOnDelete=false,
auditAllowed=true, highMessageThreshold=50000, busName=bus1,
securityGroupCacheTimeout=120, configurationReloadEnabled=true,
bootstrapPolicy=SIBSERVICE_ENABLED, permittedChains=ALL}'
```

addSIBusMember command

Use the addSIBusMember command to add a member to a service integration bus by using the wsadmin tool. A bus member can be an application server or a WebSphere MQ server.

To run the command, use the AdminTask object of the wsadmin scripting client.

The wsadmin scripting client is run from Qshell. For more information, see Configuring Qshell to run WebSphere Application Server scripts using wsadmin scripting.

Command-line help is provided for service integration bus commands:

- For a list of the available service integration bus commands in Jython and a brief description of each command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('SIBAdminCommands')
  ```

- For overview help on a given command, enter the following command at the wsadmin prompt:

  ```
  print AdminTask.help('command_name')
  ```

After using the command, save your changes to the master configuration; for example, by using the following command:

```
AdminConfig.save()
```

Purpose

The addSIBusMember command adds a new member to a service integration bus. When an application server is added as a member of a bus, a messaging engine with default settings is created automatically.

When a WebSphere MQ server is added as a member of a bus, a server proxy is created that can override the parent connection properties (host, port, channel, and SSL security configuration alias) that are defined in the WebSphere MQ server. By this means, a different set of connection properties can be assigned to each bus membership.

Target object

None.

A bus member object is created. If the bus member is a server, a messaging engine is also created.

Required parameters

-bus *bus_name*
The name by which the service integration bus is known. You can use the listSIBuses command to list the names of existing buses.

Conditional parameters

-node *node_name*

-server *server_name*

To add an application server as a bus member, specify both the name of the node on which the server runs, and the name of the server.

If you specify these parameters, do not specify the **-wmqServer** parameter.

-wmqServer

To add a WebSphere MQ server as a bus member, specify the name of the WebSphere MQ server. This is the name that was specified in the **-name** parameter when the WebSphere MQ server was created.

If you specify this parameter, do not specify the **-node** or **-server** parameters.

Optional parameters

-description *text*

An optional description for the bus member, for administrative purposes.

-virtualQueueManagerName

The override value for the name of the WebSphere MQ server virtual queue manager. When sending messages to WebSphere MQ, the WebSphere MQ gateway queue manager sees the bus as a remote queue manager. The virtual queue manager name is the name that is passed to WebSphere MQ as the name of this remote queue manager. The default value is the name of the bus. If this value is not a valid name for a WebSphere MQ queue manager, or if another WebSphere MQ queue manager already exists that has the same name, then replace the default value with another value that is a valid and unique name for a WebSphere MQ queue manager. To be valid, the name must meet the following criteria:

- It must contain between 1 and 48 characters.
- It must conform to the WebSphere MQ queue naming rules (see the *Rules for naming WebSphere MQ objects* topic in the WebSphere MQ information center).

-host

The override value for the WebSphere MQ server bus member host attribute. This value is the host name or IP address of the host to which a connection is established to communicate with a queue manager or queue-sharing group. Use this parameter if the **-wmqServer** parameter is specified.

-port

The override value for the WebSphere MQ server bus member port attribute. The port number is monitored by a queue manager listener or queue-sharing group listener, which is listening for connections. The default value is 1414. Use this parameter if the **-wmqServer** parameter is specified.

-channel

The override value for the WebSphere MQ server bus member channel attribute. This is the name of the server connection channel that is used to establish a connection to the WebSphere MQ queue manager or WebSphere MQ for z/OS queue sharing group. The default value is SYSTEM.DEF.SVRCONN. Use this parameter if the **-wmqServer** parameter is specified.

-securityAuthAlias

The override value for the WebSphere MQ server bus member **securityAuthAlias** attribute. This is the authentication alias that is supplied when connecting to the WebSphere MQ server. This parameter has no default. Use this parameter if the **-wmqServer** parameter is specified.

-transportChain

The override value for the WebSphere MQ server bus member **transportChain** attribute. This is the name of the transport chain to use when communicating with WebSphere MQ. The default value is OutboundBasicWMQClient. Use this parameter if the **-wmqServer** parameter is specified.

-trustUserIds TRUE | FALSE
The override value for the WebSphere MQ server bus member **trustUserIds** attribute. This determines whether user IDs that are received in messages from WebSphere MQ are propagated into messages. The application user ID is always set from the **jsAppUserIdRFH2** value. If this is not present (either because the key/value pair is not present in the <sib> folder of the RFH2 header, or because the message does not have a RFH2 header), this field is not set. This parameter has two possible values:

TRUE User IDs are propagated into messages.

FALSE
User IDs are not propagated into messages.

The default value is TRUE. Use this parameter if the **-wmqServer** parameter is specified.

-fileStore
Create a file store to use as a message store for the messaging engine. A file store is a type of message store that directly uses files in a file system through the operating system. The alternative is to use a data store. For more information, see the related links.

-logSize *logsize*
The size of the log file in MB. Use this parameter if the **-fileStore** parameter is specified.

-logDirectory *logdirectoryname*
The name of the log file directory if you do not want to use the default log directory. Use this parameter if the **-fileStore** parameter is specified.

-minPermanentStoreSize *minpermanentstoresize*
The minimum size of the permanent store file in MB. Use this parameter if the **-fileStore** parameter is specified.

-minTemporaryStoreSize *mintemporarystoresize*
The minimum size of the temporary store file in MB. Use this parameter if the **-fileStore** parameter is specified.

-maxPermanentStoreSize *maxpermanentstoresize*
The maximum size of the permanent store file in MB. Use this parameter if the **-fileStore** parameter is specified.

-maxTemporaryStoreSize *maxtemporarystoresize*
The maximum size of the temporary store file in MB. Use this parameter if the **-fileStore** parameter is specified.

-unlimitedPermanentStoreSize TRUE | FALSE
A parameter that specifies whether the permanent store size is unlimited. This parameter has two possible values:

TRUE The permanent store size is unlimited.

FALSE
The permanent store size is limited. If you use this option, supply a **-maxPermanentStoreSize** parameter.

Use this parameter if the **-fileStore** parameter is specified.

-unlimitedTemporaryStoreSize TRUE | FALSE
A parameter that specifies whether the temporary store size is unlimited. This parameter has two possible values:

TRUE The temporary store size is unlimited.

FALSE
The temporary store size is limited. If you use this option, supply a **-maxTemporaryStoreSize** parameter.

Use this parameter if the **-fileStore** parameter is specified.

-permanentStoreDirectory *permanentstoredirectoryname*
The name of the permanent store directory if you do not want to use the default permanent store directory. Use this parameter if the **-fileStore** parameter is specified.

-temporaryStoreDirectory *temporarystoredirectoryname*
The name of the temporary store directory if you do not want to use the default temporary store directory. Use this parameter if the **-fileStore** parameter is specified.

-dataStore
Create a data store to use as a message store for the messaging engine.

A data store consists of the set of tables that a messaging engine uses to store persistent data in a database. See "Data store tables" on page 1967 for a list of the tables that comprise a data store. All the tables in a data store are held in the same database schema. You can create multiple data stores in the same database, provided that you use a different schema name for each data store. The alternative is to use file store (the default). For more information, see the related links.

-createDefaultDatasource TRUE | FALSE
A parameter that specifies whether to create a default data source when the messaging engine is created. This parameter has two possible values:

TRUE Create a default data source.

FALSE
Do not create a default data source.
